## Tea tree oil

**HISTORICAL NOTE** The Bundjalong Australian Aboriginal people of northern New South Wales knew of the medicinal qualities of this plant's leaves for many centuries and used it to treat burns, cuts and insect bites. It was not until the 1700s that it became known in the Western world as 'tea tree' because Captain Cook found its aromatic leaves an enjoyable substitute for real tea. The first official report of its medicinal use appeared in the *Medical Journal of Australia* in 1930, when a Sydney surgeon wrote of its impressive wound-healing and antiseptic qualities (Murray 1995). In modern times, tea tree oil has become widely accepted as a standard treatment for wounds and minor skin infections.

### COMMON NAME

Tea tree

### OTHER NAMES

Australian tea tree oil, melaleuca, melasol, narrow-leaved paperbark, paperbark tree oil, punk tree, ti tree oil

### BOTANICAL NAME/FAMILY

*Melaleuca alternifolia* (family Myrtaceae)

### PLANT PARTS USED

Essential oil from leaves and branches

### CHEMICAL COMPONENTS

Tea tree oil contains almost 100 components, of which the majority are monoterpenes and their alcohol-related derivatives (Pazay et al 2012). Active constituents include cineole, alpha-cadinine, terpinenes, pinenes, alpha-terpineol, aromadendrene, terpinenols and terpinolene (Duke 2003).

The constituent 1,8-cineole appears to be responsible for the undesirable allergenic effects sometimes observed with tea tree oil products (Pazay et al 2012).

### Antibacterial and antiparasitic

In vitro studies have demonstrated that tea tree oil has activity against a wide range of bacterial species such as *Corynebacterium* spp., *Escherichia coli*, including extended-spectrum beta-lactamase strains, *Enterococcus* spp., including vancomycin-resistant strains, *Klebsiella pneumoniae*, *Micrococcus* spp. (*M. luteus*, *M. varians*), *Propionibacterium acnes*, *Streptococcus pyogenes*, *Pseudomonas aeruginosa*, *Acinetobacter baumannii*, *Staphylococcus* spp. (*S. aureus*, including methicillin-resistant strains (MRSA), *S. capitis*, *S. epidermidis*, *S. haemolyticus*, *S. hominis*, *S. marcescens*, *S. saprophyticus*, *S. warneri* and *S. xylosum*) (Bagg et al 2006, Carson et al 2006, Concha et al 1998, De Mondello et al 2003, Hada et al 2001, Messenger et al 2005, Murray 1995, Papadopoulos et al 2006, Tortorano et al

2008, Warnke et al 2012) and against the protozoa, *Trichomonas vaginalis* (Azimi et al 2011).

It is suggested that the antibacterial activity of tea tree is due to its ability to effectively bind to the bacterial cell wall (Chung et al 2007). Tea tree oil disrupts the permeability barrier of cell membrane structures of microorganisms and denatures the proteins (Carson et al 2002, Cox et al 2000, Gustafson et al 1998, Tao & Zhang 2006). This activity is similar to pharmaceutical disinfectants such as chlorhexidine and quaternary ammonium compounds.

Purified components have been found to have greater antibacterial and fungicidal activities than the whole oil, with terpinen-4-ol being the most active constituent, displaying strong antimicrobial and anti-inflammatory properties (Loughlin et al 2008, Pazyar et al 2012, Terzi et al 2007).

### Antifungal

Tea tree oil demonstrates antifungal activity against *Candida* species according to in vitro and in vivo studies (Agarwal et al 2010, Mondello et al 2003, Ramage et al 2012). Antifungal activity has also been demonstrated against other yeasts and fungi, including *Fusarium graminearum*, *F. culmorum*, *Pyrenophora graminea* (Williamson et al 2007) and *Pityrosporum ovale* (Satchell et al 2002a), and other dermatophytes (Pazyar & Yaghoobi 2012).

### Antiviral

An in vitro study has identified activity against herpes simplex virus types 1 and 2 (Schnitzler et al 2001). Tea tree oil has also been shown to be effective in treating hand warts caused by human papillomavirus (Millar & Moore 2008) as well as inhibiting viral replication of Influenza A/PR/8 in vitro (Garozza et al 2011).

### Oestrogenic and antiandrogenic activities

Studies in human cell lines have indicated that tea tree oil has oestrogenic and antiandrogenic activities. These actions may have contributed to the effective treatment of cases of prepubertal gynaecomastia, with topical use (Henley et al 2007).

### Anticancer activity

In vitro data suggest that tea tree oil may confer antitumour activity by inhibiting growth of melanoma cells, including drug-resistant cells (Bozzuto et al 2011). A murine study reported that topical application of tea tree oil (10%) had a cytotoxic effect on tumour cells, while simultaneously activating local immune response mechanisms (Ireland et al 2012).

### Other actions

Tea tree oil is reported to have anti-inflammatory activity (Carson et al 2006) and animal studies have demonstrated that inhalation of tea tree oil has both anti-inflammatory and immunomodulatory actions that are likely to be mediated by the

hypothalamic-pituitary axis (Golab & Skwarlo-Sonta 2007). The anti-inflammatory action of the constituent terpinen-4-ol, including inhibition of tumour necrosis factor- $\alpha$ , interleukin-1 (IL-1), IL-8 and prostaglandin E<sub>2</sub>, may prove useful in the treatment of psoriasis (Pazyar & Yaghoobi 2012); however, clinical studies have yet to be conducted.

### CLINICAL USE

Topical tea tree oil preparations have been investigated in a number of clinical studies, either as the oil itself or as an ingredient of gels, creams or ointments. In vitro studies suggest that the penetration of topical tea tree oil components through the skin is limited, therefore local effects should be expected with little systemic response (Cross et al 2008).

#### Acne vulgaris

A randomised, double-blind, placebo-controlled study of 60 patients found that a topical 5% tea tree oil gel was an effective treatment for mild to moderate acne vulgaris (Enshaieh et al 2007). This result is supported by a single-blind, randomised clinical trial involving 124 patients with mild to moderate acne which showed that a similar gel significantly improved the condition and reduced the number of acne lesions. These benefits were similar to those produced by 5% benzoyl peroxide lotion, but the tea tree oil gel was better tolerated and produced fewer side effects (Bassett et al 1990).

#### Athlete's foot, tinea pedis

Two randomised, double-blind studies have tested three different strengths of tea tree oil cream (10%, 25% and 50% w/w) for both symptom relief and curative effects in tinea pedis (Satchell et al 2002a, Tong et al 1992). Based on these studies, it appears that there is a dose-response as the higher concentrations of tea tree oil cream performed better than the lowest-tested concentration. Symptom relief was achieved for most patients; however, none of the tested preparations achieved negative mycology in all cases.

The first study involved 104 subjects with tinea pedis (athlete's foot) and compared 10% w/w tea tree oil cream to 1% tolnaftate or placebo creams (Tong et al 1992). In this study, significantly more tolnaftate-treated patients (85%) than tea tree oil- (30%) and placebo-treated (21%) patients showed conversion to negative culture at the end of therapy. However, tea tree oil cream reduced symptoms as effectively as tolnaftate 1%. A more recent randomised, double-blind, controlled study by the same group used two preparations of more concentrated tea tree oil (25% and 50% w/w) for the treatment of interdigital tinea pedis in 158 patients over 4 weeks (Satchell et al 2002a). In the 50% tea tree oil group, 68% of patients had a significant response and 64% achieved negative mycology. In the 25% tea tree group, 72% of patients responded and 50% were cured. The placebo responder rates

were 39% and 31%, respectively, with 3% of patients using tea tree developing dermatitis.

It has been suggested that the fungicidal activity of tea tree and other essential oils can be enhanced using footbaths heated to 42°C (Inouye et al 2007).

### Toenail infection (onychomycosis)

A randomised, double-blind multicentre study involving 177 volunteers found that 6 months' treatment with 1% clotrimazole solution (applied twice daily) or 100% tea tree oil (applied twice daily) produced similar results, improving nail appearance and associated symptoms (Buck et al 1994). Additionally, 3 months after either treatment ceased, continued improvement or complete resolution was observed in approximately half of participants. Another randomised, double-blind, placebo-controlled study investigated the effects of a combined tea tree oil (5%) and butenafine hydrochloride (2%) cream in chronic toenail onychomycosis and found that, after 6 weeks, 80% of patients achieved a cure with active treatment compared with none using placebo cream (Syed et al 1999).

### MRSA infection

Tea tree oil has been shown to have activity against MRSA and coagulase-negative *Staphylococci* (Brady et al 2006, Loughlin et al 2008), providing a basis for research in this area. Clinical trials with 5% tea tree oil body wash, 10% cream and 4% nasal ointment have been conducted, producing encouraging results. As yet, no definitive conclusions can be made about the best forms, concentrations and treatment regimens necessary to prevent and/or treat MRSA infection.

Washing with a 5% tea tree oil for 5 days has been shown to be effective in removing MRSA on the skin (Dryden et al 2004) and tea tree oil has been effectively used against biofilm formation on tympanostomy tubes in vitro (Park et al 2007). A combination of 4% tea tree oil nasal ointment and 5% tea tree oil body wash was found to be superior to the standard 2% mupirocin nasal ointment and triclosan body wash used for the eradication of MRSA (Caelli et al 2000).

While the study by Caelli et al (2000) suggests tea tree is more effective than mupirocin, other studies have shown it to be effective, but not superior to this standard treatment for MRSA (Bradley 2011). A review reported on two randomised controlled trials ( $n = 30$ ,  $n = 224$ ), both of which demonstrated that tea tree oil was effective, although not to the same extent as mupirocin. In the larger trial, 224 patients were given either mupirocin 2% nasal ointment, chlorhexidine gluconate 4% soap and silver sulfadiazine 1% cream or tea tree 10% cream and tea tree 5% body wash for 5 days (Dryden et al 2004). Rates of MRSA clearance were similar: 41% in the tea tree group and 49% using standard treatment. Mupirocin was significantly more effective at clearing nasal carriage (78%) than tea tree cream (47%), although tea tree treatment was more

effective than both chlorhexidine and silver sulfadiazine at clearing superficial skin sites and skin lesions.

An uncontrolled case study series ( $n = 12$ ) reported that an aqueous solution of tea tree oil (3.3%) was unsuccessful in eradicating MRSA from wounds, with none of the 12 participants being MRSA-negative after treatment. The study also reported that use of tea tree oil did not inhibit healing (Edmondson et al 2011).

Overall, tea tree oil may be an effective antimicrobial agent when appropriately used at bactericidal concentrations; however it remains to be seen whether its application at sublethal concentrations may contribute to the development of antibiotic resistance in human pathogens (McMahon et al 2007).

### Vaginitis and cervicitis

Limited clinical data and results from in vitro studies support the use of tea tree oil for vaginitis and cervicitis caused by *Trichomonas vaginalis* (Azimi et al 2011, Jandourek et al 1998, Vila & Caniguel 2006).

An open study found that intravaginal application of tampons saturated in a diluted emulsified solution successfully healed vaginitis and cervicitis ( $n = 130$ ) caused by *T. vaginalis*. A combination of vaginal pessaries containing 0.2 g tea tree oil inserted nightly and daily douching with 0.4% tea tree oil in water resulted in clinical cure from trichomonal vaginitis (Peña 1962). Positive results from in vitro studies provide further support for this indication. There is now a need to confirm these results under double-blind conditions.

A case report shows that a 5-day course of 200 mg tea tree oil in a vegetable oil base inserted into the vagina may also be successful at treating vaginal candidiasis, with eradication of anaerobic bacterial vaginosis being confirmed after 1 month (Blackwell 1991). While further clinical evidence is lacking, in vitro studies demonstrate that tea tree oil is moderately effective against *Candida albicans* (Agarwal et al 2010).

### Cystitis

A randomised, double-blind study investigated the effects of tea tree oil, administered as 8 mg essential oil (taken three times daily) in an enteric-coated capsule, in 26 women with chronic idiopathic colibacillary cystitis (Belaiche 1988). After the 6-month test period, 54% of women receiving active treatment were symptom-free compared with only 15% receiving placebo. Although symptom-free, 50% of women in the tea tree group still showed evidence of infection.

### Gingivitis

Tea tree oil was as effective as chlorhexidine against *Streptococcus mutans*, the bacteria that causes gingivitis, in a controlled study of 30 individuals (Groppo et al 2002). A more recent double-blind, randomised, longitudinal study evaluated and compared

the effects of tea tree oil gel (2.5%) and chlorhexidine gel (0.2%) in 49 patients with severe chronic gingivitis (Soukoulis & Hirsch 2004). Subjects brushed with the tea tree, chlorhexidine or placebo gel twice daily for a period of 8 weeks. Tea tree oil significantly reduced the papillary bleeding index and gingival index, but did not reduce plaque.

### Dandruff

Tea tree oil may be effective for improving, but not eradicating, dandruff according to a randomised, single-blind, parallel-group study (Satchell et al 2002b). In the study, tea tree oil shampoo (5%) was compared to placebo in 126 patients with mild to moderate dandruff over 4 weeks (Satchell et al 2002b). The tea tree oil group achieved a 41% improvement as compared to 11% in the placebo group, with no adverse effects.

### Head lice eradication

In test tube studies, topical application of tea tree oil was extremely effective against head lice, with 93% of lice and 83% of eggs destroyed (Veal 1996). In a more recent in vitro study, a 1% concentration of tea tree oil was found to be effective against head lice, with 100% mortality within 30 minutes (Di Campli et al 2012). Phenols, phenolic ethers, ketones and oxides appear to be the major toxic components responsible for this activity. Using a mite chamber assay, tea tree oil was also found to be effective against both head lice and dust mites (Williamson et al 2007).

While these in vitro studies and anecdotal evidence provide some basis for its clinical use, large double-blind, clinical trials have yet to be conducted (Centre 2008).

### Dermatitis

Tea tree oil has been shown to reduce the severity of induced experimental contact dermatitis due to nickel sulfate and perform better than either zinc oxide or clobetasone butyrate (Wallengren 2011). Tea tree oil was tested at a 20% and 50% concentration. Similar efficacy was reported at both strengths; however there was a higher incidence of erythema at the higher dose, suggesting that the 20% dose is preferable.

Tea tree oil-containing cream may also be an effective treatment for dermatitis in dogs according to two studies. Tea tree oil cream (10%) was applied, twice daily, for 4 weeks to 53 dogs suffering from chronic dermatitis, allergic dermatitis, interdigital pyoderma, acral lick dermatitis and skinfold pyoderma (Fitzi et al 2002). At the end of the trial, 82% of the animals had a good or very good response to treatment with most symptoms disappearing, although two dogs experienced local irritation. Another trial by the same research team again evaluated the tea tree cream and blinded the study with a commercial skin care cream (Reichling et al 2004). Fifty-seven dogs were involved in this study and similar results were obtained, with drastically

reduced dermatitis in 71% of animals as compared to 41% using the control cream. A local reaction was reported in one dog.

## OTHER USES

### Herpes

Since tea tree oil exhibits antiviral activity in vitro, tea tree oil preparations have been used in the treatment of genital herpes simplex virus. Clinical trials investigating tea tree oil for this indication are not available, so it is unknown whether effects are clinically significant.

### Hair follicle mite eradication (ocular demodicosis)

Clinical research indicates a possible role for tea tree oil in the treatment of blepharitis and ocular discomfort caused by the ectoparasite *Demodex*. A randomised study involving 281 patients with symptoms of eye discomfort, who had tested positive for ocular *Demodex* infestation, were treated with weekly lid scrubs at the clinic with tea tree oil 50%, combined with twice-daily home use of an eyelid scrub that included tea tree oil 10% or weekly clinic and twice-daily home use of an eyelid scrub without tea tree oil, for a period of 4 weeks. The study was limited by poor compliance; however a 37.5% eradication rate of *Demodex* was reported in a subgroup of the treatment group who showed good compliance (use of scrub >10 times/week) (Koo et al 2012).

This finding supports those from an earlier retrospective review of 11 cases, in which eyelid scrub with 50% tea tree oil combined with daily lid hygiene and tea tree shampoo for 4 weeks was observed to effectively eradicate the hair follicle mite *Demodex folliculorum* and result in subjective and objective improvements (Gao et al 2007).

### Wart eradication

There is a case report that daily topical application of 100% tea tree oil for 12 days successfully eradicated warts on the hand of a paediatric patient (Millar & Moore 2008).

### Oral candidiasis

Results from an animal study suggest that tea tree oil and its constituent terpinen-4-ol may decrease the symptom score in oral candidiasis in azole-resistant strains of *Candida albicans* (Ninomiyama et al 2012). This encouraging result requires testing in humans to further determine efficacy.

### Idiopathic hirsutism

Preliminary evidence suggests that a combination of tea tree and lavender oil as a spray may offer some benefit in women with mild idiopathic hirsutism. One small study involving 24 women showed that application of tea tree and lavender oil for 3 months reduced hair diameter in areas affected by hirsutism, compared to no change in the placebo group. It was

proposed that this was due to antiandrogenic properties found in tea tree and lavender essential oils (Tirabassi et al 2013).

#### Practice points/patient counselling

- Tea tree has multiple actions, including antibacterial, antiviral, antiparasitic, antifungal and anti-inflammatory.
- Tea tree preparations may be effective as treatments for gingivitis, *Candida albicans* or *Trichomonas vaginalis* vaginitis and cervicitis, cystitis, head lice, blepharitis and contact dermatitis according to available research; however further clinical research is required to clarify its role.
- 100% tea tree oil is a safe and effective alternative to clotrimazole for the treatment of toenail onychomycosis.
- 5% tea tree oil gel has been shown to significantly improve acne vulgaris, with effects similar to 5% benzoyl peroxide lotion.
- 10% tea tree oil preparation is effective at treating dermatitis in dogs.
- Clinical evidence supports the use of tea tree oil preparations in MRSA infection.
- Tea tree oil should not be ingested and a test patch is advised before widespread topical application.

#### DOSAGE RANGE

Tea tree oil is used in a variety of forms, such as gels, creams, ointments, oral rinses, soaps, shampoos and paints. Minimum bactericidal concentrations are generally 0.25%.

- Onychomycosis: 100% essential oil applied twice daily for months.
- Tinea pedis: 10% essential oil in cream base applied twice daily.
- Acne: 5% essential oil in cream or gel base applied daily.
- Contact dermatitis: 20–50% tea tree oil preparation.
- Dermatitis in dogs: 10% preparation applied twice daily for 4 weeks.
- Dandruff: 5% tea tree oil shampoo daily for at least 4 weeks.
- Gingivitis: 2.5% oral gel — brush teeth with preparation twice daily for 8 weeks.
- MRSA: 2–4% nasal ointment and 5% tea tree oil body wash used for 5 days.
- Vaginitis (*Candida albicans* or *Trichomonas vaginalis*): intravaginally applied tampons saturated in a 1% emulsified solution, vaginal pessaries containing 0.2 g essential oil.
- Cervicitis (*Candida albicans* or *Trichomonas vaginalis*): intravaginally applied tampons saturated in a 20% emulsified solution.

#### TOXICITY

Tea tree oil should not be orally ingested, based on a risk of toxicity. Although no deaths have been

reported in the literature (Hammer et al 2006), accidental ingestion has resulted in confusion, disorientation, general malaise and coma, according to case reports.

One case has been reported of an infant ingesting less than 10 mL of 100% oil; this resulted in confusion and an inability to walk within 30 minutes, followed by a full recovery within 5 hours (Jacobs & Hornfeldt 1994).

#### ADVERSE REACTIONS

Anecdotal evidence from almost 80 years of use suggests that the topical use of the oil is relatively safe, and that adverse events are minor, self-limiting and occasional (Hammer et al 2006). Skin irritation, contact dermatitis, linear immunoglobulin A disease and erythema multiforme-like reactions are possible in sensitive individuals (Hammer et al 2006, Pazyar et al 2012, Posadzki et al 2012, Williams et al 2007). It has been suggested that this is underreported and that tea tree oil should be included in patch testing. Oxidised monoterpenes, such as ascaridole, are likely to be the sensitising agents (Bakker 2011, Reichling et al 2006) as tea tree oil from freshly opened products elicits no or weak reactions. It is therefore suggested that patch testing needs to be done with oxidised tea tree oil (Rutherford et al 2007).

Three cases of prepubertal gynaecomastia have been reported in boys who had used topical products containing lavender and tea tree oils, with the gynaecomastia resolving after the products were discontinued (Henley et al 2007).

#### SIGNIFICANT INTERACTIONS

None known.

#### CONTRAINDICATIONS AND PRECAUTIONS

Caution should be exercised if applying the oil to eczematous or inflamed skin as it may cause irritation. It is suggested that a small amount be first applied to a test patch, to determine whether irritation will occur, as contact dermatitis has been reported.

#### PREGNANCY USE

Insufficient reliable information is available to determine safety.

#### PATIENTS' FAQs

##### What will tea tree oil do for me?

Tea tree oil is an antiseptic substance that is effective against a wide range of common bacterial and fungal organisms. It also has antiviral, antiparasitic and anti-inflammatory actions. Scientific evidence shows that it is an effective treatment for acne and fungal infections of the toenails and feet. There is preliminary evidence that it might be useful in *Trichomonas vaginalis* vaginitis and cervicitis, cystitis, gingivitis, head lice, blepharitis and MRSA infection.

### When will it start to work?

This will depend on the indication it is being used to treat. In some cases, clinical tests are not available, so it is uncertain when, if any, effects are seen.

### Are there any safety issues?

Tea tree oil should not be ingested orally and used with caution on inflamed and sensitive skin.

## Thyme

**HISTORICAL NOTE** Although thyme has been used as a cooking spice for centuries in Europe, it is also used medicinally to treat common infections, coughs, bronchitis and asthma. Red thyme oil has been used as an antimicrobial agent since the 16th century (Bahadoran et al 2010). The 17th-century herbalist Nicholas Culpeper recommended thyme for whooping cough, gout, stomach pains and shortness of breath. It was also used in perfumes and embalming oils. In medieval times the plant was seen as imparting courage and vigour (Blumenthal et al 2000).

### COMMON NAME

Thyme

### OTHER NAMES

Common thyme, garden thyme, farigola, folia thymi, gartenthymian, herba thymi, almindelig timian, thym, thymian, thymianblätter, timo

### BOTANICAL NAME/FAMILY

*Thymus vulgaris* (family Lamiaceae)

### PLANT PARTS USED

Leaves and flowering tops

### CHEMICAL COMPONENTS

The primary constituents are the volatile oils (1–2.5%), which include phenols (0.5%), namely thymol (30–70%), eugenol and carvacrol (3–15%), also flavonoids, apigenin, luteolin and saponins and tannins. Rosmarinic acid, caffeic acid and calcium are also found in significant quantities (Chohan et al 2012, Duke 2003). The herb also contains bitter principles and salicylates.

### MAIN ACTIONS

Although thyme has not been significantly investigated in human studies, there has been some investigation into the activity of several of its constituents,

in particular, thymol and carvacrol and the volatile oil component of the herb. It is not known whether results obtained for these constituents are representative for the crude herb, but they provide some further understanding. Both the essential oil and thymol are ingredients in many proprietary products.

### Antitussive and antispasmodic effects

These actions have been attributed to the phenolic compounds in thyme (WHO 2003). Antispasmodic effects on guinea pig trachea and ileum have been demonstrated for these constituents and for the whole extract of thyme (Engelbertz et al 2008).

### Expectorant

The saponin content is believed to have expectorant activity, as demonstrated in animal studies. An in vivo trial has demonstrated improved expectoration and mucociliary clearance (Wienkotter et al 2007).

### Analgesic

In vivo research suggests that *Thymus vulgaris* extract has an inhibitory effect on pain sensation; however, the mechanism of action remains unknown (Taherian et al 2009).

### Antibacterial

Both the extract and essential oil exhibit antibacterial activity against a wide range of bacteria. This is

chiefly due to the eugenol, thymol and carvacrol constituents.

### Extract

Thyme extract has demonstrated activity of thyme extract against *Escherichia coli*, *Listeria monocytogenes*, *Streptococcus mutans* and *Salmonella enterica* in vitro (Burt et al 2005, 2007, Fabian et al 2006, Friedman et al 2002, Hammad et al 2007, Schelz et al 2006, Solomakos et al 2008). Aqueous thyme extract also has a significant inhibitory effect on *Helicobacter pylori*, reducing both its growth and its potent urease activity in vitro (Tabak et al 1996).

### Essential oil

The essential oil of thyme also has potent antibacterial properties as demonstrated in vitro against a wide range of pathogens, including clinical bacterial strains of *Staphylococcus*, *Enterococcus*, *Escherichia* and *Pseudomonas* genera, *Clostridium botulinum*, *Haemophilus influenzae*, *Klebsiella pneumoniae*, *Salmonella typhi*, *Brochothrix thermosphacta* and *P. acnes* (Kalemba & Kunicka 2003, Schmidt et al 2012, Sienkiewicz et al 2011, Zu et al 2010). *T. vulgaris* essential oil also exhibits better inhibitory effects against *H. pylori* than essential oil from *Eucalyptus globulus* (Esmaeili et al 2012).

In vitro tests have also identified antibacterial activity against four Gram-negative food-borne bacteria (*Escherichia coli*, *Salmonella abony*, *Pseudomonas aeruginosa* and *P. fragi*) (Schmidt et al 2012).

### Multi-drug resistant bacteria

Emerging in vitro evidence suggests that thyme essential oil has activity against multidrug resistant strains of *Staphylococcus*, *Enterococcus*, *Escherichia*, and *Pseudomonas* genus (Sienkiewicz et al 2012). Thyme essential oil may enter the extracellular matrix, cell membrane or cell wall of bacterial biofilms, eradicating bacteria within biofilms with greater efficiency than certain antibiotics (Kavanaugh & Ribbeck 2012).

Thyme extract and essential oil potentiates the antibacterial effects of tetracycline against methicillin-resistant *Staphylococcus aureus* in vitro (Fujita et al 2005, Warnke et al 2009, Sienkiewicz et al 2011). The antibacterial activity of thyme essential oil against antibiotic resistance strains (such as MRSA) is probably due to the significant content of thymol (48.1%) (Tohidpour et al 2010).

### Antifungal

The essential oil of thyme has exhibited antifungal activity against *Candida albicans* (Kalemba & Kunicka 2003). The constituents thymol and eugenol have demonstrated antifungal activity by establishing the ability to alter the cell wall and membrane of the yeasts *Saccharomyces cerevisiae* and *Candida albicans* (Bennis et al 2004, Braga et al 2007a, 2007b). *Thymus vulgaris* is also likely to have significant potential for the biological control of fungi in food (Centeno et al 2010).

### Azole resistance

Thymol and carvacrol found in thyme appear to exert a synergistic antifungal effect with the azole antimycotic fluconazole against *Candida* spp. according to in vitro research. Both constituents exhibited a high potency to block drug transporter pumps in resistant strains thereby restoring the sensitivity of resistant *Candida* isolates to fluconazole as well as having direct fungicidal activity (Ahmad et al 2013).

### Antiviral

Thyme oil demonstrates antiviral activity against HSV-1, HSV-2 and an aciclovir-resistant strain of the virus (Koch et al 2007, Nolkemper et al 2006, Schnitzler et al 2007). One study found that the oil decreased plaque formation by more than 90% when preincubated with HSV-2; however, no effect was observed when the oil was added prior to infection or after the absorption stage (Koch et al 2007). It was suggested that thyme essential oil interferes with the viral envelope.

### Antioxidant

Thyme and thymol exhibit significant antioxidant activity according to both in vitro and in vivo research. Several in vitro studies have investigated the antioxidant effects of thyme (Braga et al 2006a, Chizzola et al 2008, Lee et al 2005, Tsai et al 2011). One study found that eugenol, carvacrol, thymol and 4-allylphenol (5 mcg/mL) all inhibited the oxidation of hexanal for a period of 30 days, demonstrating potent antioxidant activity comparable to alpha-tocopherol (Lee et al 2005). Other research reveals that thyme had significant antioxidant effects in a N-nitrosodiethylamine-induced oxidative stress model in rats (Rana & Soni 2008), and that thyme essential oil exhibited a dose-dependent protective effect against aflatoxin-induced toxicity in rats (El-Nekeety et al 2011). Thyme aqueous extract has been shown to increase the activity of glutathione peroxidase in serum, liver and brain tissue of rats exposed to alcohol toxicity indicating an ability to increase antioxidant capacity in vivo (Shati & Elsaid 2009).

The polyphenol content of thyme is most likely to be responsible for its antioxidant activity.

### Anticancer

In vitro research reveals that thyme essential oil inhibits human head and neck squamous cell carcinoma growth in vitro (Sertel et al 2011). It also exhibits cytotoxicity against human prostate carcinoma (PC-3), human lung carcinoma (A549) and human breast cancer (MCF-7) cell lines with strongest effects against PC-3 (Zu et al 2010).

### Astringent

The tannin content of the herb is chiefly responsible for its astringent activity.

### Anthelmintic/antiparasitic

Thymol possesses anthelmintic activity, demonstrated in vitro (Newell et al 1996). In vitro research also shows that Iranian thyme essential oil is effective against trophozoites of *E. histolytica*, when compared to metronidazole (Behnia et al 2008).

### Anti-inflammatory

Dietary ingestion of the culinary herb thyme together with research using thyme oil and the constituent thymol have all identified anti-inflammatory effects. Thymol has demonstrated anti-inflammatory effects in vitro by reducing elastase (Braga et al 2006b). Moreover, thyme essential oil has shown to have anti-inflammatory effects in vivo. Carvacrol, which is present in thyme oil, exhibits an inhibitory effect on leucocyte migration (Fachini-Queiroz et al 2012) and has been shown to reduce TNF- $\alpha$ , IL-1 $\beta$ , and IL-8 secretion levels of THP-1 cells in vitro (Tsai et al 2011).

One study investigated the impact of both cooking and digestion on its biological and health promoting properties. The researchers found that thyme significantly decreased IL-8 release via inhibition of, and protection against, the action of H<sub>2</sub>O<sub>2</sub> or TNF $\alpha$  (Chohan et al 2012).

### IN COMBINATION

A combination of oregano and thyme essential oils has been shown to reduce inflammation in trinitrobenzene sulfonic acid (TNBS)-induced colitis in vivo (Bukovska et al 2007). A dose of 0.2% thyme and 0.1% oregano led to a reduction in IL-1 beta, IL-6, GM-CSF and TNF $\alpha$ . The oils also decreased mortality rate, increased body weight and reduced histological damage (Bukovska et al 2007).

### OTHER ACTIONS

Thyme may possess antithrombotic properties (Naemura et al 2008).

### CLINICAL USE

Thyme has not been significantly investigated in controlled studies, therefore information is generally derived from evidence of activity and traditional use.

#### Respiratory tract infections

Thyme extract has been used to treat the common cold, bronchitis, laryngitis and tonsillitis. It is orally ingested or used in a gargle for local activity. The herb's significant antibacterial activity provides a biological basis for its use.

#### Bronchitis — in combination

Encouraging data have been reported for chronic bronchitis treated by thyme in combination with other herbs in large ( $n > 3000$ ) comparative clinical trials, although no data are available for thyme as a stand-alone treatment (Ernst et al 1997). A

combination of thyme and primrose root (1 mL five times/day) has been found to be beneficial in both double-blind and single-blind trials (Gruenwald et al 2005, 2006). The double-blind, placebo-controlled, randomised, multicentre trial in 150 outpatients with acute bronchitis found that 58.7% of participants in the treatment group were symptom-free at the end of the 7 to 9 days compared to 5.3% in the placebo group (Gruenwald et al 2005). A double-blind, placebo-controlled, multicentre study investigated the efficacy of the same combination in 361 outpatients with acute bronchitis or severe cough (Kemmerich 2007). The combination successfully reduced coughing fits by 67.1% compared to 51.3% on days 7 to 9 ( $P < 0.0001$ ). The active group reported a 50% reduction in coughing on average 2 days earlier than the placebo group. The singular effect of thyme in this formula, however, is uncertain.

A postmarketing surveillance study investigated the effects of a different mixture containing thyme and ivy as a syrup (Bronchipret Saft) in 1234 children and adolescents with acute bronchitis (Marzian 2007). Coughing fits reduced by 81.3% by day 10 and the responder rates for the various age groups were 92.0 to 96.5%. The singular effect of thyme in this formula however is uncertain.

Thyme is approved by Commission E in the treatment of bronchitis, whooping cough and upper respiratory tract catarrh (Blumenthal et al 2000).

#### Candida vaginitis — in combination

A prospective, single-blind, two-stage clinical trial involving 64 women found that a topical cream containing garlic and thyme was as effective as clotrimazole treatment for candidal vaginitis (Bahadoran et al 2010). Treatment was used for 7 nights by both groups. Clinical symptoms were decreased by at least 50% in more than 83% of women using the herbal cream compared to 92% in the clotrimazole group, but the difference was not significantly different.

#### Diarrhoea

The astringent properties of thyme provides a theoretical basis for its application in this condition.

#### Gastritis and dyspepsia

The bitter principles present in the herb and its antispasmodic activity provide a theoretical basis for its use in these conditions.

#### Skin disinfection (topical use)

Thyme extract has been used topically for infection control in minor wounds. The herb's antimicrobial and astringent activity provides a theoretical basis for this use.

### OTHER USES

Traditionally, it has been used to aid in labour and delivery, promote menstruation and topically for warts and inflamed swellings (Fisher & Painter

1996). It has also been used to treat enuresis in children.

**DOSAGE RANGE**

**Internal use**

- Fluid extract (1:1): 1–2 mL up to three times a day.
- Fluid extract (1:2): 15–40 mL/week.
- Tincture (1:5): 2–6 mL three times daily.
- Infusion of dried herb: 1–4 g three times daily.

**External use**

- 5% infusion used as a compress.

It has been used together with garlic in a vaginal cream to treat vaginitis caused by *Candida* infection; however, the research report does not specify the concentration of these ingredients (Bahadoran et al 2010).

**ADVERSE REACTIONS**

The volatile oil is considered an irritant topically and can cause nausea and vomiting, headache, dizziness, convulsions, cardiac or respiratory arrest if taken internally (Newell et al 1996). As such, the crude herb is considered far safer.

Contact dermatitis reactions have been reported with topical use (Lorenzi et al 1995).

**SIGNIFICANT INTERACTIONS**

Thyme may induce enzymes in phase one and two detoxification in the liver (Sasaki et al 2005). The clinical significance of this is unknown.

**CONTRAINDICATIONS AND PRECAUTIONS**

Contraindicated in people who are allergic to the Lamiaceae (Labiatae) family of plants. Other cautions are gastritis, enterocolitis and congestive heart failure (Ernst et al 2001).

**PREGNANCY USE**

Essential oil not recommended in pregnancy.

**PATIENTS' FAQs**

**What will this herb do for me?**

When taken internally, thyme is used to treat bronchitis, symptoms of the common cold, diarrhoea and dyspepsia. It is also used as an antiseptic gargle for sore throats and can be diluted and applied externally to minor wounds.

Thyme has strong antibacterial activity and antifungal actions and is used as a treatment for common infections such as bronchitis and upper respiratory tract infections. It is also used as a food preservative, for relieving symptoms of dyspepsia and diarrhoea.

**When will it start to work?**

The lack of human studies for this herb make it difficult to determine when effects will start to occur.

**Are there any safety issues?**

Thyme should not be used by people allergic to the Lamiaceae (Labiatae) family of plants or in pregnancy, and it should be used with caution in gastritis, enterocolitis and congestive heart failure.

**Practice points/Patient counselling**

- Thyme is an aromatic and medicinal plant that has been used in traditional medicine, in phytopharmaceutical preparations, as a food preservative, and as an aromatic ingredient.
- Although thyme is used as a cooking spice, it is also used medicinally to treat common upper respiratory tract infections, coughs, bronchitis and asthma, dyspepsia and diarrhoea.
- Thyme extract is used as a gargle for pharyngitis or applied topically (5% dilution) as a compress to wounds due to its antimicrobial and astringent activities.
- Thyme has significant antibacterial and antifungal activity against a wide range of microorganisms. Preliminary evidence suggests activity against azole-resistant *Candida* and multidrug resistant strains of *Staphylococcus*, *Enterococcus*, *Escherichia* and *Pseudomonas* genus.
- Thyme has not been significantly investigated in controlled trials, so much information is based on traditional use or evidence of activity.
- Thyme has antispasmodic, antimicrobial, antitussive, astringent and anthelmintic activities as demonstrated in vitro or in animal studies.

## Tribulus

**HISTORICAL NOTE** Widely distributed in the Mediterranean region, Middle East and southern Africa, tribulus is an important plant used in traditional Ayurvedic, Arabic and Chinese medicine. Different parts of the tribulus plant are used to treat a variety of conditions, such as cough, colicky spasms, diarrhoea, haemorrhage, cardiovascular disease, rheumatic pain, gout, various kidney disorders, including kidney stones, and as an insect repellent.

**COMMON NAME**

Tribulus

**OTHER NAMES**

Al-gutub, cat's-head, devil's-thorn, devil's-weed, goathead, puncture vine, qutiba

**BOTANICAL NAME/FAMILY**

*Tribulus terrestris* (family Zygophyllaceae)

**PLANT PARTS USED**

Leaf or fruit

**CHEMICAL COMPONENTS**

Different parts of the plant contain different constituents in varying ratios. Chemical constituents extracted from tribulus include phenolic compounds, saponins, sterols and alkaloids (Hammoda et al 2013). Overall, the steroidal saponin content is considered the most important and includes constituents such as protodioscin, diosgenin, yamogenin, epismilagenin, tigogenin, neotigogenin, gitogenin and neogitogenin (Miles et al 1994). New steroidal saponins continue to be isolated from extracts of tribulus fruit (Chen et al 2012, Hammoda et al 2013, Huang et al 2003, Su et al 2008, 2009, Xu et al 2008, Zhang et al 2011). The significance of this is yet to be determined. Beta-sitosterol, vitamin C, potassium and calcium are also found in the herb (Li et al 1998). Two major alkaloids have been identified: harmine and norharmine (Bourke et al 1992).

Of the steroidal saponins, protodioscin is considered the chief constituent responsible for the plant's effects on libido and sexual functioning. Preliminary observations suggest that *Tribulus terrestris* grown in different soils does not consistently produce this constituent and considerable variations have been identified in commercial products (Ganzera et al 2001). Steroidal saponins consist of a furostanol- or spirostanol-based aglycone and an oligosaccharide attached to a steroid nucleus. Steroidal saponins are very common in the plant kingdom and are natural components in many foods, such as asparagus, garlic and oats.

**MAIN ACTIONS**

Tribulus has not undergone significant clinical investigation; therefore, evidence of activity primarily derives from animal and in vitro studies. Additionally, some studies have investigated the pharmacological effects of the isolated saponin content.

**Increases libido and enhances sexual function**

Administration of tribulus extracts to animals improves libido and increases sexual behaviour and spermatogenesis.

Results from a 2002 animal study have produced positive results suggestive of aphrodisiac activity (Gauthaman et al 2002). The study compared the effects of subcutaneous testosterone, an orally

administered tribulus extract containing protodioscin (45% dry weight) or placebo over 8 weeks in castrated rodents. Both testosterone and tribulus treatments significantly improved sexual behaviour compared with controls, although testosterone was the more effective treatment.

A follow-up study by the same research team added further data (Gauthaman et al 2003). In this study, rats were treated with 2.5, 5 and 10 mg/kg once daily for 8 weeks. The results showed a considerable increase in sexual behaviour and slight weight gain compared to controls. Interestingly, the results were more pronounced at the lower dose range.

Tribulus standardised to 20% saponins was administered to sexually sluggish male rats (50 mg/kg body weight and 100 mg/kg body weight). A dose-dependent improvement in sexual behaviour was observed with the treatment as characterised by an increase in mount frequency, intromission frequency and penile erection index, as well as a decrease in mount latency, intromission latency and ejaculatory latency. The enhancement of sexual behaviour was more prominent on chronic administration of tribulus (Singh et al 2012).

The exact mechanism by which tribulus influences sexual behaviour is not known, but increasing androgenic status and nitric oxide (NO) release have been proposed to be chiefly responsible (Gauthaman et al 2002). More specifically, some reports have suggested that increases in dehydroepiandrosterone (DHEA) and testosterone are possible (Adimoelja 2000, Gauthaman et al 2002). The constituent protodioscin is considered the most important for this action and has been reported to directly convert to DHEA (McKay 2004). Additionally, ex vivo tests have observed proerectile effects with protodioscin due to increased release of NO from the endothelium and nitroergic nerve endings (Adaikan et al 2000). Hormonal effects of tribulus were tested in primates, rabbits and rats. Administration of tribulus demonstrated a statistically significant increase in testosterone and DHEA levels in the primates, an increase of these hormones in rabbits, but very little increase in rats (Gauthaman & Ganesan 2008). Animal studies show that chronic administration more favourably enhances sexual function compared with acute dosing (Singh et al 2012).

Whether these hormonal effects are seen in humans remains unclear. One study investigated the influence of tribulus extract on androgen metabolism in 21 healthy 20–36-year-old men. Testosterone, androstenedione and luteinising hormone (LH) levels in the serum were measured 24 hours before supplementation, and at 24, 72, 240, 408 and 576 hours after supplementation. No significant differences were observed between the supplemented groups at two different concentrations (10 mg or 20 mg/kg body weight daily) and placebo (Neychev & Mitev 2005). Longer clinical trials measuring androgen-enhancing activity of tribulus are required to validate these actions.

### Hormone modulation

Saponins from tribulus appear to increase follicle-stimulating hormone (FSH) in women, which in turn increases levels of oestradiol (Mills & Bone 2000). The presence of steroidal saponins could be responsible for intrinsic hormonal activity by directly stimulating female endocrine-sensitive tissues; however, studies in ovariectomised rats showed that this plant was not able to stimulate endocrine-sensitive tissues, including the uterus and vagina, indicating a lack of oestrogenic activity in vivo (Mazaro-Costa et al 2010). Comparatively, a luteinising effect of tribulus has been demonstrated in polycystic ovaries in vivo. After supplementation with tribulus, ovarian cysts significantly decreased and the number of corpora lutea and primary and secondary follicles significantly increased compared with placebo in a rat model. The results suggest that tribulus may also increase LH (Dehghan et al 2012).

### Antimicrobial

Antimicrobial activity of organic and aqueous extracts from fruits, leaves and roots of *Tribulus terrestris* were tested. The most active extract against both Gram-negative and Gram-positive bacteria was ethanol extract of the fruits against *Bacillus subtilis*, *Bacillus cereus*, *Corynebacterium diphtheriae* and *Proteus vulgaris*. The strongest antifungal activity was against *Candida albicans* (Al-Bayati & Al-Mola 2008). Another study extracted and identified two saponins from tribulus, and demonstrated potent antifungal activity against *C. albicans*. Saponins appear to exert their antifungal action by damaging the cell membrane, causing leakage of cellular material. They may also inhibit fungal hyphae (Zhang et al 2006). More recently, tribulus fruiting body extract has been used in the process of synthesising silver nanoparticles — a novel nanotechnology approach. The antibacterial property of synthesised nanoparticles was observed in multidrug-resistant bacteria, including *Streptococcus pyogenes*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Bacillus subtilis* and *Staphylococcus aureus* (Gopinath et al 2012).

### Diuretic

A large oral dose of 5 g/kg tribulus was shown to have greater diuretic activity than frusemide 120 mg/kg in vivo (Al Ali et al 2003). The dose required for this effect does not appear to be clinically practical.

### Urolithic

With regard to kidney stones, tribulus has been found to decrease the amount of urinary oxalate in rats (Sangeeta et al 1994) and produce significant dose-dependent protection against experimentally induced uroliths in animal studies (Anand et al 1994, Sangeeta et al 1994). Experimental studies further found that tribulus was effective in preventing the deposition of crystals on glass beads in the urinary bladder of rats, dissolving phosphate-type

calculi in an in vitro model, and dissolving uric acid and cystine stones to some extent (Prasad et al 2007). In vitro studies using human urine suggest that the diuretic properties of tribulus may be the most crucial mechanism for preventing urinary stone formation (Joshi et al 2005). More recent research demonstrated that extract of dried tribulus exhibited a concentration-dependent inhibition on the growth of calcium oxalate crystals. In addition, when epithelial renal cells were injured by exposure to oxalate for 72 hours, tribulus extract prevented cell injury in a dose-dependent manner. These results suggest that tribulus may not only prevent growth of calcium oxalate crystals, but also has a cytoprotective role (Aggarwal et al 2010).

### Antispasmodic

A dose-dependent antispasmodic activity causing a significant decrease in peristaltic movements has been demonstrated with the isolated saponin content of tribulus (Arcasoy et al 1998).

### Cardioprotective activity

Tribulus is shown to have some cardioprotective actions (Ojha et al 2008). A Chinese report of successful treatment of angina pectoris with the saponin content of tribulus suggests that the preparation dilates coronary arteries and improves coronary circulation (Wang et al 1990). A triterpene saponin of tribulus may play a role in cardiocyte survival during chemical hypoxia-ischaemia, as demonstrated in vitro (Sun et al 2008).

In another study 10 mg/kg/day of the aqueous extract of the fruit has shown antihypertensive effects in an animal trial when compared to control. The authors concluded that effects are possibly due to inhibition of angiotensin-converting enzyme activity (Sharifi et al 2003). More recent research demonstrates that the antihypertensive effect appears to result from a direct arterial smooth-muscle relaxation, possibly involving NO release and membrane hyperpolarisation (Phillips et al 2006). Tribulus saponins not only lowered serum lipidaemia, but also relieved left ventricular remodelling, and improved cardiac function in the early stage after myocardial infarct in a hyperlipidaemia mouse model (Guo et al 2007). The mechanism of action is suggested to be a reduction in cardiac muscle cell apoptosis by regulating protein expressions (Guo et al 2006).

A study undertaken in rabbits found tribulus significantly lowered serum lipid profiles and decreased endothelial cellular surface damage and rupture. Results also suggested tribulus may partially repair the endothelial dysfunction resulting from hyperlipidaemia (Tuncer et al 2009).

### OTHER ACTIONS

Experiments with healthy mice have found that *Tribulus terrestris* significantly inhibits gluconeogenesis, influences glycometabolism and reduces triglyceride and total cholesterol levels (Li et al 2001).

Tribulus demonstrates some protection against oxidative stress in rats with induced diabetes (Amin et al 2006) and the saponins are found to have a hypoglycaemic action.

An in vitro test has also identified cyclooxygenase-2 inhibition activity (Hong et al 2002), suggesting possible anti-inflammatory actions. An animal study using a percolated extract of the fruits of tribulus at a dose of 100 mg/kg showed a significant analgesic effect compared to the control group with a lower gastric ulcerogenicity than indomethacin (Heidari et al 2007). Diabetic rats exhibited significant hyperalgesia after treatment with standardised aqueous extract of tribulus, through modulation of oxidative stress and inflammatory cytokine release (Ranjithkumar et al 2013). Two isolated constituents, tribulosin and beta-sitosterol-D-glucoside, have shown anthelmintic activity in vitro against *Caenorhabditis elegans* (Deepak et al 2002).

Protection against mercury-induced nephrotoxicity was demonstrated with 7 days' administration of tribulus fruit extract (6 mg/kg body weight) in an animal study (Kavitha & Jagadeesan 2006).

## CLINICAL USE

Evaluation of the efficacy of tribulus is hampered by the lack of quality clinical trials. The trials that are available tend to use small sample sizes, lack placebo groups and often test a combination of herbs. Nonetheless, the evidence so far is promising and warrants larger controlled trials using tribulus independently of other herbal and nutritional supplements.

### Increases libido and enhances sexual function

The observed pharmacological effects on androgen status and results from animal models indicating an aphrodisiac activity (Gauthaman et al 2002) and increase in sexual behaviour (Gauthaman et al 2003; Singh et al 2012) provide a theoretical basis for the use of tribulus. Unfortunately, clinical trials using stand-alone tribulus treatment have not been published to determine its effects in humans.

## IN COMBINATION

A formula Tradamixina (containing 150 mg of alga *Ecklonia bicyclis*, 396 mg of *Tribulus terrestris* and 144 mg of D-glucosamine and N-acetyl-D-glucosamine per capsule) was tested in a double-blind randomised controlled trial involving 70 male patients experiencing low libido. The formula was taken as two capsules daily and compared to tadalafil 5 mg/daily. After 2 months the combination product produced a significant increase in serum total testosterone levels ( $230 \pm 18$  ng/dL vs  $671 \pm 14$  ng/dL) and free testosterone levels ( $56 \pm 2.4$  pg/mL vs  $120 \pm 3.9$  pg/mL) ( $P < 0.005$ ), while those taking tadalafil had a small non-significant increase in both markers. Both groups showed improved scores in the International Index of Erectile Function (IIEF) and Sexual Quality of Life Questionnaire-Male. The combination formula improved libido in aged males without the side effects of tadalafil (Iacono et al 2012a).

## Erectile dysfunction

### IN COMBINATION

A mixture of nine oriental herbs, including tribulus, was evaluated using both in vitro and in vivo experiments on laboratory animals and demonstrated an improvement in sexual activity and erectile function (Park 2006). The same formula was tested in 150 men with erectile dysfunction in an observational study. The formulation was administered as two capsules daily for 2 months. IIEF scores increased in the treated group by 78% in the mild erectile dysfunction group, 80% in the moderate erectile dysfunction group, and 108% in the severe erectile dysfunction group compared with the baseline. The mean IIEF scores amongst all patients indicated a significant improvement in erectile dysfunction after 2 months (Iacono et al 2011).

### Ergogenic aid

Tribulus has been touted as a natural anabolic supplement or ergogenic aid, capable of producing large gains in strength and lean muscle mass in 5–28 days. The observed pharmacological effects on androgen status provide a theoretical basis for this activity; however, clinical trials have produced disappointing results.

A small, randomised, placebo-controlled study found that treatment with tribulus (3.21 mg/kg body weight daily) had no effects on body composition and exercise performance in resistance-trained men after 8 weeks (Antonio et al 2000). The study has been criticised by some athletes, as the dose of tribulus tested was very low and not indicative of the doses used in real life. A more recent randomised controlled trial by Rogerson et al (2007) compared the effects of tribulus extract (450 mg/day) to placebo in 22 Australian elite male rugby league players during their preseason training period. The double study was conducted over 5 weeks and found that muscular strength and fat-free mass increased significantly in both groups, with no advantage seen for tribulus treatment. Additionally, no significant differences were seen for urinary testosterone/epitestosterone ratio compared with placebo. Once again, the trial has been criticised as using subtherapeutic doses which do not reflect manufacturer recommendations or current use.

A study undertaken in two females found tribulus 500 mg three times daily for 2 days had no impact on endogenous testosterone metabolism and was well below the cut-off values defined by the World Anti-Doping Agency (Saudan et al 2008).

### Menopausal symptoms

Saponins from tribulus appear to increase FSH in women, which in turn increases levels of oestradiol (Mills & Bone 2000). The primary site of action of steroidal saponins is probably the hypothalamus (Trickey 1998). In postmenopausal women, steroidal saponin-containing herbs like tribulus have been used to alleviate oestrogen withdrawal symptoms. Clinical studies are unavailable to determine whether the effect is significant.

### Kidney stones

A human trial was conducted with a herbal combination containing *Tribulus terrestris* and another Ayurvedic herb, *Bergenia ligulata*, in the treatment of 14 patients with renal calculi and 16 patients with ureteric calculi. A total of 28.57% of patients with renal calculi and 75% patients with ureteric calculi passed their calculi completely and in other patients, there was a marked or partial expulsion of calculi along with changes in the shapes and sizes of calculi (Prasad et al 2007). The role of tribulus in achieving these results is unknown.

### Benign prostatic hyperplasia (BPH)

Tribulus has been included in combination formulas for the relief of symptoms of BPH. Standardised extracts of *Muraya koenigii* and *Tribulus terrestris* leaves were compared against tamsulosin in a double-blind randomised controlled trial involving 46 men >50 years. Patients received either the plant drug in a dose of two capsules twice daily or tamsulosin 400 mcg once daily for 12 weeks with two interim follow-up visits at the end of 4 and 8 weeks. The exact dose of the herbs was not disclosed. Median International Prostate Symptom Score (IPSS) declined from 17.0 (12.0–19.0) to 9.0 (5.0–13.0) with the plant drug and from 14.0 (11.0–18.0) to 8.0 (6.0–13.0) with tamsulosin after 12 weeks of treatment. The decline was individually significant in both groups (both  $P < 0.001$ ). The herbal combination proved effective for the symptomatic treatment of BPH; however, larger trials beyond 12 weeks are required to confirm these results (Sengupta et al 2011).

The compound Tradamixina plus *Serenoa repens* (80 mg of alga *Ecklonia bicyclis*, 100 mg of *Tribulus terrestris* and 100 mg of D-glucosamine and N-acetyl-D-glucosamine plus 320 mg of *Serenoa repens*) was administered daily for 2 months in 100 patients with lower urinary tract symptoms or BPH. Results showed a statistically significant difference in IPSS scores, quality of life index and BPH impact index. A decrease in overall prostate-specific antigen scores was also observed (Iacono et al 2012b).

It remains to be determined how much of a contribution tribulus makes in these clinical trials.

### OTHER USES

Traditionally, the acidic fruits are thought to be cooling and are used for painful micturition, urinary disorders, kidney stone prevention and impotence, whereas the leaves are thought to possess tonic, diuretic and anti-inflammatory properties and are used to increase menstrual flow. Interestingly, preliminary research into the pharmacological actions of tribulus or its constituents provides some support for several of these uses.

### DOSAGE RANGE

In Australia, preparations containing both the fruit and the root are available that are standardised to saponin content. As no clinical studies are available,

the manufacturers' recommended dose is included here, which is 2–30 g/day.

- Leaf: 750–1500 mg/day of extract standardised to contain 45% protodioscin.

### TOXICITY

Although toxicity levels in humans are not known, extensive grazing on tribulus by sheep produces a syndrome known as 'staggers', which is characterised by nervous and muscular locomotor disturbances (Bourke 1984). Outbreaks are repeatedly associated with drought periods during which sheep graze on large areas of *Tribulus terrestris* for many months at a time (Bourke 1995, Glastonbury et al 1984). Investigation with isolated harmaline and norharmaline found naturally in tribulus has found these constituents to be responsible for the 'staggers' syndrome (Bourke et al 1992).

Hepatogenous photosensitivity has also been reported among sheep grazing on *Tribulus terrestris* for long periods (Bourke 1984, Glastonbury et al 1984, McDonough et al 1994, Miles et al 1994, Tapia et al 1994, Wilkins et al 1996). A small animal study examined the clinical, laboratory and pathological findings of this disease in sheep and concluded that tribulus was responsible for hepatogenous photosensitivity (Aslani et al 2003). Laboratory and pathology tests found significantly increased white blood cells, bilirubin, total serum protein and plasma fibrinogen, and histological findings showed crystalloid materials in the bile ducts with hepatocyte degeneration. A year later, the same research team found very similar results in goats (Aslani et al 2004).

A case report describes a male patient who developed hepatotoxicity, nephrotoxicity and neurotoxicity after consuming tribulus water in an attempt to pass kidney stones; he consumed 2 L over 2 days. The patient presented having had two episodes of seizure preceded by severe weakness in the lower limbs, malaise and poor appetite. His vital signs were normal except for rising blood pressure to 180/110 mmHg, very high serum aminotransferases and creatinine levels. The patient's symptoms resolved after he was treated with anticonvulsant, antihypertensive and prednisolone medication, and haemodialysis treatment (Talasaz et al 2010). This reaction has been described in animals grazing long term on tribulus; however no other reports have been described relating to toxicity in animal or human trials. This report did not detail the exact quantity of tribulus taken, or how it was extracted. There was no testing performed to confirm the product had not been adulterated.

### ADVERSE REACTIONS

Gastrointestinal disturbance may occur in sensitive individuals due to the saponin content.

### SIGNIFICANT INTERACTIONS

Controlled studies are not available and currently no interactions are known.

### Practice points/Patient counselling

- Tribulus has been used traditionally in various parts of the world to treat colicky spasms, diarrhoea, cardiovascular disease and various kidney disorders, including kidney stones, and as an insect repellent.
- Tribulus has not undergone significant clinical testing, so much information is speculative and based on animal and test tube studies.
- Popular as an aphrodisiac, some research suggests that it increases levels of DHEA, testosterone and NO release, providing a theoretical basis for this activity. Until controlled studies are available, it is uncertain whether these effects are clinically significant.
- Tribulus is also popular among athletes as an ergogenic aid and to increase muscle strength; however, clinical studies using low-dose tribulus have not supported this use. Larger controlled studies testing higher doses for longer periods that are reflective of real-world use are required to determine its efficacy.
- Emerging studies propose it may have an impact in combination with other herbs for the treatment of BPH.

### CONTRAINDICATIONS AND PRECAUTIONS

People with androgen-sensitive tumours should avoid use.

### Warfarin

A herbal combination of *Tribulus terrestris*, *Panax ginseng* and *Avena sativa* was reported to significantly increase international normalised ratio values in two patients prescribed warfarin. It is unknown if the tribulus contributed to this effect (Turfan et al 2012).

### PREGNANCY USE

Not to be used in pregnancy.

### PATIENTS' FAQs

#### What will this herb do for me?

Preliminary research suggests that this herb increases androgen levels and improves sexual function, but human studies are not available to confirm these effects.

#### When will it start to work?

This is unknown. Animal models indicate chronic use is more effective than short-term use.

#### Are there any safety issues?

Pregnant and lactating women and people with androgen-sensitive tumours should avoid use.

## Tulsi

**HISTORICAL NOTE** The tulsi plant is regarded by Hindus as the holiest of all plants and within Ayurveda, tulsi is known as 'The Incomparable One', 'Mother Medicine of Nature', and 'The Queen of Herbs' (Singh et al 2010). Tulsi is revered as being without equal for both its medicinal and spiritual properties. Every part of the plant including the surrounding soil is revered and considered sacred and many Hindi households have tulsi plants growing in special places in their home, typically in an ornate earthen pot in a courtyard where evening and morning prayers are held.

Within Ayurveda, tulsi is regarded as one of the most esteemed plants that regulates the three doshas, and serves and 'elixir of life' that promotes longevity. As a potent adaptogen, tulsi is recommended to be taken over long periods to prevent and treat diseases such as anxiety, cough, asthma, malaria, fever, diarrhoea, dysentery, arthritis, eye diseases, otalgia, indigestion, hiccups, vomiting, gastropathy, cardiopathy, genitourinary disorders, lumbago, skin diseases, leucoderma, ringworm, insect, snake and scorpion bites and verminosis (Gupta et al 2002, Maheshwari et al 2012, Mohan et al 2011, Mondal et al 2009, Pattanayak et al 2010, Singh et al 2010).

## COMMON NAME

Tulsi (Hindi), *Ocimum sanctum* (Latin for 'sacred fragrant lipped basil') or *Ocimum tenuiflorum* (Latin

for 'basil with small flowers') also known as Tulasi in Tamil and Holy or Sacred Basil in English. There are different cultivars of tulsi including purple leaf

(Krishna), green leaf (Rama) and wild forest (Vana) tulsi

### BOTANICAL NAME/FAMILY

Genus species: *Ocimum sanctum* Family: Lamiaceae

### PLANT PARTS USED

The whole plant including leaves, stem, flower, root, seeds and oil are all used medicinally.

### GROWING/STORAGE

Tulsi grows as a herbaceous shrub growing up to 1–2 m high.

Like any medicinal plant optimal cultivation, harvesting, preservation and storage methods are required to preserve tulsi's medicinal value and it is suggested that tulsi should be grown in rural areas free from environmental pollution and employing organic methods (Singh et al 2010). This is supported by the finding of toxic elements at almost twice the concentration in tulsi leaves grown in polluted compared to unpolluted areas (Singh & Mittal 2003).

The tradition of revering the soil in which tulsi grows is supported by recent research that found that endophytic fungi from tulsi roots have in vivo hepatoprotective activity (Shukla et al 2012). Tulsi growth is also reported to double when plants are inoculated with *Glomus intraradices* (arbuscular mycorrhizal fungus) and *Azospirillum lipoferum*, a Plant Growth-Promoting Rhizobacteria (Padma-vathi & Ranjini 2011) and yields of tulsi oil have been found to increase with cutting (Zheljzakov et al 2008).

Concerns about product quality in European 'Tulsi' products have been raised by reports of a high frequency of substitution with surrogate herbs such as *Ocimum basilicum* (Jürges et al 2009). This may be addressed using HPLC fingerprints to ensure batch-to-batch quality assurance along with adulteration and safety evaluation of standardised extracts (Chanda et al 2013). Microscopical assays have also been used to reliably identify dried or fragmented specimens and discriminate surrogate species from true tulsi (Jürges et al 2009). The quality of tulsi products is also influenced by storage and packaging with a significant effect on fresh weight loss, phenolic compounds, shelf life and anti-oxidant activity (Boonyakiat & Boonprasom 2010). Polyethylene bags packed with ethylene absorbers has been recommended to maintain the quality of stored tulsi (Wongs-Aree & Jirapong 2007).

### CHEMICAL COMPONENTS

Tulsi is highly aromatic with a clove-like odour arising from its high eugenol content (Dutt 1939, Kumar et al 2013, Maimes 2004). Tulsi contains various phytochemicals and has a high antioxidant content with constituents that include alkaloids, glycosides, flavonoids, tannins, terpenoids and saponins along with nutrients such as vitamins A and C, zinc, calcium, iron and chlorophyll (Boonyakiat &

Boonprasom 2010, Maimes 2004, Padalia & Verma 2011, Shafqatullah et al 2013, Singh et al 2010).

Tulsi leaves contain high levels of ursolic acid and oleanolic acid which account for many medicinal activities (Sarkar et al 2012, Verma & Joshi 2005) with the ursolic acid content of dried leaf powder being up to 11% (Vetal et al 2012) as well as being found in tulsi roots (Zaffer Ahmad et al 2012). Tulsi oil contains many volatile monoterpenes (51.1%) and sesquiterpene hydrocarbons (27.5%) with major constituents including phenolic compounds such as eugenol (up to 71%) and carvacrol (3%) and rosmarinic acid which have antioxidant and anti-inflammatory properties (Dutt 1939, Chanda et al 2013, Kumar et al 2013, Raju et al 1999). Non-phenolic constituents including methyl eugenol (8–45%) (Gbolade & Lockwood 2008, Raseetha Vani et al 2009, Zheljzakov et al 2008), which exhibits antioxidant and free radical scavenging activities (Sathaye & Redkar 2012). Other constituents include methyl chavicol, eucalyptol,  $\alpha$ -humulene, humulene-epoxide II, (-)-*trans*-caryophyllene,  $\alpha$ -*trans*-bergamotene, and  $\gamma$ -cadinene (Zheljzakov et al 2008), along with anti-stress agents ocimumoside A and ocimumoside B (Ahmad et al 2012b, Gupta et al 2007b).

As with many herbs, chemical components and subsequent biological activity vary with cultivar type (Wangcharoen & Morasuk 2007), plant part used (Shafqatullah et al 2013), preparation method (Mondal et al 2007), growing location (Johnson 2012) and season (Raseetha Vani et al 2009) and storage conditions (Boonyakiat & Boonprasom 2010, Wongs-Aree & Jirapong 2007). For example, the antioxidant capacity of red holy basil was found to be higher than white or green holy basil (Merai et al 2003, Wangcharoen & Morasuk 2007) and the saponin content of stems is higher than leaves (Shafqatullah et al 2013, Shetty et al 2006).

The components, biological activity and amounts of oil obtained from fresh and dried leaves have been found to differ greatly according to cultivar and preparation technique. Up to nine times more eugenol (antibacterial component) has been found in fresh leaves and more  $\beta$ -caryophyllene and caryophyllene oxide (antifungal components) in dried leaves (Mondal et al 2007). The oil content of fresh leaves is reported to be 0.31 mL/100 g (Sathaye & Redkar 2012) with the oil in dried leaves ranging from 0.17 to 0.50% (Zheljzakov et al 2008).

Tulsi is reported to contain copper, nickel, zinc, potassium and sodium in trace amounts (Narendhirakannan et al 2005) and to contain more zinc, magnesium and calcium than tea and to not hyper-accumulate toxic metals such as chromium and lead (Dash et al 2008). It is suggested that trace elements in tulsi may serve as an indicator of environmental pollution as concentrations of potentially toxic elements such as cadmium, caesium, chromium, mercury, scandium and selenium were found to be almost twice as high in tulsi leaves grown in polluted compared to unpolluted areas (Singh & Mittal 2003).

## MAIN ACTIONS

Tulsi is one of the most important herbs in Ayurveda and is used extensively in several other ancient systems of medicine including Greek, Roman, Siddha and Unani, where it is valued for its broad spectrum of pharmacological activity and therapeutic actions and wide margin of safety.

Tulsi's actions have been documented in extensive *in vitro* and *in vivo* research and a few human studies and recent reviews suggest that these actions are extensive and include: antimicrobial (including antibacterial, antiviral, antifungal, antiprotozoal, anti-malarial, anthelmintic), mosquito repellent, antidiarrhoeal, antioxidant, anticataract, anti-inflammatory, chemopreventive, radioprotective, hepato-protective, neuro-protective, cardio-protective, anti-diabetic, anti-hypercholesterolaemic, anti-hypertensive, anti-carcinogenic, analgesic, anti-pyretic, anti-allergic, immunomodulatory, central nervous system depressant, memory enhancer, anti-asthmatic, anti-tussive, diaphoretic, anti-thyroidic, anti-fertility, anti-ulcer, anti-emetic, anti-spasmodic, anti-arthritis, adaptogenic/anti-stress, anti-cataract, anti-leucodermal and anti-coagulant activities (Gupta et al 2002, Mahajan et al 2012, Mohan et al 2011, Mondal et al 2009, Pandey & Madhuri 2010, Pattanayak et al 2010, Prakash & Gupta 2005).

### Adaptogenic antifatigue / anti-stress

In rodent stress models, treatment with tulsi normalises many of the physiological and biochemical changes associated with physical fatigue and stress. In forced-swim tests an aqueous suspension of 70% alcoholic extract of tulsi is reported to enhance aerobic glucose metabolism and improve swimming time, body weight, lipid peroxidation, and normalise biochemical parameters with lowering of malondialdehyde and lactic acid levels in rat liver and muscle (Venu Prasad & Khanum 2012). Similar results are observed in mice supplemented with an ethanolic extract of tulsi leaves, with improved swim duration and normalisation of cold-restraint stress-induced biochemical changes (Anju 2011). A methanolic tulsi leaf extract, in combination with extracts from *Withania somnifera* root and *Zingiber officinalis* rhizome, was further found to have significant corrective effect on swimming-induced oxidative damage on rat cardiac, skeletal and brain tissues (Misra et al 2006).

Pretreatment with ocimumoside A and B prevented both restraint-induced and chronic unpredictable stress-induced changes in the monoaminergic and anti-oxidant systems in the frontal cortex, striatum and hippocampus of rats with an efficacy similar to that of standard antistress (*Panax quinquefolium*) and antioxidant (melatonin) drugs (Ahmad et al 2012b, Singh et al 2010). Posttreatment with aqueous tulsi extract further protected different regions of the rat brain against the detrimental effect of restraint-induced stress with reduced lipid peroxidation, and normalisation of nucleic acids and

proteins (Tabassuma et al 2009) while hydroalcoholic tulsi extracts protected rat heart from chronic-restraint stress-induced changes (Sood et al 2006).

### Reduction of noise stress

Broadband white noise exposure is often used as an experimental model for stress that results in changes in immune response, neurotransmitter levels and ECG responses, along with increased corticosterone levels and oxidative stress in discrete brain regions. Tulsi extracts have been shown to significantly attenuate the effects of acute and chronic, noise-induced oxidative stress on rat brains (Samson et al 2006, 2007), normalise noise-induced changes in plasma corticosterone levels (Archana & Namasivayam 2002, Dwivedi 1997, Sembulingam et al 1997) and prevent noise stress-induced ECG changes (Sembulingam & Sembulingam 2005).

Ethanolic extracts of tulsi have also been found to normalise the action of noradrenaline, adrenaline, dopamine, and serotonin in discrete regions of the brains of rats exposed to chronic noise stress (Ravindran et al 2005) and reverse acute noise-induced reductions in total acetylcholine content and increases in acetylcholinesterase activity in rat cerebral cortex, corpus striatum, hypothalamus and hippocampus (Sembulingam et al 2005). Tulsi has further been shown to reverse or prevent noise-stress-induced changes in immune parameters of rats (Sembulingam et al 1999) with normalisation of leucocyte levels, thymus weight, antibody titre, spleen weight, neutrophil function and cell count (Archana & Namasivayam 2000).

### Antidepressant / anxiolytic

Tulsi has been shown to have antianxiety and antidepressant properties in experimental rodent models (Chatterjee et al 2011, Raghavendra et al 2009, Tabassum et al 2010). Ursolic acid from tulsi leaves has been shown to have anxiolytic activity comparable to diazepam (Pemminati et al 2011) and tulsi has demonstrated antidepressant activity comparable to imipramine in animal models of depression (Moinuddin et al 2011, Sakina et al 1990).

Ethanol and chloroform extracts of tulsi stem and leaf are effective in preventing tonic convulsions induced by transcorneal electroshock (Jaggi et al 2003) and an ethanol extract of tulsi leaves has been shown to prolong the pentobarbitone-induced lost reflex time, decrease the severity and recovery time of electroshock and pentylenetetrazole-induced convulsions, and decreased apomorphine-induced fighting time and ambulation in 'open field' studies in mice. The extract also lowered immobility in a manner comparable to imipramine in rodent forced swimming behavioural despair models. This action was blocked by haloperidol and sulphiride and enhanced with the potent D<sub>2</sub>-receptor agonist bromocryptine, suggesting an action on dopaminergic neurones (Sakina et al 1990).

A methanol extract of tulsi roots has demonstrated minor tranquilliser activity in rodents

(Mukherjee et al 2009) with central nervous stimulant properties and/or anti-stress activity comparable to the antidepressant desipramine (Maity et al 2000). In a human study of 35 psychiatric patients with generalised anxiety disorders 500 mg of tulsi twice daily for 30 or 60 days significantly attenuated the disorders and their associated stress and depression (Bhattacharyya et al 2008).

### Anti-inflammatory

Tulsi extracts including fresh leaves (Ankur & Sheetal 2012), essential oil (Singh & Majumdar 1995a, 1995b, 1997), ethanol extracts of callus and leaf tissue (Singh & Jaggi 2003), lyophilised aqueous extract (Fernández et al 2004), and extracted eugenol (Thakur & Pitre 2009) have been shown to have anti-inflammatory activity in both acute and chronic inflammatory animal models including carrageenan-induced paw oedema (Ankur & Sheetal 2012, Fernández et al 2004, Singh 1998, Singh & Majumdar 1995a, 1997, Thakur & Pitre 2009), turpentine oil-induced joint oedema (Singh & Majumdar 1996), PGE<sub>2</sub>, leukotriene and arachidonic acid-induced paw oedema (Singh 1998), cotton pellet granuloma (Fernández et al 2004), turpentine oil-induced granuloma pouch and formalin-induced oedema models (Ankur & Sheetal 2012).

Tulsi oil has further been demonstrated to significantly inhibit the rise in protein concentration and dye leakage in peritoneal fluid in experimentally induced peritoneal inflammation in mice and carrageenan-induced pleurisy in rats, with significant inhibition of leucocyte migration, vascular permeability and leucocyte migration following an inflammatory stimulus (Singh & Majumdar 1999a). Tulsi has also been shown to significantly reduce hydroxyl free radical-induced lipid peroxidation associated with copper sulfate toxicity (Shyamala & Devaki 1996).

The anti-inflammatory activity of tulsi is attributed to its eugenol (Thakur & Pitre 2009) and linoleic acid content and the inhibition of both the cyclooxygenase and lipoxygenase pathways of arachidonate metabolism (Singh 1998, Singh & Majumdar 1997). This is indicated by its activity in inflammation models that are insensitive to selective cyclooxygenase inhibitors (Singh et al 1996) and the anti-inflammatory effects of tulsi have been assessed as similar to non-steroidal anti-inflammatory drugs such as phenylbutazone (Singh & Majumdar 1995a), ibuprofen, naproxen, aspirin (Kelm et al 2000) and indomethacin (Kalabharathi et al 2011).

### Antioxidant

The antioxidant properties of tulsi are attributed to peroxidase (Anbuselvi et al 2013) and a high content of phenolic compounds (Sundaram et al 2012) including eugenol, luteolin and apigenin (Dutta et al 2007) with red tulsi being reported to have significantly higher total phenolic content and antioxidant capacity than white tulsi (Merai et al 2003, Wangcharoen & Morasuk 2007).

Tulsi's antioxidant properties are demonstrated in vitro by free radical (Juntachote & Berghofer 2005, Sundaram et al 2012) superoxide anion, 1,1-diphenyl-2-picrylhydrazyl and nitric oxide scavenging activity as well as by anti-lipid peroxidation, Fe<sup>2+</sup> chelation and reducing power assays (Juntachote & Berghofer 2005 Rege et al 2012, Saiful Islam et al 2011). Tulsi is also documented to enhance endogenous anti-oxidant defences in vitro through increasing levels of glutathione and other anti-oxidant molecules and induction of endogenous anti-oxidant enzymes (Shivnanajappa & Joshi 2012).

In animal studies hydro-alcoholic tulsi extracts have been found to reduce lipid peroxidation, increase reduced glutathione content and superoxide dismutase and catalase in normal and immune-compromised rats (Gupta et al 2007a) and protect against lipid peroxidation in experimentally-induced anaemic-hypoxia oxidative stress in rabbits (Jyoti et al 2007, Sethi et al 2003). Experimental evidence further suggests that the antioxidant properties of tulsi may serve to protect against the damaging effects of cerebral (Ahmad et al 2012a, Yanpallewar et al 2004) and cardiac ischaemia (Arya et al 2006, Panda & Naik 2009, Sharma et al 2001, Sood et al 2005) and protect against cataracts (Gupta et al 2005, Halder et al 2009, Sharma et al 1998) and swimming stress- (Anju 2011, Misra et al 2006, Venu Prasad & Khanum 2012) and restraint stress-induced oxidative damage (Tabassum et al 2010), as well as ameliorating sciatic nerve transection-induced peripheral neuropathy in rats (Muthuraman et al 2008) and reducing acute and chronic cocaine-mediated oxidative stress in mice.

### Reducing agent for nanoparticle processing

The antioxidant properties of tulsi

Tulsi extracts have been shown to have high oxidative stability at neutral and acidic pH, and exhibit strong dose-dependent superoxide anion scavenging activity, Fe<sup>2+</sup> chelating activity, and reducing power (Juntachote & Berghofer 2005). The reducing power of aqueous tulsi leaf extracts has been used as a novel reductant and stabiliser for rapid and ecofriendly biosynthesis of stable nanoparticles of silver (Mallikarjuna et al 2011, Patil et al 2012, Singhal et al 2011, Subba Rao et al 2013), gold (Philip & Unni 2011) and platinum (Soundarajan et al 2012).

Silver nanoparticles (AgNPs) stabilised by Tulsi leaf extract were found to have enhanced antimicrobial activity against well-known pathogenic strains, namely *Staphylococcus aureus* and *E. coli* with the nanoparticles being found to be stabilised by eugenols, terpenes, and other aromatic compounds present in the aqueous extract (Ramteke et al 2013) although the room-dried stem and root of OS has also been used (Ahmad et al 2009, 2010). Tulsi has also been shown to inhibit corrosion of mild steel in hydrochloric acid (Kumpawat et al 2010,

Shyamala & Kasthuri 2011) and zinc in sulfuric acid (Sharma et al 2009).

### Hepatoprotection

Tulsi extracts have been shown to have protective effects against a wide range of toxic insults in numerous *in vitro* and *in vivo* models. The hepatoprotective effects of tulsi is attributed to its anti-oxidative potency with aqueous extracts producing significant dose-dependent reductions in lipid peroxidation and butylparaben-induced changes in non-enzymatic and enzymatic antioxidants (Shah & Verma 2012).

Tulsi is reported to mitigate against the toxic effects of common pesticides including restoration of endocrine and histopathological abnormalities induced by rogor AQ (Verma et al 2007), protection against chlorpyrifos-induced genotoxicity (Khanna et al 2011) and experimental endosulfan-induced immunotoxicity (Bharath et al 2011) and attenuation of immunotoxicity and oxidative stress produced by lindane (Mediratta et al 2008).

Further *in vivo* evidence suggests that tulsi can protect against the toxic effects of pharmaceuticals and other chemicals, including reduction of hepatorenal toxicity caused by paracetamol in mice (Makwana & Rathore 2011), hepatotoxicity induced by anti-tubercular drugs (Ubaid et al 2003) and meloxicam in rats (Mahaprabhu et al 2011) and protection against paracetamol-induced liver damage in rats that is enhanced by co-administration with silymarin (Lahon & Das 2011). In other mouse studies, tulsi is reported to prevent haloperidol-induced extrapyramidal side effects (Pemminati et al 2007), protect against ethanol-induced oxidative stress (Bawankule et al 2008) and provide hepatoprotection from exposure to carbon tetrachloride (Enayatallah et al 2004).

### Cancer protection

Tulsi extract is seen to provide protection against chemical carcinogenesis in various animal models. This activity is suggested to act at least in part via tulsi's anti-oxidant properties (Prakash & Gupta 2000) with elevation of glutathione levels and decrease in lipid peroxidation and heat shock protein expression as well as by modulating phase I and II detoxification enzymes and inhibiting anti-proliferative activity (Rastogi et al 2007). This is supported by evidence that alcoholic tulsi leaf extract significantly elevates liver enzymes important in the detoxification of carcinogens and mutagens including cytochrome p-450, cytochrome b5, aryl hydrocarbon hydroxylase, and glutathione S-transferase. Tulsi also significantly elevates extra-hepatic glutathione-S-transferase and reduced glutathione levels in mice liver, lung, and stomach tissues (Banerjee et al 1996) as well as reducing the extent of lipid and protein oxidation, upregulating antioxidant defences and inhibiting 9,10-dimethylbenz-anthracene (DMBA)-induced genotoxicity and oxidative stress in rats (Manikandan et al 2007). Tulsi leaf extracts have also been found to reduce

DMBA-DNA adduct formation in rat hepatocytes (Prashar et al 1998) and produce a dose-dependent decrease in the genotoxic damage of cyproterone acetate on human lymphocytes (Siddique et al 2007).

Further evidence of tulsi's chemo-preventive activity comes from various animal cancer models. Topical treatment with an ethanolic extract of tulsi leaves is reported to reduce tumour incidence, and the cumulative number of papillomas in DMBA-induced skin papillomagenesis in mice (Prashar et al 1994, Prashar & Kumar 1995). Oral administration of fresh tulsi leaf paste, aqueous and ethanolic extracts have also demonstrated *in vivo* activity against DMBA-induced hamster buccal pouch carcinogenesis with reduced incidence of papillomas and squamous cell carcinomas and increased survival rate (Karthikeyan et al 1999b).

Animal studies also suggest that tulsi is effective in enhancing oxidant-antioxidant status, cell proliferation, apoptosis and angiogenesis in rat forestomach carcinogenesis models (Manikandan et al 2008). Tulsi has also been found to reduce tumour volume and increase survival in mice bearing Sarcoma-180 solid tumours (Karthikeyan et al 1999a), increase survival times and restore haematological parameters in Ehrlich Ascites Carcinoma treated mice (Saiful Islam et al 2011), induce apoptosis in squamous cervical cancer cell lines (Jha et al 2012) and reduce the number of azoxymethane-induced colon tumours in rats (Gajula et al 2009, 2010).

Antitumour and antimetastatic properties of tulsi are further suggested by induction of apoptosis in human non-small cell lung carcinoma cells *in vitro* and inhibition of growth of Lewis lung carcinoma *in vivo* (Magesh et al 2009). Antimetastatic properties are also suggested by inhibition of cell adhesion and invasion and cytotoxicity against Lewis lung carcinoma associated with dose-dependent enhancement of anti-oxidative enzymes such as superoxide dismutase, catalase and glutathione peroxidase (Kim et al 2010).

### Radiation protection

Tulsi extracts have been demonstrated to have radio-protective effects and reduce the oxidative and chromosomal damage induced by gamma radiation, and radioactive iodine in various *in vitro* and *in vivo* models. Polysaccharides isolated from tulsi have been found to have scavenged reactive oxygen species and prevent gamma radiation-mediated cell deaths in mouse splenocytes and prevent radiation-induced oxidative damage to liposomal lipids and plasmid DNA (Subramanian et al 2005).

Aqueous tulsi extracts are reported to be more radio-protective than alcoholic extracts with greater survival enhancement in mice exposed to whole-body gamma radiation (Devi & Ganasoundari 1995). A 50% alcoholic aqueous tulsi extract has demonstrated anti-melanoma and radio-protective activity with significant reduction in tumour volume and survival rate of mice with B16F10 metastatic

melanoma cell line-induced metastasis. The extract also reduced radiation-induced chromosomal damage and increased glutathione activity after lethal doses of gamma radiation (Monga et al 2011). Ursolic acid from tulsi is also reported to enhance radiation-induced apoptosis in cancer cell lines and inhibit tumorigenesis in B16F10 melanoma cells implanted into mice, suggesting that it may be used as a radiosensitiser and enhance therapeutic efficacy of radiotherapy in a variety of human cancers (Koh et al 2012).

The free radical-inhibiting activity of tulsi flavonoids is reported to be significantly greater than dimethylsulfoxide (Ganasoundari et al 1997, Uma Devi et al 2000) and low doses of the water-soluble flavonoids orientin and vicenin from tulsi have been shown to scavenge free radicals and protect against radiation-induced cellular damage and significantly reduce lipid peroxidation and enhance glutathione and anti-oxidant enzymes activity in mice bone marrow (Uma Devi et al 1998, 2000, Uma Devi & Ganasoundari 1999) and human lymphocytes (Vrinda 2001). Pretreatment with tulsi flavonoids also leads to a significant reduction in the percentage of aberrant metaphases and other aberrations in bone marrow cells of irradiated mice (Ganasoundari et al 1997, Uma Devi et al 1998). Tulsi further provides mice protection against death from radiation-induced gastrointestinal and bone marrow syndrome (Uma Devi et al 1999) as well as preventing radiation-induced bone marrow damage at clinically-relevant radiation doses (Nayak & Uma Devi 2005).

Pretreatment with tulsi also provides a radio-protective effect after exposure to high-dose radioactive iodine ( $^{131}\text{I}$ ) in rats (Joseph et al 2011). Similarly, in mice exposed to radioactive iodine tulsi produced significant reductions in lipid peroxidation in kidneys and salivary glands and less depletion of reduced glutathione in liver (Bhartiya et al 2006) as well as normalisation of salivary gland weight when given in conjunction with turmeric and vitamin E (Bhartiya et al 2010). Tulsi flavonoids are further reported to significantly increase glucose-6-phosphate dehydrogenase in neutrophils from oral cancer patients given radiation (Reshma et al 2008) and enhance glutathione in erythrocytes of irradiated oral cancer patients (Reshma et al 2005).

### Heavy-metal toxicity

Animal evidence suggests that tulsi offers significant protection against lead, arsenic, cadmium, chromium and mercury toxicity. Tulsi has been found to protect against lead toxicity with normalisation of biochemical and haematological parameters in cockerels (Prakash et al 2009a, 2009b) and rats (Akilavalli et al 2011, Karamala et al 2011, Sujatha et al 2012) and significant dose-dependent protective effects on lead-induced brain damage (Sujatha et al 2011) and liver injury (Akilavalli et al 2011). Further evidence suggests that Tulsi leaf extract reduces arsenic-induced oxidative stress and assists

in the depletion of arsenic from blood, liver and kidneys, suggesting a use for tulsi during chelating therapy with a thiol chelator (Sharmila Banu et al 2009). Tulsi has also been shown to protect against cadmium-induced toxicity with significant decreases in anti-oxidant enzyme activity and ascorbate levels (Ramesh & Satakopan 2010).

Tulsi leaf extract also has protective effects against chromium- and mercury-induced genetic damage as revealed in cytogenetic assays using *Allium cepa* root tip cells, with lower doses of the leaf extract being found to be more effective than higher doses (Babu & Maheswari 2006). Tulsi also provides protection against mercuric chloride-induced toxicity in mice (Kumar Sharma et al 2002) with pre- and posttreatment of tulsi leaf extract protecting against renal damage against mercuric chloride-induced toxicity (Sharma et al 2005).

### Antidiabetic

Tulsi has been found to have effective anti-diabetic activity in human trials (Agrawal et al 1996, Devra et al 2012, Kochhar et al 2009, Rai et al 1997b) as well as in numerous in vitro (Hannan et al 2006) and animal models, including studies on rats (Chattopadhyay 1993, Eshrat & Mukhopadhyay 2006, Hussain et al 2001, Muralikrishnan et al 2012, Reddy et al 2008, Singh et al 2012, Suanarunsawat & Songsak 2005, Vats et al 2004), mice (Dusane & Joshi 2012, Gholap & Kar 2004, Vats et al 2004), rabbits (Gupta et al 2006) and the first report on fish as a diabetes model where an aqueous extract of tulsi produced a dose-dependent drop in serum glucose levels in hyperglycaemic tilapia (Arenal et al 2012).

Studies on streptozotocin-induced diabetic rats have reported that aqueous tulsi extracts reduce fasting blood glucose, serum lipid profile and lipid peroxidation products, improve glucose tolerance and increase anti-oxidant enzymes activity (Hussain et al 2001, Muralikrishnan et al 2012), reduce plasma glucose and HbA<sub>1c</sub>, and improve retinal changes on angiography (Eshrat & Mukhopadhyay 2006). Further studies on streptozotocin-induced diabetic mice provide evidence of glucosidase inhibition and islet-cell protection (Dusane & Joshi 2012). Tulsi's antidiabetic actions include stimulatory effects on insulin secretion (Hannan et al 2006), potentiation of the action of exogenous insulin (Chattopadhyay 1993) and hypoglycaemic, antiperoxidative and cortisol-lowering activity, leading to the suggestion that it may potentially regulate corticosteroid-induced diabetes mellitus (Gholap & Kar 2004).

Further studies on streptozotocin-induced diabetic rats using alcoholic tulsi extracts provide evidence of dose-dependent hypoglycaemic effects and antihyperglycaemic effects (Chattopadhyay 1993, Vats et al 2004, Zaffer Ahmad et al 2012) along with reversal of diabetic induction, protection of renal glomerular filtration and liver function (Suanarunsawat & Songsak 2005), correction of

dyslipidaemia (Zaffer Ahmad et al 2012) and normalisation of carbohydrate metabolism enzymes such as glucokinase, hexokinase and phosphofructokinase (Vats et al 2004).

Tulsi extracts have been further shown to prevent weight gain, hyperglycaemia, hyperinsulinaemia, hypertriglyceridaemia and insulin resistance in rats fed a diabetogenic diet (Chattopadhyay 1993, Reddy et al 2008) and to significantly reduce fasting blood sugar, uronic acid, total amino acids, total cholesterol, triglyceride, phospholipids and total lipids in diabetic rats (Rai et al 1997a). Tulsi extracts have also been observed to have antidiabetic activity and reduce lipid levels in alloxan-induced diabetic rats (Patil et al 2011) and in combination with *Pterocarpus marsupium* (Indian kino tree), tulsi has been shown to restore endogenous anti-oxidant levels in alloxan-induced diabetic rats to the pre-diabetic status and rectify dyslipidaemia (Singh et al 2012). Fresh tulsi leaves have also been found to significantly lower blood glucose and improve the anti-oxidant status of alloxan-induced diabetic rabbits (Sethi et al 2004), although rabbits displayed not hypoglycaemic effect with tulsi essential oil (Gupta et al 2006).

In randomised, controlled human trials involving patients with noninsulin-dependent diabetes mellitus, supplementation with tulsi leaves is reported to decrease fasting and postprandial blood glucose, improve lipid profiles (Agrawal et al 1996, Rai et al 1997b) and reduce diabetic symptoms such as polydipsia, polyurea, polyphagia and tiredness, sweating, burning feet, itching and headache (Kochhar et al 2009). The results of a randomised controlled trial of tulsi in people with metabolic syndrome further suggest that tulsi supplementation not only helps to control blood glucose, but also improves blood pressure and lipid profile (Devra et al 2012).

### Lipid lowering

Tulsi extracts including aqueous and alcoholic leaf extracts as well as tulsi essential oil have been observed to have lipid-lowering effects in a number of animal models including rats fed high-cholesterol diet (Suanarunsawat et al 2009, 2010a, 2010b, 2011), alloxan-induced diabetic rats (Patil et al 2011), healthy rabbits (Dahiya et al 2011, Sarkar et al 1994) and hypercholesterolaemic rabbit models (Khanna et al 2010, Samak et al 2007) as well as in a small human trial (Verma et al 2012). The lipid-lowering and cardio-protective effects of tulsi are attributed to a rise of bile acid synthesis using cholesterol as precursor, and antioxidative activity protecting the liver from hypercholesterolaemia (Suanarunsawat et al 2011) along with the suppression of liver lipid synthesis (Suanarunsawat et al 2009).

Administration of tulsi leaves or aqueous or ethanolic leaf extracts to healthy and/or hypercholesterolaemic rabbits is reported to bring about significant lowering of serum total cholesterol, triglyceride and LDL-cholesterol levels and significant increases in the HDL-cholesterol (Ashok et al 2007, Dahiya

et al 2011, Khanna et al 2010, Sarkar et al 1994) with associated anti-atherogenic effects (Samak et al 2007) and dose-dependent liver and aortic tissue protection from hypercholesterolaemia-induced peroxidative damage (Geetha et al 2004). Similar lipid-lowering effects with tulsi have been observed in rats fed high-cholesterol diets (Suanarunsawat et al 2011) and in alloxan-induced diabetic rats (Patil et al 2011). Administration of tulsi essential oil is also reported to produce significant lipid-lowering effects in rats (Suanarunsawat et al 2009, 2010a, 2010b) and rabbits (Gupta et al 2006) fed high-cholesterol diets.

### Antimicrobial

Tulsi has been traditionally used for its bactericidal, fungicidal, pesticidal and medicinal values and recent evidence suggests that constituents such as eugenol, methyl chavicol, linalool, isoeugenol, and methyl isoeugenol all contribute to activity against many pathogenic fungi and bacteria as well as stored grain insects, pests and mosquitoes (Vasudevan et al 1999).

### Antibacterial

While no human trials have been published, there is evidence to suggest that tulsi may have potential to help in the treatment of various human infections including urinary tract infections (Ali & Dixit 2012), skin and wound infections (Geeta et al 2001, Singh et al 2005), typhoid fever (Goel et al 2010a, Mandal et al 2012, Parag et al 2010), cholera (Geeta et al 2001, Parag et al 2010), tuberculosis (Farivar et al 2006), gonorrhoea (Shokeen et al 2005), acne (Sawarkar et al 2010, Viyoch 2006) and *Klebsiella* and cryptococcal pneumonia (Geeta et al 2001, Saini et al 2009).

Tulsi essential oil also exhibits broad-spectrum antibacterial activity (Rajeswara Rao et al 2011) including activity against *Staphylococcus aureus*, *Bacillus pumilus* and *Pseudomonas aeruginosa* (Singh et al 2005). The methanol, ethanol and chloroform extracts of tulsi have shown antimicrobial activity comparable with standard antibiotics against common human pathogens such as *Bacillus subtilis*, *Staphylococcus aureus*, *Staphylococcus saprophyticus*, *Escherichia coli*, *Proteus vulgaris* and *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *B. subtilis* (Deo et al 2011, Kamble & Deshmukh 2008, Kumar et al 2012, Sagar & Thakur 2012, Sharma et al 2012) as well as activity against commensal bacteria such as *Lactobacillus*, *Staphylococcus epidermidis* and *Citrobacter* (Kumar et al 2012). The flavanoids, orientin and vicenin, obtained from tulsi leaves have also been shown to have synergistic antibacterial activity against organisms causing human urinary tract infections such as *Escherichia coli*, *Proteus*, *Staphylococcus aureus*, *Staphylococcus cohnii* and *Klebsiella pneumoniae* (Ali & Dixit 2012).

### Antifungal

Tulsi essential oil has broad-spectrum antifungal activity (Kumar et al 2013, Rajeswara Rao et al

2011). This has led to suggestions that it may be used to prevent biodeterioration of herbal raw materials (Kumar et al 2013) and spoilage of food stuffs during storage (Kumar et al 2010). Tulsi oil's broad anti-fungal action has been assessed as superior to some prevalent synthetic antifungals against at least 12 commonly-occurring fungi and has been shown to inhibit aflatoxin B<sub>1</sub> production (Kumar et al 2010). Tulsi has also been found to have comparable anti-fungal activity to the standard fungicide carbendazim against *Pyricularia grisea* Sacc. which causes rice blast disease in greenhouse and field conditions and to retain this activity over a 24-month storage period (Tewari 1995, Upadhyaya et al 2012).

Tulsi oil has in vitro activity against fungal pathogens including *Candida* species (Amber et al 2010, Deo et al 2011, Khan et al 2010a, 2010b) with selective fungicidal activity against fluconazole-sensitive and fluconazole-resistant *Candida* isolates (Amber et al 2010). Linalool is assessed as the most active constituent (Khan et al 2010a, 2010b) and ethanolic extracts of tulsi leaves has also been found to have anti-cryptococcus activity when combined with *Cassia alata* extract (Ranganathan & Balajee 2000). Tulsi also has fungicidal activity against clinically isolated dermatophytes (Balakumar et al 2011) with petroleum ether extract, but not aqueous extract, exhibiting broad-spectrum activity against human pathogenic dermatophytes such as *Trichophyton mentagrophytes*, *T. tonsurans* and opportunistic fungi such as *Candida albicans*, *Trichosporon beigelii* (Das et al 2010) and *Malassezia furfur* (Chandra et al 2011).

### Antimalarial

Tulsi ethanolic leaf extract has been found to have excellent in vitro anti-plasmodial activity against *Plasmodium falciparum* without producing chemical injury to erythrocytes. It is suggested that this anti-plasmodial activity might be due to the presence of alkaloids, glycosides, flavonoids, phenols, saponins, triterpenoids, proteins, resins, steroids and tannins and that the ethanolic leaf extracts of tulsi contains lead compounds for the development of antiplasmodial drugs (Inbaneson et al 2012).

Tulsi oil as well as leaf extracts have also been found to have larvicidal activity against dengue, malaria, and filariasis-transmitting mosquito larvae including activity against larvae of *A. aegypti* as well as *C. quinquefasciatus* (Anees 2008, Gbolade & Lockwood 2008, Krishan et al 2007, Rajamma et al 2011, Verma Prashant et al 2006).

### Anti-parasitic

Tulsi essential oil and its constituent eugenol have shown potent in vitro anthelmintic activity against the roundworm *Caenorhabditis elegans* (Asha et al 2001) but not against the flatworm *Fasciola gigantica* (Jeyathilakan et al 2010). Compounds isolated from tulsi also showed potent leishmanicidal activity (Suzuki et al 2009). Tulsi oil and its petroleum

ether extract also demonstrate selective insecticide activity, being highly toxic against the silkworm parasite *E. sorbillans* and comparatively less toxic to the silk worm *Antheraea assama* larvae (Bora & Khanikor 2011).

### Anti viral

Dichloromethane and methanol extracts of tulsi has anti-herpes simplex virus activity at various steps of the viral multiplication cycle (Yucharoen et al 2011). Dry tulsi leaves are also reported to enhance immune activity in poultry infected with infectious bursal disease virus (Sadekar et al 1998).

### Immune enhancement

Tulsi seed oil has been shown to modulate both humoral and cell-mediated immune responsiveness in non-stressed and stressed animals as evidenced by increases in anti-sheep red blood cell antibody titre and a decrease in percentage histamine release from peritoneal mast cells of sensitised rats (humoral immune responses), and decrease in footpad thickness and percentage leucocyte migration inhibition (cell-mediated immune responses). The inhibition of these responses by the central benzodiazepine receptor antagonist flumazenil has led to the suggestion that this immunomodulatory action is mediated by GABAergic pathways (Mediratta et al 2002).

In a myelosuppressed mice model, treatment with methanolic tulsi extracts resulted in significant increases in bone marrow cellularity, total WBC count and haemoglobin concentration along with raised antibody titre and production of TNF- $\alpha$ , IL-2, IFN- $\gamma$  and IL-4 and reduced production of IL-1 $\beta$  and NF- $\kappa$ B (Hemalatha et al 2011). Similarly, in a cyclophosphamide-induced immunosuppression rat model, tulsi significantly increased lymphocyte proliferation (Tripathi et al 2008). In vitro and in vivo studies in rats further suggest that aqueous tulsi leaf extract has stimulatory effects on T and B lymphocytes with enhanced ability of spleen cells to secrete IL-2 (Goel et al 2010c).

The immunomodulatory effects of tulsi have been further demonstrated in a double-blinded, randomised, controlled, crossover trial on healthy human volunteers ( $n = 24$ ) which reported that ethanolic extracts of leaves of tulsi for 4 weeks resulted in statistically significant increases in the levels of interferon- $\gamma$ , interleukin-4, T-helper cells and NK cells (Mondal et al 2011).

Further evidence for the immunomodulatory effects of tulsi comes from aquaculture studies. Treatment with tulsi has been shown to increase survival, growth and weight and enhance antibody response and phagocytic activity in fingerlings of common carp (*Cyprinus carpio*) (Pavaraj et al 2011) and Indian carp (*Catla catla*) (Chitra & Krishnaveni 2011) exposed to *Aeromonas hydrophila* bacteria. Similar immunostimulatory effects were observed with increased disease resistance and stimulation of both antibody response and neutrophil activity in tilapia exposed to *Aeromonas hydrophila* (Logambal

et al 2000). These studies suggest that tulsi may be an effective immunostimulant and maintain finfish health in intensive freshwater aquaculture where loss of fish production from infectious disease is a major constraint (Chitra & Krishnaveni 2011, Harikrishnan 2008, Logambal et al 2000, Pavaraj et al 2011).

### **Cognitive enhancement**

Tulsi exhibits cognition enhancement, antidepressant and anxiolytic activity in Alzheimer's disease models in rats, with improved reference memory, working memory, spatial learning and anti-oxidant activity (Raghavendra et al 2009). Tulsi extracts are also reported to have memory-enhancing effects in restraint stress-induced memory impaired rats (Kumar et al 2007) and to significantly decrease acetylcholinesterase activity and improve passive avoidance tasks in experimentally-induced cognitive dysfunction (Giridharan et al 2011). Tulsi is also reported to have memory-enhancing and anti-amnesic effects in mice (Dokania et al 2011) and ameliorate the amnesic effect of scopolamine and ageing-induced memory deficits (Joshi & Parle 2006a, 2006b).

### **OTHER ACTIONS**

#### **Diuretic**

Tulsi extracts have been shown to have diuretic activity similar to that of the loop diuretic frusemide in healthy rats (Pai et al 2013).

#### **Aphrodisiac**

An ethanolic extract of tulsi demonstrated aphrodisiac activity with significant and sustained increase in the sexual activity of normal male mice (Pande & Pathak 2009).

#### **Anti-hypotensive**

Tulsi oil has been observed to have a hypotensive effect in anaesthetised dogs attributed to its peripheral vasodilatory action (Singh et al 2001).

#### **Anticoagulant**

Tulsi oil was observed to increase blood-clotting time with the effect attributed to inhibition of platelet aggregation comparable to aspirin (Singh et al 2001).

#### **Antipyretic**

Tulsi oil has been observed to reduce typhoid-paratyphoid A/B vaccine-induced pyrexia in rodents with antipyretic activity deemed to be similar to that of aspirin (Singh & Majumdar 1995). The antipyretic activity of tulsi oil is attributed to prostaglandin inhibition and peripherally acting analgesic activity (Singh et al 2007).

### **CLINICAL USES**

Tulsi and related basil species are commonly used as culinary herbs to enhance the taste and nutrition of many food preparations around the world (Singh et al 2010). Despite a wide variety of reported uses,

the clinical uses of tulsi are mainly based on traditional use and supported by preclinical research. Currently there are very few published human trials that document the clinical benefits of tulsi other than a handful of trials in patients with diabetes or metabolic syndrome and a few studies investigating its use as a mouthwash and for dealing with stress.

### **Adaptogen / stress**

Tulsi has been traditionally used to assist in dealing with the stresses of daily life and promote general health, wellbeing and longevity. Tulsi is a potent adaptogen with a unique combination of anti-oxidant, anti-inflammatory, antimicrobial and other actions that combine to help the body and mind adapt and cope with a wide range of physical, emotional, chemical and infectious stresses and restore physiological and psychological functions to a normal healthy state (Anbuselvi et al 2013, Maheshwari et al 2012, Singh et al 2010).

Recent evidence attests to tulsi's ability to protect against stress and reduce physical fatigue in multiple experimental animal models (Maheshwari et al 2012) and these studies are supported by a recent 6-week, randomised, double-blind, placebo-controlled study involving 150 people that found that tulsi extract significantly improved general stress scores as well as symptoms such as forgetfulness, frequent feeling of exhaustion, and sexual and sleep problems of recent origin (Saxena et al 2012).

### **Air travel**

The unique combination of wide-ranging pharmacological activities makes tulsi one of the most suited herbs to help in the prevention and improvement of air travel health problems (Singh & Gilca 2008). There are various levels of evidence that tulsi has adaptogenic, anti-microbial, antiradiation, anti-oxidant, anticoagulant, anti-inflammatory, anti-restraint- and noise-stress, immune and cognitive enhancement activity. These actions may help address many issues faced by modern air travellers such as infection, fatigue, thrombosis, and dealing with anxiety, restraint, noise, hypoxia, radiation, industrial chemicals and poor sleep.

### **Metabolic syndrome / diabetes**

Tulsi has shown efficacy in improving the glucose and lipid profiles of diabetic patients in a number of human clinical trials. In a 1-month trial with 27 NIDDM patients on hypoglycaemic drugs, supplementation with tulsi powder was seen to significantly lower blood glucose and glycated proteins as well as reducing triglycerides and total and LDL and VLDL cholesterol levels (Rai et al 1997b). In a further randomised, placebo-controlled, single-blind, crossover trial, treatment with tulsi leaves was seen to produce significant decreases in fasting and postprandial blood glucose levels and improve mean total cholesterol levels (Agrawal et al 1996).

More recently, a randomized controlled trial of 100 patients with metabolic syndrome found that

5 mL of tulsi extract twice daily for three months improved clinical and biochemical parameters of metabolic syndrome with significantly reduced blood glucose, blood pressure and improved lipid profile (Devara et al 2012). A further 3-month study of 99 males with NIDDM reported that 2 g of tulsi leaf powder, neem leaf powder or both showed significant reduction in diabetic symptoms such as polydipsia, polyurea, polyphagia and tiredness, sweating, burning feet, itching and headache and non-significant improvements in anthropometric parameters with the greatest effect seen with combination treatment (Kochhar et al 2009).

### Ischaemic heart disease and stroke

The antioxidant properties of tulsi, including augmentation of endogenous antioxidants and suppression of oxidative stress are suggested to contribute to potential prophylactic and therapeutic uses in ischaemic heart disease. Tulsi has been shown to have cardioprotective effects against isoproterenol-induced myocardial necrosis in rats (Arya et al 2006, Sharma et al 2001, Sood et al 2005).

The anti-inflammatory, antioxidant and cognition-enhancing properties of tulsi also suggest a role in treating cerebral reperfusion injury and cerebrovascular insufficiency based on rat models of cerebrovascular insufficiency and dementia. Tulsi has been shown to reduce brain injury after middle cerebral artery occlusion (Ahmad et al 2012a) and protect against cerebral reperfusion injury and cerebral hypoperfusion functional disturbances such as exploratory behaviour and memory as well as structural changes such as cellular oedema, gliosis and perivascular inflammatory infiltrate in rats (Yanpallewar et al 2004).

### Pain

Alcoholic tulsi leaf extracts have demonstrated analgesic activity in mice models that suggest both centrally and peripherally mediated anti-nociceptive actions involving an interplay between various neurotransmitter systems (Khanna & Bhatia 2003). Further studies using tulsi seed oil in experimental pain models in rodents suggest that tulsi seed oil has peripheral rather than centrally-mediated analgesic activity as analgesia with tulsi was not associated with an increase in pain threshold (Singh & Majumdar 1995a). Tulsi has also been shown to reduce oxidative stress and calcium levels in rats and ameliorate sciatic nerve transection-induced peripheral neuropathy (Muthuraman et al 2008) and vincristine-induced neuropathic pain, suggesting a role in chemotherapy induced-painful neuropathy (Kaur et al 2010).

### Arthritis

The anti-inflammatory, antioxidant and analgesic properties of tulsi all suggest a role in arthritis and tulsi oil has been found to have significant antiarthritic activity in animal models including formaldehyde- or adjuvant-induced arthritis and

turpentine-induced joint edema (Singh & Majumdar 1996, Singh et al 2007).

### Cataract

Tulsi delays the onset and subsequent maturation of cataract in naphthalene-induced cataract in rabbits and galactose-induced cataracts in rats (Sharma et al 1998). Aqueous tulsi extracts have further been shown to protect against selenite-induced cataract development in rat pups and morphological and biochemical changes in isolated rat lenses, with a significant increase in anti-oxidant enzyme levels, preservation of normal lens protein profile and inhibition of protein insolubilisation (Gupta et al 2005). Tulsi is also reported to protect against hydrogen peroxide-induced cytotoxic changes in human lens epithelial cells (Halder et al 2009).

### Allergy / asthmatic

Tulsi has been shown to have anti-asthmatic activity in animals with inhibition of preconvulsive dyspnoea in guinea pigs (Singh & Agrawal 1991, Sridevi et al 2009). A 50% ethanol extract of fresh leaves, volatile oil extracted from fresh leaves and fixed oil from the seeds, but not a 50% ethanol extract of dried leaves, is reported to significantly protect guinea pigs against histamine- and acetylcholine-induced pre-convulsive dyspnoea as well as inhibiting carrageenan-, serotonin-, histamine- or PGE<sub>2</sub>-induced hind paw oedema (Singh & Agrawal 1991).

Tulsi leaf extracts have also been shown to have anti-anaphylactic and anti-allergic activity with mast cell stabilisation, suppression of IgE, and inhibition of release of inflammatory mediators in rat and guinea pig models (Sridevi et al 2009). Mast cell stabilisation has also been demonstrated with ursolic acid from tulsi leaves (Rajasekaran et al 1989) and with tulsi ethanolic extract and isolated flavonoidal fraction (Choudhary 2010).

### Ulcer

Extracts of tulsi have been shown to have anti-ulcer and ulcer healing activity in many different animal models including aspirin-, indomethacin-, alcohol-, histamine-, reserpine-, serotonin-, acetic acid-, meloxicam-, cold restraint-, pyloric ligation-, and stress-induced ulceration in experimental animal models (Dharmani et al 2004, Kath & Gupta 2006, Mahaprabhu et al 2011, Singh & Majumdar 1999a). Tulsi's anti-ulcer effects are attributed to the reduction of offensive factors such as acid-pepsin secretion and lipid peroxidation and the enhancement of gastric defensive factors such as mucin secretion, cellular mucus, longevity of mucosal cells (Dharmani et al 2004, Goel et al 2005, Sairam et al 2000, Singh & Majumdar 1999a).

### Wound healing

Tulsi has many pharmacological actions that suggest a role in wound healing including antioxidant, anti-inflammatory, analgesic and antimicrobial activity. It is suggested that the combination of anti-inflammatory,

analgesic and antibacterial activities in a single herb is unique to tulsi (Singh et al 2007) and that tulsi may be particularly suited to the management of staphylococcal wound infections (Singh et al 2005), abnormal healing and hypertrophic scars (Shetty et al 2008).

Alcoholic and aqueous tulsi extract have been shown to reduce oxidative stress and significantly increase wound-breaking strength, percent wound contraction, granulation tissue weight, hydroxyproline, hexuronic acid, hexosamines, superoxide dismutase, catalase, reduce glutathione and significantly decrease lipid peroxidation in experimental incision, excision and dead space wounds in rats (Shetty et al 2006, 2008). Application of tulsi extract in petroleum jelly is also reported to enhance early wound healing and elevate TNF- $\alpha$  production in rats (Goel et al 2010b).

### Antifertility / antiandrogenic

Tulsi is reported to have anti-fertility effects (Sethi et al 2010) although very few workers have explored the detailed effects of tulsi on the reproductive system (Ahmed et al 2002b). A benzene extract of tulsi leaves is reported to have a reversible antiandrogenic effect in rats (Ahmed et al 2002a) and extremely high doses of an oil extract of tulsi leaves (300 mg/kg) is reported to reduce reproductive function and fertility in male rats and rabbits (Narayana 2011, Parandin & Haeri Rohani 2010, Sethi et al 2010) and there is an early report of tulsi leaves having antizygotic, anti-implantation and early abortifacient effect in women and in experimental animals (Vora 1969).

### Mouth wash

The broad antibacterial and antifungal activity of tulsi has led to suggestions that it may serve as a herbal mouth wash (Kothari et al 2006, Kukreja & Dodwad 2012). Tulsi is said to be good for treating halitosis and mouth ulcers (Malik et al 2012) and ethanolic extracts of tulsi have demonstrated in vitro antimicrobial activity against *Streptococcus mutans* with maximal effect at 4% concentration (Agarwal et al 2010). In a controlled crossover study involving 45 school children, twice-daily rinsing with tulsi extract was as effective as 0.2% chlorhexidine and Listerine in reducing the salivary *S. mutans* levels (Agarwal & Nagesh 2011). Another trial involving 50 subjects randomised to either chlorhexidine or a Ayurvedic multiherbal mouthwash containing tulsi along with other herbs such as cloves, neem, triphala and licorice, found the herbal mouthwash was preferred for its taste and convenience of use, and acted as a potent plaque inhibitor, although not quite as effective as chlorhexidine (Malhotra et al 2011). In a further randomised controlled trial involving 60 participants the Ayurvedic multiherbal mouthwash twice daily for 15 days was found to be as effective as chlorhexidine and more effective than Listerine in preventing plaque and gingivitis (Maimes 2004).

### Hand sanitiser

In addition to serving as a mouthwash, tulsi has been used as a herbal hand sanitiser in combination with *Eucalyptus globulus* leaf and has been found to be more effective than a standard reference against *E. coli*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Bacillus subtilis* and *Saccharomyces cerevisiae* and *Candida albicans* (Wani et al 2013).

### OTHER USES

#### Bioremediation of contaminated air and soil

Tulsi plants may be used to reduce air pollution and hundreds of thousands of tulsi plants have been planted around the Taj Mahal in Agra to help protect the iconic marble building from environmental pollution damage (Sethi et al 2010, Vora 1969). It has also been suggested that Tulsi may be used to bioremediate contaminated soil while still serving as a source of essential oil as tulsi plants may accumulate arsenic without detectable amounts appearing in the oil (Siddiqui et al 2012).

#### Water treatment

Tulsi has demonstrated anti-microbial activity against many water-borne pathogens including *Escherichia coli*, *Salmonella typhi*, *Pseudomonas pyocyaneus*, *Vibrio cholerae*, *Shigella dysenteriae* and *Proteus vulgaris* within specified contact time (Parag et al 2010). The broad spectrum antimicrobial properties of tulsi against pathogenic Gram-positive and Gram-negative bacteria have led to suggestions that tulsi may be used for water purification (Parag et al 2010) as well as in the food industry to prevent spoilage (Mishra & Mishra 2011).

Tulsi may be also used to remove fluoride in water and therefore prevent fluorosis, which causes dental and skeletal decay and is endemic in at least 25 countries. It is reported that 75 mg of fresh leaves added to 100 mL of water with a fluoride concentration of 5 ppm removed nearly 95% of the fluoride in 20 minutes and that boiling or shaking a handful of stems and dried tulsi leaves will decontaminate 20 litres of water with a removal efficiency of 74–78% (Maheshwari et al 2012).

#### Food and herb preservation

The anti-oxidant properties of tulsi may also have uses in food storage and preservation with dried tulsi powder reducing lipid oxidation in cooked ground pork (Juntachote et al 2006, 2007), extending the oxidative stability of ghee (Merai et al 2003) and doubling the non-refrigerated shelf-life of tofu (Anbarasu & Vijayalakshmi 2007). Tulsi essential oil has broad-spectrum anti-fungal activity (Kumar et al 2013, Rajeswara Rao et al 2011) and this has led to suggestions that it may be used to prevent biodegradation of herbal raw materials (Kumar et al 2013) and spoilage of foodstuffs during storage (Kumar et al 2010). Tulsi oil's broad antifungal action has been assessed as superior to some

prevalent synthetic antifungals against at least 12 commonly occurring fungi and has been shown to inhibit aflatoxin B<sub>1</sub> production (Kumar et al 2010). Tulsi has also been found to have comparable antifungal activity to the standard fungicide carbendazim against *Pyricularia grisea* Sacc. which causes rice blast disease in greenhouse and field conditions and to retain this activity over a 24-month storage period (Tewari 1995, Upadhyaya et al 2012).

### Animal rearing

Tulsi has also been shown to be effective against many animal pathogens. Intramammary infusion of aqueous extract of tulsi leaf has been found to reduce subclinical bovine mastitis and enhance lysosomal enzymes-content of milk polymorphonuclear cells (Mukherjee 2006, Mukherjee et al 2005). Tulsi and garlic have also been found to have in vitro activity against mixed bacterial cultures causing infectious endometritis in repeat breeding crossbred cows (Kumar et al 2011). Tulsi supplementation was also seen to enhance feed intake, nutrient utilisation, body weight gain and feed conversion efficiency in a 3-month trial in goats (Deka 2009) and to increase survival, growth and weight of fish in freshwater aquaculture systems (Chitra & Krishnaveni 2011, Logambal et al 2000, Pavaraj et al 2011).

### DOSAGE

It is suggested the best way to use tulsi is raw as a fresh whole herb rather than as extracts. If fresh whole herbs are not available, tulsi can be given as 300–600 mg of dried leaves daily for prevention, or 600–1800 mg in divided doses as therapy. Tulsi is often recommended for prolonged periods with increased stamina and immunological resistance taking up to one month to take effect. It is often recommended to consume a few fresh tulsi leaves each day and tulsi can also be consumed regularly for prolonged periods of time as a caffeine-free herbal tea that is considered an instant energy provider, staminator and life-long tonic for all ages (Singh et al 2010).

Physicochemical and sensory testing of a functional drink suggests that a preparation of 10% tulsi extract and 5% hill lemon (galgal) juice was adjudged best and had a storage stability of 6 months (Barwal et al 2009). It has been suggested that tulsi seeds can act as a natural super-disintegrant that can be used in the formulation of fast-melt tablets that disintegrate instantaneously within the mouth and can be consumed without water (Malik et al 2012).

### TOXICITY

Tulsi has been used for generations for its ability to detoxify and it is not reported to have any toxic effects. Tulsi is reported to have an extremely wide safety margin with the ratio between the lethal (LD<sub>50</sub>) and effective (ED<sub>50</sub>) doses being more than 300 (Singh et al 2010).

Acute and subacute toxicity experiments in rats of three standardised tulsi extracts found the extracts were well tolerated, with no adverse changes in mortality, morbidity, gross pathology, body weight, and biochemical parameters (Chanda et al 2013). Tulsi oil is not cytotoxic to mammalian cells (Zheljazkov et al 2008) and the LD<sub>50</sub> is reported to be 42.5 mL/kg, with long-term use of oil at 3 mL/kg not producing any untoward effects in rats (Singh & Majumdar 1995a, Singh et al 2007).

### ADVERSE REACTIONS

Tulsi has a long history of traditional use with no reports of adverse effects.

### SIGNIFICANT INTERACTIONS

There are no reports of any significant interactions with tulsi. As tulsi has anti-diabetic and anti-platelet actions there is a theoretical possibility of interactions with anti-coagulant or anti-diabetic medications but such interactions have not been reported.

### PREGNANCY USE

Very few workers have explored the detailed effects of tulsi on the reproductive system and there is very little reliable information on the use of tulsi in pregnancy. High doses of tulsi are best avoided in pregnancy and although tulsi is traditionally used throughout pregnancy in Africa (Malan & Neuba 2011), there is some animal evidence to suggest that high doses of tulsi may have antifertility and abortifacient effects (Ahmed et al 2002b).

### Practice points/Patient counselling

- Tulsi is considered unique amongst medicinal herbs for its wide variety of actions and ability to treat and prevent a range of diverse conditions.
- Tulsi can be taken as a dried herb, herbal tea or fresh leaves and is recommended for regular ongoing use to assist in adaptation to stress of daily life and promote health and longevity.
- Tulsi may help address many issues faced by modern air travellers such as infection, fatigue, thrombosis, and dealing with anxiety, restraint, noise, hypoxia, radiation, industrial chemicals and poor sleep.

### PATIENTS' FAQs

#### *What will this herb do for me?*

Tulsi may enhance the ability to cope with a variety of different stresses, help prevent and treat a wide range of diseases and promote longevity when taken over long periods of time.

#### *When will it start to work?*

The stamina enhancing effects may take a week to one month to develop. Regular use is said to bestow

a range of benefits and give appreciable improvement is health lasting for a month or more after discontinuation (Singh et al 2010).

### Are there any safety issues?

Tulsi appears to be extremely safe and has been used for countless generations in different cultures and systems of medicine without any specific safety concerns. There is a theoretical possibility that tulsi's anti-platelet actions may interact with anti-coagulant medications or cause bleeding with surgery and that tulsi's anti-diabetic action may interact with hypoglycaemic medications but such interactions have not been reported. High doses of tulsi are best avoided in pregnancy.

## Turmeric

**HISTORICAL NOTE** Turmeric is a perennial herb, yielding a rhizome that produces a yellow powder that gives curry its characteristic yellow colour and is used to colour French mustard and the robes of Hindu priests. It has been used in Hindu religious ceremonies, and Hindus also apply a mixture of turmeric and sandalwood powder on their foreheads (Jagetiya & Aggarwal 2007). Turmeric was probably first cultivated as a dye, and then as a condiment and cosmetic. It is often used as an inexpensive substitute for saffron in cooking and in the 13th century Marco Polo marvelled at its similarities to saffron. In Chinese medicine, turmeric was used in the treatment of inflammatory and digestive disorders and was also used in tooth powder or paste (Anonymous 2001). In Ayurvedic medicine, it was used to treat a wide variety of disorders, including rheumatism, skin conditions, inflammation, intestinal worms, hepatic disorders, biliousness, dyspepsia, diarrhoea, constipation and colic (Jagetiya & Aggarwal 2007). In addition to its use in cardiovascular disease and gastrointestinal disorders, research has focused on turmeric's antioxidant, hepatoprotective, anti-inflammatory, anticarcinogenic and antimicrobial properties

(Anonymous 2001). Curcumin was first discovered from the rhizomes of turmeric by Harvard College laboratory scientists Vogel and Pelletier and published in 1815 (Gupta et al 2013). Turmeric is believed to promote the flow of *qi* (Jagetia & Aggarwal 2007).

## COMMON NAME

Turmeric

## OTHER NAMES

Chiang-huang, curcuma, curcumae longae rhizoma, curcuma rhizome, e zhu, haldi, haridra, Indian saffron, jiang huang, jiang huang curcumae rhizoma, turmeric rhizome, turmeric root, yellow root, yu jin, zedoary

## BOTANICAL NAME/FAMILY

*Curcuma longa* (family Zingiberaceae [ginger])

## PLANT PART USED

Dried secondary rhizome (containing not less than 3% curcuminoids calculated as curcumin and not less than 3% volatile oil, calculated on dry-weight basis).

## CHEMICAL COMPONENTS

Turmeric rhizome contains 5% phenolic curcuminoids (diarylheptanoids), which give turmeric the yellow colour. The most significant curcuminoid is curcumin (diferuloylmethane). It also contains up to 5% essential oil, including sesquiterpene (e.g. Zingiberene), sesquiterpene alcohols, sesquiterpene ketones, and monoterpenes.

Turmeric also contains immune-stimulating polysaccharides, including acid glucans known as ukonan A, B and C (Evans & Trease 2002).

## MAIN ACTIONS

Most research has focused on a series of curcumin constituents found in turmeric. Many of the animal studies involve parenteral administration as oral turmeric or curcumin was considered less active because curcumin is poorly absorbed by the gastrointestinal tract and only trace amounts appear in the blood after oral intake (Ammon & Wahl 1991). Curcumin possesses anti-inflammatory, antioxidant, immuno-modulatory, wound-healing, anti-proliferative and antimicrobial activities (Dulbecco & Savarino 2013). Curcumin may, however, have significant activity in the gastrointestinal tract, and systemic effects may take place as a consequence of local gastrointestinal effects or be associated with metabolites of the curcuminoids.

## ANTIOXIDANT

Studies have shown that turmeric, as well as curcumin, has significant antioxidant activity (Ak & Gulcin 2008, Bengmark 2006, Menon & Sudheer 2007, Shalini & Srinivas 1987, Soudamini et al 1992). Turmeric not only exerts direct free radical scavenging activity, it also appears to enhance the antioxidant activity of endogenous antioxidants, such as glutathione peroxidase, catalase and quinine reductase. Curcumin has been shown to induce phase II detoxification enzymes (glutathione

peroxidase, glutathione reductase, glucose-6-phosphate dehydrogenase and catalase) (Iqbal et al 2003). Additionally, its antioxidant effects are 10-fold more potent than ascorbic acid or resveratrol (Song et al 2001). In addition to curcumin, turmeric contains the antioxidants protocatechuic acid and ferulic acid, and exhibits significant protection to DNA against oxidative damage in vitro (Kumar et al 2006).

Turmeric's antioxidant activity may protect against damage produced by myocardial and cerebral ischaemia (Al-Omar et al 2006, Fiorillo et al 2008, Shukla et al 2008) and diabetes (Farhangkhoei et al 2006, Jain et al 2006, Kowluru & Kanwar 2007). Turmeric has been shown to restore myocardial antioxidant status, inhibit lipid peroxidation and protect against ischaemia-reperfusion-induced myocardial injuries in two animal studies (Fiorillo et al 2008, Mohanty et al 2004). The mechanism is likely to be due to curcumin's antioxidant and anti-inflammatory effects. Curcumin has also been found to prevent protein glycosylation and lipid peroxidation caused by high glucose levels in vitro (Jain et al 2006) and to improve diabetic nephropathy (Srinivasan 2005) and retinopathy (Kowluru & Kanwar 2007). Turmeric has also been shown to suppress cataract development and collagen cross-linking, promote wound healing, and lower blood lipids and glucose levels (Jain et al 2006, Panhatcharam et al 2006).

## Anti-inflammatory

There have been a large number of studies examining the anti-inflammatory effects of curcumin. There is strong molecular evidence published for curcumin's potency to target multiple inflammatory diseases (Henrotin et al 2013). Turmeric is a dual inhibitor of the arachidonic acid cascade. Curcumin has been shown to exert anti-inflammatory effects via phospholipase, lipo-oxygenase, COX-2, leukotrienes, thromboxane, prostaglandins, nitric oxide (NO), collagenase, elastase, hyaluronidase, monocyte chemoattractant protein-1, IFN-inducible protein, TNF- $\alpha$  and IL-12 (Chainani-Wu 2003, Lantz et al 2005, Rao 2007). Due to its anti-inflammatory effects, curcumin has shown promise in many chronic disorders such as arthritis, allergies, arteriosclerosis, colitis, diabetes, respiratory disorders, hepatic injury, pancreatic disease, intestinal disorders, eye diseases, neurodegenerative diseases and various cancers (Aggarwal et al 2007, Bengmark 2006).

The anti-inflammatory effect of curcumin was tested in adjuvant-induced chronic inflammation rats, where it was found that curcumin significantly reduced C-reactive protein, TNF- $\alpha$ , IL-1 and NO, with no significant changes observed in PGE<sub>2</sub> and leukotriene B<sub>4</sub> levels or lymphocyte proliferation (Banerjee et al 2003). Curcumin has also been shown to inhibit inflammation in experimental

pancreatitis via inhibition of NF- $\kappa$ B and activator protein-1 in two rat models (Gukovsky et al 2003).

### NF-kappa-B inhibition

The many and varied effects of curcumin may be partly associated with the inhibition of the transcription factor, nuclear factor-kappa beta (NF- $\kappa$ B), and induction of heat shock proteins (HSP). NF- $\kappa$ B is a transcription factor pivotal in the regulation of inflammatory genes and is also closely associated with the heat shock response, which is a cellular defence mechanism that confers broad protection against various cytotoxic stimuli. Inhibition of NF- $\kappa$ B may reduce inflammation and protect cells against damage (Chang 2001) and curcumin has been found to attenuate experimental colitis in animal models through a mechanism correlated with the inhibition of NF- $\kappa$ B (Salh et al 2003). The clinical significance of this is unclear.

### Gastrointestinal effects

#### Hepatoprotective

Extracts of both turmeric and curcumin have been found to prevent and improve carbon tetrachloride-induced liver injury, both in vivo and in vitro (Abu-Rizq et al 2008, Deshpande et al 1998, Fu et al 2008, Kang et al 2002, Wu et al 2008). Curcumin also protects against dimethylnitrosamine-induced liver injury (Farombi et al 2008), reverses aflatoxin-induced liver damage in experimental animals (Soni et al 1992) and effectively suppresses the hepatic microvascular inflammatory response to lipopolysaccharides in vivo (Lukita-Atmadja et al 2002). An ethanol-soluble fraction of turmeric was shown to contain three antioxidant compounds — curcumin, demethoxycurcumin and bisdemethoxycurcumin — which exert similar hepatoprotective activity to silybin and silychristin in vitro (Song et al 2001).

Several different mechanisms may contribute to turmeric's hepatoprotective activity. Curcumin has been shown to prevent lipoperoxidation of subcellular membranes in a dosage-dependent manner, due to an antioxidant mechanism (Quiles et al 1998) and turmeric may also protect the liver via inhibition of NF- $\kappa$ B (see above), which has been implicated in the pathogenesis of alcoholic liver disease. Curcumin also appears to chelate hepatic and serum iron in vivo (Jiao et al 2006, 2009). Iron is pro-oxidant to the liver, which may be problematic during hepatic disease. Recent research also suggests that curcumin may be useful in preventing hepatic fibrosis caused by chronic liver disease (Fu et al 2008, O'Connell & Rushworth 2008). Curcumin also blocks endotoxin-mediated activation of NF- $\kappa$ B and suppresses the expression of cytokines, chemokines, COX-2 and iNOS in Kupffer cells (Nanji et al 2003).

#### Cholagogue and hypolipidaemic

The extracts of turmeric and curcumin have shown dose-dependent hypolipidaemic activity in vivo (Asai & Miyazawa 2001, Babu & Srinivasan 1997, Keshavarz 1976, Manjunatha & Srinivasan 2007a,

2007b, Ramirez-Tortosa et al 1999, Soudamini et al 1992). One in vivo study suggests that curcumin may stimulate the conversion of cholesterol into bile acids, and therefore increase the excretion of cholesterol (Srinivasan & Sambaiah 1991). A further study demonstrated that supplementation with turmeric reduces fatty streak development and oxidative stress (Quiles et al 2002). Curcumin also increases LDL receptor mRNA (Peschel et al 2007). Oral curcumin has also been shown to stimulate contraction of the gall bladder and promote the flow of bile in healthy subjects (Rasyid & Lelo 1999).

#### Antispasmodic

Curcuminoids exhibit smooth muscle relaxant activity possibly mediated through calcium channel blockade, although additional mechanisms cannot be ruled out (Gilani et al 2005). Curcuminoids produced antispasmodic effects on isolated guinea pig ileum and rat uterus by receptor-dependent and independent mechanisms (Itthipanichpong et al 2003).

#### Cancer

Curcumin has been studied for its wide-ranging effects on tumourigenesis, angiogenesis, apoptosis and signal transduction pathways (Gururaj et al 2002, Mohan et al 2000, Thaloor et al 1998). It is known to inhibit oncogenesis during both the promotion and the progression periods in a variety of cancers (Anto et al 1996, Kuttan et al 1985, Menon et al 1999, Ruby et al 1995). Curcumin was found to possess chemopreventive effects against cancers of the skin, stomach, colon, prostate, and breast, as well as oral cancer in mice.

#### Chemoprevention

Chemoprevention refers to reversing, suppressing or preventing the process of carcinogenesis. Carcinogenesis results from the accumulation of multiple sequential mutations and alterations in nuclear and cytoplasmic molecules, culminating in invasive neoplasms. These events have traditionally been separated into three phases: initiation, promotion and progression. Typically, initiation is rapid, whereas promotion and progression can take many years. Ultimately, chemoprevention aims at preventing the growth and survival of cells already committed to becoming malignant (Gescher et al 1998, 2001).

Curcumin has been found to inhibit the invasion, proliferation and metastasis of various cancers in vivo (Kunnumakkara et al 2008). Curcumin has been found to effectively block carcinogen-induced skin (Azuine & Bhide 1992), colon (Rao et al 1995a, 1995b, 1995c, 1999) and liver (Chuang et al 2000) carcinogenesis in animals. It has been suggested that the chemoprotective activity of curcumin occurs via changes in enzymes involved in both carcinogen bioactivation and oestrogen metabolism. This is supported by the findings that curcumin treatment produced changes in CYP1A, CYP3A and GST in mice (Valentine et al 2006) and alleviated the CCl<sub>4</sub>-induced inactivation of CYPs 1A, 2B, 2C and 3A isozymes in rats, possibly

through its antioxidant properties, without inducing hepatic CYP (Sugiyama et al 2006).

Oral curcumin inhibited chemically-induced skin carcinogenesis in mice (Huang et al 1992) and curcumin prevented radiation-induced mammary and pituitary tumours in rats (Inano & Onoda 2002). Curcumin and genistein (from soybeans) inhibited the growth of oestrogen-positive human breast MCF-7 cells induced individually or by a mixture of the pesticides endosulfane, dichlorodiphenyltrichloroethane (DDT) and chlordane, or 17-beta oestradiol (Verma et al 1997). Another study found that curcumin inhibited breast cancer metastases in immunodeficient animals (Bachmeier et al 2007). This may be due to the ability of curcumin to reduce NF- $\kappa$ B and therefore downregulate the two inflammatory cytokines CXCL1 and CXCL2 (Bachmeier et al 2008).

### Apoptosis

Apoptosis (programmed cell death) plays a crucial role in regulating cell numbers by eliminating damaged or cancerous cells. Curcumin has been shown to induce apoptosis in many different cancer cell lines, including breast, leukaemia, lymphoma, melanoma, ovarian, colorectal, lung and pancreatic in vitro (Kim et al 2001, Kuo et al 1996, Li et al 2007, Lin et al 2007, Lev-Ari et al 2006, Marin et al 2007, Skommer et al 2006, 2007, Tian et al 2008). Curcumin has also increased apoptosis in breast and ovarian cancers in vivo (Bachmeier et al 2007, Lin et al 2007). Curcumin has been demonstrated to induce apoptosis in human basal cell carcinoma cells associated with the p53 signalling pathway, which controls intracellular redox status, levels of oxidation-damaged DNA and oxidative stress-induced apoptosis (Jee et al 1998). Curcumin has also been found to induce apoptosis in human mutant p53 melanoma cell lines and block the NF- $\kappa$ B cell survival pathway and suppress the apoptotic inhibitor known as XIAP. Because melanoma cells with mutant p53 are strongly resistant to conventional chemotherapy, curcumin may overcome the chemoresistance of these cells and provide potential new avenues for treatment (Bush et al 2001).

Curcumin has also been found to inhibit prostate cancer cell growth in mice (Dorai et al 2001) and decrease proliferation and induce apoptosis in androgen-dependent and androgen-independent prostate cancer cells in vitro. This was found to be mediated through modulation of apoptosis suppressor proteins and interference with growth factor receptor signalling pathways (Dorai et al 2000). However, in a further study with rats curcumin did not prevent prostate carcinogenesis (Imaida et al 2001).

### Antiproliferative

Reduction in proliferation and/or increased apoptosis will lead to tumour regression; however, a more potent effect will be achieved if the two mechanisms occur simultaneously. Curcumin has been shown to do this. The inhibition of cell

proliferation is partly related to inhibition of various kinases, such as protein kinase and phosphorylase kinase (Reddy & Aggarwal 1994), and inhibition of several oncogenes and transcription factors. For example, turmeric inhibited epidermal growth factor receptor (EGF-R) signalling via multiple mechanisms, including downregulation of the EGF-R protein, inhibition of intrinsic EGF-R tyrosine kinase activity and inhibition of ligand-induced activation of the EGF-R (Dorai et al 2000). These mechanisms may be particularly important in preventing prostate cancer cells from progressing to a hormone refractory state (Dorai et al 2000). Curcumin has also been found to suppress the growth of multiple breast cancer cell lines and deplete p185neu, the protein product of the HER2/neu proto-oncogene, which is thought to be important in human carcinogenesis (Hong et al 1999).

### Antimetastatic

Curcumin demonstrated the ability to reduce lung metastases from melanoma cells in mice. The activity of curcumin is varied. In cell adhesion assays, curcumin-treated cells showed a dose-dependent reduction in their binding to four extracellular matrix proteins (binding to proteins is associated with the spreading of the cancer). Another study found that curcumin effectively suppressed COX-2, vascular endothelial growth factor and intercellular adhesion molecules, while enhancing the expression of antimetastatic proteins, tissue inhibitor metalloproteinases-2, non-metastatic gene 23 and E-cadherin, a transmembrane protein that plays an important role in cell adhesion (Kuttan et al 2007). Curcumin-treated cells showed a marked reduction in the expression of integrin receptors (integrins functionally connect the cell interior with the extracellular matrix, another process necessary for metastases).

### Chemotherapy

Curcumin enhanced the cytotoxicity of chemotherapeutic agents in prostate cancer cells in vitro by inducing the expression of certain androgen receptor and transcription factors and suppressing NF- $\kappa$ B activation (Hour et al 2002). Curcumin enhanced the antitumour effect of cisplatin against fibrosarcoma (Navis et al 1999), fluorouracil and oxaliplatin in colorectal cancer (Du et al 2006, Li et al 2007) and gemcitabine and paclitaxel in bladder cancer (Kamat et al 2007). Curcumin also attenuated multidrug resistance in a non-small cell lung cancer cell line (Andjelkovic et al 2008) and acted as a radiosensitiser for cervical cancer in vitro (Javvadi et al 2008).

Curcumin, however, was found to significantly inhibit cyclophosphamide-induced tumour regression in an in vivo model of human breast cancer. It is suspected that this occurred as a result of inhibition of free radical generation and blockade of JNK function. As such, curcumin intake should be limited in people undergoing treatment for breast cancer with cyclophosphamide until further

investigation can clarify the significance of these findings (Somasundaram et al 2002).

### Immunomodulation

Curcumin administration was found to significantly increase the total white blood cell count and circulating antibodies in mice. A significant increase in macrophage phagocytic activity was also observed in curcumin-treated animals (Antony et al 1999). However, curcumin has also been demonstrated to have some immunosuppressive activity. Curcumin inhibits PAR2- and PAR4-mediated human mast cell activation by blocking the ERK pathway (Baek et al 2003).

An in vivo study using a cardiac transplant model found that curcumin also significantly reduced expression of IL-2, IFN- $\gamma$  and granzyme B (a serine protease associated with the activity of killer T-lymphocytes and NK cells) and increased mean survival time. Curcumin was further shown to work synergistically with the antirejection drug cyclosporin (Chueh et al 2003).

Curcumin also modulates other interleukins and has been shown in vitro to be a potent inhibitor of the production of the pro-inflammatory cytokine IL-8, thereby reducing tumour growth and carcinoma cell viability. Curcumin not only inhibited IL-8 production but also inhibited signal transduction through IL-8 receptors (Hidaka et al 2002) and inhibited cell proliferation, cell-mediated cytotoxicity and cytokine production most likely by inhibiting NF- $\kappa$ B target genes (Gao et al 2004).

### Cardiovascular effects

#### Antiplatelet

Curcumin has been shown to inhibit platelet aggregation in vivo (Chen et al 2007, R. Srivastava et al 1985, 1986) and in vitro (Jantan et al 2008, KC Srivastava 1989, KC Srivastava et al 1995). The anticoagulant effect of curcumin is weaker than that of aspirin, which is four-fold more potent than curcumin in treatment of collagen- and noradrenaline-induced thrombosis. Curcumin 100 mg/kg and aspirin 25 mg/kg resulted in 60% protection from thrombosis (Srivastava et al 1985).

#### Anti-atherogenic

A hydro-ethanolic extract of turmeric was found to decrease LDL oxidation, lower the oxidation of erythrocyte and liver membranes, as well as have a vitamin E-sparing effect in rabbits fed a diet high in saturated fat and cholesterol (Mesa et al 2003, Ramirez-Tortosa et al 1999). The atheroscleroprotective potential of turmeric was further demonstrated by an animal study that found turmeric lowered blood pressure and reduced the atherogenic properties of cholesterol (Zahid Ashraf et al 2005). Curcumin also inhibits the proliferation and migration of vascular smooth muscle cells in vitro (Yang et al 2006).

Many in vivo studies have investigated the effects of dietary curcumin on blood cholesterol in diabetic

animals (Babu & Srinivasan 1997, Manjunatha & Srinivasan 2007a, 2007b, Pari & Murugan 2007). The two Manjunatha and Srinivasan studies found that curcumin significantly lowered plasma cholesterol, but only lowered hepatic cholesterol in animals with normal baseline cholesterol. Additionally, hepatic alpha-tocopherol and glutathione levels and serum glutathione peroxidase and glutathione transferase were increased. Babu and Srinivasan (1997) also found a significant decrease in blood triglyceride and phospholipid levels. In a parallel study in which diabetic animals were maintained on a high cholesterol diet, curcumin lowered cholesterol and phospholipid and countered the elevated liver and renal cholesterol and triglyceride levels seen in the diabetic animals (Babu & Srinivasan 1997).

### Wound healing

Wound healing is a highly ordered process, requiring complex and coordinated interactions involving peptide growth factors, of which transforming growth factor-beta (TGF-beta) is one of the most important. Nitric oxide is also an important factor in healing, and its production is regulated by iNOS. Topical application of curcumin accelerated wound healing in normal and diabetic rats. The wound healing is partly associated with the regulation of the growth factor TGF-beta-1 and iNOS (Mani et al 2002). Curcumin's wound-healing ability has been confirmed in several other animal studies (Sidhu et al 1998, Sidhu et al 1999). Wounds of animals treated with curcumin showed earlier re-epithelialisation, improved neovascularisation, increased migration of various cells, including dermal myofibroblasts, fibroblasts and macrophages into the wound bed, and a higher collagen content (Sidhu et al 1999). It appears to be effective when used orally or as a local application.

Curcumin has also demonstrated powerful inhibition against hydrogen peroxide damage in human keratinocytes and fibroblasts (Phan et al 2001) and pretreatment with curcumin significantly enhanced the rate of wound contraction, decreased mean wound-healing time, increased synthesis of collagen, hexosamine, DNA and NO and improved fibroblast and vascular densities in full thickness wounds in mice exposed to whole-body gamma-radiation (Jagetia & Rajanikant 2004).

### Antibacterial/Antimicrobial

Curcumin is a highly pleiotropic molecule that was first shown to exhibit antibacterial activity in 1949 (Gupta et al 2013). Turmeric is used as an antimicrobial for preserving food (Jayaprakasha et al 2005) and has been found to have antifungal activity, as well as inhibiting aspergillus growth and aflatoxin production in feeds (Gowda et al 2004).

Curcumin has also been found to have dose-dependent, antiprotozoan activity against *Giardia lamblia* with inhibition of parasite growth and adherent capacity, induction of morphological alterations

and apoptosis-like changes in vitro (Perez-Arriaga et al 2006). Curcumin has also shown in vitro and in vivo activity against malaria, with inhibition of growth of chloroquine-resistant *Plasmodium falciparum* in vitro and enhancement of survival in mice infected with *P. berghei* (Reddy et al 2005).

### OTHER ACTIONS

Curcumin's anti-inflammatory and antioxidant actions may be useful in preventing neurodegenerative diseases, such as Alzheimer's disease and Parkinson's disease, and curcumin has been found to target multiple pathogenic cascades in preclinical models (transgenic and amyloid infusion models) of Alzheimer's disease (Cole et al 2005, Calabrese et al 2006). Curcumin has also been found to dose-dependently inhibit neuroglial proliferation, with low doses being as effective as higher doses, given a longer period of treatment (Ambegaokar et al 2003). It may also enhance immune clearance of amyloidosis in the brain (Zhang et al 2006).

Theracurmin, a highly absorptive curcumin dispersed with colloidal nanoparticles, recently exhibited an inhibitory action against alcohol intoxication after drinking in humans. This was shown by the reduced acetaldehyde concentration of the blood (Sasaki et al 2011).

Curcumin (20 mg/kg body weight) treatment significantly inhibited chemical (ovalbumin)-induced airway constriction and airway hyperreactivity in an animal model of asthma (Ram et al 2003), thereby indicating potential anti-asthma effects.

Curcumin inhibits P-glycoprotein in numerous in vitro studies (Anuchapreeda et al 2002, Limtrakul et al 2004, Nabekura et al 2005). The clinical significance of this observation has yet to be determined.

### CLINICAL USE

In practice, turmeric and the various curcuminoids are used in many forms and administered via various routes. This review will focus mostly on those methods of use that are commonly used and preparations, such as oral dose forms and topical applications. Turmeric may be used as a single therapeutic agent or in combination with other herbal medicines or nutrients, such as the omega-3 polyunsaturated fatty acids. There is strong molecular evidence published for curcumin's potency to target multiple inflammatory diseases (Henrotin et al 2013).

### Arthritis

Curcumin is one of the most promising natural ingredients in the treatment of arthritis. It exhibits several mechanisms of action which make it an excellent candidate. In vitro studies have shown that curcumin inhibits NF- $\kappa$ B activation and translocation induced by IL-1 $\beta$  and the consequent expression of NF- $\kappa$ B induced pro-inflammatory genes, COX-2 and VEGF (Henrotin et al 2013). In a randomised, controlled, double-blind study, curcumin 1200 mg/day was compared with phenylbutazone in subjects with rheumatoid arthritis (RA).

### Rheumatoid arthritis

Curcumin was found to be effective in improving morning stiffness, walking time and joint swelling; however, the effects of phenylbutazone were stronger (Deodhar et al 1980). A more recent randomised study involving 45 patients with active RA found that treatment with curcumin (500 mg/day) was more effective than diclofenac sodium (50 mg/day) for reducing the Disease Activity Score (DAS) 28, together with tenderness and swelling, as measured by the American College of Rheumatology (ACR) criteria (Chandran & Goel 2012). In particular, the treatment was safe and well tolerated.

### Osteoarthritis

A proprietary complex of curcumin with soy phosphatidylcholine (Meriva, Indena SpA), which corresponded to 200 mg curcumin daily, was shown to decrease the global WOMAC score by 58% ( $P < 0.05$ ) at 3 months, increase walking distance and significantly reduce C-reactive protein levels in volunteers with osteoarthritis, thereby indicating a significant anti-inflammatory effect. In comparison, the control group only experienced very modest effects (Belcaro et al 2010b). To test the long-term effects of curcumin treatment, a follow-up study of 100 people with OA was conducted, which showed significant improvements to both the clinical and biochemical end points for Meriva (1 gm/day) compared to controls at 8 months (Belcaro et al 2010a). The WOMAC score was decreased by more than 50%, whereas treadmill-walking performance was increased almost threefold. From a biochemical perspective, serum inflammatory biomarkers such as IL-1 $\beta$ , IL-6, soluble CD40 ligand, soluble vascular cell adhesion molecule-1, and erythrocyte sedimentation rate were also significantly decreased in the treatment group. Of particular importance, there was a significant decrease in the requirement for NSAIDs and reduced gastrointestinal complications.

### IN COMBINATION

Curcumin combined with boswellia, withania and zinc produced a significant drop in pain and disability in osteoarthritis (OA) of the knee in a randomised, double-blind, placebo-controlled crossover study of 42 patients (Kulkarni et al 1991); however, the contribution of curcumin to these results is unknown.

### Cancer

Epidemiological data suggest that curcumin consumption reduces the rate of colorectal cancer (Hergenbahn et al 2002) and curcumin has wide-ranging chemopreventive activity in preclinical carcinogenic models (Plummer et al 2001), most notably for gastrointestinal cancers (Ireson et al 2001). In 1987 Kuttan et al treated 62 patients with external cancerous lesions with topical curcumin and found remarkable symptomatic relieving activity (Kuttan et al 1987). There was a reduction in smell, itching, lesion size and pain. Interestingly, the effect lasted for several months in most patients. Since then, curcumin, either alone or in combination with other

agents, has demonstrated potential against colorectal cancer, pancreatic cancer, breast cancer, prostate cancer, multiple myeloma, lung cancer, oral cancer, and head and neck squamous cell carcinoma (HNSCC) (Gupta et al 2013).

Curcumin appears to be a well-tolerated adjunctive treatment option for patients with pancreatic cancer. Twenty-five participants took 8 g of curcumin daily. Despite significant inter-patient variations in blood curcumin levels, NF- $\kappa$ B, COX-2 and phosphorylated signal transducer and activator of transcription 3 were all downregulated in peripheral blood mononuclear cells (Dhillon et al 2008).

In a phase 1 study, curcumin taken orally for 3 months at a starting dose of 500 mg/day was found to produce histological improvement in cases of bladder cancer, oral leucoplakia, intestinal metaplasia of the stomach, cervical intraepithelial neoplasm and Bowen's disease (Cheng et al 2001).

An ethanol extract of turmeric, as well as an ointment of curcumin, was found to produce remarkable symptomatic relief in patients with external cancerous lesions (Kuttan et al 1987) and there are clinical reports to suggest that curcumin could be safe and effective in the treatment of idiopathic inflammatory orbital pseudotumours (Lal et al 2000).

Curcumin has a potential use in breast cancer as it has been found to inhibit the migratory activity of breast cancer cells, proliferative rate, adhesion, and invasion through down-regulating the expression of NF- $\kappa$ B p65 (Liu & Chen 2013). Cell proliferation assays have shown that curcumin exhibited anti-proliferative effects on MDA-MB-231 and BT-483 breast cancer cells in a time- and dose-dependent manner. Curcumin decreased matrix metalloproteinases-1 expression in MDA-MB231 and BT-483 breast cancer cells. Down-regulation of NF- $\kappa$ B inducing genes (NF- $\kappa$ B p65) was also observed (Liu et al 2009). Curcumin may provide a clinically useful tool for the suppression of vascular endothelial growth factor (VEGF) in tumour cells. It has been found that curcumin suppressed breast tumour angiogenesis by negating osteopontin or medroxyprogesterone acetate-induced VEGF expression. Curcumin was found to inhibit  $\alpha$ 6 $\beta$ 4 signalling and functions by altering intracellular localisation of  $\alpha$ 6 $\beta$ 4, and prevented its association with signalling receptors such as the epidermal growth factor receptor (EGFR) and Protein Kinase B (Akt). In addition, the combination of epigallocatechin gallate (EGCG) and curcumin is efficacious in both in vitro and in vivo models of ER $\alpha$ -breast cancer. In these processes, the regulation of VEGFR-1 may play a key role in the antitumour activities (Liu & Chen 2013). Poly (ADP-ribose) polymerase 1 (PARP-1) plays a significant role in cellular protection against radiation. Targeting PARP-1 may provide an effective way of maximising the therapeutic value of curcumin and antioxidants for cancer prevention (Liu & Chen 2013). More research needs to be conducted for the potential use of curcumin in breast cancer patients.

## Cardiovascular disease

Effects of curcumin on risk factors for atherosclerosis were investigated in a 6-month randomised, double-blind, placebo-controlled clinical trial (Chuengsamarn et al 2014).

## Hyperlipidaemia

Turmeric may be associated with a decrease in the risk of cardiovascular disease and an intake of 200 mg of a hydro-ethanolic extract of turmeric may decrease total blood lipid peroxides as well as HDL- and LDL-lipid peroxidation, in addition to normalising plasma fibrinogen levels and apolipoprotein B/apolipoprotein A ratio (Miquel et al 2002).

A placebo-controlled, randomised, double-blind study investigated the effects of curcumin on the serum lipids in 36 elderly men and women (Baum et al 2007). The participants were randomised to receive 4 g/day of curcumin, 1 g/day of curcumin or placebo for 6 months. Neither active product significantly altered triglyceride or cholesterol levels at 1 or at 6 months. It was noted that the curcumin concentration was greater after capsule administration of curcumin compared to that of powder administration.

In an open trial, 10 healthy volunteers received 500 mg/day of curcumin for 7 days. A significant decrease in the level of serum lipid peroxides (33%), increase in HDL cholesterol (29%) and a decrease in total serum cholesterol (11.63%) were noted. It also reduced serum lipid peroxides (Soni & Kuttan 1992). In a subsequent study, a 45-day intake (by healthy individuals 27–67 years of age) of a turmeric hydro-alcoholic extract at a daily dose equivalent to 20 mg of curcumin resulted in a significant decrease in serum lipid peroxides (Ramirez-Bosca et al 1995). A daily intake of turmeric equivalent to 20 mg of curcumin for 60 days also decreased peroxidation of both HDL and LDL in 30 healthy volunteers ranging in age from 40 to 90 years. The effect was quite striking in the persons with high baseline values of peroxidised compounds in these lipoproteins, although no apparent change took place in the persons having low baseline values (Ramirez et al 1997). Larger trials are needed to test the efficacy of turmeric in dyslipidaemia.

## Diabetes

Turmeric has been used for the treatment of diabetes in Ayurvedic and traditional Chinese medicine (Zhang et al 2013). A systematic review suggests that curcumin could favourably affect most of the leading aspects of diabetes, such as insulin resistance, hyperglycaemia, hyperlipidaemia, and islet apoptosis and necrosis, as well as diabetes-related liver disorders, adipocyte dysfunction, neuropathy, nephropathy, and vascular diseases. Increased inflammation and levels of circulating ROS have been identified in the progression of diabetes. Potential mechanisms in the treatment of diabetes include antioxidant, anti-inflammatory (reduced IL-6, NF $\kappa$ B, TNF $\alpha$ ) and delayed islet ROS production. The authors conclude that studies need to be carried out in humans to

confirm the potential of curcumin in limitation of diabetes and other associated disorders.

A 9-month randomised, double-blind, placebo-controlled trial in a prediabetic population showed that curcumin significantly lowered the number of prediabetic individuals who eventually developed type 2 diabetes (16.4% vs 0%) (Chuengsamarn et al 2012). HbA<sub>1C</sub>, fasting plasma glucose (FPG), and oral glucose tolerance test (OGGT) measured at 2 hours were significantly lower in the curcumin-treated group when compared with the placebo group ( $P < 0.01$ ) in all visits at 3, 6 and 9 months. The curcumin-treated group showed a lower level of homeostasis model assessment-insulin resistance (HOMA-IR) (3.22 vs. 4.04;  $P < 0.001$ ). In addition, the curcumin treatment appeared to improve overall function of  $\beta$ -cells, with very minor adverse effects.

### Dyspepsia/peptic ulcers

A randomised, controlled, double-blind, prospective, multicentre pilot study compared the effects of dried extracts of greater celandine and turmeric with placebo in 76 patients with colicky abdominal pain in the right upper quadrant due to biliary dyskinesia. Abdominal pain was reduced more quickly with active treatment; however, other symptoms such as fullness, nausea and vomiting did not respond (Niederau & Gopfert 1999). Another randomised, placebo-controlled, double-blind study that investigated the efficacy of turmeric for treatment of dyspepsia and flatulence in 116 adult patients with acidic dyspepsia, flatulent dyspepsia or atonic dyspepsia found that 87% of patients receiving turmeric responded compared to 53% receiving placebo (Thamlikitkul et al 1989).

In a study of 24 patients with duodenal or gastric ulcers varying between 0.5 and 1.5 cm in diameter, 300 mg of turmeric given five times daily, 30–60 minutes before meals, at 4 pm and at bedtime, successfully healed 48% of ulcers after 4 weeks and 76% after 12 weeks. Of 20 patients who had erosion gastritis and dyspepsia, the same treatment produced a satisfactory reduction in abdominal pain and discomfort after the first and second week (Prucksunand et al 2001). Turmeric has also been positively compared to a liquid antacid for the treatment of gastric ulcer in a controlled clinical trial (Kositchaiwat et al 1993).

### Irritable bowel syndrome (IBS)

Turmeric extract shows promise in the symptomatic treatment of IBS, according to a partially blinded, randomised study by Bundy et al (2004). The study of 207 volunteers with diagnosed IBS complying with the Rome II criteria were randomly assigned to receive either 72 mg or 144 mg of turmeric a day or placebo for 8 weeks (Bundy et al 2004). The group receiving the lower dose (72 mg/day) experienced a significant 53% decrease in irritable bowel symptoms, whereas higher treatment (144 mg/day) resulted in a 60% decrease when compared to

placebo ( $P < 0.001$ ). Abdominal discomfort was also reduced by 22% and 25% of patients in the 72 mg and 144 mg groups, respectively ( $P < 0.001$ ). Approximately two-thirds of the participants in the active groups reported overall symptom improvement and had better quality-of-life scores.

### Inflammatory bowel disease

An open-label pilot study has produced preliminary data to suggest that curcumin may be effective in inflammatory bowel disease (Holt et al 2005). Five patients with Crohn's disease received 360 mg of curcumin three times a day for 1 month, followed by four times a day for another 2 months. The Crohn's disease activity index (CDAI), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) fell significantly in four out of five patients. Five patients with ulcerative proctitis were also enrolled and received 550 mg of curcumin twice a day for 1 month, then three times a day for another month. Overall, stool quality was greatly improved and frequency was significantly reduced. Two patients were able to eliminate their concomitant medications altogether, while another two patients were able to reduce them. The CRP and ESR also returned to within normal limits by the cessation of the study.

A randomised, double-blind, multicentre trial of 89 patients examined the efficacy of curcumin as a maintenance therapy in ulcerative colitis (Hanai et al 2006). Patients in the active group received 1 g of curcumin, twice a day (e.g. 1 g after breakfast and 1 g after the evening meal) with sulfasalazine or mesalazine as compared to placebo plus sulfasalazine or mesalazine. At the end of the study period, 4.7% of patients in the curcumin group relapsed during treatment compared to 20.5% in the placebo group ( $P = 0.040$ ). The clinical activity index ( $P = 0.038$ ) and endoscopic index ( $P = 0.0001$ ) were also significantly improved. This is a promising result that may have great clinical significance.

### Ophthalmology

Studies demonstrate the potential therapeutic role and efficacy of curcumin in eye relapsing diseases, such as dry eye syndrome, allergic conjunctivitis, anterior uveitis, glaucoma, maculopathy, and ischaemic and diabetic retinopathy (Pescosolido et al 2013). Curcumin treatment has resulted in a partial, but significant, inhibition of neuronal and vascular damage during ischaemic or oxidative stress, angiogenesis, and inflammatory diseases. The mechanism by which curcumin induces its effects is yet to be fully elucidated. A number of studies have shown its relevance as a potent anti-inflammatory and immunomodulating agent. In addition, curcumin with its pleiotropic activities can modulate the expression and activation of many cellular regulatory proteins such as chemokines, interleukins, haematopoietic growth factors, and transcription factors, which in turn inhibit cellular inflammatory responses and protect cells (Pescosolido et al 2013).

## Psoriasis

A phase 2, non-blind, open-label trial investigated the effect of curcuminoid C3 complex (500 mg, 3 capsules three times a day) in 12 patients with plaque psoriasis for 12 weeks followed by a 4-week observation period (Kurd et al 2008). Results were poor with the intention-to-treat analysis response rate only reaching 16.7%. Of the eight patients who completed the trial, two participants responded with good results (83% and 88% improvement in symptoms); however, this could be due to a placebo effect. Overall, the medication was well tolerated with only mild side effects being reported, due to either gastrointestinal upset or hot flushing.

Topical curcumin reduced the severity of active, untreated psoriasis as assessed by clinical, histological and immunohistochemical criteria in an observational study of 10 patients. Curcumin was also found to decrease phosphorylase kinase, which is involved in signalling pathways, including those involved with cell migration and proliferation (Heng et al 2000). Topical administration of curcumin also induced normal skin formation in the modified mouse tail test (Bosman 1994). The effects are thought to be due to immune-modulating, anti-inflammatory and cyclo-oxygenase inhibitory actions. The downregulation of pro-inflammatory cytokines supports the view that turmeric antioxidants may exert a favourable effect on psoriasis-linked inflammation. Moreover, because IL-6 and IL-8 are growth factors for keratinocytes, their inhibition by those antioxidants may reduce psoriasis-related keratinocyte hyperproliferation (Miquel et al 2002).

## OTHER USES

### Chronic anterior uveitis

An open study of 32 patients found that orally administered curcumin improved symptoms and reduced recurrences of chronic anterior uveitis (a condition often associated with other autoimmune disorders) with an efficacy comparable to corticosteroid therapy, yet without significant side effects (Lal et al 1999).

### Oral submucous fibrosis

Turmeric extract 3 g, oil 600 mg and oleoresin 600 mg effectively relieved symptoms and reduced the number of micronuclei (a sign of damage to the DNA and chromosomal integrity) in circulating lymphocytes and oral mucosal cells in patients with oral submucous fibrosis, a debilitating disease of the oral cavity mainly caused by chewing betel nut or tobacco (Hastak et al 1997).

### Reducing alcohol intoxication

Theracurmin exhibited an inhibitory action against alcohol intoxication after drinking in humans, as evidenced by the reduced acetaldehyde concentration of the blood (Sasaki et al 2011).

## DOSAGE RANGE

### Internal use

- Tablet formulas are available, singular or in combination with other anti-inflammatory/antioxidant herbs, where the curcuminoids are formulated with phosphatidylcholine (phospholipid) to increase the relative absorption.
- Powdered turmeric: 1.5–3 g/day in water or cooking.
- Liquid extract (1:1) in 45% ethanol: 5–15 mL/day.
- Powdered extract standardised to 95% curcumin: 100–300 mg/day. Higher doses used for arthritis.

Due to its low solubility, oral bioavailability (Henrotin et al 2013; Pescosolido et al 2013) and systemic bioavailability (Henrotin et al 2013), the biomedical potential of curcumin is not easily realised unless it is taken in a bioavailable form such as theracurmin or Meriva (Indena TM). Multiple approaches are needed to overcome this limited solubility and poor bioavailability of curcumin. Some of these approaches include the synthesis of curcuminoids and development of novel formulations of curcumin, such as emulsions, sustained released tablets (Pescosolido et al 2013), nanoparticles and liposomal encapsulation (Pescosolido et al 2013, Zhang et al 2013).

Theracurmin is a highly absorptive curcumin dispersed with colloidal nanoparticles. Healthy human volunteers were administered orally 30 mg of Theracurmin or curcumin powder. The area under the blood concentration-time curve of Theracurmin was 27-fold higher than that of curcumin powder (Sasaki et al 2011). Something to note is the difference in particle size of Theracurmin vs curcumin (mean particle size (D50% diameter) was 0.19 μm and 22.75 μm, respectively). Water dispersion studies observed homogenised very small particles in the Theracurmin sample, while the curcumin powder showed crystal aggregates with various sizes around several dozen micrometres (Sasaki et al 2011).

Dose-escalating studies have indicated the safety of curcumin at doses as high as 12 g/day over 3 months (Gupta et al 2013). Pharmacologically, curcumin does not show any dose-limiting toxicity when it is administered at doses of up to 8 g/day for three months (Pescosolido et al 2013).

### External use

- Turmeric powder of standardised powdered extract applied as a paste or poultice — half a cup of turmeric combined with 1 teaspoon of carbonate of soda and then mixed with hot water to make a paste; spread on gauze and apply to affected area.

## ADVERSE REACTIONS

The safety of dietary curcumin is demonstrated by the fact that it has been consumed for centuries at levels of up to 10 mg/day by people in certain countries (Ammon & Wahl 1991). Curcumin was

non-toxic to humans in doses up to 8000 mg/day when taken by mouth for 3 months (Cheng et al 2001). Multiple other human trials have also found it to be safe with no alteration of liver or renal function tests (Chainani-Wu 2003, Prucksunand et al 2001, Ramirez-Bosca et al 1995, Ramirez et al 1997, Sharma et al 2001). Nausea and diarrhoea are possible effects of curcumins ranging from 0.45 to 3.6 g/day when taken for 1 to 4 months. This also caused an increase in serum alkaline phosphatase and lactate dehydrogenase contents in human participants (Sharma et al 2004).

Large doses of turmeric powder may cause gastrointestinal irritation in some persons (Shankar et al 1980), and very high dosages have been shown to reduce fertility in male rats (human equivalent doses would be 35 g turmeric/70 kg adult) (Bhagat & Purohit 2001). Normal therapeutic dosages of turmeric are not expected to affect fertility. Contact dermatitis has been reported (Hata et al 1997), as has a single case of anaphylaxis (Robinson 2003).

### SIGNIFICANT INTERACTIONS

Controlled studies are not available, so interactions are based on evidence of activity and are largely theoretical and speculative.

#### Antiplatelet drugs

Turmeric has a theoretical interaction with antiplatelet drugs; antiplatelet properties have been demonstrated for curcumin, therefore it may produce an additive effect. The clinical significance of this interaction is unclear and likely to be dose-dependent.

#### Anticoagulants

Theoretically, high-dose turmeric preparations may increase the risk of bleeding when used together with anticoagulant drugs — caution is advised.

#### Cyclophosphamide

Animal studies suggest that curcumin may reduce drug efficacy — avoid.

### CONTRAINDICATIONS AND PRECAUTIONS

Turmeric is contraindicated in bile duct obstruction (Blumenthal et al 2000) and high doses are probably best avoided in males and females wanting to conceive.

Curcumin is also contraindicated in breast cancer patients treated with cyclophosphamide until the significance of an *in vivo* model of breast cancer, which found that curcumin reduced the tumour regression effects of chemotherapy, is clarified (Somasundaram et al 2002).

Due to antiplatelet activity and possible increased risk of bleeding, use of concentrated extracts should be suspended 1 week prior to major surgery; however, usual dietary intakes are likely to be safe.

### PREGNANCY AND LACTATION USE

When used as a spice, this herb is most likely to be safe; however, the safety of therapeutic doses has not been established. Turmeric has been demonstrated not to be mutagenic *in vitro* (Nagabhushan & Bhide 1986) or to be teratogenic in mice (Garg 1974, Vijayalaxmi 1980). Constituents and/or metabolites of turmeric and curcumin were transferred to suckling pups, but no ill effect on the offspring was reported.

### Practice points/Patient counselling

- In Ayurvedic medicine, turmeric is used to strengthen the overall energy of the body, relieve gas, dispel worms, improve digestion, regulate menstruation, dissolve gallstones, relieve arthritis and purify the blood (Blumenthal et al 2000).
- In Traditional Chinese medicine (TCM), turmeric is used for bruises, sores, ringworm, chest pain, toothache and jaundice. Turmeric was also recommended for abdominal pain, mass formation in the abdomen and amenorrhoea (Blumenthal et al 2000).
- Turmeric is commonly used in foods and is likely to be a safe and healthy addition to the diet.
- Turmeric has been shown to have antioxidant, anti-inflammatory and anti-atherosclerotic activities; however, further clinical evidence is needed before it can be recommended to treat specific conditions.
- Clinical evidence suggests that turmeric may provide benefit for people with dyspepsia, peptic ulcer, hyperlipidaemia and arthritis and there is emerging evidence to suggest that turmeric may help prevent a number of cancers as well as being useful as an adjuvant in cancer treatment.

### PATIENTS' FAQs

#### What will this herb do for me?

In countries where people use turmeric extensively in cooking (generally in curries), the intake seems to be associated with a lower level of certain chronic conditions, possibly including cancer, gastrointestinal diseases and arthritis. There have been some encouraging studies supporting this. Curcumin has shown promising effects for symptomatic relief in numerous inflammatory conditions such as rheumatoid arthritis, osteoarthritis, inflammatory bowel disease, IBS, peptic ulcer, psoriasis and in various cancers, diabetes and eye conditions. Ideally, oral use of preparations where bioavailability has been improved is likely to give the best results.

#### When will it start to work?

In some studies, the effect began to be noticed after 2 weeks. However, as most of the conditions where

turmeric may be beneficial are chronic in nature, treatment with turmeric should be considered long term.

### Are there any safety issues?

Turmeric is considered very safe at normal dietary or therapeutic dosages with turmeric extracts. High doses are generally not recommended during pregnancy or for those wanting to conceive.

# Tyrosine

**HISTORICAL NOTE** Tyrosine has been used by the military in the United States and the Netherlands to counter the stressful effects of cold, prolonged and excessive physical activity. It also appears to improve cognition and performance in soldiers under psychologically stressful conditions and has been scientifically shown to improve physical and mental endurance (Deijen et al 1999).

## BACKGROUND AND RELEVANT PHARMACOKINETICS

Tyrosine is a conditionally essential aromatic amino acid. It can be consumed through the diet or synthesised in the body from phenylalanine, except in phenylketonurics. Human studies also indicate that people with chronic renal failure have impaired conversion of phenylalanine to tyrosine, leading to low tyrosine and higher phenylalanine levels in plasma and other tissues (Kopple 2007). This is because the kidney plays a major role in the uptake of phenylalanine and its hydroxylation and release as tyrosine. L-Tyrosine is absorbed in the small intestine by active transport and transported to the liver, where it is involved in a number of biochemical reactions, such as protein synthesis and oxidative catabolic reactions. L-Tyrosine that is not metabolised in the liver is distributed via the systemic circulation to various tissues in the body where it is involved in the synthesis of a number of catecholamines and hormones (Hendler & Rorvik 2001), incorporated into protein structures or deaminated for gluconeogenesis. Peak plasma tyrosine levels occur 2 hours after administration and remain elevated for 6–8 hours (Glaeser et al 1979).

There is some question as to tyrosine's ability to cross the blood–brain barrier and this may explain some of the negative results demonstrated in clinical trials. In vivo studies demonstrate that concentrations in the brain are influenced by protein ingested, not only in a single meal, but also when the protein content of the diet is modified over longer periods (Peters & Harper 1985). Proper flow is dependent upon the ratio of tyrosine to other large neutral amino acids (phenylalanine, tryptophan, methionine, leucine, isoleucine and valine) that compete for uptake by transporter proteins (Glaeser et al 1979).

A rat study has demonstrated that combining the essential fatty acid alpha-linolenic acid with L-tyrosine, via a special bond, produces an active biological molecule with potent dopaminergic activity, suggesting that alpha-linolenic acid may play a dual role as a carrier for tyrosine and as a membrane- and receptor-improving agent (Yehuda 2002). In addition, in vivo research has determined that tyrosine nitration in brain proteins is exacerbated by low levels of vitamin D in the blood stream, leading to alterations in glucose metabolism and mitochondrial changes. Cognition was improved

in subjects with normal vitamin D status, indicating that vitamin D is an important antioxidant cofactor in the normal functioning of tyrosine (Keeney et al 2013).

## CHEMICAL COMPONENTS

L-Tyrosine is the form generally used. Tyrosine is also known as beta-(*para*-hydroxyphenyl) alanine, alpha-amino-*para*-hydroxyhydrocinnamic acid and (*S*)-alpha-amino-4-hydroxybenzenepropanoic acid.

## FOOD SOURCES

Good dietary sources include soy products, chicken, fish, almonds, avocados, bananas, dairy products, meat, eggs, nuts, beans, oats, wheat, lima beans, pumpkin seeds, sesame seeds and fermented foods such as yoghurt and miso.

## DEFICIENCY SIGNS AND SYMPTOMS

The following have been associated with low levels of tyrosine:

- Depression
- Low blood pressure
- Low body temperature
- Restless legs syndrome
- Hypothyroidism.

## MAIN ACTIONS

### Neurotransmitter and hormone production

Many of the pharmacological actions of tyrosine relate to its role as a precursor for a number of neurotransmitters and hormones. Tyrosine forms dihydroxyphenylalanine (DOPA), which is then converted to dopamine, and this, in turn, forms noradrenaline and adrenaline. Folate, vitamins B<sub>3</sub>, B<sub>6</sub>, B<sub>12</sub> and C, iron, copper and other nutrients are required for the metabolism of tyrosine to catecholamines.

The rate of synthesis and release of monoamine neurotransmitters (serotonin) and catecholamines (dopamine, noradrenaline and adrenaline) in the brain are directly modified by the availability of their amino acid precursors tryptophan, phenylalanine and tyrosine. The availability of these amino acid precursors is largely dependent on physiological and pathophysiological factors and others that compete with them for a common transporter across the blood–brain barrier (the large neutral amino acids or LNAAs). As a result, factors which affect

the amino acid precursors from crossing the blood-brain barrier in sufficient levels can affect brain function (Fernstrom & Fernstrom 2007). It has been suggested that, under some circumstances (such as when catecholamine neurons are firing rapidly), insufficient amino acid transport is most likely to affect brain function (Parker & Brotchie 2011).

Interestingly, tyrosine supplementation (or loading) does not always have a clinical effect: some *in vivo* research has demonstrated that excess tyrosine in the brain or cerebrospinal fluid samples does not always reflect enhanced catecholamine synthesis or turnover, possibly due to feedback mechanisms or substrate inhibition (Badawy et al 2010). Tyrosine and sometimes its precursor phenylalanine are converted into dopamine and noradrenaline. L-tyrosine undergoes hydroxylation into L-3, 4-dihydroxyphenylalanine (L-DOPA) in the presence of a rate-limiting catalytic enzyme, tyrosine hydroxylase and its cofactors, including  $\text{Fe}^{2+}$ ,  $\text{O}_2$  and tetrahydropteridine. Further, L-DOPA undergoes decarboxylation to form dopamine, and then to noradrenaline in some neurons (Lakhan & Vieira 2008, Ruhé et al 2007). Elevating tyrosine concentrations in brain catecholamine neurons (particularly dopamine and noradrenaline neurons) can stimulate neurotransmitter production in actively firing neurons but not in those that are quiescent or firing slowly (Fernstrom 2000). Therefore tyrosine plays an essential role in the body as a precursor to the catecholamine neurotransmitters, as illustrated above, and although the biochemical pathways are well understood, the effects on brain function are not.

### Thyroid hormones

As tyrosine is a precursor for the synthesis of thyroid hormones, it is involved in the regulation of basal metabolic rate, oxygen use, cellular metabolism, growth and development (Tortora & Grabowski 1996).

Tyrosine undergoes iodination to form monoiodotyrosine ( $\text{T}_1$ ), a second iodination produces diiodotyrosine ( $\text{T}_2$ ), and these combine to produce the active thyroid hormones known as triiodothyronine ( $\text{T}_3$ ) and tetraiodothyronine or thyroxine ( $\text{T}_4$ ) (Tortora & Grabowski 1996).

Tyrosine is also involved in the production of other compounds, such as melanin, enkephalins and some types of oestrogen (Haas 1992, Tortora & Grabowski 1996).

### Antioxidant

L-Tyrosine, a monophenolic amino acid, demonstrates antioxidant activity in various assays, including 1,1-diphenyl-2-picryl-hydrazyl (DPPH) free radical scavenging, 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) radical scavenging, superoxide anion radical scavenging, hydrogen peroxide scavenging, total ferric ion reducing power and metal chelating on ferrous ion activities, as well as inhibition of lipid peroxidation of linoleic acid emulsion (Gulcin 2007).

## CLINICAL USE

Clinical trials tend to investigate tyrosine in combination with other amino acids, typically LNAAs, which are tryptophan, phenylalanine, valine, leucine and isoleucine or in combination with the branched-chain amino acids (BCAAs: valine, leucine and isoleucine). Conditions which have an underlying dopaminergic-based pathology, such as Parkinson's disease, phenylketonuria, reward deficiency syndrome and depression, have received particular attention.

### Phenylketonuria

In phenylketonuria (PKU), a severe deficiency of phenylalanine hydroxylase prevents the conversion of phenylalanine to tyrosine, resulting in a build-up of phenylalanine, which may cause severe mental retardation and a deficiency of tyrosine. PKU is treated by restricting the dietary intake of natural protein and substituting a protein source that lacks phenylalanine but is fortified with tyrosine. Unfortunately, free tyrosine supplementation has not always been shown to consistently improve neuropsychological function in PKU; this is possibly because tyrosine levels naturally fluctuate through the day and increases in plasma tyrosine levels are not sustained, so brain influx remains suboptimal despite tyrosine supplementation (Kalsner et al 2001). In practice, plasma tyrosine levels need to be monitored for diurnal variation (normal: 45 micromol/L) and biochemical evidence of tyrosine deficiency should be established before tyrosine supplementation is considered (Poustie & Rutherford 2000, van Spronsen et al 2001).

Due to the fact that tyrosine deficiency is typical in PKU patients, current guidelines recommend high-tyrosine protein supplementation from the time when a PKU infant starts weaning (MacDonald et al 2012). Infant formulas can include up to three times the concentration of phenylalanine compared to breast milk, therefore caution should be taken when using formulas in infants with PKU (Feillet & Agostoni 2010). The PKU diet is difficult to maintain in adolescence and adult life, and new strategies have been suggested, such as the supplementation of LNAAs as an alternative to phenylalanine restriction (Giovannini et al 2012). The use of the LNAAs therapy has been shown to improve amino acid profiles as well as increase tyrosine and tryptophan concentrations in the blood, which are precursors for dopamine and serotonin (Koch et al 2003). A short-term double-blind placebo controlled study, using LNAAs supplementation in patients with PKU, showed a lowering of blood phenylalanine concentration by an average of 39% from baseline (Matalon et al 2007). An LNAAs blend with tyrosine as the primary ingredient was also found to increase the synthesis of melatonin in patients with PKU (Yano et al 2013). Significant associations have been demonstrated in correlation analyses between depressive symptoms and long-term high-phenylalanine, low-tyrosine (indicating poor dietary

control) or low-tyrosine diets in adolescents (Sharman et al 2012). Further studies are required to determine the value of additional tyrosine supplementation in depressed patients with PKU.

### Cognitive function in PKU

Tyrosine supplementation (100 mg/kg/day) taken over 4 weeks is not sufficient to counteract the decline in cognitive function seen when people with PKU relax or stop their dietary regimen, according to a double-blind, placebo-controlled crossover study (Pietz et al 1995). However, a later double-blind study found that, when people with PKU maintain their restricted diet and medications, the addition of LNAA had a beneficial effect on executive functioning (Schindeler et al 2007). Subjects adding LNAA supplementation to their usual management experienced significant improvements in executive functions, particularly in verbal generativity and flexibility when compared to the placebo group.

### Enhanced cognition

Therapeutically, tyrosine supplements are used to enhance levels of its derivatives and, therefore, improve cognitive function.

One double-blind randomised controlled trial found that treatment with L-tyrosine (150 mg/kg) following one night's sleep loss significantly reduced the usual performance decline on a psychomotor task compared to placebo (Neri et al 1995). There was also a significant reduction in lapse probability on a high-event-rate vigilance task and the cognitive improvement effects lasted approximately 3 hours after dosing.

### IN COMBINATION

Other randomised controlled trials have compared the effects of a balanced amino acid drink with one lacking in tyrosine and phenylalanine and shown that tyrosine-depleted individuals experienced impaired spatial recognition memory and spatial working memory and an increase in plasma prolactin levels (Harmer et al 2001, McTavish et al 2005). Subjective feedback indicated that the participants felt better on the amino acid drink containing tyrosine compared to the other, although ratings of depression and other aspects of cognitive function were unchanged (Harmer et al 2001).

### Depression

Tyrosine is a popular supplement in mild depression, due to its role as a precursor to both dopamine and noradrenaline and the fact that tyrosine depletion may play a role in the pathogenesis of depression.

Whether or not tyrosine deficiency is a causative factor or consequence in depression remains poorly understood. Two studies have been conducted which suggest an association between low tyrosine levels and depression. One recent study compared serum levels of various neurotransmitter precursors between 60 hospitalised patients with major depressive disorder and 110 healthy volunteers and found

that people with major depressive disorder had lower serum levels of tyrosine than controls (Sa et al 2012). Previously, an early study compared plasma tyrosine levels of 38 endogenous depressed patients with those of neurotic depressive and schizophrenic patients as well as healthy controls at four different time points during the day (Benkert et al 1971). A significant decrease in the 11 a.m. tyrosine level in the endogenous depressives was observed when compared with the other three groups; however, the 8 a.m. tyrosine concentration was similar for all.

Whether tyrosine supplementation has a major effect on mood and depression is still unclear as interventional clinical studies have produced inconsistent results (Parker & Brotchie 2011). The studies have tended to be small and relatively short, usually 4 weeks at most, making any definitive conclusions difficult from the available evidence. It also appears possible that some patients are more likely to be affected by fluctuations in tyrosine levels than others. This was suggested in a meta-analysis which reviewed eight acute phenylalanine / tyrosine depletion studies and suggested that such depletion (of noradrenaline and dopamine) did not decrease mood in healthy controls but did have such a mood effect in vulnerable patients who are in remission and are still in receipt of antidepressant medication (Ruhé et al 2007).

One study found that tyrosine- and phenylalanine-depleted individuals became less content and more apathetic than those given a balanced amino acid mixture (McLean et al 2004). However, a separate study in individuals with a past history of recurrent depression found that tyrosine depletion did not alter objective or subjective measures of mood (McTavish et al 2005), although plasma prolactin levels did increase and performance on a spatial recognition memory task was impaired (McTavish et al 2005). One prospective, randomised, double-blind, placebo-controlled trial of 65 subjects with major depression comparing L-tyrosine (100 mg/kg/day), imipramine (2.5 mg/kg/day) and placebo for 4 weeks failed to confirm an antidepressant effect for tyrosine (Gelenberg et al 1990). A small, double-blind placebo-controlled study involving 14 outpatients with major depression found that tyrosine (100 mg/kg/day) taken for 4 weeks led to remission in four (of six) people whereas three people (of eight) receiving placebo experienced remission (Gelenberg et al 1980).

In contrast, another early study involving patients with signs of dopamine-dependent depression found that treatment with oral tyrosine (3200 mg/day) caused an immediate improvement in mood, as judged by clinical impression and objective test scores (Montgomery-Asperg Depression Rating Scale) and sleep parameters from day 1 of treatment (Mouret et al 1988a).

### Attention-deficit hyperactivity disorder (ADHD)

There is insufficient research to determine whether supplementation with tyrosine in ADHD produces any benefits. Many of the amino acids needed by the body to manufacture neurotransmitters, such as

phenylalanine, tyrosine and tryptophan, are found to be low in the blood of adults and children with ADHD, and tyrosine has been shown to be beneficial for attention in two reviews of treatments for adults with ADHD (Arnold et al 2013, Pellow et al 2011).

An 8-week open trial of L-tyrosine in 12 adults with attention-deficit disorder (residual type) demonstrated benefits at 2 weeks; however tolerance developed after 6 weeks, rendering the treatment ineffectual (Reimherr et al 1987). Previous studies had reported similar effects (Wood et al 1985).

#### IN COMBINATION

A retrospective single-blinded pilot study of 85 paediatric patients demonstrated significant improvements when supplemented over 8–10 weeks with a mix of tyrosine, tryptophan and other cofactors, including vitamin C, B vitamins and selenium (Hinz et al 2011a).

#### Reward deficiency syndrome

Tyrosine depletion appears to affect reward-based processing (McLean et al 2004) and tests involving reward/punishment processing are affected by dopamine depletion (Roiser et al 2005). A lack of dopamine receptors and/or dopamine depletion states have been implicated in a number of conditions or destructive behaviours thought to be caused by poorly functioning biochemical reward systems. Individuals tend to be at risk of multiple addictive, impulsive and compulsive behavioural problems, such as severe alcoholism, cocaine, heroin, marijuana and nicotine addiction, pathological gambling, sex addiction, chronic violence, posttraumatic stress disorder, risk-taking behaviours and antisocial behaviour. As such, the use of tyrosine as a precursor to dopamine has a theoretical basis for use in this condition (Blum et al 2000).

Molecular genetic studies are implicating the gene for the D<sub>2</sub> dopamine receptor (DRD<sub>2</sub>) as well as other genes in reward deficiency syndrome and in obesity, leading to excessive craving behaviour (Blum et al 2008, Chen et al 2008). One review concluded that utilising natural dopaminergic repletion therapy to promote long-term dopaminergic activation would ultimately lead to a common, safe and effective modality to treat reward deficiency syndrome behaviours, including substance use disorders, ADHD, obesity and other reward-deficient aberrant behaviors (Chen et al 2008). However, achieving amino acid balance can be difficult; therefore many trials have used a combination of amino acids in the treatment protocol.

Tyrosine is part of a treatment program known as neuroadaptogen amino acid therapy, which has been researched in 27 human clinical trials, including double- and triple-blind placebo-controlled evaluations. Along with D- and L-phenylalanine, L-tryptophan, L-glutamine, chromium, pyridoxine and the herbs passionflower and rhodiola, this formula has been shown to promote the release of dopamine at the reward sites of the brain (Chen et al 2011).

Reward deficiency syndrome has also been proposed as a possible mechanism explaining the tendency to drug and alcohol addiction in schizophrenia (Green et al 1999). To date, no large controlled studies are available to determine the clinical effects of tyrosine supplementation in this condition.

#### Drug withdrawal

Tyrosine has been used to aid in the withdrawal of cocaine, caffeine and nicotine. Anecdotal reports and animal studies suggest it is successful; however, large controlled studies are not available to determine clinical significance.

L-tyrosine supplementation has been considered because chronic cocaine use is believed to cause catecholamine depletion and cocaine withdrawal has been associated with major depression. To date, results from trials using tyrosine as a stand-alone treatment during cocaine withdrawal have produced disappointing results (Chadwick et al 1990, Galloway et al 1996). Although untested as yet, the effects of tyrosine may be of most assistance where a deficiency of dopamine D<sub>2</sub> receptors is suspected, such as in reward deficiency syndrome.

#### Stress adaptation

Physical and emotional stress can impair performance and memory. In order to reduce the adverse effects of stress on these functions, improvements in stress adaptation are sought, including through the use of supplements such as tyrosine. Tyrosine appears to enhance the release of catecholamines when neurons are firing at an increased rate due to stress, but not at their basal rates (Young 2007). Several clinical studies have explored the effects of tyrosine in volunteers exposed to stressful situations, generally producing positive results on some parameters (see 'Clinical note: allostatic responses to stress' in the Siberian ginseng monograph for more information about stress adaptation).

A number of studies have been conducted by the US and Dutch military, so extrapolation to other population groups should be made with caution.

Tyrosine supplementation was found to reduce the effects of stress and fatigue on cognitive performance in a study conducted with a group of 21 cadets during a demanding military combat training course. Subjects received a protein-rich drink containing (2 g) tyrosine five times daily or a carbohydrate-rich drink with the same amount of calories (255 kcal). Assessments on day 6 of the course showed that the tyrosine group performed better on a memory and a tracking task than the control group and further experienced a decrease in systolic blood pressure; however, no effects on mood were observed (Deijen et al 1999).

Other studies indicate that high-dose tyrosine (150 mg/kg) may also improve some aspects of performance and help sustain working memory when multitasking in stressful situations. One placebo-controlled trial involving 20 people found that administration of tyrosine significantly enhanced accuracy and working memory during the

multiple-task battery 1 hour after ingestion. However, tyrosine did not significantly alter performance on the arithmetic, visual or auditory tasks during the multiple task, or modify any performance measures during the simple task battery (Thomas et al 1999).

### Cold stress and heat stress

Similar results were obtained in another controlled trial that investigated the effects of tyrosine (150 mg/kg) on memory tasks in cold (4°C) conditions. Two hours after ingesting L-tyrosine, matching accuracy significantly improved in the cold and was at the same level as administration of either tyrosine or placebo at a comfortable 22°C (Shurtleff et al 1994). Two small trials have shown that tyrosine supplementation (total 300 mg/kg) alleviates working memory decrements induced by cold exposure (~10°C) (Mahoney et al 2007) and may also improve the psychomotor task of marksmanship (O'Brien et al 2007).

Other beneficial effects have been obtained with tyrosine supplementation in volunteers exposed to cold stress. A double-blind, placebo-controlled, crossover study found that tyrosine (100 mg/kg) could protect humans from some of the adverse consequences of a 4.5 hour exposure to cold and hypoxia. Tyrosine significantly decreased symptoms, adverse moods and performance impairment in subjects who exhibited average or greater responses to these environmental conditions (Banderet & Lieberman 1989).

A pilot study of 10 healthy males from the Indian army in a double-blind crossover trial showed that administration of 6.5 g tyrosine 90 minutes prior to a 90-minute exposure at 45°C + 30% humidity increased the catecholamine levels and reduced the impairment of cognitive performance during heat exposure. Serum levels of catecholamines and reaction time testing were improved in the tyrosine group (Kishore et al 2013).

## OTHER USES

### Hepatocellular carcinoma

In patients with hepatocellular carcinoma (HCC), tyrosine and BCAA supplementation reduces the frequency of early recurrence of HCC after hepatic resection or radiofrequency thermal ablation (Ichikawa et al 2013, Nishikawa et al 2013). A recent multicentre open clinical trial ( $n = 247$ ) tested the supplementation of 5.5–12 g/day tyrosine/BCAAs to cirrhosis patients without HCC with an average observation/supplementation period of 728 days (Kawaguchi et al 2014). Key findings included that tyrosine/BCCA supplementation significantly reduced all-cause mortality, and significantly reduced the risk of hepatocarcinogenesis. A significant predictor of HCC development in this study was a low BCAA:tyrosine ratio, possibly due to insulin resistance (a significant risk factor for HCC) caused by a low BCAA:tyrosine ratio (Kawaguchi et al 2011). In addition, bacterial infection (the cause of 25% of the deaths in the non-BCAA group) was not a cause

of death in the BCAA-supplemented group at all (Kawaguchi et al 2014). This reinforces previous research that reported a preventive effect of BCAAs on bacterial infections in liver transplant recipients via upregulation of immune cell functioning (Shirabe et al 2011).

### Premenstrual syndrome

Although tyrosine is used to reduce symptoms of irritability, depression and fatigue associated with premenstrual syndrome, this is largely based on theoretical considerations and the observation that a significant reduction in tyrosine levels occurs during the premenstrual period, according to one study (Menkes et al 1994).

This study further found that tryptophan depletion caused a significant aggravation of premenstrual symptoms, particularly irritability, and symptom magnitude was correlated with reduction in tryptophan relative to other amino acids.

### Reproductive effects

Although no controlled studies are available, tyrosine is sometimes used for lowered libido as it indirectly increases testosterone and dopamine levels, both factors important in this condition. Five female lambs with delayed puberty who received a single oral dose of L-tyrosine (100 mg/kg body weight) exhibited significantly higher progesterone concentrations than a control group. Three came into heat and two became pregnant compared to none in the control group (El-Battawy 2006).

### Parkinson's disease

The process of Parkinson's disease (degeneration of the postsynaptic neurons of the substantia nigra) is associated with depletion of dopamine, tyrosine and tyrosine hydroxylase, noradrenaline and serotonin. Parkinson's disease depletion of these neurotransmitters is compounded by further depletion with L-dopa (Charlton 1997). As noted in the literature, administration of only L-dopa or improperly balanced L-dopa further depletes tyrosine and other amino acids (Hinz et al 2011b). In addition, the depletion of tyrosine by L-dopa would have an impact on other systems where tyrosine acts as a precursor, such as with thyroid hormones. Administration of tyrosine has been shown to increase dopamine production in the central nervous system of patients with Parkinson's disease (Growdon et al 1982), and in addition, multiple case studies have demonstrated that patients taking L-dopa require a minimum administration of 5000–6000 mg/day of tyrosine to prevent significant urinary dopamine fluctuations (Hinz et al 2011b).

### Weight loss

Tyrosine supplements have been used in weight loss, based on biochemical considerations and in vivo research, suggesting tyrosine could potentially suppress appetite and stimulate brown adipose tissue due to its enhancement of noradrenaline synthesis.

Additionally, as a precursor for thyroid hormones it may also increase the basal metabolic rate.

### Schizophrenia

Whether tyrosine is helpful with or hinders cognitive functioning in schizophrenia is yet to be determined. Theoretically, some have cautioned against the use of tyrosine due to the possibility of a significant increase in neurotransmitter synthesis and cognitive functioning (Cass & Holford 2001); however studies also show that aberrant tyrosine kinetics in patients with schizophrenia might be associated with cognitive dysfunction — a core feature of schizophrenia. It has been noted that, in patients with schizophrenia, cognitive dysfunction was found to be related to a high affinity of tyrosine to transport-binding sites in fibroblasts but not to the transport capacity, so therefore despite the fact that tyrosine binds strongly to receptors, the actual transport and conversion to dopamine are low in these patients (Wiesel et al 2005).

### Cognitive enhancement in Alzheimer's dementia and traumatic brain injury

Clinical studies have shown that cognitively impaired subjects have significant levels of mitochondrial dysfunction and oxidative protein damage. In particular, tyrosine nitration is a common early indicator/biomarker of cognitive impairment, including those with an ageing brain, and of age-related neurodegenerative disorders such as Alzheimer's dementia (Butterfield et al 2007). The oxidative stress-induced modification of tyrosine residues can elicit significant changes in protein structure and function which, in some cases, may contribute to biological ageing and age-related pathologies such as neurodegeneration (Feeney & Schoenich 2012).

Clinical research is not available to determine the effects of modified tyrosine intake.

### Fatigue

Fatigue is a common feature associated with a range of chronic and/or progressive conditions, interfering with normal activities and general quality of life. Patients with chronic liver diseases such as primary biliary cirrhosis often suffer from profound fatigue, and research has confirmed that aberrant tyrosine metabolism and plasma amino acid concentrations are a feature of fatigued patients when compared to healthy controls, whereby a significant and independent association has been documented between lower tyrosine levels and all measures of fatigue (ter Borg et al 2005). Further studies are required to confirm these findings.

Low tyrosine levels have been identified in subjects with chronic fatigue syndrome, suggesting a possible role for supplementation in this condition (Georgiades et al 2003).

### Narcolepsy

Abnormalities of the dopaminergic system are thought to be part of the underlying aetiology of

this disorder, therefore tyrosine is used on the theoretical basis that an increase in dopamine levels will produce an improvement (Roufs 1990).

A randomised, double-blind, placebo-controlled study of L-tyrosine (9 g/day for 4 weeks) that tests this theory has been conducted in 10 subjects with narcolepsy and cataplexy. While receiving tyrosine, subjects reported feeling less tired, less drowsy and more alert; however, ratings of daytime drowsiness, cataplexy, sleep paralysis, nighttime sleep, overall clinical response and measurements of multiple sleep latency and tests of speed and attention did not detect a significant difference with placebo (Elwes et al 1989). An earlier trial of longer duration, however, reported that within 6 months all eight participants were free from daytime sleep attacks and cataplexy (Mouret et al 1988b).

### Nemaline myopathy

Five patients (four infants and one adolescent) with nemaline myopathy (the most common congenital myopathy, characterised by facial and bulbar weakness, resulting in eating difficulties, recurrent aspiration and poor control of oral secretions) received L-tyrosine (250–3000 mg/day). All infants experienced an initial decrease in sialorrhoea and an increase in energy levels. The adolescent experienced improved strength and exercise tolerance (Ryan et al 2008).

### DOSAGE RANGE

- As tyrosine is considered to be a non-essential amino acid, there is no specific recommended daily intake. The typical dose in clinical trials appears to be 100–150 mg/kg. Divided dosing may be beneficial as levels remain above baseline for 6–8 hours following administration.
- Depression, premenstrual syndrome and chronic fatigue: 500–1000 mg before meals three times daily.
- Stress: 1500 mg/day in divided doses.
- Decreased libido, Parkinson's disease, drug detoxification and weight loss: 1–2 g/day in divided doses.
- Natural stimulant: 500–1000 mg on an empty stomach first thing in the morning.
- Alertness following sleep deprivation: 150 mg/kg/day.
- As individual sensitivity to tyrosine can vary, it is recommended to start at 100 mg/day and gradually increase dose (Cass & Holford 2001).

### ADVERSE REACTIONS

Adverse reactions include migraine headache, mild gastric upset, nausea, headache, fatigue, heartburn, arthralgia, insomnia and nervousness (Hendler & Rorvik 2001).

High blood pressure may occur in susceptible individuals — hypertensive patients taking tyrosine should be monitored closely.

**Practice points/Patient counselling**

- Tyrosine is a conditionally essential amino acid that is ingested from the diet or produced from phenylalanine in the body.
- Many of the pharmacological actions of tyrosine relate to its role as a precursor to a number of neurotransmitters and thyroid hormones.
- Protein sources enriched with tyrosine but lacking in phenylalanine are used in PKU.
- Tyrosine supplements are used to improve cognitive function, in the management of depression or reward deficiency syndrome associated with noradrenaline or dopamine depletion, and to enhance stress adaptation systems.
- Due to its effects on neurotransmitters, it may elevate blood pressure in susceptible people when taken in high doses, and increase the effects of amphetamines, ephedrine, phenylpropanolamine, thyroxine and pharmaceutical antidepressants.

**SIGNIFICANT INTERACTIONS****Amphetamine, ephedrine, phenylpropanolamine**

L-Tyrosine (200 and 400 mg/kg) has been shown to increase the side effect of anorexia caused by phenylpropanolamine, ephedrine and amphetamine in a dose-dependent manner in rats (Hull & Maher 1990) — observe patients using this combination.

**Antidepressant drugs**

Monoamine oxidase inhibitors (MAOIs), tricyclic antidepressants or selective serotonin reuptake inhibitors: theoretically, concurrent use may result in elevated blood pressure and/or enhanced antidepressant effects. In the case of MAOIs, some tyrosine may be metabolised to tyramine and concurrent use with MAOIs may lead to a hypertensive crisis.

Tyrosine should be avoided unless under medical supervision.

**Central nervous system stimulants**

Tyrosine is a precursor to a number of neurotransmitters, so additive effects may occur — caution.

**Oestrogens and antiandrogen therapy**

Oestrogens and antiandrogen therapies have been shown to decrease plasma levels of tyrosine by up to 18.3% after 4 and 12 months in transsexual patients, therefore supplementation may be suggested (Giltay et al 2008).

**Levodopa**

L-Dopa competes with tyrosine for uptake, therefore concurrent use may decrease the uptake of both substances, reducing efficacy (Awad 1984, DiPiro et al 1999, Riederer 1980) — avoid unless under medical supervision.

**CONTRAINDICATIONS AND PRECAUTIONS**

- Malignant melanoma: a theoretical concern exists that tyrosine supplementation may promote the division of cancer cells (McArdle et al 2001). Tyrosine is contraindicated until safety is established.
- Manic conditions: caution exists due to the theoretical possibility that tyrosine may significantly increase neurotransmitter synthesis (Cass & Holford 2001), and until further studies are undertaken, monitoring is recommended.
- Hyperthyroidism and Graves' disease: theoretically tyrosine may aggravate these conditions as it is a precursor to thyroxine (van Spronsen et al 2001).
- Alkaptonuria and tyrosinaemia (inborn errors of tyrosine metabolism).
- Hypertension: use tyrosine with caution at high dose.
- Ecstasy users should be aware that MDMA increases the concentration of tyrosine in the brain, causing long-term depletion of serotonin (Breier et al 2006).

**PREGNANCY USE**

High-dose supplements should be used with caution in pregnancy.

**Morphine sulfate**

L-Tyrosine potentiates morphine-induced analgesia by 154% (Hull et al 1994) and 200 mg/kg significantly potentiated the antinociceptive action of morphine in mice, although L-tyrosine alone did not produce a significant antinociceptive effect (Ali 1995). Observe patients taking tyrosine and morphine sulfate concurrently — there is a potential beneficial interaction.

**Thyroid hormone medication**

Additive effects are possible because tyrosine is a precursor to thyroid hormones — observe patients taking tyrosine concurrently with thyroid hormone medication.

**PATIENTS' FAQs****What will this supplement do for me?**

Tyrosine supplementation appears to increase the levels of important brain chemicals and thyroid hormones. As such, it may elevate mood and alertness, and enhance the body's ability to deal with stress.

**When will it start to work?**

Although some research suggests that effects begin within 1–2 hours, it may take up to 1 week for maximal effects to be seen.

**Are there any safety issues?**

Theoretically, tyrosine may increase blood pressure in susceptible individuals and also interact with a number of medicines, such as pharmaceutical antidepressants and thyroid treatment. It is also not recommended in pregnancy.

## Valerian

**HISTORICAL NOTE** The sedative effects of valerian have been recognised for over 2000 years, having been used by Hippocrates and Dioscorides in ancient Greece. Over the past 500 years, valerian has been widely used in Europe for nervousness or hysteria and also to treat dyspepsia and flatulence. Legend has it that the Pied Piper used valerian in his pockets to attract the rats out of Hannover. Valerian was widely used by the Eclectic physicians and listed in the United States Formulary until 1946.

### COMMON NAME

Valerian and Mexican Valerian

### OTHER NAMES

All-heal, amantilla, balderbrackenwurzel, baldrian, baldrianwurzel, fragrant valerian, heliotrope, herbe aux chats, katzenwurzel, phu germanicum, phu parvum, valeriana, wild valerian

### BOTANICAL NAME/FAMILY

*Valeriana officinalis*, *Valeriana edulis* (family Valerianaceae)

### PLANT PART USED

Rhizome

### CHEMICAL COMPONENTS

Valtrates, didrovaltrates, isovaltrates, monoterpenes, sesquiterpenes, caffeic, gamma-amino butyric and chlorogenic acids, beta-sitosterol, methyl 2-pyrrolketone, choline, tannins, gum, alkaloids, a resin. Essential oils (0.5–2%) in the plant contain the compounds bornyl acetate and the sesquiterpene derivatives valerenic acid, valeranone and valeranal.

The chemical composition of valerian varies greatly depending on such factors as plant age and growing conditions. Processing and storage of the herb also affects its constituents, such as the iridoid esters, which are chemically unstable.

### MAIN ACTIONS

#### Anxiolytic and hypnotic

Both in vivo and numerous clinical studies confirm sedative or hypnotic activity for valerian (Ammer & Melnizky 1999, Balderer & Borbely 1985, Della Loggia et al 1981, Donath et al 2000, Dorn 2000, Gerhard et al 1996, Gessner & Klasser 1984, Leathwood & Chauffard 1985, Leuschner et al 1993, Lindahl & Lindwall 1989, Schulz et al 1994, Wheatley 2001). Anxiolytic activity has been demonstrated, most recently seen with a valerian extract with high valerenic acid concentration (Felgentreff et al 2012). Antidepressant activity has been seen most recently with an ethanolic extract of valerian (Phytofin Valerian 368) in an experimental model (Hattesoehl et al 2008).

Extensive pharmacological research has been conducted to identify the main active constituents responsible for these effects. It is apparent that multiple components are at work and several neurobiological mechanisms underlie these actions. Recent in vivo testing has identified that the chief component responsible for the anxiolytic activity of valerian is the valerenic acid content (Felgentreff et al 2012). In the study, two extracts of valerian were tested with different valerenic acid ratios. A stronger anxiolytic effect was seen in test animals for the higher concentration extract (12:1) compared to

a lower ratio extract (1:1.5). Binding studies confirmed an affinity to GABAergic binding sites. In an in vitro cell culture model, valerenic acid and its derivatives, acetoxyvalerenic acid and hydroxyvalerenic acid, were shown to cross the blood–brain barrier (BBB) to a slower extent than the GABAA modulator diazepam. Valerenic acid was the slowest to permeate in the study, followed by hydroxyvalerenic acid and acetoxyvalerenic acid. The research suggested that these compounds do not cross into the CNS by passive diffusion and instead are transported over the BBB by an as yet unknown transport system (Neuhaus et al 2008).

In vitro tests so far have demonstrated that valerian stimulates the release of GABA, inhibits GABA reuptake and may modulate GABA activity at GABAA receptors (Ortiz et al 1999, Santos et al 1994). The sesquiterpenic acids (valerenic acid and acetoxyvalerenic acid) seem to be at least partly responsible for this effect. This was discovered when a valerian ethyl acetate extract containing high levels of valerenic acid exhibited strong enhancement of GABA receptor activation, whereas the removal of sesquiterpenic acids from the extract led to a loss of GABA enhancement (Trauner et al 2008).

An alternative explanation for the anxiolytic properties of valerian may be CNS depression via inhibition of glutamate receptors as suggested by in vitro and animal models (Del Valle-Mojica et al 2011a, 2011b, 2012). There is also evidence of agonist effects at the human A<sub>1</sub> adenosine receptor for the methanolic extract (Schumacher et al 2002).

### Antispasmodic, vasorelaxant and anti-convulsant

Both in vitro and in vivo studies provide evidence of antispasmodic activity on smooth muscle using various models (Hazelhoff et al 1982, Occhiuto et al 2009, Estrada-Soto et al 2010, Rezvani et al 2010). Valerian extracts and valepotriates in aqueous and ethanolic extracts exhibited antispasmodic activity as demonstrated by decreasing uterine contractility in isolated human uterine muscle. The effect occurred in a concentration-dependent manner and is thought to be due to calcium-channel blocker activity (Occhiuto et al 2009). *Valeriana edulis* demonstrated a significant concentration-dependent vasorelaxant activity on isolated rat aorta which also appeared to be due to a calcium-channel blocker mechanism (Estrada-Soto et al 2010). Antiepileptic activity was observed for an aqueous extract of valerian (500 mg/kg) which reduced seizure activity in rats. The mechanism of action was thought to be activation of the adenosine system (Rezvani et al 2010).

### OTHER ACTIONS

A pharmacokinetic study with healthy adults found that typical doses of valerian are unlikely to produce clinically significant effects on the CYP2D6 or CYP3A4 pathways of metabolism (Donovan et al 2004). These results were confirmed in another human pharmacokinetic study that found no

evidence of valerian affecting CYP3A4/5, CYP1A2, CYP2E1 and CYP2D6 activity (Gurley et al 2005). There is some in vitro evidence that suggests valerian may increase glucuronidation via the UDP-glucuronosyltransferase (UGT) enzymes. However, this has not been confirmed in humans (Mohamed et al 2010, 2011).

### CLINICAL USE

In practice, valerian is rarely used as a stand-alone treatment and is often combined with other sedatives or relaxant herbs, such as chamomile, passion-flower, skullcap, lemon balm and hops.

### Insomnia

Numerous randomised controlled trials (RCTs) have investigated the effects of different valerian preparations as a treatment for insomnia. Some studies have involved people with confirmed sleep disturbances and others involved healthy subjects with no sleep problems. Treatment time-frames varied from acute (1 dose) to longer term (over 1 month) and doses have varied considerably. Some studies use only subjective data such as self-reported sleep quality whereas others use objective measures such as polysomnographs. Additionally, some studies use herbal combinations which include valerian, whereas others use valerian alone as monotherapy. As a result, interpreting the evidence is difficult.

Overall, the research suggests that valerian improves the subjective quality of sleep and may reduce sleep latency, enabling people to fall asleep a little more quickly. It generally shows no significant effect among people without sleep disturbances. Some research also suggests that best results are obtained with continuous use after several days to weeks and in some studies, a herbal combination of valerian with lemon balm or hops is more effective than placebo.

Findings from a pharmacokinetic study indicate that valerian has a short period of activity as it demonstrated that valerenic acid (a pharmacologically active marker compound for valerian) was increased in serum within an hour of ingestion, reached maximal levels between 1 and 2 hours, then fell with a marked decrease within 4 hours and no detectable levels observed after 8 hours (Anderson et al 2005). This pharmacokinetic pattern is also consistent with the finding that valerian does not produce residual morning sedation.

A number of different valerian products have been studied in clinical trials (e.g. Baldosedron, Baldrien-Dispert, Euvegal, Harmonicum Much, Seda-Kneipp, Sedonum, Valdispert, Valverde and Valerina Nutt). The LI 156 valerian extract is one of the most studied.

One of the first major systematic reviews was conducted by Stevinson and Ernst (2000), who identified 19 studies involving valerian treatment that were published prior to May 1999. Of these, nine were chosen for inclusion because they were randomised, measured sleep parameters and tested

single ingredient valerian products. Three studies considered the cumulative effects of long-term use of valerian, whereas six investigated the effects of single-dose treatment. Two of the three studies investigating repeated administration of valerian found that effects were established by 2 weeks. The most rigorous placebo-controlled study showed that valerian LI 156 (600 mg) produced improvement on nearly all measures between weeks 2 and 4 (Vorbach et al 1996 as reported by Stevinson & Ernst 2000). The 4-week study involved 121 volunteers and assessed clinical effectiveness using four validated rating scales. At the end of the study, valerian was rated better than placebo on the Clinical Global Impression Scale, and at study conclusion (day 28) 66% of patients rated valerian effective, compared to 26% with placebo. Of the six studies investigating acute effects, valerian produced positive results in three whereas in the other three it was no better than placebo.

Interpretation of study results is difficult because of varying research methodologies. For example, some studies used surveys whereas others used EEG readings; some were conducted at home and others in hospitals or sleep laboratories, and pre-bedtime variables (e.g. caffeine consumption) were not fully controlled. Additionally, some studies used healthy volunteers with no sleep disturbances with little scope to observe further improvements. Since then, several other studies have been published.

In 2007, a comprehensive systematic review conducted by Taibi et al identified 37 separate studies of which 29 were controlled trials which evaluated valerian for both efficacy and safety, and eight were open-label trials which evaluated for safety only (Taibi et al 2007). The search was not limited to English language publications, thereby identifying many additional studies published by European research groups, including 17 studies published in German. The review evaluated data from RCTs and trials of other designs that investigated ethanolic extracts of valerian, aqueous extracts of valerian and valerian herbal combination treatments in people with sleep disturbances and in those who were considered healthy.

Six randomised, double-blind studies of an ethanolic extract of valerian (mainly LI 156 Sedonium) at a dosage between 300 and 600 mg before bedtime were assessed (Taibi et al 2007). Two studies measured polysomnographic outcomes and four collected only subjective measures of sleep quality. Overall, the ethanolic extract was not found to significantly affect objective or subjective sleep outcomes compared to placebo, however it did improve subjective sleep quality ratings in a manner similar to benzodiazepines. If we assume benzodiazepines perform better than placebo, then this is a positive outcome.

Seven studies evaluated the effects of aqueous preparations of valerian (Valdispert, Dixa SA Switzerland) at doses ranging from 400 mg/night to 450 mg three times daily (Taibi et al 2007). Four

studies involved healthy subjects, two were of elderly people with sleep disturbances and one study was of people with difficulties in sleep onset. Once again, methodologies were highly varied. Only one study excluded volunteers with medical conditions that could contribute to poor sleep. As may be expected with such variations, results were mixed. The two studies involving elderly volunteers produced contradictory results, whereas reduced subjective latency was demonstrated in people with sleep onset disturbances. Healthy volunteers appeared to gain no benefit from the treatment.

Five further studies used valerian extracts which were standardised to valepotriate content (Taibi et al 2007). Three of these studies used *V. edulis* (one used Harmonicum Much) as a source of valepotriates and one used *V. wallichii* (Valmane). The dose of valepotriates varied from 60 to 120 mg and one preparation of *V. officinalis* used a preparation standardised to 450 mg of valerenic acid (Mediherb, Queensland, Australia). While methodologies varied considerably, overall standardised extracts appeared to reduce sleep disturbances when compared to placebo. A dose of 100 mg valepotriates taken three times a day was found to significantly improve sleep quality ratings in people withdrawing from benzodiazepines when compared to placebo. Additionally, 60 to 120 mg valepotriates was similarly effective in people who had reported disturbed sleep.

### Valerian herbal combinations

In the 2007 systematic review by Taibi et al, 10 studies evaluating valerian herbal combinations were reviewed. Four studies tested valerian–lemon balm and six studies tested valerian–hops in combination (Taibi et al 2007). The studies using valerian–lemon balm combinations were shown to reduce sleep latency and increase sleep quality in people suffering sleep disturbances, whereas no change was observed in healthy subjects. In contrast, studies with valerian–hops combinations found no significant improvements using polysomnographic equipment or subjective sleep outcomes (Taibi et al 2007). The hops–valerian treatments used were ZE 91019 (Alluna) or another product sHova (extraction unknown).

In 2007, a later randomised placebo controlled study was published that compared a valerian–hops combination (Ze 91019) to valerian monotherapy (Ze 911) (Koetter et al 2007). The herbal combination treatment contained the same amount of valerian (500 mg) as monotherapy, thereby allowing researchers to evaluate what contribution hops (120 mg) would make to the outcomes measured. Volunteers suffering from non-organic insomnia were given either treatment or placebo for 4 weeks. In contrast to previous studies cited by Taibi et al, the valerian–hops combination was significantly superior to placebo in reducing sleep latency, improving clinical global impression scores and increasing slow-wave sleep, while the single valerian extract failed to show benefits beyond placebo.

A 2008 randomised placebo-controlled double-blinded trial ( $n = 42$ ) investigating a combined preparation of valerian and hops (Dormesax) found that the time spent in deeper sleep was significantly higher for the active treatment group compared to the placebo group ( $P < 0.01$ ) (Dimpfel et al 2008). The treatment was administered 15 minutes before an 8-hour EEG recording to a group of poor sleepers, as identified by a validated sleep questionnaire (Schlaffragebogen SF-B). An un-medicated first night was used as a reference and compared to a second night where volunteers received either treatment. The findings between the reference and medication night in regards to time spent in deeper sleep were also statistically significant ( $P < 0.01$ ). This suggests that a single dose preparation may be effective in achieving deeper sleep. The dose used was 2 mL of a liquid extract (a 1:10 fresh-plant tincture of *Valeriana officinalis* radix equivalent to 460 mg plus a 1:12 fresh-plant tincture of *Humulus lupulus* strobilus equivalent to 460 mg in 61% ethanol).

### Valerian monotherapy

A 2010 meta-analysis analysed results from 18 RCTs where valerian was used as monotherapy compared to placebo (Fernández-San-Martín et al 2010). Studies varied greatly in design with variations in sample size, population groups, diagnostic criteria, dosage and follow-up times. The outcome measures were improved sleep quality with a dichotomous variable, improved sleep quality identified through visual analogue scales and improved sleep latency (measured via polysomnography or self-reporting questionnaires). Analysis found that valerian did not demonstrate statistical significance in improving sleep latency, but did improve sleep quality when the outcome was measured as a dichotomous variable, but not using a visual analogue scale. This indicates that participants taking valerian subjectively perceived greater sleep quality however this was not confirmed with quantitative measurements. Adverse effects between valerian and placebo were comparable with the exception of diarrhoea. Diarrhoea was more frequent in patients taking Valerian (18%) compared with those taking a placebo (8%,  $P = 0.02$ ).

### Restless legs syndrome and insomnia

Whether valerian improves sleep quality and symptoms in people with restless legs syndrome (RLS) is unclear according to this triple-blind, placebo-controlled RCT (Cuellar et al 2009). Thirty-seven volunteers were treated for 8 weeks with either valerian capsules twice daily (800 mg dried *Valeriana officinalis* radix equivalent to 1.16 mg valerenic acid/day) or placebo. The primary aim was to assess sleep quality using the Pittsburgh Sleep Quality Index and sleepiness using the Epworth Sleepiness Scale. The secondary aim was to assess changes in RLS symptom severity using the International RLS Symptom Severity Scale. Although the treatment group

displayed a greater improvement in the majority of RLS symptoms and sleep quality, the findings were not statistically significant.

### POST-MENOPAUSAL WOMEN WITH INSOMNIA

A 2010 triple-blind, controlled trial involving 100 postmenopausal women aged 50 to 60 years experiencing insomnia found that more women treated with valerian capsules (Sedamin 530 mg concentrated valerian root extract per capsule) twice daily for 4 weeks experienced improved sleep quality (30%) compared to those taking placebo (4%;  $P < 0.001$ ) (Taavoni et al 2011). The improvement in sleep quality was based on changes to the Pittsburgh Sleep Quality index, a self-rated questionnaire assessing subjective sleep quality, latency, duration, sleep disturbances, use of sleep medication and daytime dysfunction.

In contrast, a small ( $n = 16$ ) randomised, double-blind, crossover, controlled trial of healthy women aged 55–80 years with insomnia, valerian capsules (300 mg of a concentrated *Valeriana officinalis* L. root extract Nature's Resource standardised to contain 0.8% valerenic acid /day) taken 30 minutes before bedtime for 2 weeks has no significant effect on sleep latency, sleep efficiency, wake after sleep onset or self-rated sleep quality (Taibi et al 2009). Interestingly, there was a significant increase ( $+17.7 \pm 25.6$  minutes,  $P = 0.02$ ) in nocturnal wakefulness in the valerian group compared to placebo ( $+6.8 \pm 26.4$  minutes, NS) which the authors attributed to a paradoxical stimulating effect as cited in the traditional literature (Bone 2003). Side effects were minor and did not differ significantly between valerian and placebo. The study used results gathered over 9 nights in the laboratory using a self-reported morning sleep questionnaire and polysomnographic recordings and at home by daily self-reported sleep logs and actigraphy.

### Comparisons with benzodiazepines

Three randomised studies have compared valerian monotherapy with benzodiazepine drugs. One double-blind trial found that subjects treated with either 600 mg valerian (ethanolic extract) or 10 mg oxazepam experienced significantly improved sleep, with no statistically significant differences detected between the treatments (Dorn 2000). Another study comparing the immediate sedative effects and residual effects of a valerian and hops preparation, a sole valerian preparation, flunitrazepam and placebo found that subjective perceptions of sleep quality were improved in all treatment groups; however, only flunitrazepam treatment impaired performance the morning after, as assessed both objectively and subjectively (Gerhard et al 1996). Furthermore, 50% of subjects receiving flunitrazepam reported mild side-effects compared with only 10% from the other groups.

A 2002 double-blind randomised trial compared the effects of valerian extract LI 156 (Sedonium)

600 mg/day to 10 mg oxazepam over 6 weeks in 202 patients with non-organic insomnia (Ziegler et al 2002). The multicentre trial took place at 24 study centres in Germany and found that valerian treatment was at least as efficacious as oxazepam, with both treatments improving sleep quality. Subjectively, 83% of patients receiving valerian rated it as 'very good' compared with 73% receiving oxazepam.

### Children

The efficacy and tolerability of a valerian and lemon balm combination (Euvegal forte) was tested in a large, open, multicentre study of 918 children (aged under 12 years) with restlessness and nervous sleep disturbance (dyssomnia) (Muller & Klement 2006). Both investigators' and parents' ratings revealed a reduction in the severity of symptoms for most patients. The study reported that 81% of children with dyssomnia experienced an improvement and 70% of children with restlessness improved. Treatment was generally rated as good or very good and considered well tolerated. Each Euvegal forte tablet consisted of 160 mg valerian root dry extract (*Valeriana officinalis* L.) with a drug-extract ratio of 4–5:1 (extraction solvent ethanol 62% v/v) and 80 mg lemon balm leaf dry extract (*Melissa officinalis*) with a drug-extract ratio of 4–6:1 (extraction solvent ethanol 30% v/v). The standard dosage of Euvegal forte (4 tablets daily) was used by 75% of patients and chosen by the investigator.

### Anxiety and psychological stress states

Less investigation has taken place to determine the role of valerian as a treatment for anxiety states.

A randomised study found that low-dose valerian (100 mg) reduced situational anxiety without causing sedation (Kohnen & Oswald 1988). Positive results were also obtained in a smaller open study of 24 patients suffering from stress-induced insomnia who found treatment (valerian 600 mg/day for 6 weeks) significantly reduced symptoms of stress and insomnia (Wheatley 2001). Another randomised trial compared the effects of a preparation of valepotriates (mean daily dose 81.3 mg) with diazepam (mean daily dose 6.5 mg) and placebo in 36 outpatients with GAD under double-blind conditions (Andreatini et al 2002). After 4 weeks' treatment, all groups had significant reductions in Hamilton anxiety (HAM-A) scale scores; however, only those receiving valepotriates or diazepam showed a significant reduction in the psychic factor of HAM-A.

Kava kava is a herbal medicine also used in the treatment of anxiety and found to be effective in clinical studies (Pittler & Ernst 2002). A study that compared the effects of kava kava to valerian and placebo in a standardised mental stress test found that both herbal treatments reduced systolic blood pressure, prevented a stress-induced rise in heart rate and decreased self-reported feelings of stress (Cropley et al 2002).

A 2006 Cochrane review concluded there is insufficient evidence to draw any conclusions about

the efficacy or safety of valerian compared with placebo or diazepam for anxiety disorders (Miyasaka et al 2006). RCTs involving larger samples and comparing valerian with placebo or other interventions used to treat of anxiety disorders, such as antidepressants, are needed.

### Obsessive-Compulsive Disorder (OCD)

High dose valerian treatment may have a role to play in OCD, according to a placebo-controlled RCT. Thirty-one adult outpatients who met the DSM-IV-TR criteria for OCD received valerian capsules (765 mg/day of concentrated dried valerian extract/day) or placebo for 8 weeks. Patients were assessed using the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) at weeks 2, 4, 6 and 8. Assessment at weeks 4, 6 and 8 found the treatment group displayed significantly lower scores compared to the placebo group ( $P = 0.043$ ,  $P = 0.07$ ,  $P = 0.00$ ). In regards to frequency of side effects, no significant difference was found between the groups. However, there was a greater incidence of somnolence with valerian treatment compared to placebo ( $P = 0.02$ ) (Pakseresht et al 2011).

### Muscle spasm, cramping and dysmenorrhoea

Valerian preparations have long been used to treat a wide variety of gastrointestinal disorders associated with spasms such as diarrhoea, colic and irritable bowel syndrome. It has also been used to relieve cramping in dysmenorrhoea. Valerian is likely to exert some degree of antispasmodic activity based on its pharmacological actions.

Recently, a double-blind, randomised clinical trial involving 100 female students experiencing moderate to severe dysmenorrhoea found valerian treatment provided some significant benefits compared to placebo (Mirabi et al 2011). The study compared a valerian preparation (containing 255 mg of powdered valerian root per capsule) or placebo capsules which were taken 3 times daily for the first 3 days of each cycle and continued for two menstrual cycles. Pain severity was measured three times daily using a visual analogue scale (VAS) and a multidimensional verbal scoring system was used to assess the severity of associated symptoms (fatigue, lack of energy, nausea and vomiting, diarrhoea, headache, mood swings and syncope). Active treatment reduced pain severity from 7.45 out of 10 at baseline to 1.99 in the second cycle compared to the placebo group, where the change was from 7.06 to 4.41. The duration of pain in the intervention cycles was also shorter in the valerian group ( $P = 0.01$ ). No statistically significant differences were seen in the severity of associated systemic symptoms, with the exception of syncope ( $P = 0.006$ ).

## OTHER USES

### Fibromyalgia

One randomised study, which was investigator blinded, tested the effects of whirl baths with plain

water or with water containing pine oil or valerian on pain, disturbed sleep and tender point count in 30 outpatients with generalised fibromyalgia. Valerian significantly improved wellbeing and sleep, together with decreasing tender point count, whereas baths with pine oil worsened pain and plain water baths reduced pain but had no effect on wellbeing and sleeplessness (Ammer & Melnizky 1999).

### Benzodiazepine withdrawal

Although no clinical studies are available, the herb is also used in practice to reduce dependency on benzodiazepine drugs. Valerian is prescribed together with other herbal medicines and psychological counselling while the benzodiazepine dose is slowly reduced.

### DOSAGE RANGE

- Infusion of dried root: 3–9 g/day.
- Liquid extract (1:2): 2–6 mL/day.
- Tincture (1:5): 5–15 mL/day.
- When used for insomnia, valerian should be taken approximately 1 hour prior to bedtime.

### According to clinical studies

- Anxiety: 100 mg–600 mg/day of the dried root or valepotriates (mean daily dose 81.3 mg).
- Insomnia: doses above 600 mg/day of dried root taken 1 hour before bedtime. Ethanolic extract of valerian: 300–600 mg before bedtime. Aqueous preparations of valerian: 400 mg/night to 450 mg three times daily. Standardised extracts: 60–120 mg valepotriates or 450 mg of valerenic acid before bedtime.
- For benzodiazepine withdrawal: 100 mg valepotriates taken three times daily.
- Fibromyalgia: Bath — 20 mL liquid extract (ratio not specified) per 200 L of 36–37°C water, three times per week.

### TOXICITY

A combined extract of *Valeriana officinalis*, *Passiflora incarnata* and *Crataegus oxyacantha* demonstrated no toxicity, genotoxicity or mutagenicity in rats, mice and dogs at high doses over 180 days (Tabach et al 2009). According to one case report, a dose of valerian taken at approximately 20-fold the recommended therapeutic dose appears to be benign (Willey et al 1995).

### Hepatotoxicity

Two rare idiosyncratic reactions of valerian-associated hepatotoxicity have been reported. A 27-year-old woman displayed epigastric pain and fatigue for 2 weeks along with raised liver enzymes while taking a 300 mg capsule twice a day for the prior 3 months (Valerian Root, Mason Vitamins) (Cohen et al 2008). Another case report of hepatotoxicity in a 50-year-old woman was reported who had taken valerian tea for 3 weeks (5 cc extract of valerian root thrice weekly), along with consuming 10 tablets of vaimane (containing 125 mg

dry valerian extract / tablet). The woman was asymptomatic, but routine blood tests revealed elevated liver enzymes and bilirubin along with inflammation on liver biopsy and a diagnosis of drug-induced hepatitis was made. Over 10 months her transaminase levels returned to normal. The patient did not undergo a rechallenge with valerian and the case report did not mention any preexisting health conditions, concomitant medications or state whether the valerian was tested to rule out adulteration, contamination or substitution (Vassiliadis et al 2009). It is not clear in either case whether the herbal treatment was tested for authenticity or contamination, making interpretation difficult.

### ADVERSE REACTIONS

As with numerous pharmaceutical sedatives, next morning somnolence is a possible side-effect of therapy; however, evidence from two human studies suggests this is not associated with valerian use (Gerhard et al 1996, Kuhlmann et al 1999). Additionally, evidence from a pharmacokinetic study indicates this is highly unlikely.

Vivid dreams were reported in one study; however, this is considered rare by clinicians (Wheatley 2001).

Paradoxical stimulating effects have been observed in clinical practice and in one study of postmenopausal women; however, this also appears to be rare (Mills & Bone 2000).

Occasionally, headache and gastrointestinal symptoms have been reported (Ernst et al 2001).

### Practice points/Patient counselling

- It appears scientific evidence supports the use of valerian as a treatment for insomnia; however, it appears that ongoing use may be more effective than single-dose use and effects on sleep progress over several weeks. It is often used together with other herbs for better effect, such as lemon balm and hops.
- It appears to be best suited to reducing sleep latency (i.e. time taken until falling asleep) and improves subjective assessments of sleep. Therefore valerian may be more effective for sleep onset insomnia than sleep maintenance insomnia.
- There is no evidence of next-day somnolence or significant adverse effects.
- Valerian may also relieve symptoms of stress and anxiety, with several studies observing effects similar to benzodiazepines; however, further research is required.
- Due to its pungent odour, solid-dose forms may be preferable.

### SIGNIFICANT INTERACTIONS

#### Pharmaceutical sedatives / benzodiazepines

Theoretically, potentiation effects may occur at high doses; however, this has not been tested under clinical conditions — observe patients taking valerian

concurrently with pharmaceutical sedatives. This interaction may be beneficial under professional supervision.

There is a case report of a 40-year-old male taking lorazepam (2 mg/24 hours) for 2 months without side effects and then self-medicating with valerian (*Valeriana officinalis*) and passionflower (*Passiflora incarnata*) infusion (dose unknown) for 2 nights. On the third night he took 3 tablets at 1-hour intervals before going to sleep (containing 300 mg of valerian and 380 mg of passionflower extract/tablet). This was repeated on the fourth night and strong handshaking, dizziness and palpitations were experienced, followed by a heavy drowsiness that made him fall asleep. These symptoms disappeared when the herbal treatment was discontinued. While this effect may be due to the herbal medicine increasing the inhibitory activity of benzodiazepines binding to the GABA receptors, until the preparation can be tested, causality remains unclear (Carrasco et al 2009).

### Alcohol

RCTs have shown no potentiation effects with alcohol use (Ernst et al 2001).

### Haloperidol

In a rat study, oxidative stress parameters in the liver were increased when haloperidol was taken in combination with valerian via a significant increase in lipid peroxidation levels (enhanced oxidation of thiobarbituric acid reactive species and dichlorofluorescein reactive species, as well as an inhibition of hepatic d-ALA-D activity). The significance in humans is unknown — observe patients taking valerian concurrently with haloperidol (Dalla Corte et al 2008).

### CONTRAINDICATIONS AND PRECAUTIONS

No known contraindications. Care should be taken when driving a car or operating heavy machinery when high doses are used.

### PREGNANCY USE

No restrictions are known; however, safety has not been well established in pregnancy. No significant negative effects have been reported in toxicological tests with animals and none reported in clinical studies (Upton 1999). A combined extract of *Valeriana officinalis*, *Passiflora incarnata* and *Crataegus oxyacantha* in rats did not alter the oestrus cycle, did not affect fertility and did not induce teratogenesis in the offspring born from females treated during the entire pregnancy (Tabach et al 2009).

### PATIENTS' FAQs

#### What will this herb do for me?

Valerian is classified as a mild, sedative herbal medicine. It can reduce the time it takes to fall asleep at

night, improve the way people feel about their quality of sleep and may also relieve stress and anxiety during the day. When added to a bath, it may increase relaxation, wellbeing and reduce some forms of pain.

#### When will it start to work?

For some, valerian works within an hour of the first dose; however, research suggests it works best after several weeks of regular use for insomnia.

#### Are there any safety issues?

From the available evidence, next-day drowsiness is uncommon and physical addiction highly unlikely. Taking high doses during the day may increase drowsiness, so care is needed when driving a car or operating heavy machinery.

## Vitamin A

**HISTORICAL NOTE** In ancient Egypt and Greece, physicians recommended the liver of an ox to cure night blindness. Although this could be interpreted as applying the liver locally, it could also refer to ingesting some, which would have provided a good source of vitamin A and proven to be a cure for night blindness caused by deficiency (Shils et al 2006). Modern-day scientific research into vitamin A began in 1913, with its discovery at both Yale and Wisconsin Universities. Researchers at both sites independently noticed that the substance could promote survival and growth of young animals. Since then, each decade has brought important new discoveries about vitamin A. The period from the 1960s to the 1980s was particularly fruitful, as several proteins essential for transport and metabolism of vitamin A were isolated and purified. During the 1980s, another major discovery was made when a link between childhood mortality and subclinical deficiency was identified. Vitamin A research continues to interest a wide spectrum of researchers and influence public health initiatives.

### BACKGROUND AND RELEVANT PHARMACOKINETICS

The term ‘vitamin A’ refers to a family of fat-soluble dietary compounds that are structurally related to

retinol, and share its biological function. Vitamin A is found in foods as itself or as a precursor, which is converted into vitamin A in the body. The precursors, known as carotenes, are found in deep yellow, green and red-coloured plants.

Retinyl esters, retinol or carotenoids from the diet, or supplements, are hydrolysed in the small intestine where they are absorbed as retinol into the mucosal cells (Miller et al 1998). Entering the body within the lipid core of chylomicrons, they are transported through lymph to blood, where it then recycles between plasma and tissues numerous times, before arriving at the liver. The liver performs three key tasks in relation to vitamin A. It is responsible for regulating the secretion of retinol to specific transport proteins known as 'retinol-binding proteins', it serves as a major storage organ and is the major site of vitamin A catabolism. Vitamin A metabolites are excreted mainly through the faeces and urine.

The body has a good capacity for vitamin A storage; however, its ability to rapidly dispose of excess vitamin A is quite limited (Shils et al 2006), with the efficacy of beta-carotene conversion to retinol in humans found to decrease with increasing dietary dose (Novotny et al 2010). This may explain why vitamin A can accumulate to toxic levels when intake greatly exceeds requirements.

This monograph will focus on preformed vitamin A and retinoic acid only. Further information about the carotenoids can be found in other monographs.

## FOOD SOURCES

Preformed vitamin A (retinyl esters) is chiefly found in foods of animal origin, such as liver, red meat and eggs, as well as in fish, milk, butter and cream. A number of studies have proposed use of beta-carotene-rich orange sweet potato to improve vitamin A status in deficient African countries (Hotz et al 2012a, 2012b).

Cooking can destroy up to 40% of the vitamin A content of food (Wahlqvist et al 1997).

## DEFICIENCY SIGNS AND SYMPTOMS

- Night blindness, which can progress to complete blindness if left untreated
- Keratinisation of epithelial surfaces, causing them to dry and harden
- Poor dental health
- Compromised immune function
- Reduced reproductive capabilities.

### Primary deficiency

Primary deficiency is caused by prolonged dietary deprivation. In large areas of the world, vitamin A deficiency is endemic, causing widespread blindness and mortality (Sklan 1987).

### Secondary deficiency

Secondary deficiency can develop when absorption, storage or transport is reduced or carotene is not adequately converted to vitamin A. Conditions associated with risk of secondary deficiency include malabsorption syndromes, such as coeliac disease and cystic fibrosis (CF), pancreatic disease, duodenal bypass, congenital partial obstruction of the jejunum,

obstruction of the bile ducts, giardiasis, diabetes and kwashiorkor.

## MAIN ACTIONS

Vitamin A is an essential nutrient required for life and serves two very different biological functions. First, in the form of retinaldehyde, it constitutes the light-sensitive component of the retina, rhodopsin, and second, in the form of retinoic acid, it activates a large number of transcription factors (McCaffery & Drager 1993).

### Antioxidant vs pro-oxidant activity

Vitamin A exhibits free radical scavenging properties and is generally considered an antioxidant molecule. Vitamin A bound to protein kinase C is an essential cofactor in redox activation of the mitochondrial signalling pathway (Acin-Perez et al 2010, Hoyos et al 2012).

Despite this, in vivo evidence has demonstrated that, at high doses, vitamin A elicits pro-oxidant effects, including increased superoxide production, mitochondrial redox dysfunction and increased oxidative and nitrosative stress in rat brains (Behr et al 2012, de Oliveria et al 2008, 2009, 2012). Pro-oxidant activity associated with vitamin A supplementation has been noted in several other rat models, including the neonatal lung (Pasquali et al 2010), kidney, liver and plasma (Schnorr et al 2011).

### Growth and development

Vitamin A is essential for embryonic growth, with crucial roles in the induction of neurogenesis and control of neuronal patterning (Shearer et al 2012). Deficiency, as well as excess, has been shown to be teratogenic in animal studies, suggesting the same may be true in humans. It is currently unclear whether vitamin A itself or one of its metabolites or both are responsible for the teratogenic effects seen with high exposure (Miller et al 1998).

Vitamin A is also necessary for healthy bone formation and osteoblastogenesis. In vivo, vitamin A deficiency was associated with delayed bone healing in mice and the suppression of osteoblast differentiation-related genes (Tanaka et al 2010).

### Immune function and maintenance of epithelial surfaces

Vitamin A maintains the health of epithelial cells in the body, which form an important barrier to infection, and the function of the immune system. Despite limited human studies, there is an increasing body of evidence from animal studies to suggest that adequate vitamin A status is an important factor for the maintenance of T-cell function and the prevention of prolonged inflammatory reactions (Ross 2012). Vitamin A stores in healthy men have been positively associated with several measures of innate immune activity, including natural killer (NK) and NK T cells and monocyte oxidative burst (Ahmed et al 2009).

A pilot study also found that vitamin A supplementation increased yellow fever virus (YFV)- and tetanus toxin-specific immune responses, including lymphocyte proliferation and production of YFV-specific interleukin-5 (IL-5), IL-10 and tumour necrosis factor- $\alpha$  (Ahmed et al 2008).

Comparably, studies in animal models and cell lines show that vitamin A and related retinoids play a major role in immunity, including expression of mucins and keratins, lymphopoiesis, production of antibodies, and the function of neutrophils, NK cells, macrophages, T lymphocytes and B lymphocytes (Liu et al 2014, Semba 1999).

In vivo, a vitamin A-deficient diet was shown to alter rat intestinal microflora, as well as alter mucin dynamics, downregulate defensin 6 expression and upregulate Toll-like receptor expression, ultimately interfering with the integrity of the gastrointestinal mucosal barrier (Amit-Romach et al 2009). It has also been shown to potentiate antibody responses and lymphocyte proliferation in response to antigens, reduce intestinal inflammation and restore the integrity and function of mucosal surfaces (Dong et al 2010, Semba 1994).

### Vision

Vitamin A is involved in ocular health and function in two distinct ways. First, in the form of retinaldehyde, it is an essential component of rhodopsin and is necessary for maintaining vision (Wahlqvist et al 1997). Deficiency states initially cause a reversible night blindness that can progress to complete blindness due to photoreceptor degeneration (McCaffery & Drager 1993). Second, as retinoic acid, it maintains normal differentiation of cells in the conjunctiva, cornea and other ocular structures, with deficiency resulting in xerophthalmia (dry eye) and corneal ulceration. In xerophthalmia, the cells lining the cornea lose their ability to produce mucus, and therefore lubrication of the eye becomes compromised. Dirt particles that eventually enter the eye are more easily able to scratch the surface, increasing the risk of infection and, ultimately, blindness.

In vivo, retinyl palmitate eye drops (1500 IU/mL) in conjunction with antibiotics were shown to promote corneal healing through inhibition of vascular endothelial growth factor-A, matrix metalloproteinase-9 and transforming growth factor- $\beta$ , as well as activation of thrombospondin 2, compared to antibiotics alone in rats subjected to corneal alkali burn injury (Kim et al 2012). A rat model of obesity-associated retinal degradation, dietary supplementation with oral vitamin A was found to modulate expression of retinal genes in obese rats, which corroborated with immunohistochemical and histological data showing improved retinal health compared to non-supplemented rats (Tiruvalluru et al 2013).

### Chemoprevention

Studies in cell culture and animal models have documented the capacity for natural and synthetic

retinoids to reduce carcinogenesis significantly in skin, breast, liver, colon, cervical, prostate and other sites (Ross 1999). The mechanism of action responsible has not been fully elucidated, but several theories exist. It has been known since early in the 20th century that vitamin A deficiency can induce meta-plastic changes to epithelial cells (De Luca et al 1997). Retinoic acid is thought to act as an inhibitor of carcinogenesis by interfering with promotion rather than with initiation, which may be blocked by inhibition of proliferation, stimulation of differentiation or induction of apoptosis (Niles 2000). Other research suggests it may also inhibit the final stage when malignant conversion of a benign tumour to a carcinoma occurs (De Luca et al 1997).

### Cognitive development and function

Pregnancy-related vitamin A deficiency in rats was found to affect postnatal expression of retinoic acid receptor- $\alpha$  and N-methyl-D-aspartate receptor unit 1 in the hippocampus (Zhang et al 2011). When subjected to water maze tests, pups from vitamin A-deficient dams had significantly reduced capacity for spatial learning, short-term memory, long-term memory and the ability to learn new things. A derivative of vitamin A has also been found to suppress hippocampal cellular proliferation, resulting in disturbed hippocampal-dependent learning in mice (Crandall et al 2004).

In vivo, vitamin A deficiency has been associated with circadian rhythm and circadian-dependent genes in a number of studies. In rats, vitamin A deficiency was shown to affect circadian expression in the hippocampus through the modification of rhythmic profiles of retinoic acid receptors (Navigatore-Fonzo et al 2013). Similarly, within the rat hippocampus, vitamin A deficiency was associated with modulation of the cognition-related genes, brain-derived neurotrophic factor and RC3, as well as affecting the circadian oscillation of a number of clock proteins (Golini et al 2012).

Conversely, a model of vitamin A supplementation at 9000 IU/kg over 28 days found increased  $\alpha$ -synuclein content, impaired mitochondrial electron transport chain activity and increased superoxide production in both rat substantia nigra and striatum (de Oliveria et al 2009).

These studies implicate a role for vitamin A in modulation of central nervous system activity, including memory and learning, and warrant further investigation.

### Promotion of aortic valve calcification

A recent study found that long-term dietary intake of vitamin A resulted in aortic valve stenosis and leaflet calcification in vivo (Huk et al 2013). This study suggests those patients on chronic vitamin A or vitamin A-derivative therapy, or who have dietary hypervitaminosis A, may be at increased risk of developing calcific aortic valve disease.

## Alterations to spermatogenesis

A comprehensive *in vivo* study identified the effects of a chronic vitamin A-deficient diet on sperm health in mice (Boucheron-Houston et al 2013). This study identified that the earliest measurable effects were seen after 12 weeks, whereby expression of retinoic acid receptors and retinol-binding protein were reduced. Subsequent direct and indirect effects of vitamin A deficiency included the arrest of germ cell differentiation, increased germ cell apoptosis, altered spermatogonia transcriptome profile and disruption of somatic cell organisation.

## CLINICAL USE

### Deficiency: prevention and treatment

Traditionally, vitamin A supplementation has been used to treat deficiency or prevent deficiency in conditions associated with risk of vitamin A deficiency, such as diabetes, hyperthyroidism, protein deficiency, intestinal infections and infestations and CF.

### Paediatrics

#### Reducing infection severity

Vitamin A deficiency impairs systemic immunity and increases the incidence and severity of infections during childhood, particularly measles and infectious diarrhoea (Chen et al 2013). There is also evidence to suggest that infectious diseases, such as measles, depress serum retinol concentrations, by >30% according to one study (Enwonwu & Phillips 2004). This phenomenon does not just occur in under-nourished populations. A study of well-nourished children in the United States with measles identified that 50% had concurrent vitamin A deficiency (Arrieta et al 1992). A 2010 Cochrane review determined that vitamin A supplementation in infants reduced the incidence of diarrhoea (relative risk [RR] 0.85) and measles morbidity (RR 0.50); however there was no significant effect of vitamin A supplementation on cause-specific mortality of measles, respiratory disease or meningitis (Imdad et al 2010).

It is suspected that infectious diseases influence retinol metabolism through mechanisms that are more complex than simple loss of retinol stores (Enwonwu & Phillips 2004). Impaired synthesis of retinol-binding protein and transthyretin and decreased expression of the receptors for retinoic acid could also be responsible. As such, the use of vitamin A in the treatment of infectious disease is not limited to developing countries, but may also have application in well-nourished populations.

In areas where vitamin A deficiency may be present, the World Health Organization (WHO) recommends administration of an oral dose of 200,000 IU (or 100,000 IU in infants) of vitamin A per day for 2 days to children with measles (D'Souza & D'Souza 2002a, 2002b). It has also

been recommended that prophylactic vitamin A supplements be given to all infants and young children (0–59 months), pregnant women and postpartum women, 6 weeks after delivery, in these same areas (Ross 2002). A randomised, triple-blinded controlled trial found that postpartum supplementation of breastfeeding mothers ( $n = 276$ ) with 400,000 IU of vitamin A did not confer any additional benefits over use of 200,000 IU vitamin A on risk of child developing fever, diarrhoea, otitis, acute respiratory infections or the need for antibiotic treatment over a 6-month period (Fernandes et al 2012).

According to a 2005 Cochrane review, the WHO recommendation of two large doses of vitamin A does successfully lower the risk of death from measles in hospitalised children under the age of 2 years, but not in all children with measles (Huiming et al 2005).

#### Reducing secondary infections associated with measles

A meta-analysis of six clinical trials found a 47% reduction in the incidence of croup in children with measles who were treated with 200,000 IU of vitamin A on two consecutive days. One study in the analysis reported a 74% reduction in the incidence of otitis media, but this was not confirmed in others. A statistically significant decrease in the duration of diarrhoea, pneumonia, hospital stay and fever was also observed (D'Souza & D'Souza 2002a).

#### Reducing childhood mortality in neonates

It has been estimated that a 23–30% reduction in young child mortality is possible with improvements in vitamin A status. This is most marked for deaths due to acute gastroenteritis and measles, but not acute respiratory infections or malaria (Ramakrishnan & Martorell 1998), and is particularly the case for older preschool children, whereas the effect on infants is less clear.

In neonates, data from meta-analyses are conflicting in terms of the benefit or harm associated with vitamin A supplementation and risk of mortality. A 2011 Cochrane review determined that data from seven trials (51,446 neonates) suggested a potential benefit of supplementing neonates with vitamin A at birth in reducing mortality in the first half of infancy in developing countries (Haider et al 2011). However, due to wide confidence intervals, small number of studies and the existence of highly conflicting trial data, the authors have recommended cautious interpretation of the findings (Haider et al 2011). In contrast, a 2011 Cochrane review of 18 trials determined that there was no convincing evidence to suggest vitamin A supplementation within the first 6 months of infancy reduced infant morbidity or mortality in low and middle incomes (Gogia & Sachdev 2011). Discrepancies between these two analyses may be due to Haider and colleagues focusing on data only from developing countries.

When stratified by sex-specific effects, a 2010 meta-analysis found no overall benefit but had confidence intervals (Kirkwood et al 2010b). This is consistent with studies which have found trends for harm associated with vitamin A use both in girls only (Benn et al 2008, 2010) and in boys only (Malaba et al 2005). It has been suggested that inconsistencies observed may be a result of non-specific interactions with routine vaccinations, the administration of which generally coincides with vitamin A administration (Benn et al 2009a, 2009b).

### Reducing childhood mortality in infants

In contrast to neonatal data, evidence for vitamin A supplementation in infants aged 6 months to 5 years is much stronger. A 2010 Cochrane review of 43 trials ( $n = 215,633$ ) found a reduced risk of all-cause mortality for vitamin A compared with control (RR 0.76, 95% confidence interval [CI] 0.69–0.83). While the study concluded that further placebo-controlled trials were likely to be unnecessary, studies which compared different doses and delivery mechanisms for vitamin A were warranted (Imdad et al 2010).

In areas of endemic vitamin A deficiency, vitamin A supplementation was not found to lower the incidence of illness such as diarrhoea, dysentery or fever; however, it did reduce mortality, with fewer case fatalities in young children with these diseases compared to placebo (Tielsch et al 2007). In newborn infants supplemented with 50,000 IU of vitamin A, all-cause mortality at 6 months was reduced by 15% (Klemm et al 2008).

### Reducing febrile neutropenia

In a cohort of 49 children with cancer, those with plasma retinol levels below 20 mcg/dL at diagnosis had a greater risk of developing episodes of febrile neutropenia compared to children with higher vitamin A status (Wessels et al 2008).

### Very-low-birth-weight (VLBW) infants

Supplementing VLBW infants with intramuscularly administered vitamin A is associated with a reduction in death or oxygen requirement at 1 month of age (Darlow & Graham 2007).

### Reducing renal scarring secondary to pyelonephritis

An open-label randomised controlled trial ( $n = 61$ ) found that, in children aged 1 month to 10 years, the treatment of acute pyelonephritis with routine antibiotics and vitamin A supplements significantly reduced the worsening of lesions and development of renal scarring at 6-month follow-up (Sobouti et al 2013). Similarly, a single intramuscular injection of vitamin A (25,000 IU in infants <12 months; 50,000 IU in >12 months) in conjunction with routine antibiotics reduced renal scarring at 3-month follow-up compared to antibiotics alone in first-time cases of pyelonephritis (Ayazi et al 2011).

### Reducing risk of bronchopulmonary dysplasia in premature newborns

Compared to receipt of inhaled nitric oxide alone, the combination of inhaled nitric oxide with vitamin A supplementation in premature newborns with respiratory failure reduced the incidence of bronchopulmonary dysplasia and death following bronchopulmonary dysplasia (Gadhia et al 2014). At 1-year follow-up, mental development in infants who had received nitric oxide and vitamin A was significantly improved compared to those who had received nitric oxide alone. No effect of vitamin A supplementation was seen in premature newborns who did not receive inhaled nitric oxide.

### Reducing infection-associated hearing loss

While a cluster randomised, double-blinded, placebo-controlled trial found no difference in the prevalence of middle-ear infection in preschool children receiving vitamin A supplements vs placebo, a follow-up study found that children who had ear discharge in early childhood had a 42% reduced risk of hearing loss (odds ratio [OR] 0.58, 95% CI 0.37–0.92) (Schmitz et al 2012).

### Reducing the risk of HIV transmission from mother to infant

The dominant mode of acquisition of HIV infection for children is mother-to-child transmission. Currently, this results in more than 2000 new paediatric HIV infections each day worldwide. A 2009 systematic review of randomised controlled trials ( $n = 7528$  women) found that there was no evidence of an effect of either prenatal or postnatal vitamin A supplementation on the risk of mother-to-child transmission of HIV (RR 1.06, 95% CI 0.89–1.26) (Kongnyuy et al 2009). This is in agreement with a 2011 Cochrane review, which analysed results from five trials, which enrolled 7528 HIV-infected pregnant women, and found no evidence to support the use of vitamin A supplementation for this indication (Wiysonge et al 2011). One benefit that was identified for vitamin A supplementation was an improvement in infant birth weight. Neither maternal nor neonatal vitamin A supplementation significantly affected the overall mortality of children exposed to HIV by 2 years of age. Interestingly, in infants who were HIV-negative at baseline but positive by 6 weeks of age, supplementation reduced mortality by 28%, whereas in infants who did not become HIV-positive by 6 weeks, supplementation doubled the risk of mortality by age 2 years. It has been suggested that vitamin A supplementation may have increased viral load among babies who subsequently became infected during breastfeeding, but this remains untested (Humphrey et al 2006b).

### Fetal growth

Low levels of vitamin A impair fetal growth. In a cross-sectional study on 100 neonate-mother pairs, lower placental and neonatal levels of vitamin A

were associated with prematurity and intrauterine growth retardation (Agarwal et al 2008). However, supplementation with either vitamin A or  $\beta$ -carotene did not affect birth weight, infant length or head, arm and chest circumference compared to placebo in a trial of 13,709 Bangladeshi newborns (Christian et al 2013). Gestational age and preterm birth rate were also found to be unaffected by supplementation.

### Congenital malformations

A case-control study determined that, in normal-weight mothers, intake of dietary vitamin A below the recommended levels during pregnancy was associated with a significantly increased risk of offspring having congenital diaphragmatic hernia (Beurskens et al 2013).

Despite this finding, due to limited sample size, study design and acknowledged teratogenicity of vitamin A, it is still recommended that women avoid supplementation unless on the advice of a medical professional.

### Risk of schizophrenia in fetus

Data from the Prenatal Determinants of Schizophrenia study suggested that low maternal vitamin A levels during the second trimester of pregnancy were associated with threefold increased risk of schizophrenia spectrum disorders following adjustments for age and maternal education (OR 3.04, 95% CI 1.06–8.79). No association between schizophrenia spectrum disorders and maternal vitamin A status was observed in the third trimester (Bao et al 2012). The clinical relevance or causality of this association is unclear.

### Cancer prevention

Most forms of cancer arise from cells that are influenced by vitamin A (Wardlaw et al 1997). Combined with its antioxidant and immunomodulatory activities, vitamin A has been considered as a potential chemopreventive agent. Research thus far using cell cultures and animal models has identified the ability for natural and synthetic retinoids to reduce carcinogenesis significantly in skin, breast, liver, colon, prostate and other sites (Krinsky 2002). A look at the literature shows that impressive treatment results have mainly been obtained for synthetic retinoids and the relationship between natural vitamin A ingestion and cancer is less clear in humans.

In a cohort study of 3254 Japanese subjects aged from 39 to 85 years, high serum levels of carotenoids were associated with reduced mortality rates of cancer of all sites or of cardiovascular disease, while high serum levels of beta-carotene, total carotene, provitamin A and total carotenoids reduced risk of colorectal cancer or stroke at follow-up after 11.7 years. Serum retinol and tocopherols, however, were not associated with a reduction in risk of mortality from cancer or cardiovascular disease (Ito et al 2006).

### Prostate cancer

Despite numerous large-scale studies, there is conflicting evidence surrounding the role of vitamin A and its derivatives on prostate cancer risk, with support for positive, negative and null effects. Due to these inconsistencies, studies designed at clarifying the underlying biological mechanisms of the vitamin A-prostate cancer association are required. A Finnish randomised, double-blind, placebo-controlled trial investigating cancer incidence in adult male smokers ( $n = 29,133$ ) found that, at baseline, subjects in the highest quintile of serum alpha-tocopherol had improved prostate cancer survival after 3 years (hazard ratio [HR] 0.26, 95% CI 0.09–0.71) (Watters et al 2009). No effects on survival were seen with baseline serum beta-carotene, baseline serum retinol or supplemental beta-carotene. Similarly, a nested case-control study within the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (692 prostate cancer cases, 844 controls) found that, although serum retinol concentrations were not associated with overall prostate cancer risk, the highest versus lowest concentrations of serum retinol were associated with a 42% reduction in risk of aggressive prostate cancer ( $P = 0.02$ ) (Schenk et al 2009).

Conversely, a large prospective 3-year study in the Alpha-Tocopherol, Beta-Carotene Cancer Prevention Study cohort ( $n = 22,843$ ) found that men with higher retinol concentrations at baseline were more likely to develop prostate cancer (HR 1.19, 95% CI 1.03–1.36) (Mondul et al 2011). In the Carotene and Retinol Efficacy Trial, which tested a daily dose of 30 mg beta-carotene and 25,000 IU retinyl palmitate in smokers, secondary outcomes analysis found that men in the intervention arm who used additional supplements also had an increased risk of aggressive prostate cancer (RR 1.52, 95% CI 1.03–2.24) (Neuhouser et al 2009).

It should be noted that several large studies nested within multicentre trials have also found no associations between the plasma concentrations of carotenoids, retinol or tocopherols and overall prostate cancer risk or more risk of more aggressive prostate cancer phenotypes (Beilby et al 2010, Gilbert et al 2012, Key et al 2007). A cohort study of 1985 men previously exposed to asbestos found that, while increasing the intake of vitamin C-rich vegetables such as peppers and broccoli was associated with reduced risk of prostate cancer, vitamin A intake (supplement of 7.5 mg retinol daily) did not lower risk (Ambrosini et al 2008).

### Gastric cancer

In a large nested case-control study of patients with gastric cancer, a higher plasma concentration of beta-cryptoxanthin, zeaxanthin, retinol and alpha-tocopherol was associated with a significantly lower risk of developing gastric cancer (Jenab et al 2006). A high intake of vitamin A, alpha-carotene and beta-carotene was associated with a reduced risk of

gastric cancer in a prospective cohort study of 82,002 Swedish adults. However, no protective effect was found from beta-cryptoxanthin, lutein and zeaxanthin or lycopene intake (Larsson et al 2007).

In contrast, studies in Japanese cohorts have yielded conflicting results. A prospective study of Japanese community-dwelling subjects ( $n = 2467$ ) found that, over 14 years, increased dietary intake of vitamin A was associated with increased incidence of gastric cancer, irrespective of location or histological type of cancer (Miyazaki et al 2012). A larger study among 36,745 Japanese subjects (aged 40–69) with *Helicobacter pylori* infection did not find a statistically significant association between plasma levels of retinol or lutein/zeaxanthin, lycopene, alpha- or gamma-tocopherol and the risk of gastric cancer (Persson et al 2008). Due to the limited generalisability of these studies (small isolated population and disease-specific subjects respectively), the effects of vitamin A on gastric cancer in Japanese populations remain unclear.

### Lung cancer

A number of epidemiological studies have identified an inverse association between risk of lung cancer and serum carotenoid levels, but intervention studies have produced conflicting results. In general, vitamin A is supplied together with carotenoids, making it difficult to determine the role of vitamin A as a stand-alone agent. (See Beta-carotene monograph for further discussion.) The pooled analysis of the primary data from eight prospective studies involving 430,281 subjects found those with the highest quintile of intake of vitamins A, C and E and folate from food only had a statistically significant 28% reduction in the risk of lung cancer compared to those in the lowest quintile. This protective effect was lost, however, after adjusting for multiple risk factors for lung cancer, including smoking habits (Cho et al 2006). In a case-controlled study involving 333 patients diagnosed with primary lung cancer, however, a significantly lower risk of lung cancer was associated with a higher intake of vitamin A, alpha-carotene and beta-carotene-rich food. Interestingly, no protective effect was observed for vitamin A consumed as supplements (Jin et al 2007). In patients exposed to blue asbestos, low plasma retinol levels were associated with increased risk of developing mesothelioma and lung cancer (Alfonso et al 2006). Patients with lung cancer have been found to have similar levels of retinol but lower levels of serum metabolites retinyl palmitate and retinoic acid levels compared to healthy controls, suggesting retinol metabolism may be impaired in these patients (Moulas et al 2006).

### Cervical cancer

Meta-analysis of 15 trials ( $n = 12,136$ ) determined that vitamin A intake was associated with a reduced cervical cancer risk (OR 0.59, 95% CI 0.49–0.72); however this analysis did not contain any

randomised controlled trials or cohort studies; thus confirmation of this trend is still required using large high-quality trials (Zhang et al 2012).

A 2013 Cochrane review determined that retinoids are not effective in causing regression of severe cervical intraepithelial neoplasm (CIN3); however limited evidence suggests they may have some effect in moderate cervical intraepithelial neoplasm (CIN2) (Helm et al 2013). The review also stated that data for mild cervical intraepithelial neoplasm (CIN1) were currently inadequate to determine the effect of retinoids.

### Other cancers

Vitamin A intake, including supplements and dietary sources, was inversely associated with risk of non-Hodgkin's lymphoma among 154,363 postmenopausal women in the Women's Health Initiative study (HR 0.83, 95% CI 0.69–0.99) (Kabat et al 2012).

A nested case-control study within the Multiethnic Cohort Study found that there was no significant association between plasma carotenoids, tocopherols or retinol in women with breast cancer compared to healthy controls (Epplein et al 2009). In a prospective cohort study involving 89,835 women aged between 40 and 59 years, dietary intake of carotenoids or vitamins A, C or E was not found to be associated with a reduced risk of ovarian cancer (Silvera et al 2006). While a prospective study of 88,759 women and 47,828 men found the intake of vitamins A and C from food was inversely associated with the risk of renal cell cancer in men, the total retinol intake from sources such as supplements, liver, vitamin A-fortified milk and cereals was not associated with a reduction in risk. The beneficial effects may possibly be due to other protective nutrients or chemicals in carotenoid-containing foods (Lee et al 2006).

### Adjunct in chemotherapy

Vitamin A (350,000–500,000 IU/day) was randomly allocated to patients in a group of 100 with metastatic breast carcinoma treated by chemotherapy (Israel et al 1985). Patients supplemented with vitamin A showed a greater than twofold increase in the complete response compared to controls (38% vs 15%;  $P < 0.02$ ). Among chemotherapy responders in both groups, the projected 43-month survival rate was 93% in vitamin A-supplemented responders vs 30% in non-supplemented responders ( $P < 0.02$ ).

### Infections

#### Urinary tract

A placebo-controlled, double-blinded study involving 24 patients found a single dose of 200,000 IU vitamin A in addition to antimicrobial therapy significantly reduced recurrent urinary tract infections. In the treatment group, the rate of infection reduced to 0.12 attacks/month in the first 6-month period, and 0.29 attacks/month in the second 6-month

period, compared to 0.47 attacks/month and 0.44 attacks/month respectively in the control group (Yilmaz et al 2007).

#### Lower respiratory tract

A 2008 Cochrane systematic review of nine randomised controlled trials involving 33,179 children examined the effectiveness and safety of vitamin A in preventing acute lower respiratory tract infections (LRTIs) in children up to 7 years old. Six studies used megadose vitamin A (100,000–206,000 IU) (every 4 months for a year or as once off), while four studies used low-dose vitamin A (5000 IU daily, 10,000 IU weekly, 8333 IU weekly, and 20,000 IU or 45,000 IU every 2 months). Most studies did not find a beneficial effect on LRTI. While two studies found vitamin A supplementation prevented acute LRTIs in children with low serum retinol or those with a poor nutritional status, unexpectedly, three studies found vitamin A was associated with negative outcomes, including an increased incidence of acute LRTI, and increased symptoms of cough, fever and rapid breathing. The authors concluded that the effect of vitamin A was influenced by the child's nutritional status or weight, with supplementation increasing the acute LRTI episodes in 'normal' children (Chen et al 2008).

#### HIV

The Zimbabwe Vitamin A for Mothers and Babies (ZVITAMBO) project examined the effects of a vitamin A supplementation on serum retinol concentration, and mortality and morbidity among HIV-positive and HIV-negative postpartum women. A single 400,000 IU dose of vitamin A given during the immediate postpartum period had no effect on maternal mortality of both HIV-negative and -positive women after 2 years compared to placebo. Among HIV-positive women, the supplementation reduced clinic visits for treatment for malaria, cracked and bleeding nipples, pelvic inflammatory disease and vaginal infection, but did not lower overall rates of hospitalisation. While vitamin A deficiency was more common among HIV-positive women, serum levels of retinol were unresponsive to supplementation, except in those with a CD4 count of less than  $200 \text{ cells} \times 10^6/\text{L}$  (Zvandasara et al 2006). In a subsample of HIV-negative women enrolled in ZVITAMBO trial, a single dose of 400,000 IU vitamin A within 96 hours postpartum did not reduce the incidence of HIV infection; however, HIV-negative women with low vitamin A levels (serum retinol  $< 0.7 \text{ micromol/L}$ ) were 10.4 times more likely to acquire HIV. In women with low vitamin A who received supplementation, there was a slightly (non-significantly) lower incidence of HIV (Humphrey et al 2006a).

#### Bacterial vaginosis

In a cluster-randomised, placebo-controlled trial, the weekly supplementation of vitamin A or  $\beta$ -carotene in women ( $n = 1812$ ) from early-stage

pregnancy reduced the prevalence and incidence of bacterial vaginosis during the third trimester and at 3 months postpartum compared to placebo (Christian et al 2013).

#### Hepatitis C virus

A recent study found a strong association between chronic hepatitis C virus infection and serum vitamin A deficiency ( $P < 0.0001$ ). The presence of this deficiency in patients was found to be a strong predictor for non-response to interferon-based antiviral therapy, thus further study to determine whether increasing serum vitamin A levels can modulate responsiveness to therapy is warranted (Bitteto et al 2013).

#### Other infections

Children with acute upper respiratory tract infection and acute upper respiratory tract infection with wheezing were found to have lower serum retinol levels compared to healthy controls (Amaral et al 2013). Whether this association was a result of poorer health status overall or a result of vitamin A's effects on airway function is unclear.

A randomised placebo-controlled trial ( $n = 154$ ) found that supplementation with a single 200,000 IU vitamin A dose plus 15 mg zinc/day for 8 weeks did not affect treatment outcomes, including smear time, culture conversion, weight gain or radiological resolutions, in patients with pulmonary tuberculosis (Visser et al 2011).

Vitamin A supplementation has also been associated with reduced incidence of *Giardia* spp. infections (Lima et al 2010).

#### Clinical note — Retinitis pigmentosa

Retinitis pigmentosa describes a group of hereditary retinal dystrophies, characterised by the early onset of night blindness, followed by a progressive loss of the visual field. The underlying pathology is a defect that alters the function of the rod photoreceptor cell and subsequent degeneration of these cells (van Soest et al 1999).

#### Dermatology

Numerous clinical studies have shown beneficial effects of vitamin A or its derivatives on skin diseases such as acne, psoriasis, ichthyoses, keratodermas, skin cancers, lichen planus and ultraviolet-induced skin damage and photoageing (Futoryan & Gilchrist 1994). Currently, most research has been conducted with synthetic retinoid derivatives and is not representative of the effects of natural vitamin A. In a study of 100 newly diagnosed, untreated acne patients (mean age 21 years), plasma levels of both vitamin A and vitamin E were found to be significantly lower compared to age-matched healthy controls. An inverse relationship was also found between plasma vitamin A concentrations and the severity of the acne (El-Akawi et al 2006).

Topical vitamin A improves the appearance of older skin, and may also increase its resistance to injury and ability to heal. A 9-month, double-blind randomised placebo-controlled trial ( $n = 48$ ) found that 0.1% retinol topical application once daily significantly improved wrinkles under the eyes, fine lines and skin tone evenness compared to an equivalent application containing no retinol in Caucasian women aged 41–60 (Bellemère et al 2009). This study determined that the 0.1% retinol product promoted keratinocyte proliferation *ex vivo* and *in vivo*, and induced epidermal thickening *ex vivo*. Similarly, a lotion containing 0.4% retinol was tested in a 6-month randomised controlled trial involving 36 elderly subjects aged between 80 and 96 years. The lotion was applied three times a week to left or right upper arm, with a lotion without retinol used on the other arm. The retinol-treated skin had fewer fine wrinkles and reduced roughness compared to the skin treated with the non-retinol lotion. The effects are due to an increase in glycosaminoglycan, which helps the skin retain water, and increased collagen production (Kafi et al 2007).

### Ophthalmological diseases

#### Retinitis pigmentosa

A 2013 Cochrane review of three trials ( $n = 866$ ) determined that currently there is no clear evidence for the benefit of using vitamin A with or without fish oils for treatment of retinitis pigmentosa (Rayapudi et al 2013). Due to limited trials included and inadequate power to detect clinically relevant changes, it was recommended in this review that future studies look to address these shortcomings.

It is thought that vitamin A transport or the retention capacity of the retina is abnormal in retinitis pigmentosa, or defects in the pigment epithelium involving vitamin-associated proteins occurs (Sharma & Ehinger 1999).

#### Xerophthalmia

Xerophthalmia is responsible for at least half of all cases of measles-associated blindness and is the cause of at least half a million cases of paediatric blindness worldwide (Sommer 1998). This condition is associated with vitamin A deficiency and protein malnutrition.

#### Dry-eye syndrome

An open-label randomised controlled trial ( $n = 300$  eyes) found that retinyl palmitate (0.05%, four times per day) significantly improved blurred vision, tear film break-up time and impression cytological findings after 3 months compared to an 'artificial tears' control (0.5% carboxymethylcellulose, four times per day) in the treatment of refractory dry-eye syndrome (Kim et al 2009).

#### Retinopathy of prematurity

A double-blind, randomised controlled trial ( $n = 89$ ) found that vitamin A supplementation (10,000 IU for three times a week for 6–12 doses) in infants

born at less than 32 weeks' gestation did not affect plasma retinol between groups, but did increase retinal sensitivity by 36 weeks' postmenstrual age (Mactier et al 2012).

### Reducing morbidity and mortality of pregnant women

It has been suggested that vitamin A supplements in pregnancy may improve outcomes, including maternal mortality and morbidity. Studies to date are conflicting. While some large-scale analyses have determined no benefit in the reduction of morbidity and mortality (Hurt et al 2013, West et al 2011), others suggest that vitamin A has benefit in specific populations which have high prevalence of gestational night blindness and very high risk of maternal mortality (Kirkwood et al 2010a, West et al 1999, 2010).

A 2010 Cochrane review of 16 trials found that vitamin A supplementation does not affect the risk of maternal mortality (RR 0.78, 95% CI 0.55–1.10) or perinatal mortality (van den Broek et al 2010). It was also determined that vitamin A had no effect on a number of neonatal outcomes, including neonatal mortality, stillbirth, neonatal anaemia, preterm birth or the risk of having a low-birth-weight baby. One trial from Nepal found that vitamin A supplementation reduced the risk of maternal night blindness (RR 0.70, 95% CI 0.60–0.82). Benefits to anaemia were also found in vitamin A-deficient populations and in women with HIV.

On the whole, current evidence does not support use of vitamin A supplementation during 'normal' pregnancy. Further clarification of the specific subset populations who would benefit from supplementation is recommended.

Vitamin A during or after pregnancy has not been found to reduce postpartum mortality in HIV-positive women. (See discussion under **Infections: HIV**, above.)

### Leucoplakia

A Cochrane review of treatments for the prevention of malignant transformation of leucoplakia identified five randomised controlled trials involving 245 patients which tested vitamin A and retinoids (used topically or as oral treatment), and one study each for beta-carotene and lycopene. While these studies failed to demonstrate prevention of malignant transformation of leucoplakia, they were associated with a small but significant rate of clinical resolution when compared with placebo or absence of treatment. Retinoic acid and lycopene may also result in histological improvement, though results were based on only a small number of patients. Adverse effects were reported in studies using 13-*cis*-retinoic acid (1–2 mg/kg/day), and high-dose vitamin A (300,000 IU per week) (Lodi et al 2006).

### Asthma

A study evaluated serum vitamin A concentrations in 26 well-nourished Japanese children with asthma

(mean age of 5.5 years) with C-reactive protein concentration  $<0.6$  mg/dL, to exclude the acute-phase response. Mean serum vitamin A concentrations were significantly lower in asthmatic children compared to controls, and there was also a significant correlation between C-reactive protein and serum vitamin A concentrations in children with asthma (Mizuno et al 2006). This observation was also reported in a case-control study involving 96 subjects which found low serum levels of vitamin A (and lycopene) were associated with an increased risk of bronchial asthma (Riccioni et al 2007).

Based on *in vivo* work, it has been suggested that vitamin A deficiency during pregnancy at a critical point in fetal development can result in chronic airway hyperresponsiveness (Chen et al 2014). This study identified that retinoic acid plays a crucial role in restricting airway smooth-muscle differentiation during murine lung development, with disruption of this process via vitamin A deficiencies resulting in altered airways expression of smooth-muscle markers that persisted postnatally. Vitamin A has also been shown to modify collagen IV and laminin chain composition in weanling rat pup airways following deficiency, which is only partly reversible with retinoic acid supplementation (Esteban-Pretel et al 2013).

### Lung function in cystic fibrosis

Patients with CF may have impaired absorption of fat-soluble vitamins such as vitamin A. Some studies indicate vitamin A status is associated with respiratory health in patients with CF. Whether supplemental vitamin A has any benefits in CF is still speculative. A Cochrane systematic review did not find any eligible randomised or quasi-randomised controlled trials, and could not provide any firm conclusions on the effects (beneficial or harmful) of supplementation with vitamin A (O'Neil et al 2008). Previously, a small study involving 38 patients with stable CF (mean age of 15.3 years) found a significant correlation between serum vitamin A concentrations and lung function measurements, including forced expiratory volume in 1 second, forced vital capacity and peak expiratory flow (Aird et al 2006). Similarly, a retrospective study found CF patients with reduced vitamin A and E levels (even within the normal range) had increased incidence of pulmonary exacerbations (evaluated by a scale of clinical status, including symptoms and chest examination findings) (Hakim et al 2007). It is possible the antioxidant activity of vitamin A reduces oxidative damage to lung tissues and in this way provides some protection in CF. While patients with CF and pancreatic insufficiency are at increased risk of deficiency of fat-soluble vitamins, including vitamin A, two studies examining vitamin A status in CF patients found CF patients had higher intake and serum retinol levels compared to those without CF (Graham-Maar et al 2006, Maqbool et al 2008). Monitoring may be required to prevent excessive vitamin A supplementation.

### Osteoporosis

Whether high-dose vitamin A supplementation increases the risk of osteoporosis remains unclear.

Evidence supporting the association comes from cell studies, animal studies and some, but not all, human observational studies. Four large, prospective observational studies reported a positive association between vitamin A intake and osteoporosis and fracture rates (Feskanich et al 2002, Melhus et al 1998, Michaelsson et al 2003, Promislow et al 2002). These studies suggested that the amount needed to reduce bone density may be as low as 1500 retinol equivalents (RE), although vitamin A is normally regarded as safe in amounts up to 3000 RE (Peniston & Tanumihardjo 2006). In contrast, numerous studies have failed to find a significant association (Ambrosini et al 2013, Barker et al 2005, Houtkooper et al 1995, Kaptoge et al 2003, Kawahara et al 2002, Rejnmark et al 2004, Sowers & Wallace 1990, Wolf et al 2005). In a study comparing vitamin A intake, serum vitamin A and bone turnover markers in postmenopausal women, no statistical differences were found between those with osteoporosis compared with those without (Peniston et al 2006). The inconsistency in results may be partly due to the difficulty in accurately assessing vitamin A intake and status, as well as the multiple variables influencing bone health (Ribaya-Mercado & Blumberg 2007).

### Anaemia

Vitamin A and iron are interdependent nutrients, with iron required for the metabolism of vitamin A and maintenance of circulating levels of retinol, and vitamin A required for the mobilisation of iron from its stores for use in haemoglobin synthesis. Some studies have found improving vitamin A status in deficient individuals improves anaemia (Al-Mekhlafi et al 2013, Berger et al 2007, Hyder et al 2007, Zimmermann et al 2006). This is thought to be due to the involvement of vitamin A in regulation of iron regulator proteins, and the subsequent expression of iron metabolism genes (Jiang et al 2012). In a double-blind, randomised trial, 81 children (77% with low vitamin A status) received either vitamin A (200,000 IU) or placebo at baseline and again after 5 months. After 10 months, compared to the placebo group, the vitamin A-treated group had increased levels of retinol, increased haemoglobin and mean corpuscular volume and decreased the serum transferrin receptors, indicating improved iron-deficient erythropoiesis. Prevalence of anaemia in the treated group decreased from 54% to 38%. Ferritin levels in the vitamin A group were also decreased, suggesting vitamin A increased mobilisation of hepatic iron stores (Zimmermann et al 2006). In a study comparing the impact of vitamin A on the health of children aged 12–59 months in rural Indonesia, it was found that those who had not received their vitamin A treatment in the previous 6 months were significantly more likely to be anaemic, underweight, wasted and have higher rates

of diarrhoea and fever than children who received vitamin A (Berger et al 2007).

Alternatively, some studies found no association between iron deficiency and vitamin A. In a randomised controlled trial in central Africa, 700 pregnant women (2–24 weeks' gestation) with haemoglobin <11.0 g/dL were treated with either vitamin A (5000 IU or 10,000 IU) or placebo, plus iron (60 mg elemental iron as ferrous sulfate), folate (0.25 mg) and sulfadoxine/pyrimethamine for antimalarial prophylaxis until delivery. While women in the vitamin A-treated groups were less likely to have depleted vitamin stores at the end of the pregnancy, there were no significant differences in anaemia, severe anaemia and iron status compared with the placebo group. This population was thought to be less vitamin A-deficient compared with Asian countries such as Indonesia and Nepal, where positive results have previously been found (van den Broek et al 2006). Similarly, a randomised, placebo-controlled trial conducted with mothers and their infants in Zimbabwe observed no effect on haemoglobin or anaemia levels evaluated 8–14 months after supplementation (400,000 IU for mothers and 50,000 IU for infants) (Miller et al 2006). In a double-blind trial involving HIV-1-infected pregnant women from Tanzania, subjects were randomised to receive daily supplements of 30 mg beta-carotene + 5000 IU preformed vitamin A only, multivitamins (vitamins B, C and E), preformed vitamin A and beta-carotene plus multivitamins, or placebo. All women also received iron and folate supplements during pregnancy. While haemoglobin concentrations significantly improved in women in the multivitamin group and their children, those in the beta-carotene and vitamin A-only group did not significantly differ from placebo (Fawzi et al 2007).

In children with sickle cell anaemia, 12-month supplementation of vitamin A with the recommended doses for healthy children, based on age and sex, did not improve serum retinol concentration (Dougherty et al 2012). This suggests that higher doses may be required in this population, although more research is required.

### Mortality risk

In a Cochrane systematic review, the effect of antioxidant supplements on mortality in primary or secondary prevention randomised clinical trials was evaluated; vitamin A used as sole treatment or in combination with other antioxidants (15 trials, mean dose of 20,219 IU) had no significant effect on mortality. In fact, after excluding the high-bias risk, trials analysis found vitamin A significantly increased mortality in five trials (Bjelakovic et al 2008). This finding requires further investigation to confidently rule out the possible effect of confounders.

### Deficiency as a predictor for coronary events

The PRIME study prospectively evaluated European men aged 50–59 ( $n = 9758$ ) who were free from coronary heart disease at baseline over 5 years

### Clinical note — Vitamin A toxicity in two young children

In 2001, a report of two children admitted to hospital with symptoms of vitamin A toxicity was published in the *Medical Journal of Australia*. One case involved a 2-year-old girl with anorexia, lethargy and leg pain, an erythematous rash over her back and elbows and irritability. All symptoms resolved over 2 weeks following withdrawal of the supplement. The second case involved a child who had previously been prescribed oral etretinate by a dermatologist (for an unspecified period of time), which was ceased 3 months prior to vitamin A supplementation. In both cases, the dose of vitamin A taken was in excess of that provided by standard over-the-counter products (Coghlan & Cranswick 2001).

(Gey et al 2010). The study found that plasma retinol levels below 601 mcg/L in a fifth of men placed them at a threefold relative risk of developing coronary heart disease. Due to the limited number of control subjects, confirmation of these findings in a larger population is warranted.

### OTHER USES

Vitamin A has also been used in the treatment of menorrhagia and premenstrual syndrome, to prevent glaucoma and cataract, and in Crohn's disease, sinusitis and rhinitis.

### DOSAGE RANGE

- Vitamin A activity is expressed as a unit called microgram RE (Miller et al 1998): 1 microgram RE = 1 mcg all-*trans* retinol or 6 mcg all-*trans* beta-carotene or 3.33 international units (IU) of vitamin A or 1 mcg RE is equivalent in activity to 1.78 mcg of retinyl palmitate and 10 IU activity from beta-carotene.

Recent changes to the Therapeutic Goods Act regarding vitamin A require the following statement be included on the labels of vitamin A preparations for internal use:

The recommended adult daily intake of vitamin A from all sources is 700 microgram RE (2330 IU) for women, and 900 microgram RE (3000 IU) for men.

**WARNING** — when taken in excess of 3000 microgram RE daily, vitamin A may cause birth defects.

If you are pregnant, or considering becoming pregnant, do not take vitamin A supplements without consulting your doctor or pharmacist.

### Australian recommended daily intake (in mcg RE)

#### Children

- 1–3 years: 300 mcg/day
- 4–8 years: 400 mcg/day

- 9–13 years: 600 mcg/day
- Girls, 14–18 years: 700 mcg/day
- Boys, 14–18 years: 900 mcg/day.

#### Adults

- Females: 700 mcg/day
- Males: 900 mcg/day
- Upper level of intake: 3000 mcg/day.

#### Pregnancy

- <18 years: 700 mcg/day
- >18 years: 800 mcg/day
- Lactation: 1100 mcg/day
- Deficiency without corneal changes: 10,000–15,000 IU/day for 1–2 weeks, until clinical improvement is apparent
- General treatment doses: 10,000–50,000 IU/day have been used short term.

#### According to clinical studies

- Reducing secondary infection in children with measles: 200,000 IU of vitamin A on two consecutive days when vitamin A deficiency may be present (not to be consumed at this dose long-term)
- Retinitis pigmentosa: 15,000 IU/day.

#### TOXICITY

Cumulative toxicity is possible when doses greater than 100,000 IU are ingested long-term. Acute toxicity is very difficult to induce in adults, as doses above 2,000,000 IU are required (Hendler & Rorvik 2001).

Early signs of toxicity include dry rough skin, cracked lips, coarse hair, sparse hair, alopecia of eyebrows, diplopia, dryness of the mucous membranes, desquamation, bone and joint pain, fatigue and malaise, nausea and vomiting and psychological changes mimicking depression and schizophrenia.

Later signs include irritability, increased intracranial pressure and headache, dizziness, liver cirrhosis, fibrosis, vomiting, haemorrhage and coma (Miller et al 1998).

People with chronic renal disease typically have elevated plasma retinol levels and therefore may be at greater risk of toxicity if supplementation is used. It is important to note that beta-carotene is not associated with teratogenic effects or vitamin A toxicity and is considered a far safer nutrient.

#### ADVERSE REACTIONS

In general, doses of vitamin A that do not exceed physiological requirements have no adverse effects. A Cochrane review determined that there was an increased risk of vomiting within the first 48 hours following vitamin A supplementation (Imdad et al 2010).

#### SIGNIFICANT INTERACTIONS

##### Chemotherapeutic agents

Adjunctive treatment may improve drug response — consider individual patient characteristics, form

and presentation of cancer, drugs used before administration — use only under professional supervision.

##### Cholestyramine

Reduces vitamin A absorption — increase dietary intake of vitamin A-rich foods or consider supplementation with long-term use.

##### Colchicine

Colchicine may interfere with vitamin A absorption and homeostasis — co-administer for beneficial interaction.

##### HMG-CoA reductase inhibitor drugs (statins)

These drugs increase the serum levels of vitamin A, the clinical significance of which is unclear — observe patients taking this combination (Muggeo et al 1995).

##### Isotretinoin

Toxicity may be increased — avoid this combination.

##### Minocycline

Long-term vitamin A use with this drug increases the risk of pseudotumour cerebri — use with caution.

##### Oral contraceptives

Increased vitamin A levels occur in oral contraceptive pill users due to longer storage in the liver

#### Practice points/Patient counselling

- Vitamin A is a fat-soluble antioxidant that is chiefly stored in the liver.
- It is involved in maintaining vision and healthy immune function; it is necessary for growth and development, reproductive capability and healthy epithelial cell function.
- It is used to treat and prevent deficiency states, and there is clinical evidence that supplementation reduces the incidence and severity of infections during childhood, particularly measles and infectious diarrhoea, reduces the incidence of croup and otitis media in children with measles, and may be useful in retinitis pigmentosa.
- Vitamin A deficiency is widespread in some countries, increasing the risk of childhood infectious disease, mortality and deficiency-associated blindness.
- While primary vitamin A deficiency is less common in Western countries, there are a number of drugs and surgical procedures, including bariatric surgery, which can result in secondary deficiency occurring.
- Excessive vitamin A supplementation can induce a toxicity state that can have serious, sometimes irreversible, consequences.

(Tyrer 1984) — use caution with large doses of retinol.

### Orlistat

Reduces vitamin A levels — increase dietary intake of vitamin A-rich foods or consider supplementation with long-term use.

### Tetracyclines

Adjunctive use may increase side effects such as headaches, pseudotumour cerebri — avoid.

#### **?** CONTRAINDICATIONS AND PRECAUTIONS

Doses greater than 10,000 IU/day long-term should be used with caution.

People with liver or renal disease, alcoholism or severe osteoporosis should use vitamin A supplements with caution.

#### **P** PREGNANCY USE

In the United States, sources state that doses up to 10,000 IU/day are safe in pregnancy, but Australian authorities recommend that supplements containing  $\geq 2500$  IU of vitamin A per dose must have pregnancy warning statements on their labels. Excessive use of vitamin A during pregnancy has been associated with heart defects in vivo (Feng et al 2013).

It is important to note that beta-carotene, found naturally in plants, is not associated with teratogenic effects or vitamin A toxicity.

The teratogenicity of 13-*cis*-retinoic acid, a synthetic derivative of vitamin A available in Australia as Roaccutane, is well established and that substance is contraindicated in pregnancy.

#### **!** PATIENTS' FAQs

##### *What will this vitamin do for me?*

Vitamin A is essential for health and is involved in many different biochemical processes in the body. Some research has suggested that it reduces the incidence and severity of some infectious diseases in children. Vitamin A or its synthetic derivatives have also been used in many skin conditions, such as acne, psoriasis, ultraviolet-induced skin damage and photoaging and the treatment of some cancers.

##### *When will it start to work?*

This will depend on the form of vitamin A being used and the indication it is being used to treat.

##### *Are there any safety issues?*

Taking high doses of vitamin A long-term can cause side effects and is contraindicated in pregnancy.

## Vitamin B<sub>1</sub>

**HISTORICAL NOTE** The Chinese medical book *Neiching* describes beriberi in 2697 BC, but it was not known for a long time that vitamin B<sub>1</sub> deficiency was responsible. The neurological symptoms such as leg weakness characteristic of thiamin deficiency were also recorded in the 1890s in chicks fed a diet of polished rice. In 1912, thiamin was isolated from rice bran and in the mid-1930s the structure of vitamin B<sub>1</sub> was determined (Gropper & Smith 2013). Since it was found not to contain an amine group, the 'e' was dropped from its name (thiamine → thiamin).

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin B<sub>1</sub> is a water-soluble compound required by all tissues. It is also known as thiamin (previously thiamine), anti-beriberi factor, antineuritic factor and its active coenzyme form, thiamin diphosphate (TDP), also called thiamin pyrophosphate (TPP). Thiamin's phosphate ester functions as a coenzyme and its ability to shift between different degrees of phosphorylation makes it a key nutrient in energy pathways.

There are two sources of thiamin: dietary and bacterial, which is synthesised by normal intestinal microflora. Thiamin is absorbed, predominantly in the jejunum and ileum as free (unphosphorylated) thiamin, by a saturable rate-limiting transport mechanism and may be passive or active. Passive absorption occurs at high concentrations, while at physiological levels, two active thiamin transporters, ThTr1 and ThTr2, are utilised. The activity of these transporters is inhibited by alcohol. The absorption of thiamin in the gastrointestinal tract can also be impaired by the presence of naturally occurring antithiamin factors such as thiaminases, found in raw fish, and polyhydroxyphenols, found in coffee, tea, blueberries, red cabbage and Brussels sprouts (Groff & Gropper 2009). Interestingly, calcium and magnesium exacerbate the effect of the polyhydroxyphenols. Conversely, thiamin preservation in the gastrointestinal tract is enhanced by vitamin C and citric acid (Gropper & Smith 2013).

Thiamin is transported via the portal circulation, travelling in plasma either free, bound to albumin, or as thiamin monophosphate, to the liver, where it is phosphorylated to its TDP coenzyme form (80% total body thiamin), which is also its most

active state. Magnesium is required as a cofactor for this conversion/activation while alcohol has an inhibitory effect. Thiamin is taken up into brain by a blood-brain barrier transporter and via cerebrospinal fluid (CSF) (Fernstrom & Fernstrom 2013). Thiamin is excreted mainly by the kidneys. Thiamin is found in high concentrations in skeletal muscle, heart, liver, kidneys and brain and its half-life is approximately 15 days (Singleton & Martin 2001).

### CHEMICAL COMPONENTS

Thiamin (vitamin B<sub>1</sub>) is a water-soluble substance, composed of two heterocyclic moieties, substituted thiazole and pyrimidine rings joined by a methylene bridge (Rapala-Kozik 2011). It does not contain an amine group, as originally postulated.

### FOOD SOURCES

Thiamin found in plant foods exists in its free form, while 95% of thiamin found in animal foods occurs primarily as TDP (Gropper & Smith 2013).

Brewer's yeast, lean meat and legumes are considered the richest sources of thiamin. Other sources include cereals, grains, pasta, wheat germ, soy milk, seeds and peanuts.

It is possible to lose up to 85% of the thiamin content in meat through cooking and canning, and up to 60% from cooking vegetables (Tanphaichit 1999); cooking foods in water will further exacerbate the loss (Gropper & Smith 2013). There is also loss through refining of grains and polishing of rice (where the germ and bran have been removed, leaving only the endosperm). However, in Australia the fortification of wheat flour used for making bread with thiamin is mandatory to compensate for this loss (FSANZ 2012). Thiamin is not stable in

alkaline environments; a pH of 8 or above destroys its activity (Gropper & Smith 2013).

### DEFICIENCY SIGNS AND SYMPTOMS

The body only stores a small amount of thiamin and signs of deficiency tend to develop within 15–18 days of restricted intake.

Despite an expansive understanding of the role of thiamin at the cellular level, many aspects of the pathophysiological manifestations of thiamin deficiency remain unexplained (Gropper & Smith 2013). Beriberi (*beri* means weakness) is the classic deficiency state. General early or subclinical deficiency signs and symptoms include fatigue, weakness, rigidity (due to corresponding increase in lactic acid production), poor memory, sleep disturbances, chest wall pain, anorexia, abdominal discomfort and constipation. Other characteristic signs and symptoms include retarded growth, oedema, cardiomyopathy, bradycardia, heart failure and peripheral neuropathy (Combs 2012).

There are four forms of beriberi: dry, wet, acute and cerebral, otherwise known as Wernicke–Korsakoff syndrome. Dry beriberi is associated with muscle weakness and wasting, especially of the lower limbs, peripheral neurological changes and nerve conduction problems that may lead to symmetrical foot drop with calf tenderness (Gropper & Smith 2013). In addition to neurological changes, wet beriberi is associated with cardiovascular changes such as cardiomegaly and tachycardia. It is characterised by peripheral vasodilation, oedema due to sodium and water retention, increased cardiac output and myocardial failure, which can become fatal in severe cases. Acute beriberi occurs most commonly in infants and is associated with nausea and vomiting, convulsions, lactic acidosis, tachycardia and cardiomegaly; acute attacks may result in death if thiamin deficiency is not rapidly corrected.

Cerebral beriberi involves alterations to ocular and cognitive function secondary to bilateral symmetrical brain lesions in the paraventricular grey matter, producing ataxia, which can also be fatal. Ophthalmoplegia (paralysis of the ocular muscles), nystagmus (involuntary, constant eyeball movement) and ataxia are the recognised triad of symptoms of Wernicke’s encephalopathy. People with alcohol dependency are particularly at risk due to reduced consumption of food (thus thiamin intake), decreased absorption (Gropper & Smith 2013) and increased requirements due to decreased liver function (which impairs TDP formation).

Additionally, Wernicke–Korsakoff syndrome has been reported in several other conditions, such as hyperemesis gravidarum, hyperemesis due to gastroplasty (Kuhn et al 2012), acute psychosis after gastric bypass (Walker & Kepner 2012), gastric lap band (Becker et al 2012) and bariatric surgery (Lu’o’ng & Nguyen 2011, Sriram et al 2012), hyperthyroidism and inadequate parenteral nutrition (Bonucchi et al 2008, Gardian et al 1999, Ogershok et al 2002,

Seehra et al 1996, Spruill & Kuller 2002, Tan & Ho 2001, Togay-Isikay et al 2001, Toth & Voll 2001). A 2007 case report of thrombocytopenia in a patient with Wernicke–Korsakoff syndrome, responsive to thiamin repletion, has introduced the possibility that this may constitute an unusual feature of the deficiency picture (Francini-Pesenti et al 2007).

While it is well recognised that the brain, heart and neuronal tissue are classically affected by thiamin deficiency, a recent *in vivo* study has found evidence of an endogenous self-preservation mechanism for brain and heart tissue that becomes established within 4 weeks of a thiamin-deficient diet (Klooster et al 2013). After this period, brain tissue transketolase activity remained constant and TDP (TPP) levels were significantly conserved in brain and heart tissue. The authors have suggested that other tissues could be suffering thiamin deficiency despite the absence of classical beriberi or Wernicke–Korsakoff syndrome (Lu’o’ng & Nguyen 2011, Sriram et al 2012). The length of time by which this self-preservation response can be effective during periods of low thiamin intake remains to be tested.

#### **Clinical note — Thiamin deficiency is not uncommon in the elderly**

Several observational studies have reported that thiamin deficiency is not uncommon in the elderly. A study of 118 elderly hospital patients identified a moderate deficiency incidence of 40% (Peppersack et al 1999). Similar results were obtained in another survey, where marginal thiamin deficiency had an incidence of 31% and frank deficiency of 17% in 36 non-demented elderly patients admitted to an acute geriatric unit. Delirium occurred in 32% of patients with normal thiamin status and 76% of thiamin-deficient patients ( $P < 0.025$ ), although one or more other possible causes for delirium were present in all cases (O’Keefe et al 1994). The importance of including thiamin deficiency in diagnostic work-ups of at-risk individuals is underscored by the high mortality rate in Wernicke–Korsakoff syndrome (10–20%), reported to be the direct result of underdiagnosis (Bonucchi et al 2008). Similarly, it is important to keep in mind that there is significant interindividual variability in both susceptibility to thiamin deficiency and its consequences (Al-Nasser et al 2006).

Preliminary research suggests that inadequate intake could also increase susceptibility to neurodegeneration, particularly in aged organisms (Nixon et al 2006, Pitkin & Savage 2004).

#### **Primary deficiency**

Primary deficiency is caused by inadequate dietary intake of thiamin, particularly in people subsisting mainly on highly polished rice (de Montmollin et al

**Clinical note — Thiamin food fortification in Australia and New Zealand**

Australia New Zealand Food Standards Code, Standard 2.1.1 Amendment No. 111 2009 Cereals and Cereal Products, defines ‘a number of products composed of cereals, qualifies the use of the term “bread”, and requires the mandatory fortification of flour for bread making with thiamin in Australia’ (Australian Government Comlaw 2009).

2002) or unfortified refined grain products. Insufficient intake may also occur in anorexia. Historically, those receiving total parenteral nutrition (TPN) without adequate additional thiamin were at risk of a primary deficiency. Current TPN formulae include 3 mg thiamin (Merck Manual Professional 2009).

**Secondary deficiency**

Secondary deficiency is caused by an increased requirement, as in hyperthyroidism, pregnancy, lactation, fever, acute infection, increased carbohydrate intake, folate deficiency, malabsorption states, hyperemesis, prolonged diarrhoea, strenuous physical exertion, breastfeeding, adolescent growth and states of impaired utilisation such as severe liver disease, alcoholism, chronic haemodialysis, diabetes (types 1 and 2) and people taking loop diuretics long-term. Additionally, pyruvate dehydrogenase deficiency can result in deficiency (Beers & Berkow 2003, Thornalley et al 2007, Wardlaw et al 1997, Wahlqvist et al 2002). Alternatively, latent primary thiamin deficiencies produce overt clinical features when the patient is exposed to thiamin metabolism stressors, such as those listed above, e.g. pregnancy, surgery (Al-Nasser et al 2006).

**MAIN ACTIONS****Coenzyme**

Carbohydrate and branched-chain amino acid metabolism.

Thiamin serves as a cofactor for several enzymes involved in carbohydrate catabolism, including pyruvate dehydrogenase complex, where TDP/TPP converts pyruvate to acetyl CoA (Fattal-Valevski 2011), transketolase and alpha-ketoglutarate, and for the branched-chain alpha-keto acid dehydrogenase complex that is involved in amino acid catabolism (Singleton & Martin 2001). Some of these enzymes are also important in brain oxidative metabolism (Molina et al 2002).

**Neurotransmitter biosynthesis**

Thiamin is involved in the biosynthesis of a number of neurotransmitters, including acetylcholine and gamma-aminobutyric acid. As TTP, it may also be involved in nerve impulse transmission (Gropper & Smith 2013).

**DNA**

Thiamin is involved in the synthesis of DNA precursors, therefore its use is increased in people with tumours.

**Neuropsychological actions and neurodegenerative diseases**

Thiamin is taken up into brain by a blood-brain barrier transporter and via CSF (Fernstrom & Fernstrom 2013). It is involved in neurotransmitter biosynthesis and is required for neurotransmission, nerve conduction, blood CSF barrier functionality and muscle action.

In the form of TTP, it plays an essential role in the physiology of the nervous system as it concentrates in nerve and muscle cells and activates membrane ion channels. TTP represents the smallest percentage of thiamin forms in humans; however, its phosphorylation of key regulatory proteins and the activation of high-conductance anion channels in nerve cells demonstrate its vital role in nervous system physiology (Gangolf et al 2010, Rapala-Kozik 2011). Thiamin deficiency leads to impaired oxidative metabolism due to impaired thiamin-dependent enzyme activity, and subsequently results in a multitude of negative events in the brain, including oxidative stress, lactic acidosis, blood-brain barrier disruption, decreased glucose utilisation and inflammation (Jhala & Hazell 2011). The consequence of such impaired metabolism alters brain function and can result in structural damage, neurodegeneration and, ultimately, neuronal cell loss (Jhala & Hazell 2011, Rapala-Kozik 2011).

Severe thiamin deficiency in the nervous tissue of animals reduces TPP levels and causes loss of coordinated muscle control. Upon correcting thiamin levels these anomalies are reversed, suggesting no permanent neural damage or destruction (Fernstrom & Fenstrom 2013). However, evidence from animal studies suggests that impaired blood CSF barrier function, secondary to thiamin deficiency, allows passage of neuroactive substances into the brain, damaging the choroid plexus (Nixon et al 2006). In Wernicke-Korsakoff syndrome, selective damage of mammillary bodies, the thalamus and pons has been observed, and analysis at the cellular level shows microglial activation and astrocyte proliferation (Hazell 2009, Hazell et al 1998, Rapala-Kozik 2011, Wang & Hazell 2010). Furthermore, in Wernicke-Korsakoff syndrome, the activity of all TDP-dependent enzymes is reduced, which in turn leads to decreased glutamate, aspartate and gamma-aminobutyric acid production, mitochondrial disintegration, lactate accumulation, acidosis and ultimately neuronal cell loss (Rapala-Kozik 2011).

**Energy production**

The B vitamins collectively function as coenzymes particularly involved in mitochondrial energy production. TDP, specifically, is utilised as a cofactor in pyruvate dehydrogenase, alpha-ketoglutarate

dehydrogenase and branched-chain alpha-keto acid dehydrogenase. Evidence suggests that impaired mitochondrial energy production and decreased antioxidant activity, secondary to thiamin deficiency, may be responsible for the neuronal damage associated with this deficiency.

### Antioxidant

While thiamin does not have any direct free radical scavenging activity, it has been postulated that, in thiamin deficiency, the neuronal damage and cellular energy depletion may be due to oxidative stress; high nitric oxide synthase production and formation of peroxynitrites have been observed and may be responsible for the deactivation of ketoglutarate dehydrogenase (Gibson & Blass 2007, Huang et al 2010, Rapala-Kozik 2011).

### Mood

In addition to thiamin's important roles in neurotransmitter production, neurotransmission and nerve conduction, a deficiency of thiamin impedes the brain's ability to utilise glucose for energy. Subsequent manifestations include a plethora of neuropsychological effects, including mental depression, anxiety, irritability, apathy, poor concentration, forgetfulness and dementia. An early study found that as little as 50 mg/day thiamin per day for 2 months improved thiamin status in deficient individuals and was associated with greater mental clarity (Benton et al 1997).

### CLINICAL USE

Many of the clinical uses of thiamin supplements are conditions thought to arise from a marginal deficiency, but some indications are based on the concept of high-dose supplements acting as therapeutic agents. In practice, vitamin B<sub>1</sub> is usually recommended in combination with other B group vitamins.

### Deficiency: treatment and prevention

Thiamin supplements are traditionally used to treat or prevent thiamin deficiency states in people at risk (see *Secondary deficiency*, above).

### Hyperemesis

Although thiamin supplementation will not reduce the symptoms of hyperemesis, it may be necessary in cases of hyperemesis gravidarum and hyperemesis due to gastroplasty and gastric lap band surgery in order to avoid deficiency, which has been infrequently reported in these situations. Permanent multifocal neurological dysfunction has been reported in women, including adolescent women, within 3 months of undergoing gastroplasty and gastric lap band surgery and reporting hyperemesis (Becker et al 2012, Kuhn et al 2012, Towbin et al 2004, Walker & Kepner 2012). It may be precipitated in part by intravenous (IV) fluids containing dextrose, and is more commonly seen when the patient's liver transaminases are elevated, which may

contribute to the encephalopathy (Becker et al 2012, Francini-Pesenti et al 2007, Gardian et al 1999, Kuhn et al 2012; Seehra et al 1996, Spruill & Kuller 2002, Tan & Ho 2001, Togay-Isikay et al 2001, Toth & Voll 2001, Welsh 2005).

### Alcoholism

In alcoholism, a state of decreased intake, absorption, utilisation and increased requirement for thiamin occurs, necessitating increased intakes to avoid deficiency states (D'Amour et al 1991). In cases of Wernicke's encephalopathy, monitoring of thiamin status and prophylactic IV treatment will inhibit the progression to Korsakoff's psychosis (Thomson & Marshall 2005). Ongoing research has revealed that the cerebellar neurotoxicity associated with excess alcohol is more likely to be mediated predominantly by thiamin deficiency than by direct ethanol cytotoxicity, as previously believed (Mulholland et al 2005); however, there is growing evidence of a strong negative synergy between the two that extends well beyond the increased need for thiamin as a result of alcohol consumption (Nixon et al 2006). In the treatment of Wernicke's encephalopathy, two studies have found IV or intramuscular (IM) administration of 100–500 mg of thiamin over 30 minutes for 3 days necessary to sufficiently raise plasma thiamin levels, and improve thiamin uptake and transport across the blood–brain barrier (Francini-Pesenti et al 2009, Sechi & Serra 2007).

### Total parenteral nutrition

Several case reports show that patients who have received TPN without proper replacement of thiamin are at risk of developing deficiency signs and Wernicke's encephalopathy (Francini-Pesenti et al 2007, Hahn et al 1998, van Noort et al 1987, Vortmeyer et al 1992, Zak et al 1991). Preliminary evidence suggests that current TPN formulations are not sufficient to ensure thiamin repletion in all patients (Francini-Pesenti et al 2009).

### Hyperthyroidism

Although a somewhat rare sequela, a handful of case reports describe Wernicke–Korsakoff's syndrome in patients suffering thyrotoxicosis (Bonucchi et al 2008).

### Surgical patients

Several case reports detailing Wernicke's encephalopathy in surgical patients highlight why this patient group should be considered 'high-risk' for thiamin deficiency: malnutrition, high stress levels, vomiting and ileus all increase thiamin requirements substantially (Al-Nasser et al 2006, Francini-Pesenti et al 2007). Several authors suggest that thiamin deficiency may be latent in the preoperative patient, with surgery or postoperative TPN precipitating clinical manifestation, and consequently recommend preoperative screening for thiamin status (Al-Nasser et al 2006).

### Acute alcohol withdrawal

Several guidelines for the support of alcohol withdrawal recommend a dose of 100 mg thiamin administered IV or IM before routine administration of dextrose-containing solutions (Adinoff et al 1988, Erstad & Cotugno 1995).

### Alzheimer's disease (AD)

Thiamin status has been investigated and found, amongst other nutrients, to have an inverse relationship with cognitive function in the elderly (Nourhashemi et al 2000). More specifically, AD has been associated with reduced plasma levels of thiamin, according to several clinical studies (Gold et al 1995, 1998, Molina et al 2002). One study analysing cerebral cortex samples from autopsied patients with AD found slight reductions in TDP levels compared with matched controls (Mastrogiacoma et al 1996). Others have demonstrated reduced activities of thiamin-dependent enzymes, together with a strong correlation between these reductions and the extent of the dementia pathology in autopsied brains (Gibson & Blass 2007). Proposed mechanisms for the relationship between thiamin and AD are varied, ranging from its role as an antioxidant and its critical contribution to the Krebs cycle to its involvement in the production of acetylcholine, disturbances of which have all been implicated in AD pathology (Bubber et al 2004, Butterfield et al 2002, Gibson & Blass 2007, Kruse et al 2004). Animal research points towards the shared features of thiamin deficiency and AD pathology in the brain, in particular, with increased oxidative stress and inflammation precipitating neuronal loss in specific brain areas and concomitant promotion of plaque formation (Karuppagounder et al 2009).

Investigation with high-dose thiamin supplementation in this population has produced mixed results (Blass et al 1988, Meador et al 1993, Mimori et al 1996). One double-blind, placebo-controlled, cross-over study showed that a dose of 3000 mg thiamin/day produced higher global cognitive ratings, as assessed by the Mini-Mental State Examination, compared with a niacinamide placebo. However, there were no changes to clinical state and behavioural ratings (Blass et al 1988). Another clinical study of unknown design found positive results with a dose ranging between 3 and 8 g/day of thiamin (Meador et al 1993), whereas a long-term study using high-dose supplementation produced negative results (Mimori et al 1996).

Although promising overall, a 2001 Cochrane review stated that it is still not possible to draw any conclusions about the effectiveness of thiamin supplementation in AD (Rodriguez-Martin et al 2001). In practice, it is often used as part of a broad-spectrum approach with other B group vitamins in age-related cognitive decline; however, further research is required to determine whether this method produces more consistent results, particularly as an adjunct to standard pharmaceutical treatments (Gibson & Blass 2007).

### Diabetes

Given thiamin's essential role in the key carbohydrate metabolic enzymes transketolase, pyruvate dehydrogenase and alpha-ketoglutarate dehydrogenase and the glucose toxicity that occurs secondary to thiamin deficiency (Nixon et al 2006), there is growing interest in the therapeutic potential of this nutrient in diabetes. Preliminary research of thiamin status in diabetic patients reveals significantly high rates of deficiency ( $\approx 75\%$  of type 1 and 2 diabetics), secondary to greatly increased renal losses (Thornalley et al 2007). It has been suggested that reduced thiamin availability may exacerbate diabetic metabolic dysfunction, particularly with respect to microvascular complications. This finding adds to the evidence produced earlier in test tube studies demonstrating that thiamin improves endothelial function, while protecting against insulin-mediated vascular smooth-muscle cell proliferation (Arora et al 2006).

In diabetes, benfotiamine, a synthetic derivative of thiamin (see section on [Supplemental forms](#), below), induces key thiamin-dependent enzymes of the pentose shunt to reduce accumulation of toxic metabolites, including advanced glycation end products (Gibson et al 2013).

An investigation into high-dose thiamin (100 mg taken three times daily) over 3 months in a small sample of type 2 diabetes mellitus patients with microalbuminuria demonstrated reversal of early-stage nephropathy in the treatment group, without altering glycaemic control, dyslipidaemia or blood pressure (Rabbani et al 2009). Another study employing thiamin, this time in IV form, improved endothelium-dependent vasodilation in hyperglycaemic patients (both diabetic and non-diabetic); however, the mechanism of action remains unclear (Arora et al 2006).

Thiamin status in non-diabetic patients is typically assessed by the well-validated red blood cell transketolase activity test. However, an established limitation in this test is its inaccuracy in diabetic patients, complicating accurate assessment in this population (Thornalley et al 2007).

### Congestive heart failure (CHF)

A large trial published in 2006 confirmed that the incidence of thiamin deficiency is notable amongst CHF patients (Hanninen et al 2006). These results were echoed by a more recent review in which the majority of studies reflect a general trend of increased risk of thiamin deficiency amongst this patient group compared with individuals free from the condition (McKeag et al 2012). It is suspected that patients with existing heart failure are at increased risk of thiamin deficiency because of diuretic-induced depletion, advanced age, malnutrition and/or periods of hospitalisation. A cross-sectional study reported that approximately one-third of hospitalised patients with heart failure had tissue levels suggestive of thiamin deficiency (Keith et al 2009).

**Clinical note — The link between glucose metabolism, Alzheimer's dementia and thiamin**

A continuous supply of glucose is essential for normal brain function and a key feature and biomarker of progression of AD is reduced glucose metabolism (Gibson et al 2013). Changes in brain glucose metabolism occur decades before the development of symptoms (Reiman et al 2004). In a multicentre, longitudinal neuroimaging study (Alzheimer Disease Neuroimaging Initiative: ADNI) launched in 2004, in which 819 adult subjects, 55–90 years old, were investigated, it was found that brain glucose utilisation was the best predictor of developing and progressing from mild cognitive impairment to AD (Jack et al 2010).

Thiamin-dependent processes responsible for glucose metabolism are diminished in brains of AD patients at autopsy and have been correlated with worse outcomes on dementia rating scales (Gibson et al 2013). Furthermore, thiamin deficiency exacerbates plaque formation and impairs memory in animal studies, while benfotiamine diminishes plaques and reverses memory deficits. Despite the linkages between diminished glucose metabolism in the brain and AD, why glucose metabolism is diminished remains elusive.

While a 2001 review concluded that there was insufficient evidence from large trials to confirm thiamin as a corrective treatment in CHF, a number of small interventional studies have assessed the effect of thiamin supplementation in patients with CHF, with promising results. In one pilot study of 6 patients treated with IV thiamin, such that their thiamin status returned to normal, there was increased left ventricular ejection fraction (LVEF) in 4 of 5 patients studied by electrocardiograph (Seligmann et al 1991). A randomised, placebo-controlled, double-blind study of 30 patients compared the effects of IV thiamin (200 mg/day) to placebo over 1 week followed by oral thiamin (200 mg/day) taken for 6 weeks. In the 27 patients completing the full 7-week intervention, LVEF rose by 22%. Other positive results have been reported from similar studies (Hanninen et al 2006). The current position of key researchers in this area is that, together with other micronutrients critical for myocardial energy production and control of oxidative stress (e.g. taurine), thiamin inadequacy is likely to exacerbate myocyte dysfunction and loss in this condition, making repletion an important therapeutic objective (Allard et al 2006).

**IN COMBINATION**

A Cochrane review of vitamin B complex for treating peripheral neuropathy, which included 13 studies (11 parallel RCTs and two quasi-randomised trials) involving 741 participants (488 treated with vitamin B alone) with alcoholic or diabetic neuropathy, concluded there are

limited data and the evidence is insufficient to determine whether vitamin B complex is beneficial or harmful in these populations (Ang et al 2008).

One study using benfotiamine (see section on [Supplemental forms](#), below), however, showed possible short-term benefit from 8-week treatment compared to placebo (Woelk et al 1998). Only 30 participants were treated with the oral benfotiamine in this study at a dosage of 320 mg/day during weeks 1–4 and 120 mg benfotiamine/day during weeks 5–8 (one capsule t.i.d.). Within the 8-week study period, benfotiamine led to a significant improvement of the threshold of vibration perception at the great toe, motor function and the overall symptom score. Marked improvement occurred in both pain and coordination (Woelk et al 1998). However, the strength of this evidence is weakened by the lack of other larger positive trials since this time.

**Dysmenorrhoea**

A Cochrane review of herbal and dietary therapies for primary and secondary dysmenorrhoea concluded that thiamin is an effective treatment when taken at 100 mg/day, although this conclusion is tempered slightly by its basis in only one large randomised controlled trial (Proctor & Murphy 2009). That trial was a randomised, double-blind, placebo-controlled, crossover design conducted over 5 months in 556 women and procured a positive improvement in >90% of the treatment cycle versus <1% in the placebo phase. The improvements observed during treatment appeared to have lasting effects, even after cessation of supplementation, for up to 3 months (Gokhale 1996). Due to the dramatic 'success' of this study, it has attracted scepticism regarding its methodology; certainly a question is why, with such positive results, an attempt to replicate the findings has not been undertaken since the mid-1990s (Fugh-Berman & Kronenberg 2003).

**Epilepsy**

A randomised, placebo-controlled trial involving 72 epileptic patients who had received long-term phenytoin treatment alone or in combination with phenobarbitone found that administration of thiamin (50 mg/day) over 6 months improved neuropsychological functions in both verbal and non-verbal IQ testing (Botez et al 1993). This study, interestingly, also found both folate supplementation (also typically depleted by the medication) and placebo ineffective. A 2009 Cochrane review investigating the role of B vitamins in controlling certain types of seizures found that thiamin supplementation improved neuropsychological functions related to psychomotor speed, visuospatial abilities, selective attention and verbal abstracting ability; however the sample was small and the authors concluded there is insufficient evidence that B vitamins improve seizure control or prevent harmful side effects of antiepileptic drugs in epileptic patients (Ranganathan & Ramaratnam 2009).

## OTHER USES

### Cataracts

A case-controlled study of 72 patients found that thiamin supplementation reduced the incidence of cortical, nuclear and mixed cataracts (Leske et al 1991).

### Coma

A general approach to patients presenting to hospital with coma is to ensure adequate oxygenation, blood flow and treatment with hypertonic glucose and thiamin (Alguire 1990, Buylaert 2000).

### Mortality in the elderly

In a recent study, higher intakes of vitamins B<sub>1</sub> and B<sub>6</sub> observed amongst Taiwanese elders were associated with increased survival rates by up to 10 years (Huang et al 2012). The Taiwanese Elderly Nutrition and Health Survey (1999–2000) interviewed 747 participants aged 65 years and over. Dietary and biochemical data were collected at baseline. Survivorship was determined until 31 December 2008. Controlled for confounders, and relative to the lowest tertile of vitamin B<sub>1</sub> or B<sub>6</sub> intakes, the hazard ratios (95% confidence interval) for tertile 3 were 0.74 (0.58–0.95) and 0.74 (0.57–0.97) (both  $P < 0.05$ ). The authors concluded that deficiencies of vitamin B<sub>1</sub> and B<sub>6</sub> were found to be clearly predictive of mortality in elderly Taiwanese.

### Polycystic ovarian syndrome

Insulin resistance is a key clinical feature in polycystic ovarian syndrome. Given the importance of thiamin in carbohydrate metabolism, it may suggest an important clinical role for thiamin in polycystic ovarian syndrome and improved insulin sensitivity (Hechtman 2011).

### Tumour proliferation

In advanced cancer, thiamin deficiency, along with many other micronutrients, frequently occurs. However TPP is involved in ribose synthesis, required for cellular replication, and hence the concern about a proliferative role ensues. In a metabolic control analysis *in vivo*, a high stimulatory effect on tumour growth of 164% was found for thiamin doses at 25 times the recommended dietary allowance (RDA) compared to controls. However, in the same study when thiamin supplementation was 2500 times the RDA for mice, the opposite effect was observed and a 10% inhibition of tumour growth was recognised. This effect was heightened, resulting in a 36% decrease, when thiamin supplementation was administered from the 7th day prior to tumour inoculation (Comin-Anduix et al 2001). Human research is urgently needed in order to elucidate any potential benefits or risks for thiamin in cancer.

### Clinical note — No protection against insect bites

One claim that has been around for many years is that high oral doses of certain B vitamins could act as a deterrent to insects such as mosquitoes. Principally, the myth has centred on thiamin. A review of prophylaxis against insect bites found that neither topical application nor oral dosing of thiamin is an effective preventive strategy (Rudin 2005).

## IN COMBINATION

The B group vitamins function as coenzymes in energy production and are a popular supplement taken by the public to lessen the impact of 'stress' and provide an energy boost. In one study, thiamin 10 mg/day significantly increased appetite, energy intake, body weight and general wellbeing and decreased fatigue, compared with placebo in a group of 80 randomly chosen women from a population with known marginal deficiency (Smidt et al 1991). Thiamin supplementation also tended to reduce daytime sleep time, improve sleep patterns and increase activity.

### Fibromyalgia

Studies have detailed thiamin metabolism disorders in fibromyalgia patients (Eisinger et al 1994, Juhl 1998). Due to its importance in energy production, it is suggested that any subsequent deficiencies due to the metabolic alteration may negatively impact energy production, potentially exacerbating the fatigue already prevalent in fibromyalgia sufferers.

### HIV

Several neuropathological reports have described brain lesions characteristic of Wernicke's encephalopathy in patients with AIDS. One study found a 23% prevalence of thiamin deficiency in AIDS patients with no history of alcohol abuse (Butterworth et al 1991), which may correlate with symptoms of fatigue and lethargy related to HIV. Another study found a decreased progression to AIDS from HIV in patients replete in vitamins B and C (Tang et al 1993).

### Neurogenic impotence

A dose of 25 mg thiamin taken orally resulted in normalisation of erection in a man with a history of chronic alcoholism and erectile dysfunction of 1 year's duration (Tjandra & Janknegt 1997). However, more recent evidence discussing the causes of neurogenic impotence suggests that thiamin deficiency is relatively rare (Finsterer 2005).

### Maple syrup urine disease

Of four paediatric patients with maple syrup urine disease, three responded to thiamin therapy with a reduction in concentration of plasma and urinary branched-chain amino and keto acids (Fernhoff et al 1985).

## IN COMBINATION

B vitamins were investigated for reducing sensitivity to painful stimuli in mice (Franca et al 2001), whereby thiamin and pyridoxine (50–200 mg/kg intraperitoneally [IP]) or riboflavin (3–100 mg/kg IP) induced an antinociceptive effect, not changed by naloxone (10 mg/kg IP), indicating that activity is not mediated by opiate pathways. The authors state that the B vitamins' antinociceptive effect may involve inhibition of the synthesis and/or action of inflammatory mediators. Furthermore, in an animal study the therapeutic effects of glucosamine hydrochloride and chondroitin sulfate as chondroprotection were enhanced by the addition of fursultiamine, a thiamin derivative, in the treatment of osteoarthritis (Kobayashi et al 2005).

## Optic neuropathy

Several case reports suggest this condition can be caused by thiamin deficiency and successfully treated with supplementation. One case report of a man developing optic neuropathy as a result of receiving TPN without thiamin for 4 weeks found that supplementation with thiamin reversed the condition (Suzuki et al 1997). Two cases of symmetrical, bilateral optic neuropathy associated with thiamin deficiency were successfully treated with thiamin supplementation.

## Fertility, preconception and health of the offspring

An animal study investigated the effects of thiamin deficiency in newly developing neuronal cells, reporting cellular membrane damage, apoptosis and irregular and ectopic cells (Ba 2008). The same paper postulates that thiamin repletion may stabilise neurons and prevent cellular death.

Another animal study by the same author investigated the impact of alcohol consumption and thiamin deficiency in the developing central nervous system (Ba 2011). Neurotoxicity caused by maternal thiamin deficiency during pre-, peri- and postnatal stages was compared with neurotoxicity caused by chronic maternal alcohol intake alone and finally compared with the combined effects. Neurodevelopmental abilities in the offspring were then measured. Both thiamin deficiency and ethanol exposure interfered with periods of intense cellular proliferation prenatally, and with cellular differentiation, synaptogenesis, axonogenesis and myelinogenesis during peri- and postnatal stages, producing neurofunctional alterations. Furthermore, perinatal effects of thiamin deficiency on primary cellular differentiation in the developing central nervous system were similar to those caused by alcohol exposure (Ba 2011).

Due to the imperative role of thiamin in female reproductive function, cellular differentiation and proliferation, and normal hormonal processes during gestation, a deficiency of thiamin during pregnancy may be implicated in an increased risk of miscarriage (Ba 2009). A limitation of this evidence is that the majority of investigations have been animal-based.

## DOSAGE RANGE

- Prevention of deficiency (adult Australian recommended dietary intake [RDI]): 1.1–1.2 mg/day
- Treatment of marginal deficiency states: 5–30 mg/day
- Critical deficiency: 50–100 mg IV or IM for 7–14 days, after which oral doses are used (Tanphaichitr 1999)
- Therapeutic dose: generally 5–150 mg/day, atypical therapeutic doses >3 g daily
- CHF: when indicated, 100 mg twice daily IV for 1–2 weeks, then 200 mg/day orally
- Dysmenorrhoea: 100 mg/day orally
- Support of alcohol withdrawal: 100 mg given IV or IM
- Fatigue (when marginal deficiency likely): 10 mg/day
- Type 2 diabetes mellitus: 100 mg three times daily
- Wernicke's encephalopathy: 100–500 mg (IV or IM) over 30 minutes for 3 days
- Mental depression: 50 mg/day for 2 months
- Mood disorders: 10 mg/day with marginal deficiency.

## Australian RDI

- Females >13 years: 1.1 mg/day.
- Males >13 years: 1.2 mg/day.

## TOXICITY

Toxicity does not occur with oral thiamin as it is rapidly excreted by the kidneys (Tanphaichitr 1999), although there is some evidence that toxicity can occur with very large doses given parenterally (Jacobs & Wood 2003).

## ADVERSE REACTIONS

Thiamin is well tolerated.

## SUPPLEMENTAL FORMS

Thiamin hydrochloride is the most common form used in supplements, which consist of 89% thiamin and 11% HCl.

Benfotiamine is an *Allium*-derived, lipid-soluble derivative of thiamin that has better bioavailability than water-soluble salts. It is the preferred form in the treatment of alcoholic and diabetic neuropathies (Ang et al 2008, Stracke et al 1996) where supplementation with thiamin or benfotiamine in rat models revealed that equivalent doses of thiamin have a fivefold lower bioavailability than benfotiamine. Its higher cellular bioavailability is due to the thiazole ring that allows easier passage across cell membranes (Balakumar et al 2010).

Oral supplements are non-toxic, but should be used with caution in patients with cancer (Comin-Anduix et al 2001). (See [Tumour proliferation](#) section, above, and [Cancer](#) section, below.)

## SIGNIFICANT INTERACTIONS

### Antibiotics

Antibiotics can reduce the endogenous production of B group vitamins by gastrointestinal flora, theoretically resulting in lowered B vitamin levels. The clinical significance of this is unclear — increase intake of vitamin B<sub>1</sub>-rich foods or consider supplementation.

### Coffee, tea, blueberries, red cabbage and Brussels sprouts

Reduce the absorption of oral thiamin — separate doses by 2 hours (Groff & Gropper 2009).

### Vitamin C and citric acid

May enhance oral bioavailability of thiamin (Gropper & Smith 2013).

### Iron

Iron precipitates thiamin, thereby reducing its absorption — separate doses by 2 hours.

### Loop diuretics

Chronic use may result in lowered levels of vitamin B<sub>1</sub> — increase intake of vitamin B<sub>1</sub>-rich foods or consider long-term supplementation.

### Other B vitamins

Thiamin deficiency commonly occurs in conjunction with poor B<sub>2</sub> and B<sub>6</sub> status (Jacobs & Wood 2003).

### Sulfites

Concomitant intake may inactivate thiamin, which has been reported in TPN solutions (Bowman & Nguyen 1983).

### Tannins

Tannins precipitate thiamin, thereby reducing its absorption — separate doses by 2 hours.

### Horsetail (*Equisetum arvense*)

Theoretically, horsetail may destroy thiamin in the stomach due to the presence of a thiaminase-like compound found in the herb. Those who have a pre-existing thiamin deficiency or are at risk of thiamin deficiency may be advised to avoid concurrent use of horsetail (Shils et al 2005).

## CONTRAINDICATIONS AND PRECAUTIONS

### Cancer

There is some evidence of thiamin being associated with nucleic acid ribose synthesis of tumour cells in its biologically activated form (Boros 2000). In a metabolic control analysis in vivo in mice, a high stimulatory effect was observed with thiamin doses of 25 times the RDA on tumour growth of 164%, when compared to controls. However, in the same study, when thiamin supplementation was 2500 times the RDA for mice, the opposite effect was

observed and a 10% inhibition of tumour growth was recognised (Comin-Anduix et al 2001).

As such, whether thiamin has any effect on tumour formation in humans remains unclear.

## PREGNANCY USE

Safe during pregnancy and lactation.

### Practice points/Patient counselling

- Thiamin is necessary for healthy functioning and is involved in carbohydrate and protein metabolism, the production of DNA and several neurotransmitters and nerve and muscle functions.
- Supplements are used to treat deficiency or prevent secondary deficiency in people at risk (e.g. alcoholism, malabsorption syndromes, hyperemesis, chronic diarrhoea, hyperthyroidism, pregnancy, lactation, fever, acute infection, folate deficiency, strenuous physical exertion, breastfeeding, adolescent growth, severe liver disease and chronic use of loop diuretics). There is a higher incidence of deficiency in people with CHF; however, it is not known whether correction of the deficiency will improve disease symptoms.
- High-dose thiamin supplements relieve symptoms of dysmenorrhoea, according to one large randomised controlled trial.
- Additionally, some early research has found an association between AD and low plasma thiamin levels, with supplementation producing some benefits; however, further investigation is still required.
- Some research has also suggested a potential use for thiamin in the improvement of vibration perception, motor function, pain and coordination associated with peripheral neuropathy. Further research is necessary.
- Oral supplements are non-toxic, but high doses should be used with caution in patients with cancer.

## ! PATIENTS' FAQs

### What will this vitamin do for me?

Thiamin is necessary for healthy functioning and is involved in carbohydrate and protein metabolism, the production of DNA and several brain chemicals and nerve and muscle functions. Supplements are taken to avoid deficiency states that can occur, for instance, in alcoholism, extreme vomiting, chronic diarrhoea or malabsorption syndromes. In high doses, it may relieve symptoms of painful menstruation and may be a useful adjunct in CHF.

### When will it start to work?

Thiamin supplements can have dramatic effects on deficiency states within 24 hours. The response time for other conditions, such as dysmenorrhoea and CHF, also appears to be reasonably fast. Within two

menstrual cycles, supplementation produced marked reductions in dysmenorrhoea, and CHF patients treated for only 7 weeks showed positive responses.

### ***Are there any safety issues?***

Taken orally, thiamin is considered non-toxic. People with cancer should consult with their doctor before taking high-dose thiamin supplements.

## Vitamin B<sub>2</sub> — riboflavin

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Riboflavin was first discovered in 1917 and was originally referred to as vitamin G in the United States. Its name reflects both its structure and colour: *ribo* refers to the presence of a ribose-like side chain, and *flavus* is Latin for yellow (Groppe & Smith

2013). Structurally, it consists of a flavin isoalloxazine ring and a sugar alcohol side chain, ribitol.

Riboflavin is a water-soluble B group vitamin that is sensitive to light (including sunlight) and alkali conditions. It is resistant to heat, oxidation and acid; therefore most means of sterilisation, canning and cooking do not affect the riboflavin content of foods (Combs 2012).

Dietary B<sub>2</sub> occurs in three forms: flavin adenine dinucleotide (FAD), flavin mononucleotide (FMN) and riboflavin phosphate (see [Food sources](#) section, below). Prior to absorption these forms must all be freed to riboflavin, which requires specific gastrointestinal phosphatase enzymes for these conversions.

Riboflavin uptake occurs mainly in the proximal part of the small intestine and involves a specialised, saturable, energy-dependent, Na<sup>+</sup>-independent carrier-mediated system, riboflavin transporter 2 (RFT2). Adaptive changes alter the number and/or activity of carriers, e.g. when large pharmacological doses of riboflavin are ingested, absorption occurs via simple diffusion. Approximately 95% of riboflavin from food is absorbed ([Food and Nutrition Board 1998](#)). There is evidence that bioavailability is optimal at 25 mg peak plasma levels, and doses in excess of this are poorly absorbed.

Absorption is enhanced by the presence of bile and the consumption of fresh foods and impeded by the presence of divalent metals (zinc, iron, copper and manganese), whereas alcohol has an inhibitory effect.

Once absorbed, much of the riboflavin is converted back into one of its active forms, as a component of two primary coenzymes, FAD (40%) and FMN (10%). Both of these belong to the class known as the flavin coenzymes (flavoenzymes, flavoproteins), which are active in redox reactions involving hydrogen transfer and consequently important for the body's energy production. The various forms are transported in blood by plasma proteins, including albumin, fibrinogen and immunoglobulins ([Gropper & Smith 2013](#)). Free riboflavin is the form that crosses most cell membranes and, in the case of the liver, calcium or calmodulin regulates riboflavin uptake. The liver, kidneys and heart contain the greatest concentrations of riboflavin.

## FOOD SOURCES

There are two sources of riboflavin: dietary and bacterial; the latter, produced by normal gastrointestinal microflora, is dependent upon the type of diet consumed, with higher synthesis resulting from intake of vegetable-based diets than from meat-based diets ([Said 2004](#)).

Riboflavin is found in a wide variety of foods, especially those of animal origin. Milk and milk products such as cheese are thought to contribute the most dietary riboflavin, providing about one-half of total intake ([Combs 2012](#), [Gropper & Smith 2013](#)). Other main food sources are organ meats, especially liver, eggs, legumes, yeast products (including Vegemite), almonds, wheatgerm, wild rice and mushrooms. It is also found to a lesser extent in fruits, vegetables and cereal grains. Refined grains are enriched with riboflavin due to its loss from the milling process that removes the bran and germ, resulting in a loss of about two-thirds of the riboflavin content ([Gropper & Smith 2013](#)). Maximum loss during cooking is 75% ([Wahlqvist 2002](#)).

Milk, eggs and enriched cereal grains contain either free or protein-bound riboflavin, while in most other foods it predominantly exists as its coenzyme derivatives or phosphorus-bound riboflavin.

## DEFICIENCY SIGNS AND SYMPTOMS

Acute deficiency of riboflavin, known as ariboflavinosis, seldom occurs in isolation and is usually associated with a deficiency of other B group vitamins ([Gropper & Smith 2013](#)).

### Primary deficiency

Primary deficiency is associated with inadequate dietary intake, such as vegetarianism and poor consumption of milk and other animal products ([Combs 2012](#)). Primary deficiency is reported to be more common in the elderly and adolescent girls.

### Secondary deficiency

Secondary deficiencies can develop in chronic diarrhoea, liver disease, chronic alcoholism, alcohol and drug use, including use of the oral contraceptive pill, adrenal or thyroid hormone insufficiency, hyperthyroid, anorexia nervosa and postoperative situations in which total parenteral nutrition solutions lack riboflavin. In most cases, riboflavin deficiency is accompanied by other vitamin deficiencies, such as deficiencies of vitamin B<sub>6</sub>, niacin and folic acid. Drugs that impair riboflavin absorption or utilisation by inhibiting the conversion of the vitamin to the active coenzymes include tricyclic antidepressants, chemotherapy drugs and psychotropic agents. There is also evidence suggesting an apparent increase in riboflavin requirements with increased physical exercise.

### Signs and symptoms of deficiency

The body's 'storage capacity' is sufficient to provide riboflavin for 2–6 weeks when riboflavin is inadequate.

Initial symptoms of riboflavin deficiency are often non-specific and include weakness, fatigue, mouth pain, angular stomatitis, cheilosis and personality changes. In animals, general signs of anorexia, impaired growth and reduced efficiency of feed utilisation have occurred.

Clinical symptoms of deficiency appear after 3–4 months of inadequate intake. Because of the fundamental role of riboflavin in metabolism, deficiency manifestations initially occur in tissues with high and rapid cellular turnover, such as epithelial tissue and skin ([Combs 2012](#)). This will account for many of the early deficiency signs, including:

- Angular stomatitis, cold sores and cheilosis
- Glossitis (inflammation of the tongue), magenta tongue ([Lo 1984](#))
- Red or bloody (hyperaemic) and swollen (oedematous) mouth or oral cavity
- Failure to grow in children
- Ocular and visual disturbances, with symptoms such as burning, itching, sensitivity to light and conjunctivitis

- Scaly and greasy dermatitis affecting the nasolabial folds, ears, eyelids, scrotum and labia majora (Lo 1984)
- Inflammatory skin conditions — desquamative dermatitis, seborrhoeic dermatitis
- Hair loss
- Poor wound healing
- Anaemia
- Peripheral nerve dysfunction (neuropathy).

### MAIN ACTIONS

Riboflavin is involved in many different biological processes and is essential for maintaining health. The flavoproteins are central to carbohydrate, protein and lipid metabolism, are involved in adenosine triphosphate production, and are essential for immune function, tissue repair processes and general growth (required for the healthy growth of skin, nails and hair). Riboflavin extends the life of red blood cells and plays a key role in fatty acid oxidation and the metabolism of several other B vitamins. In particular, riboflavin activates vitamin B<sub>6</sub> and folate, which are essential cofactors in neurotransmitter formation and metabolism (Gropper & Smith 2013).

### Coenzyme functions

Riboflavin exerts its functions as two flavin enzymes (flavoenzymes), FAD and FMN. These coenzymes are essential in carbohydrate, amino acid and lipid metabolism.

Flavoenzymes exhibit a range of redox potentials, acting as oxidising agents because of their ability to accept a pair of hydrogen atoms (Gropper & Smith 2013). Consequently, FMN and FAD function as coenzymes in cellular antioxidant protection and for a variety of oxidative enzyme systems (Combs 2012). Riboflavin increases intracellular levels of reduced glutathione (an essential antioxidant in itself) and maintains the glutathione redox cycle as part of the FAD-dependent enzyme glutathione reductase (Combs 2012). Other flavoproteins provide reducing equivalents to neutralise reactive oxygen species (free radicals).

### CLINICAL USE

A number of clinical trials have been conducted in which patients presenting with different conditions have subsequently been found to have riboflavin deficiency. Treating the deficiency in some of these cases has been shown to improve the initial presenting condition.

### Wound healing

Riboflavin deficiency lengthens the time to epithelialisation of wounds, slows the rate of wound contraction and reduces the tensile strength of incision wounds in vivo. Total collagen content is also significantly decreased, suggesting riboflavin deficiency will slow down wound-healing rate (Lakshmi et al 1989).

### Migraine headaches: prophylaxis

Three clinical studies of varying design have found that treatment with high-dose riboflavin (400 mg) can reduce the frequency of migraines; however, one double-blind study that used it in combination with magnesium and feverfew failed to show any superior effects over low-dose riboflavin (25 mg) alone.

The first was an open pilot study testing the effects of 400 mg riboflavin over 3 months in 49 patients. The mean global improvement after therapy was 68.2% (Schoenen et al 1994). Based on these results, a second study with 55 subjects was conducted using a 3-month, randomised, placebo-controlled design, with similar positive findings (Schoenen et al 1998). Riboflavin treatment produced positive results, with 59% of the treatment group experiencing a reduction in migraine frequency of at least 50%. Using an intention-to-treat analysis, riboflavin was superior to placebo in reducing attack frequency ( $P = 0.005$ ) and headache days ( $P = 0.012$ ) and the number needed to treat for effectiveness was 2.3. More recently, a 2004 open-label study retested the same high dose of vitamin B<sub>2</sub> over 6 months, once again producing a significant reduction in headache frequency, from 4 days/month at baseline to 2 days/month after 3 and 6 months of treatment ( $P < 0.05$ ). Use of abortive drugs reduced from 7 units/month to 4.5 units/month; however, the duration and intensity of each episode did not change significantly (Boehnke et al 2004).

Finally, a randomised, double-blind, controlled study using a combination of vitamin B<sub>2</sub> (400 mg), magnesium (300 mg) and feverfew (100 mg) failed to show benefits over riboflavin 25 mg alone, with both groups experiencing comparable significant reductions in number of migraines, migraine day and migraine index; however, in neither group was frequency successfully reduced by more than 50%, which was the primary outcome (Maizels et al 2004). Interestingly, the response obtained was greater than the placebo response reported in other migraine prophylaxis trials.

A Cochrane review intervention protocol (Exposito et al 2009) states there is no single theory or hypothesis that can explain all the phenomena that occur with migraines; therefore the manner in which riboflavin might prevent migraine headaches is also not clear (Bajwa & Sabahat 2008, as cited in Exposito et al 2009). Despite this, it is frequently suggested that where mitochondrial dysfunction and impaired metabolism are causal in migraine pathogenesis, riboflavin appears to be useful in its management (Maizels et al 2004, Markley 2012, Sandor 2005, Schoenen et al 1998). High-dose riboflavin assists in promoting cellular mitochondrial metabolism, thereby improving some headache symptomatology (Woolhouse 2005). These studies are important, as riboflavin displays high tolerance with a high index of safety and relatively few side effects.

### Migraine prophylaxis in children

The first study to evaluate the efficacy of riboflavin for migraine prophylaxis in children was a randomised, double-blind study of 200 mg/day versus placebo in 48 children. No differences were found in primary efficacy measure (number of patients achieving a 50% or greater reduction in the number of migraine attacks per 4 weeks) nor secondary outcome measures (mean severity of migraine per day, mean duration of migraine, days with nausea or vomiting, analgesic use and adverse effects). The authors concluded that riboflavin is not an effective therapy for preventing migraine in children. A high placebo responder rate was also seen, with implications for other studies of paediatric migraine (MacLennan et al 2008). Similar negative findings were produced in another small study by Bruijn et al (2010); however, the authors did find a significant difference ( $P = 0.04$ ) in the reduction of mean frequency of tension-type headaches in favour of riboflavin treatment.

A retrospective study of migraine prophylaxis in 41 paediatric and adolescent patients, who received higher riboflavin doses (200 or 400 mg/day for 3, 4 or 6 months), however, reported significantly decreased attack frequency and intensity ( $P < 0.01$ ) during treatment. Additionally, during follow-up, 68.4% of cases had a 50% or greater reduction in frequency of attacks and 21% in intensity. The authors concluded riboflavin to be a well-tolerated, effective and low-cost prophylactic treatment in children and adolescents suffering from migraine (Condo et al 2009).

From these studies, it is perhaps evident that riboflavin has a positive prophylaxis effect in the reduction of attack frequency and intensity with higher doses (200–400 mg) combined with longer treatment times (more than 4 weeks). The effect of taking a daily riboflavin supplement from the adult studies was maximal after 3 months (Breen 2003). It would suggest further studies of longer duration are required.

### Comparative trial

A 4-month clinical trial comparing riboflavin supplementation (400 mg/day) with beta-adrenergic antagonists (metoprolol 200 mg/day and bisoprolol 10 mg/day) found that both treatments significantly decreased the frequency of migraine headache and improved the clinical symptoms of migraine headache (Sandor et al 2000). Analysis of their effects on cortical potentials showed that the two treatments achieve these results by working through different mechanisms.

### Age-related cataract prevention

Cataract was shown to be associated with riboflavin deficiency in animals in the 1930s and subsequently with deficiencies of amino acids, vitamins and some minerals (Wynn & Wynn 1996). This has been confirmed in human studies, in which lens opacities

#### Clinical note — Causes of migraine

Numerous theories exist to explain the underlying pathology of migraine headache. One theory proposes a deficit of mitochondrial energy metabolism, as patients with migraine show decreased brain mitochondrial energy reserve between attacks. Interestingly, patients with mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes (MELAS) exhibit impaired mitochondrial energy metabolism, producing migraine-like headaches, which are in part ameliorated by prophylactic B<sub>2</sub> (Magis et al 2007).

Accordingly, riboflavin coenzyme Q10 and lipoic acid, as enhancers of mitochondrial energy efficiency, have been tested for prophylactic activity in migraine and appear to be promising agents (Magis et al 2007, Markley 2012, Schoenen et al 1994). Recent studies in experimental models add to our knowledge of the actions of riboflavin in migraine, with confirmation that it produces antinociception and anti-inflammatory effects. The analgesic activity observed is independent of opioid mechanisms (Granados-Soto et al 2004).

#### Clinical note — Age-related cataract and antioxidants

Age-related cataract is an important public health problem, because approximately 50% of the 30–50 million cases of blindness worldwide result from leaving the condition untreated (Jacques 1999). The mechanisms that bring about a loss in transparency include oxidation, osmotic stress and chemical adduct formation (Bunce et al 1990). Besides traditional risk factors such as diabetes, nutrient deficiency is also being considered, particularly nutrients with antioxidant properties.

have been associated with lower levels of riboflavin, vitamins A, C and E, iron and protein status (Leske et al 1995, Mares-Perlman et al 1995).

Glutathione reductase is a key enzyme involved in lens protection. Riboflavin levels indirectly influence glutathione reductase activity, increasing the ability of the lens to deal with free radical formation (Head 2001). One study documented severe glutathione reductase deficiency in 23% of human lens epithelium specimens, possibly reflecting a dietary deficiency of riboflavin (Straatsma et al 1991). Another study found that a significant number of people with cataracts have inactive epithelial glutathione reductase (Horwitz et al 1987).

A large cross-sectional survey of 2873 volunteers aged 49–97 years detected a link between dietary vitamin supplement and a lower incidence of both nuclear and cortical cataract. Vitamin A, niacin,

riboflavin, thiamine, folate and vitamin B<sub>12</sub> all appeared to be protective, either in isolation or as constituents of multivitamin preparations (Kuzniarz et al 2001).

A sample of 408 women from the Nurses' Health Study aged 52–74 years at baseline participated in a 5-year study that assessed nutrient intake and the degree of nuclear density (opacification). Findings revealed that the geometric mean 5-year change in nuclear density was inversely associated with the intake of riboflavin ( $P = 0.03$ ) and thiamin ( $P = 0.04$ ), and most significantly with the duration of vitamin E supplement use ( $P = 0.006$ ) (Jacques et al 2005).

The evidence currently suggests that higher intakes of riboflavin protect against the progression of age-related lens opacification.

### Congestive heart failure

A recent review of micronutrients in heart failure summarised several observational studies investigating riboflavin status (McKeag et al 2012). While the authors state the results are inconclusive, one recent study they included produced significant findings. This study measured riboflavin and pyridoxine levels in 100 patients with heart failure (as defined by Framingham criteria). The percentage of individuals with evidence of riboflavin deficiency was 27% (erythrocyte glutathione reductase activity coefficient >1.2) and this was significantly higher in patients with heart failure compared with controls (27.0% vs 2.2%;  $P = 0.001$ ) (Keith et al 2009). More research needs to be conducted in this area to determine if this could be a cause or consequence of the disease.

#### **Clinical note — Vitamin B<sub>2</sub> deficiency and protracted malaria recovery?**

In a study of 35 of 64 children suffering malarial infection, riboflavin was assessed by measuring erythrocyte glutathione reductase activity (Das et al 1988). Interestingly, in the riboflavin-deficient group, the median parasite count was in fact lower than the non-deficient group; however, the correlation between activity coefficient and parasite count was significant ( $R = -0.49$ ). Therefore the recovery process was slower in the deficient group, even though they had a relatively lower parasite count. The authors have thus inferred that riboflavin deficiency leads to inhibition of growth and multiplication of plasmodia. Its beneficial effects in malaria infection need further evaluation.

### Anticarcinogenesis

Riboflavin deficiency may cause protein and DNA damage and prevent cellular differentiation in the G1 phase of cellular division, according to cell culture studies (Manthey et al 2006, as cited by Gropper & Smith 2013).

Riboflavin deficiency has been reported to enhance carcinogenesis (Combs 2012). In a rat study the formation of single-strand breaks in nuclear DNA was more pronounced on a riboflavin-deficient diet compared to that on a normal diet (Webster et al 1973). The introduction of riboflavin reversed this trend. The authors suggest that, as DNA damage and its altered repair may relate to carcinogenesis, modulation of these parameters by riboflavin suggests a potential chemopreventive role for this vitamin.

The proposed mechanism of action is that a decrease in riboflavin produces a reduction in antioxidant protection, increasing the activation of carcinogens and oxidative DNA damage. While clinical data relative to this possibility are few, recently an inverse relationship has been found between riboflavin status and cancer risk in three observational studies (de Vogel et al 2008 as cited by Combs 2012). The cancers were specifically oesophageal squamous cell cancer and colorectal cancer. More research is required in these areas.

### Breast cancer

The majority of studies investigating the protective role of B vitamins in breast cancer have focused on folate, B<sub>6</sub> and B<sub>12</sub>. Several case-controlled studies have reported protective associations (Chen et al 2005, Lajous et al 2006, Larsson et al 2007, Yang et al 2013), while cohort studies have shown inconsistent results (Cho et al 2007, Ericson et al 2007, Shrubsole et al 2011, Stevens et al 2010). Two of these studies also included an investigation of the role of riboflavin and found no risk reduction with B<sub>2</sub> (Shrubsole et al 2011, Yang et al 2013).

#### Breast cancer — adjunctive treatment to tamoxifen

Riboflavin's importance is recognised in a range of terminal disease states, most notably in breast cancer, where its cellular absorption is significantly enhanced (Bareford et al 2008). Based on its established antioxidant properties, its role in maintaining epithelial integrity, and its influence on prostaglandin synthesis and glutathione metabolism (Premkumar et al 2008a), vitamin B<sub>2</sub> (10 mg) has been tested in combination with coenzyme Q10 (100 mg) and niacin (50 mg) (known as CORN) together with tamoxifen in breast cancer patients. The results have consistently demonstrated augmenting actions — enhanced manganese superoxide dismutase expression, resulting in prevention of cancer cell proliferation (Premkumar et al 2008b), reduction of lipid peroxides (which are elevated in breast cancer and associated with tumour promotion) (Yuvaraj et al 2008), reduced tumour markers carcinoembryonic antigen (CEA) and CA15-3 and reduced serum cytokines (interleukin-1 [IL-1]-beta, IL-6, IL-8, tumour necrosis factor-alpha and vascular endothelial growth factor) (Premkumar et al 2008a). In addition to this, CORN supplementation reduced proangiogenic markers, with a corresponding increase in antiangiogenic markers. Given that the growth and

metastasising capacity of any tumour (but particularly of breast tumours) are dependent upon angiogenesis, this could represent a means to improved prognoses (Premkumar et al 2008a). Finally, CORN supplementation was shown to moderate some of the negative side effects of tamoxifen treatment, with normalisation of lipid and lipoproteins following 90 days of treatment in postmenopausal breast cancer patients (Yuvaraj et al 2007).

**Clinical note — Riboflavin carrier protein: a new marker to predict breast cancer**

Interestingly, studies have shown that riboflavin carrier protein (RCP), an oestrogen-inducible protein that occupies a key position in riboflavin metabolism, is elevated in women with breast cancer. Oestrogen-inducible proteins such as RCP are upregulated and secreted into circulation in animal models and in women with neoplastic breast disease (Karande et al 2001). In a prospective blinded study, serum RCP levels were significantly elevated in women with breast cancer ( $n = 52$ ) as compared with control subjects ( $n = 50$ ;  $6.06 \pm 7.27$  ng/mL vs  $0.70 \pm 0.19$  ng/mL [mean  $\pm$  SD], respectively;  $P < 0.0001$ ). Furthermore, a serum RCP level of  $\geq 1.0$  ng/mL was highly predictive of the presence of breast cancer, detecting 88% of tumours in stages I–II and 100% of tumours in stages III–IV (Rao et al 1999). In another double-blind study, pre- and postmenopausal women with clinically diagnosed early and advanced breast cancer were compared with controls. This study also revealed that serum RCP levels in cycling breast cancer patients were three- to fourfold higher ( $P < 0.01$ ) than in normal counterparts (Karande et al 2001). This difference in circulatory RCP levels is further magnified to nine- to 11-fold ( $P < 0.005$ ) at the postmenopausal stage. Additionally, rising RCP levels are positively correlated with disease progression, as significantly higher RCP concentrations ( $P < 0.005$ ) are encountered in patients with advanced (compared with early) metastasising breast cancer. A more recent study also noted elevated levels of RCP in breast cancer pathways, and the authors suggest it as a new marker to predict early-stage breast cancer (Shigemizu et al 2012). The current research is not suggesting any clear role, either preventive or causative, of riboflavin and breast cancer.

**Role in folate and pyridoxine metabolism and the methylation pathologies**

Effective one-carbon metabolism relies on nutrients beyond folate, B<sub>6</sub> and B<sub>12</sub> — most notably B<sub>2</sub>, which, although attracting significantly less research attention, is critical. Riboflavin, as FAD, is the cofactor for methylenetetrahydrofolate reductase (MTHFR),

a key enzyme of the folate activation pathway, catalysing the interconversion of 5,10-methylene tetrahydrofolate and 5-methyltetrahydrofolate-converting folate into its active form (Bates 2013, Powers 2003, 2005, Sharp et al 2008). Consistent with this, there is emerging evidence of substantial interplay between folate and riboflavin in conditions previously associated principally with folate deficiency or ameliorated by folate treatment. For example, plasma levels of vitamin B<sub>2</sub> and homocysteine have been shown to correlate; that is, high homocysteine levels have in fact been found to be low in subjects with low riboflavin status (Combs 2012, de Vogel et al 2008, Ganji & Kafai 2004), especially in individuals with the MTHFR C677T genotype (McNulty et al 2006).

Of several single-nucleotide polymorphisms affecting MTHFR, the best known are the C699T and A1298C variants. The first displays thermolability and lowered reductase activity exaggerated by the loss of FAD cofactor (Allen & Prentice 2013). Preliminary studies employing combinations of folate (400 mcg) and riboflavin (5 mg) have demonstrated improved efficacy over folate alone, for example in colorectal cancer (Powers 2005).

Additionally, high doses of folate alone have been reported to modestly but significantly reduce vitamin B<sub>2</sub> levels (Powers 2005). Taken together with the knowledge that riboflavin is central to pyridoxine metabolism (McCormick 2000), there is growing interest in the therapeutic potential of riboflavin in pathologies associated with poor methylation.

**Fertility and pregnancy**

Fetal and embryonic development require adequate riboflavin status (Karande et al 2001). In a 2010 study of mice, low dietary riboflavin status negatively affected embryonic growth and cardiac development (Chan et al 2010), with a greater incidence of delayed embryos and lower embryonic weights ( $P < 0.05$ , two-factor analysis of variance). The number of embryos with ventricular septal defects was significantly greater in the riboflavin-deficient mice ( $P < 0.005$ , Fisher's exact test).

Similarly, in humans, a case-controlled family study of 276 mothers of children with congenital heart defects has shown that mothers consuming a diet high in saturated fat and low riboflavin and niacin during the preconception period markedly increased the risk of congenital heart defects in the offspring (Smedts et al 2008). Thus, it has been extrapolated that ensuring adequate riboflavin status during preconception and pregnancy may prevent such complications.

A prospective cohort study of 1461 pregnancies found that low-birth-weight offspring are more common in women consuming diets low in vitamin C, riboflavin, pantothenic acid and sugars, even after adjustment for deprivation index, smoking, marital status and parity (Haggarty et al 2009).

### Postpartum depression (PPD)

A prospective study of 865 Japanese women investigated the role of riboflavin consumption during pregnancy with risk of PPD (Miyake et al 2006). In this study, PPD was identified when subjects had an Edinburgh Postnatal Depression Scale score of  $\geq 9$  between 2 and 9 months postpartum. A total of 121 developed PPD and the results indicated that riboflavin adequacy reduced the risk of PPD (multivariate odds ratio 0.53, 95% confidence interval 0.29–0.95,  $P_{\text{trend}} = 0.55$ ). The authors concluded that moderate consumption of riboflavin may be protective, e.g. 10–50 mg/day.

### Pre-eclampsia

In a prospective study, 154 women at increased risk of pre-eclampsia were observed until delivery (Wacker et al 2000). Riboflavin deficiency was consistently found in 33.8%. The incidence of deficiency rose towards the end of the pregnancy, from 27.3% at 29–36 weeks' gestation compared with 53.3% at over 36 weeks. In the riboflavin-deficient group, mothers were 28.8% more likely to develop pre-eclampsia than in the riboflavin-adequate group (7.8%;  $P < 0.001$ , odds ratio 4.7). The authors concluded that riboflavin deficiency should be considered a possible risk factor for pre-eclampsia.

However, these results were not duplicated in a randomised, placebo-controlled, double-blind trial where a protective effect was not demonstrated in high-risk pregnant women supplemented with 15 mg of riboflavin (Neugebauer et al 2006). Such variability in results may be due to differences in study design and, in this study, the supplemental dose may be inadequate given that therapeutic levels of riboflavin ranges are 10–200 mg.

### Sickle cell anaemia

Riboflavin supplementation (5 mg twice daily for 8 weeks) in patients with sickle cell anaemia resulted in improved haematological measurements compared with controls, suggesting that riboflavin enhances erythropoiesis (Ajayi et al 1993).

### Rheumatoid arthritis

One study has suggested that patients with higher pain scores and active disease are at significantly greater risk of riboflavin deficiency than those with inactive disease (Mulherin et al 1996). In this study of 91 patients, pain score, articular index, C-reactive protein and erythrocyte sedimentation rate were all increased in those patients exhibiting riboflavin deficiency (all  $P < 0.02$ ). It is unclear whether riboflavin deficiency influences pain threshold or is a result of the disease.

### Osteoarthritis

B vitamins were investigated for reducing sensitivity to painful stimuli in mice (Franca et al 2001), whereby thiamin and pyridoxine (50–200 mg/kg,

intraperitoneally [IP]) or riboflavin (3–100 mg/kg IP) induced an antinociceptive effect, not changed by naloxone (10 mg/kg IP). The authors state the B vitamins' antinociceptive effect may involve inhibition of the synthesis and/or action of inflammatory mediators. Furthermore, in an animal study the therapeutic effects of glucosamine hydrochloride and chondroitin sulfate as chondroprotective were enhanced by the addition of fursultiamine, a thiamine derivative, in the treatment of osteoarthritis (Kobayashi et al 2005).

### OTHER USES

Riboflavin is also used to treat carpal tunnel syndrome and acne, although only case reports are available (Folkers et al 1984).

### HIV/AIDS

A decreased progression of HIV to AIDS has been found in patients replete with vitamins B and C (Tang et al 1993).

### DOSAGE RANGE

- Migraine prevention: 400 mg/day, taken for at least 3 months.
- Treating deficiency states: 10–20 mg/day until symptoms resolve or B<sub>2</sub> assays improve.
- Therapeutic levels: 10–200 mg/day.
- As an adjunct to tamoxifen in breast cancer treatment: 10 mg/day together with coenzyme Q10 100 mg/day and niacin 50 mg/day — based on preliminary evidence.
- Postpartum depression: 10–50 mg/day may be protective in at risk women.

### Australian recommended dietary intake

#### <70 years

- Women: 1.1 mg/day.
- Men: 1.3 mg/day.

#### >70 years

- Women: 1.3 mg/day.
- Men: 1.6 mg/day.

Intake of vitamin B<sub>2</sub> causes a characteristic bright yellow-orange discolouration to urine.

### TOXICITY

Riboflavin is considered an extremely safe supplement. Even at the high doses (e.g. 400 mg) used in some trials, no adverse effects are noted and riboflavin remains non-toxic.

### ADVERSE REACTIONS

General side effects noted in trials using high doses were reasonably uncommon, but included diarrhoea and polyuria (Bianchi et al 2004). One case of anaphylaxis has been reported (Ou et al 2001).

### SIGNIFICANT INTERACTIONS

Certain medicines can increase the body's requirements for riboflavin.

## Antibiotics

Antibiotic drugs can reduce endogenous production of B group vitamins — increase intake of vitamin B<sub>2</sub>.

## Oral contraceptive pill

The oral contraceptive pill may increase demand for vitamin B<sub>2</sub> (Pelton et al 2000) — consider increasing intake with long-term use.

## Tricyclic antidepressants

Reduce the absorption of riboflavin — may increase riboflavin requirements (Pelton et al 2000).

## Amitriptyline

Increases the renal excretion of riboflavin (Bianchi et al 2004) — consider increased dietary intake with long-term use.

## CONTRAINDICATIONS AND PRECAUTIONS

None known.

## PREGNANCY USE

Considered safe.

### Practice points/Patient counselling

- Vitamin B<sub>2</sub> deficiency signs include poor wound healing, hair loss, greasy dermatitis, ocular disturbances, failure to grow in children, angular stomatitis, cold sores, cracked lips and magenta tongue.
- Besides inadequate intake, deficiency can also result from chronic diarrhoea, liver disease and chronic alcoholism.
- There is some evidence suggesting that high-dose supplements (400 mg daily) significantly reduce the frequency of migraine headaches.
- Preliminary evidence suggests that regular supplementation with a multivitamin may also reduce the risk of developing cataracts.
- Supplementation results in a characteristic yellow-orange discolouration of urine.

## PATIENTS' FAQs

### What will this vitamin do for me?

Vitamin B<sub>2</sub> is essential for health and is involved in many different biochemical processes in the body. Research has suggested that, when taken in high doses, it can significantly reduce the incidence of migraine headaches.

### When will it start to work?

Deficiency is reversed rapidly with supplementation. If using riboflavin to prevent migraine headaches, 3–4 months' treatment is required to see significant effects.

### Are there any safety issues?

The vitamin is considered a safe nutrient.

## Vitamin B<sub>5</sub> — pantothenic acid

### BACKGROUND AND RELEVANT PHARMACOKINETICS

The Greek word *pantos* means ‘everywhere’. As the name pantothenic acid implies, B<sub>5</sub> is widely distributed, present in nearly all plant and animal foods. Relatively unstable, it is sensitive to heat, freezing, canning and cooking and both acid and alkali, and considerable amounts are lost through the milling of cereal grains. The intestine is exposed to two sources of pantothenic acid: dietary and bacterial. Current research suggests that bacterial synthesis

may be more dominant and important in ruminant species (Bates 1998).

Pantothenic acid is absorbed in the jejunum by passive diffusion at high concentrations, but at low concentrations it requires a sodium-dependent multivitamin transporter. Both biotin and lipoic acid share the multivitamin transporter. A study of placental tissue demonstrated that biotin uses the same transport mechanisms as pantothenic acid, which may indicate competition between these two nutrients in other tissues (Bates 1998).

Between 40% and 63% of pantothenic acid is bioavailable from the gastrointestinal tract, an amount that decreases to 10% when doses 10-fold greater than the recommended daily intake are taken (Gropper & Smith 2013). Rapid absorption seems to occur after oral doses, and increased tissue levels of coenzyme A (CoA) and other metabolites can occur within 6 hours. In leucocytes both CoA and pantothenic acid levels increase between 6 and 24 hours following oral ingestion (Kelly 2011).

In circulation, pantothenic acid is primarily found intracellularly in the red blood cells with a small amount in plasma. Organ uptake is via the same sodium-dependent multivitamin transporter and it is found as pantothenic acid, 4-phosphopantothenic acid and pantetheine in cells (Gropper & Smith 2013). The organ with the highest concentration of pantothenic acid is the liver, followed by the adrenal cortex, which reflects the large requirements of these tissues and is indicative of the biochemical role of the vitamin's coenzyme derivatives. There are contrasting opinions about whether a genuine storage capacity exists for this vitamin; however, if there is any at all, the consensus is that pantothenic acid is 'stored' in very limited amounts and in those tissues with the greatest requirements (Groff & Gropper 2009). Most pantothenic acid is used to synthesise or resynthesise CoA, which is found in high concentrations in the liver, adrenal gland, kidneys, brain and heart (Gropper & Smith 2013).

Following its absorption into cells, it can be converted to CoA or acyl carrier proteins (ACP), both of which are essential cofactors in fatty acid synthesis (Kelly 2011).

### CHEMICAL COMPONENTS

Pantothenic acid is an amide and consists of  $\beta$ -alanine and pantoic acid joined by a peptide bond. In supplements, it is often found as calcium pantothenate.

### FOOD SOURCES

The most concentrated sources are meats (especially liver), egg yolk, broad beans, legumes and potatoes, but it is also found in many other foods, such as whole grains, milk, peanuts, broccoli, avocado, mushroom and apricots. Royal jelly from bees also provides substantial amounts (Gropper & Smith 2013). Up to 50% can be lost through cooking (Wahlqvist 2002).

Approximately 85% occurs in food as a component of CoA, which is hydrolysed to pantothenic acid or pantethine during digestion.

### DEFICIENCY SIGNS AND SYMPTOMS

Due to its widespread occurrence of pantothenate in foods, deficiencies are considered unlikely, and more often in conjunction with multiple nutrient deficiencies, as would occur in generalised malnutrition (Gropper & Smith 2013). Because pantothenic acid deficiency is so rare, most information

regarding its signs and symptoms comes from experimental research in animals or cases of severe malnutrition. The deficiency picture appears to be generalised and species-specific (Bates 1998). Preliminary studies in humans using competitive analogues of pantothenic acid have produced the following symptoms:

- 'Burning feet syndrome': this affects the lower legs and is characterised by a sensation of heat (Gropper & Smith 2013, Kohlmeier 2003, Whitney 2011)
- Vomiting, fatigue, weakness, restlessness, dizziness, sleeplessness and irritability (Gropper & Smith 2013; Kohlmeier 2003)
- Neurological disturbances (Whitney et al 2011)
- Gastrointestinal disturbances, ulcers, abdominal distress (Hechtman 2012, Whitney et al 2011)
- Muscular weakness, burning cramps, paraesthesia (tingling sensation of toes and feet) (Hechtman 2012, Kohlmeier 2003)
- Loss of immune (antibody) function and increased susceptibility to infections (Kohlmeier 2003)
- Dermatitis, achromotrichia, alopecia (The Vitamins 2012)
- Adrenal hypofunction, with an inability to respond appropriately to stress. In late-stage deficiency, the adrenals atrophy and morphological damage occurs (Kelly 2011)
- Insensitivity to adrenocorticotrophic hormone
- Increased sensitivity to insulin.

Some conditions that have been associated with increased requirements are:

- Alcoholism (due to typically low intakes of vitamin B complex) (Gropper & Smith 2013)
- Diabetes mellitus (as a result of increased excretion) (Gropper & Smith 2013)
- Inflammatory bowel diseases (due to decreased vitamin absorption) (Gropper & Smith 2013).

### MAIN ACTIONS

Pantothenic acid is involved in a myriad of important chemical reactions in the body as a result of its involvement in CoA and ACP.

#### Coenzyme function

##### CoA and the Krebs cycle

Numerous metabolic activities depend on adequate availability of pantothenate. Pantothenic acid is required for CoA synthesis and most pantothenate-dependent reactions use CoA as the universal donor and acceptor of acetyl and acyl groups (Kohlmeier 2003).

As part of CoA, pantothenate participates extensively in the metabolism of carbohydrate, lipids and protein (Gropper & Smith 2013). It plays a pivotal role in cellular respiration, the oxidation of fatty acids and acetylation of other molecules, so as to enable transportation. Together with thiamine, riboflavin and niacin, it is involved in the oxidative decarboxylation of pyruvate and alpha-ketoglutarate in the Krebs cycle and ultimately is important for energy storage and release (Gropper & Smith 2013).

### Acyl carrier protein

Pantothenic acid functions in the body as a component of the acylation factors, CoA and 4'-phosphopantetheine (the prosthetic group for ACP) (Gropper & Smith 2013, Kohlmeier 2003). A few reactions use 4'-phosphopantetheine; most of these are related to lipid synthesis (Kohlmeier 2003).

### Indirect antioxidant effects

New in vitro research supports an indirect antioxidant role for pantothenic acid through its ability to increase cellular adenosine triphosphate, which in turn creates increased levels of free glutathione and enhanced protection of cells against peroxidative damage (Slyshenkov et al 2004).

### ADRENAL CORTEX FUNCTION AND NEUROTRANSMITTER SYNTHESIS

Pantothenic acid is essential in controlling stress and the ability to cope with stressful events, due to its involvement in the synthesis of the neurotransmitter acetylcholine. It plays an important role in adrenal function and, as CoA, is needed for proper adrenal cortex function and the synthesis of steroid hormones, namely cortisone. A consistent finding in animal studies conducted in the 1950s is that a deficiency of pantothenic acid initially causes adrenal hypertrophy, followed by progressive morphological and functional changes to the adrenal gland, resulting in adrenal hypofunction and an impaired stress response (Hurley & Morgan 1952, Kelly 2011).

### Other functions

Pantothenate is required in the production of many secondary metabolites such as polyisoprenoid-containing compounds (e.g. ubiquinone, squalene and cholesterol), steroid hormones, vitamin D and bile acids, acetylated compounds such as *N*-acetylglucosamine, *N*-acetylserotonin, acetylcholine, and prostaglandins and prostaglandin-like compounds (Kelly 2011).

Pantothenic acid, thiamine, riboflavin and niacin participate in the oxidative decarboxylation of alpha-ketoglutarate to succinyl-CoA, an intermediate used with glycine to synthesise haem (Gropper & Smith 2013).

### Lipid lowering

Pantethine, a metabolite of pantothenic acid, has been investigated in several clinical studies and found to exert significant lipid-lowering activity (Coronel et al 1991, Donati et al 1986, Gaddi et al 1984), with a 2005 study producing a 50% inhibition of fatty acid synthesis and an 80% inhibition of cholesterol synthesis (McRae 2005).

The mechanism of action relates to reduced insulin resistance and activation of lipolysis in serum and adipose tissue, according to in vivo research (Naruta & Buko 2001). Additionally, inhibition of HMG-CoA reductase, as well as more distal enzymes in the cholesterol synthetic pathway, is likely to be responsible (McCarty 2001).

As part of CoA, pantothenic acid is essential for the formation of acetyl CoA, an important substrate in the catabolism of fatty acids. Fat accumulation has been shown to increase with pantothenic acid deficiency, and refeeding pantothenic acid to rats originally fed a pantothenic acid-deficient diet decreased tissue fat (Shibata et al 2013).

### Wound healing

Both oral and topical administration has been shown to accelerate closure of wounds and increase strength of scar tissue in vivo (Plesofsky 2002, Vaxman et al 1990). Both in vitro and in vivo studies reveal that topical dexpanthenol, the stable alcoholic analogue of pantothenic acid, induces activation of fibroblast proliferation, which contributes to accelerated re-epithelialisation in wound healing (Ebner et al 2002).

### CLINICAL USE

Although pantothenic acid has been investigated in some studies, most investigation has occurred with several of its derivatives, chiefly an alcoholic analogue of pantothenic acid called dexpanthenol (Bepanthen; see below) and pantethine.

### Deficiency states: prevention and treatment

Due to the widespread occurrence of pantothenate in foods, deficiencies are considered unlikely, and more often in conjunction with multiple nutrient deficiencies, as would occur in generalised malnutrition (Gropper & Smith 2013). Traditionally, pantothenic acid is recommended, together with other vitamin B complex nutrients, to treat generalised malnutrition or prevent deficiency in conditions such as alcoholism, diabetes mellitus and malabsorption syndromes (Gropper & Smith 2013). The interference from some prescription drugs (antimetabolites) may also interfere with pantothenate absorption and lead to deficiencies (Kohlmeier 2003).

### Enhances wound healing

Pantothenic acid has been both used as an oral supplement and applied topically in a cream base to enhance wound healing; it has been shown to accelerate closure of wounds and increase strength of scar tissue in experimental animals (Plesofsky 2002, Vaxman et al 1990). Furthermore, fibroblast content of scar tissue has been shown to significantly increase following injections of pantothenate (20 mg/kg of body weight/24 hours) for 3 weeks (Arahamian et al 1985). Skin dehydration and irritation have been found to be reduced with the use of dexpanthenol, a pantothenate derivative (Biro et al 2003).

Although these results are encouraging, there has been little investigation in humans. One double-blind randomised controlled trial testing the effects of vitamin C (1000 mg) and pantothenic acid (200 mg) supplements over a 21-day period showed increased fibroblast proliferation but no significant

alteration to wound healing during recovery from surgical tattoo removal (Vaxman et al 1995).

### Topical use

In a randomised, double-blind trial in Mumbai, 207 women 30–60 years of age with epidermal hyperpigmentation were recruited and randomly assigned to apply a test or control facial lotion containing 4% niacinamide, 0.5% panthenol and 0.5% tocopheryl acetate to the face daily for 10 weeks (Jerajani et al 2010). Women who used the test lotion reportedly experienced significantly reduced hyperpigmentation, improved skin tone evenness, appearance of lightening of skin and positive effects on skin texture from as early as 6 weeks. Some evidence of a beneficial effect on barrier function was also observed. The authors state that these results concur with previous positive findings for topical niacinamide (Bissett 2002, Bissett et al 2005, Draelos et al 2005, Hako-zaki et al 2002, Matts et al 2002) and panthenol (Biro et al 2003, Ebner et al 2002).

Bepanthen is a well-known dermatological preparation containing dexpanthenol, an alcoholic analogue of pantothenic acid. It has been investigated in numerous studies and found to act like a moisturiser, activate fibroblast proliferation, accelerate re-epithelialisation in wound healing, have anti-inflammatory activity against ultraviolet-induced erythema and reduce itch (Ebner et al 2002). Under double-blind study conditions, epidermal wounds treated with dexpanthenol emulsion showed a reduction in erythema, and more elastic and solid tissue regeneration. Another randomised, prospective, double-blind, placebo-controlled study published in 2003 investigated the efficacy of topical dexpanthenol as a protectant against skin irritation. The study involved 25 healthy volunteers who were treated with a topical preparation containing 5% dexpanthenol or a placebo and then exposed to sodium lauryl sulfate 2% twice daily over 26 days. Treatment with topical dexpanthenol provided protection against skin irritation, whereas a statistically significant deterioration was observed in the placebo group (Biro et al 2003).

Although Bepanthen is commonly used in radiotherapy departments to ameliorate acute radiotherapy skin reactions, a prospective study of 86 patients undergoing radiotherapy showed that topical use of Bepanthen did not improve skin reactions under these conditions (Lokkevik et al 1996). In an animal study by Dorr et al (2005), negative results were similarly obtained and it is not currently recommended for individuals undergoing radiotherapy.

### Acne vulgaris

One hundred Chinese patients diagnosed with acne vulgaris (45 males and 55 females) were given oral pantothenic acid, 10 g a day in four divided doses, and a cream consisting of 20% by weight of pantothenic acid to apply to the affected areas four to six times a day. Within 1–2 days sebum production was noticeably reduced, frequency of new acne

eruptions began to decline and existing lesions started to regress within 1–2 weeks. Patients who were categorised as suffering moderate-severity acne reported complete control of acne after 8 weeks with only occasional new eruptions, while in more severe cases complete control occurred after 6 months (Leung 1995b). The author notes that daily doses of 15–20 g/day of pantothenic acid did produce faster results in severe cases and a maintenance dose was 1–5 g/day of pantothenic acid.

Interestingly, it has been shown that dexpanthenol cream can help treat some mucocutaneous adverse reactions caused by isotretinoin, a chemotherapeutic drug used to treat acne (Romiti & Romiti 2002, as cited by Kelly 2011).

### Nasal spray

A randomised controlled trial of 48 outpatients diagnosed with rhinitis sicca anterior found that dexpanthenol nasal spray is an effective symptomatic treatment for this condition (Kehrl & Sonnemann 1998). Two years later, another randomised controlled trial compared the effects of xylometazoline-dexpanthenol nasal spray versus xylometazoline nasal spray over a 2-week period in 61 patients with rhinitis after nasal surgery (Kehrl & Sonnemann 2000); it showed that the combination of xylometazoline-dexpanthenol nasal spray was significantly superior to the other treatment and well tolerated.

More recent studies support this emerging trend and point towards a reduction in ciliary and cytotoxic effects from nasal decongestants when 5% dexpanthenol is concurrently administered (Klockner et al 2003).

### Elevated cholesterol and triglyceride levels

Several clinical studies confirm that pantethine, a metabolite of pantothenic acid, exerts significant lipid-lowering activity (Coronel et al 1991, Donati et al 1986, Gaddi et al 1984).

One double-blind study of 29 patients found that 300 mg of pantethine taken three times daily resulted in significant reductions to plasma total cholesterol, low-density lipoprotein (LDL) cholesterol and triglycerides, and an increase in high-density lipoprotein (HDL) cholesterol levels (Gaddi et al 1984).

A 2005 review analysed results from 28 clinical trials encompassing a pooled population of 646 hyperlipidaemic patients who were supplemented with a mean dose of 900 mg pantethine over an average trial length of 12.7 weeks (McRae 2005). The results of these studies suggest a response to pantethine that is time-dependent, with progressively greater reductions in LDL cholesterol and triacylglycerols between month 1 and 9. The most impressive results were observed at 9 months, with a reduction of total cholesterol by 20.5%, LDL cholesterol by 27.6% and triacylglycerols by 36.5% from baseline. Although minor increases were observed in HDL levels in the early stages of most trials,

longer-term studies suggested that this is not sustained.

Of the trials studied, 22 were conducted in Italy and all were conducted between 1981 and 1991. The authors point out that no further clinical trials were published, and concluded that evidence to date has yielded positive and promising results, and further research is warranted.

### Obesity and weight loss

An investigation of vitamin B<sub>5</sub> for weight loss was conducted with 100 Chinese volunteers (40 male) aged 15–55 years, following a strict calorie-controlled diet and supplemented with 2.5 g of pantothenic acid four times a day. The average weight loss was found to be 1.2 kg per week. Ketone bodies in urine were monitored regularly and were found to be absent in most circumstances and therefore did not explain the weight loss. While feelings of neither hunger nor weakness were reported, a sense of wellbeing was observed. To maintain the weight loss, the subjects required 1–3 g/day along with continual strict dietary advice. The author attributes the success to the role of CoA in carbohydrate, fat and protein metabolism, and its key role in the biosynthesis of many lipids and steroids (Leung 1995a). However, in the absence of a control group, the weight loss that occurred could be attributed to the calorie-controlled diet rather than the inclusion of pantothenic acid.

### IN COMBINATION

Similarly, a double-blind, randomised, parallel-group, placebo-controlled study carried out on a product containing *Garcinia cambogia* extract with calcium pantothenate (standardised for the content of hydroxycitric acid and pantothenic acid) and extracts of *Matricaria chamomilla*, *Rosa damascena*, *Lavandula officinalis* and *Cananga odorata*, on body weight in overweight and obese volunteers during a 60-day treatment period found that the average reduction in body weight for the treatment group ( $n = 30$ ) was 4.67% compared with 0.63% for placebo ( $n = 28$ ;  $P < 0.0001$ ). Weight losses of  $\geq 3$  kg were recorded for 23 subjects in the treatment group and only one in the placebo group (Toromanyan et al 2007).

### OTHER USES

Pantothenic acid has been used for many other indications, but controlled studies to determine whether treatment is effective are lacking.

### Stress

As vitamin B<sub>5</sub> is essential for adrenal cortex function and the synthesis of steroid hormones, it is often used together with other B vitamins during times of stress in order to improve the body's response and restore nutrient levels. In continual deficiency, a progressive morphological and functional degradation of the adrenal glands may occur, resulting in adrenal hypofunction, and an inability to respond to stress appropriately (Hurley & Morgan 1952, Kelly

### Clinical note — Could pantothenic acid be an antiageing nutrient?

A contemporary theory of ageing implicates mitochondrial functional decline, or 'oxidative decay' of the mitochondria, as a major contributor. In light of this hypothesis, nutrients that possess a critical role in the mitochondria are being re-examined to determine their ability to prevent ageing in humans. The focus has been on pantothenic acid, biotin, lipoic acid, iron and zinc, because deficiencies of these micronutrients have been implicated in increased mitochondrial oxidation (Ames et al 2005, Atamna 2004). In addition, those with antioxidant capabilities are of particular interest, such as pantothenic acid, lipoic acid and zinc.

Because of the numerous nutrients implicated in mitochondrial health and disease, a broad-based multivitamin should be considered instead of a single-nutrient supplement for populations at increased risk of poor nutrition, such as the elderly, young, poor and obese (Ames et al 2005).

Life extension in animals supplemented with B<sub>5</sub> has been shown in several older studies (Gardner 1948a, 1948b, Pelton & Williams 1958). The first of these studies investigated the chemical components of royal jelly, a well-recognised antiageing supplement. Using *Drosophila melanogaster* (common fruit fly) as the testing medium, it was found that pantothenic acid was the primary antiageing factor (Gardner 1948a). In a follow-up study, the combination of biotin, pyridoxine and sodium yeast nucleate was shown to lengthen lifespan in *D. melanogaster*, and was further extended with pantothenic acid (Gardner 1948b). Furthermore, the mean lifespan for mice given 300 mcg/day supplementary calcium pantothenate was 653.1 days and that for the control mice was 549.8 days. The statistical difference between the two groups is  $P = 0.05$  ( $t$ -test), 0.01 ( $U$ -test).

### Clinical note — Could vitamin B<sub>5</sub> prevent neural tube defects?

Ongoing evidence from animal studies suggests that pantothenic acid may have a preventive role against neural tube defects independently of folic acid (Dawson et al 2006). Pharmaceuticals such as valproic acid that increase the risk of neural tube defect offspring have been shown also to reduce hepatic concentrations of CoA, an effect attenuated by coadministration of pantothenic acid. While the role of B<sub>5</sub> in neural tube closure remains unknown, it appears that it exerts actions both overlapping with and independent of folate.

2011, Melampy et al 1951). If pantothenic acid is supplied early enough after deficiency has been induced (i.e. before adrenal exhaustion occurs), the response to stress can be improved (Kelly 2011).

Interestingly, a large number of experiments from the 1950s (Dumm & Ralli 1953, Dumm et al 1955, Ershoff 1953, Hurley & Morgan 1952, Melampy et al 1951, Ralli & Dumm 1953) attempted to elicit the impact of pantothenic acid deficiency on adrenal function and stress response in animals; however, little research has been done since. One study in 2008 demonstrated that pantothenic acid enhanced the basal levels of corticosterone (and progesterone) in adrenal cells of male rats that had pantothenic acid (0.03%) added to their drinking water for 9 weeks. Increased sensitivity to stimulation with adrenocorticotropic hormone and a slight non-significant increase in adrenal gland weight in the pantothenic acid group were also observed (Jaroenporn et al 2008).

### Ulcerative colitis (UC)

In a pilot study of 3 patients, it was hypothesised that topically administered dexpantenol may be beneficial in increasing tissue levels of CoA, improving fatty acid oxidation and ameliorating UC (Loftus et al 1997). It was proposed that a possible cause of UC is a block in the conversion of pantothenic acid to CoA, which reduces colonic CoA activity levels, inhibits short-chain fatty acid oxidation and contributes to distal UC. The patients received 4 weeks of dexpantenol (1000 mg) enemas and the authors concluded that, despite increases in urinary pantothenic acid output, the treatment was ineffective (Loftus et al 1997). With such a minute sample size in this pilot study, further research is required to more appropriately ascertain its effectiveness. Interestingly, conditions of ulcers and colitis negatively impact the status and excretion rates of pantothenate (Bates 2013).

### Celiac disease

In 1972, a letter to the editor of the *British Medical Journal* suggested the use of pantothenic acid in patients with celiac disease who respond only partially to a gluten-free diet as they may benefit from the administration of pantothenic acid (Monro 1972). Celiac disease is a permanent enteropathy of the small bowel and may be characterised by ulceration and stricture formation, leading to narrowing and scarring. The author explains that pantothenic acid deficiency can produce atrophy of the small intestinal mucosa in animal species; in many species ulceration of the gastric and intestinal mucosa can occur, and this destruction may occur despite the sufferer consuming a gluten-free diet. Furthermore, Monro explains that 'pseudohypoadrenalism' and carbohydrate metabolism derangement with glucose intolerance are common features of both celiac disease and pantothenic acid deficiency, suggesting a potential role in the management of these symptoms with pantothenic acid administration (Monro 1972).

### Lupus erythematosus

The evidence for the use of pantothenic acid in persons with lupus erythematosus dates back to the

1950s. Kelly (2011) cites a study (Welsh 1954) that showed efficacy in lupus treatment using pantothenic acid (10–15 g/day) with 1500–3000 IU/day of vitamin E for 19 months.

One study administered doses of 10 g/day pantothenic acid, 2 g of vitamin C, 500 mg of B<sub>1</sub>, 200 mg of B<sub>6</sub>, 2 mg of B<sub>12</sub> and two tablets of Super B and two tablets of multivitamins with minerals per day to females with systemic lupus erythematosus. After 4 weeks of treatment, there were varying degrees of improvement, particularly in fatigue. Later follow-up showed that the incidence of fever was decreased and no major flares were noted. In many cases, the original systemic lupus erythematosus medications could gradually be reduced (Leung 2004). More research needs to be conducted.

### Ergogenic aid and athletic performance

Based on its role in carbohydrate metabolism as CoA, vitamin B<sub>5</sub> has been used to increase stamina and athletic performance.

Whether pantothenic acid supplementation improves overall exercise performance remains unclear. One study showed that blood lactate levels and oxygen consumption were decreased in endurance runners during prolonged exercise at 75% maximal oxygen uptake ( $VO_{2max}$ ) (Litoff et al 1985). However, the time for highly trained distance runners to reach the point of exhaustion when taking 1 g/day of pantothenic acid for 2 weeks did not increase (Nice et al 1984).

In a randomised, double-blind, counterbalanced design study, cyclists ingesting either a placebo or a combination of 1 g of allithiamin (vitamin B<sub>1</sub> derivative) and 1.8 g of a 55%/45% pantothenic/pantothenic acid compound for 7 days did not demonstrate any improvements in exercise metabolism or performance when completing a 2000-metre time trial (Webster 1998). Similarly, 1.5 g/day pantothenic acid and cysteine supplementation did not increase resting muscle CoA content, fuel selection or exercise performance in 8 males who cycled at 75%  $VO_{2max}$  until exhaustion (Wall et al 2012).

### Reducing drug toxicity

Preliminary research in animal models shows that pantothenic acid reduces the toxicity effects of kanamycin and carbon tetrachloride and, when combined with carnitine, protects against valproate toxicity (Moiseenok et al 1984, Nagiel-Ostaszewski & Lau-Cam 1990, Thurston & Hauhart 1992).

### Female alopecia — ineffective

According to a study of 46 women with symptoms of diffuse alopecia, calcium pantothenate (200 mg/day) over 4–5 months does not cause a significant improvement in this condition (Brzezinska-Wcislo 2001).

### Testicular endocrinology, sperm motility and male fertility

In one study, the physiological roles of pantothenic acid on testicular endocrinology and sperm motility were investigated in 3-week-old male rats that were fed a B<sub>5</sub>-free diet or a 0.0016% pantothenic acid diet (control) for 7 weeks. In the B<sub>5</sub>-deficient group, sperm motility was significantly reduced, plasma concentrations of testosterone and corticosterone were significantly lower and testicular weight was significantly higher (Yamamoto et al 2009).

### Female fertility

A prospective cohort study of 1461 pregnancies found that low-birth-weight offspring were more common in women consuming diets low in vitamin C, riboflavin, pantothenic acid and sugars, even after adjustment for deprivation index, smoking, marital status and parity (Haggarty et al 2009).

## DOSAGE RANGE

### Australian adequate intake

- Women: 4 mg/day (NHMRC nutrient reference values 2007).
- Men: 6 mg/day (NHMRC nutrient reference values 2007).
- Adults: 5 mg/day (Gropper & Smith 2013).
- Pregnancy: 5 mg/day (NHMRC nutrient reference values 2007) or 6 mg/day (Gropper & Smith 2013).
- Lactation: 6 mg/day (NHMRC nutrient reference values 2007) or 7 mg/day (Gropper & Smith 2013).
- Therapeutic dose: 20–500 mg/day.

### According to clinical studies

- Wound healing: dexpanthenol cream 5% applied to affected areas up to two times daily (Biro et al 2003).
- Acne vulgaris: 15–20 g/day of pantothenic acid for 6 months for severe acne (Leung 1995b).
- Acne vulgaris: 1–5 g/day of pantothenic (Leung 1995b) acid maintenance dose.
- Lipid lowering: pantethine 300 mg three times daily (McRae 2005).

## TOXICITY

No toxicity level known.

## ADVERSE REACTIONS

Pantothenic acid is well tolerated, but contact dermatitis has been reported with topical dexpanthenol.

## SIGNIFICANT INTERACTIONS

### Antibiotics

Under in vitro conditions, experimental work from the 1950s suggests that pantothenic acid

may interfere with the ability of some antibiotics (aureomycin, erythromycin and streptomycin) to inhibit the growth of certain microorganisms.

It has been speculated that these antibiotics might reduce endogenous production of vitamin B<sub>5</sub> by gastrointestinal flora or its downstream coenzymes (CoA or ACP); supplying pantothenic acid overcomes this enzyme inhibition (Watanabe et al 2010, as cited by Kelly 2011).

### Oral contraceptive pill

Taking the oral contraceptive pill may increase the requirement for pantothenic acid. Increase vitamin B<sub>5</sub>-rich foods or consider supplementation (Plesofsky 2002).

### Isotretinoin

A single study reports that a 5% dexpanthenol cream can help treat mucocutaneous adverse reactions caused by using isotretinoin for acne (Romiti & Romiti 2002).

### Acetylcholinesterase inhibitor drugs

A theoretical concern exists that pantothenic acid, since it is involved in the biosynthesis of acetylcholine, might increase the effects of acetylcholinesterase inhibitor drugs (Kelly 2011).

## CONTRAINDICATIONS AND PRECAUTIONS

None known.

## PREGNANCY USE

Considered safe when ingested at usual dietary doses.

## PATIENTS' FAQs

### What will this vitamin do for me?

Vitamin B<sub>5</sub> is essential for health and is used for many different conditions; for example, it is often used as part of a vitamin B complex supplement to aid the body during times of stress. In many of its uses research is not available to determine whether it is effective. Research generally supports its use in wound healing and in the form of pantethine to reduce cholesterol levels.

### When will it start to work?

Pantethine reduces cholesterol levels within 2 months; however, optimal results are achieved with 9 months of supplementation. Xylometazoline-dexpanthenol nasal spray reduces symptoms of rhinitis within 2 weeks. It is not known how quickly the vitamin starts to work in most other conditions.

### Are there any safety issues?

Pantothenic acid and pantethine are considered safe substances and are generally well tolerated.

**Practice points/Patient counselling**

- Deficiency is extremely rare, as pantothenic acid is widely distributed and present in nearly all plant and animal foods. Those at risk of reduced vitamin status are alcoholics, diabetics and people with malabsorption syndromes.
- Pantethine reduces total cholesterol levels significantly, according to controlled studies in both healthy and diabetic people.
- Dexpanthenol cream acts like a moisturiser, activates fibroblast proliferation, accelerates re-epithelialisation in wound healing, has anti-inflammatory activity against ultraviolet-induced erythema and reduces itch. When used in a nasal spray, it reduces symptoms of rhinitis.
- Vitamin B<sub>5</sub> supplements are commonly used together with other B vitamins during times of stress in order to improve the body's response and restore nutrient levels.
- Vitamin B<sub>5</sub> has also been used as adjunctive treatment for inflammatory conditions, such as dermatitis and asthma, as an ergogenic aid, to treat alopecia and to restore colour to greying hair, although no controlled studies are available to determine effectiveness in these conditions.

## Vitamin B<sub>6</sub>

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin B<sub>6</sub> as pyridoxine was first isolated in 1938. Pyridoxal and pyridoxamine were later identified in the mid-1940s (Groppe & Smith 2013). In total, there are six different vitamin B<sub>6</sub> forms — pyridoxine, pyridoxal, pyridoxamine and their phosphorylated derivatives, pyridoxine phosphate (PNP), pyridoxal phosphate (PLP) and pyridoxamine phosphate (PMP), all of which are found in food. PLP is the active coenzyme important for amino acid metabolism.

For absorption, phosphorylated forms are hydrolysed (dephosphorylated) to the free forms (pyridoxine, pyridoxal, pyridoxamine) by zinc-dependent alkaline phosphatase. (However, at high-ingested concentrations, the phosphorylated forms may be absorbed without dephosphorylation.)

Absorption of vitamin B<sub>6</sub> takes place in the jejunum by a passive, non-saturable process. The more acidic the environment, the greater is the absorption. Pyridoxine, pyridoxal and pyridoxamine are transported in the plasma and red blood cells to the liver, where they are metabolised predominantly to PLP. In all, 60–90% of vitamin B<sub>6</sub> found in systemic blood is in the form of PLP. Prior to cellular uptake, it must be enzymatically hydrolysed to free pyridoxal again, as extrahepatic tissues uptake only unphosphorylated forms (Groppe & Smith 2013). It is mainly stored in muscle tissue, and ultimately metabolised and excreted via the kidneys.

### CHEMICAL COMPONENTS

Vitamin B<sub>6</sub> is a water-soluble vitamin and has six vitamer forms, of which pyridoxine hydrochloride is the main form, found in supplements and used to

#### Clinical note — Marginal B<sub>6</sub> deficiency

Although frank deficiency is rare, marginal deficiency appears to be common. One study found that 100% of 174 university students tested had some degree of vitamin B<sub>6</sub> deficiency (Shizukui-shi et al 1981). A larger survey of 11,658 adults found that 71% of males and 90% of females did not meet the recommended daily intake (RDI) requirements for B<sub>6</sub> (Kant & Block 1990).

fortify foods, as it is particularly stable (Combs 2012). Pyridoxine is the alcohol form, pyridoxal the aldehyde form and pyridoxamine the amine form, each with a 5'-phosphate derivative (Groppe & Smith 2013).

### FOOD SOURCES

All six forms of vitamin B<sub>6</sub> are found in food. Vitamin B<sub>6</sub> is widely distributed in animal and plant foods. Plant foods contain mainly pyridoxine, PNP and a conjugated pyridoxine glycoside, while animal products, such as sirloin steak, salmon and chicken, are the richest sources of pyridoxal, pyridoxamine, PLP and PMP (Groppe & Smith 2013). It occurs in the highest concentrations in meats (organ meats, beef, chicken, pork), salmon, wholegrain products, legumes, eggs, vegetables, some fruits (bananas) and nuts (Combs 2012, Groppe & Smith 2013). Per milligram, Vegemite is one of the richest sources.

On average, the bioavailability of vitamin B<sub>6</sub> from the most commonly consumed foods is between 61% and 92%. Prolonged heating, milling and refining grains and food storage contribute to

substantial loss (Gropper & Smith 2013). Up to 40% can be lost through cooking (Wahlqvist 1997); however, more recent sources suggest a variation of up to 70% (Combs 2012). Plant-derived foods lose very little vitamin B<sub>6</sub> from cooking, as they contain the most stable pyridoxine, whereas animal foods that contain mostly pyridoxal and pyridoxamine lose substantial amounts (Combs 2012).

## DEFICIENCY SIGNS AND SYMPTOMS

Clinical signs and symptoms are non-specific because this vitamin is necessary for the proper functioning of over 60 enzymes (Pelton et al 2000, Wahlqvist 1997). Signs of deficiency can occur within 2–3 weeks of reduced intake, but may take up to 2½ months to develop (Gropper & Smith 2013). In adults with B<sub>6</sub> deficiency, chiefly dermatological, circulatory and neurological changes develop. In adults with chronic deficiency, a subacute or chronic neuropathy develops. In most cases, chronic deficiency is a result of the long-term use of vitamin B<sub>6</sub> antagonists such as isoniazid, hydralazine and penicillamine. Sensory symptoms appear first in the distal portion of the feet and then spread proximally to the knees and hands if medicine use continues (So & Simon 2012). In children, the central nervous system (CNS) is also affected. Signs and symptoms include:

- Seborrhoeic rash/dermatitis (similar to that seen in pellagra) on face, neck, shoulders and buttocks (Gropper & Smith 2013)
- Weakness, sleeplessness and fatigue
- Angular stomatitis and glossitis, and cheilosis (Combs 2012, Gropper & Smith 2013)
- Sideroblastic anaemia
- Hypochromic, microcytic anaemia due to impaired haem production (Gropper & Smith 2013)
- Impaired cell-mediated immunity and increased susceptibility to infection (Combs 2012)
- Renal calculi
- Elevated homocysteine levels (Lakshmi & Ramalakshmi 1998)
- Impaired niacin production from tryptophan (Combs 2012, Gropper & Smith 2013)
- Impaired glucose tolerance (Combs 2012)
- CNS effects such as irritability, confusion, lethargy, clinical depression, peripheral neuropathy, elevated seizure activity and convulsions (particularly in children) (Combs 2012, Gropper & Smith 2013), abnormal brain wave patterns and nerve conduction
- Birth defects such as cleft palate (associated with elevated homocysteine) (Weingaertner et al 2005).

Pyridoxine deficiency has also been associated with premature coronary artery disease and with impaired oxidative defence mechanisms (Miner et al 2001).

### Primary deficiency

Primary deficiency is rare because this vitamin is widely available in many foods. Groups at risk of

deficiency include breastfed babies born with low plasma B<sub>6</sub> levels, the elderly, those who consume large quantities of alcohol and individuals who are on dialysis due to abnormal vitamin loss (Groff & Gropper 2009).

### Secondary deficiency

This may result from malabsorption syndromes, cancer, liver cirrhosis and alcoholism, hyperthyroidism, congestive heart failure or use of medicines that affect B<sub>6</sub> status or activity such as isoniazid, hydralazine, penicillamine, theophylline, monoamine oxidase inhibitors (Beers & Berkow 2003, Bratman & Kroll 2000, Wardlaw 1997), corticosteroids (promote vitamin B<sub>6</sub> loss), anticonvulsants (inhibit vitamin B<sub>6</sub> activity) and the oral contraceptive pill (Gropper & Smith 2013).

## MAIN ACTIONS

### Coenzyme

In the form of PLP, vitamin B<sub>6</sub> is associated with >100 enzymes and predominantly involved in amino acid metabolism (Gropper & Smith 2013). All except one amino acid, proline, rely on vitamin B<sub>6</sub> for their biosynthesis and catabolism (Combs 2012).

It is an important coenzyme in the biosynthesis of the neurotransmitters gamma-aminobutyric acid (GABA), dopamine and serotonin (Gerster 1996). It is also involved in protein metabolism, haemoglobin synthesis, gluconeogenesis, lipid metabolism, niacin formation, immune system processes, nucleic acid synthesis and hormone modulation (Bratman & Kroll 2000, Combs 2012, Wardlaw 1997).

### Homocysteine

Homocysteine is formed from the essential amino acid methionine and about 50% is then remethylated to methionine via steps that require folic acid and vitamin B<sub>12</sub>. Vitamin B<sub>6</sub> is required for another metabolic pathway and is a cofactor for cystathionine beta-synthase, which mediates the transformation of homocysteine to cystathionine (Wilcken & Wilcken 1998).

### Serotonin, adrenaline and noradrenaline

Pyridoxine is required for the synthesis of many neurotransmitters, including serotonin, adrenaline and noradrenaline. It is a cofactor for the enzyme 5-hydroxytryptophan decarboxylase, which is involved in one of the steps that converts tryptophan to serotonin (Pelton et al 2000) and tyrosine carboxylase that converts tyrosine to dopamine, adrenaline and noradrenaline (Combs 2012). Deficiency states are therefore associated with alterations to mood and other psychological disturbances.

### Niacin synthesis

Vitamin B<sub>6</sub> is a required cofactor for kynureninase and transaminases required for tryptophan conversion to niacin (Combs 2012).

### Antioxidant

B<sub>6</sub> has been shown both *in vitro* and *in vivo* to display antioxidant activity (Anand 2005, Ji et al 2006, Kannan & Jain 2004, Matxain et al 2007).

### Antitumour

*In vitro* and *in vivo* experiments have found evidence of some antitumour action on a number of cell lines, including breast and pituitary cells (Ren & Melmed 2006, Shimada et al 2005, 2006).

### Reducing diabetic complications

According to Jain (2007), animal studies show that B<sub>6</sub> may reduce the incidence of several diabetic complications, such as retinopathy, nephropathy and dyslipidaemia. It is thought that advanced glycation end products (AGEs) contribute to the development of diabetic nephropathy and other diabetes complications, and, according to *in vivo* research, pyridoxamine (from the B<sub>6</sub> group of compounds) exerts antioxidant and anti-AGE action in the kidneys (Tanimoto et al 2007). The anti-AGE action of PLP was confirmed in a diabetic rat model, where it prevented the progression of nephropathy (Nakamura et al 2007).

### OTHER ACTIONS

Pyridoxine displayed a protective effect against neurotoxicity induced by glutamate *in vivo*, which may prove useful in hypoxic-ischaemic brain injury (Buyukokuroglu et al 2007). Another animal study indicated that neuroprotective activity preventing ischaemic damage may be due to a GABA-inhibitory effect (Hwang et al 2007).

Immune-stimulant actions, with an increase in T-helper and T-lymphocyte cells, were found in critically ill patients to whom B<sub>6</sub> was administered (Cheng et al 2006).

### Myelin formation

PLP is required for the synthesis of sphingolipids for myelin sheath formation (Ang et al 2008).

### Gene expression

In its non-coenzyme role, vitamin B<sub>6</sub> has been shown to affect gene expression by binding to DNA and modulating steroid hormones (including progesterone, androgens and oestrogens), binding to regulatory DNA regions (Oka 2001).

### CLINICAL USE

Vitamin B<sub>6</sub> supplementation is used to treat a large variety of conditions and is mostly prescribed in combination with other B group vitamins.

### Deficiency

It is traditionally used to treat vitamin B<sub>6</sub> deficiency.

### Premenstrual syndrome (PMS)

Vitamin B<sub>6</sub> supplementation is used in doses beyond RDI levels for the treatment of PMS. A 1999 systematic review of nine clinical trials involving 940

patients with PMS supports this use, finding that doses up to 100 mg/day are likely to be of benefit in treating symptoms and PMS-related depression (Wyatt et al 1999). Another double-blind randomised controlled trial of 94 patients taking a dose of 40 mg B<sub>6</sub> twice a day found that active treatment significantly decreased PMS symptoms during the luteal phase. Benefits were most pronounced for mood and psychiatric symptoms (Kashanian et al 2008).

### Comparative study

One randomised double-blind study compared the effects of pyridoxine (300 mg/day), alprazolam (0.75 mg/day), fluoxetine (10 mg/day) or propranolol (20 mg/day) in four groups of 30 women with severe PMS (Diegoli et al 1998). In this study, fluoxetine produced the best results (a mean reduction of 65.4% in symptoms), followed by propranolol (58.7%), alprazolam (55.6%), pyridoxine (45.3%) and placebo (39.4–46.1%). Symptoms responding well to pyridoxine were tachycardia, insomnia, acne and nausea (Diegoli et al 1998). Another comparative study of 60 women tested 100 mg of B<sub>6</sub> against bromocriptine and a placebo over 3 months. Both active treatments produced a significant reduction in symptoms compared to the control group; however, vitamin B<sub>6</sub> treatment was slightly more effective than bromocriptine and produced fewer side effects (Sharma et al 2007).

More recently, a systematic review investigated the role of herbs, vitamins and minerals advocated in the treatment of PMS and/or premenstrual dysphoric disorder (PMDD) to determine their efficacy in reducing the severity of PMS/PMDD symptoms (Whelan et al 2009). Data support the use of calcium for PMS, and suggest that chasteberry and vitamin B<sub>6</sub> may be effective (Whelan et al 2009).

### Dysmenorrhoea

A Cochrane review of herbal and dietary therapies for primary and secondary dysmenorrhoea found one small trial with B<sub>6</sub> that showed it was more effective at reducing pain than both placebo (in this case ibuprofen) and a combination of magnesium and vitamin B<sub>6</sub> (Davis 1988) but, due to poor reporting of data, this was not included in the meta-analysis (Proctor & Murphy 2009).

### Pregnancy

Vitamin B<sub>6</sub> has been associated with some benefits during pregnancy; however, more research is required to understand the role of B<sub>6</sub> supplementation in this population.

A 2006 Cochrane Review investigated the clinical effects of vitamin B<sub>6</sub> oral capsules or lozenges during pregnancy and/or labour to see whether there were any changes to Apgar score, birth weight, incidence of pre-eclampsia or preterm birth (Thaver et al 2006). Five trials (1646 women) were included. Vitamin B<sub>6</sub> as oral capsules or lozenges resulted in

decreased risk of dental decay in pregnant women. A small trial showed reduced mean birth weights with vitamin B<sub>6</sub> supplementation, and no significant differences in the risk of eclampsia, pre-eclampsia or low Apgar scores at 1 minute between supplemented and non-supplemented groups. No differences were found in Apgar scores at 1 or 5 minutes, or breast milk production between controls and women receiving oral or intramuscular loading doses of pyridoxine at labour (Thaver et al 2006). The authors concluded there were not enough data to be able to make any useful assessments, and further research is required. Furthermore, three of the five studies were from the 1960s (Hillman et al 1962, 1963, Swartwout et al 1960); the other two were from the 1980s (Schuster et al 1984, Temesvari et al 1983). More updated information is required.

A more recent systematic review evaluated the risks and benefits of interventions with vitamins B<sub>6</sub>, B<sub>12</sub> and C during pregnancy on maternal, neonatal and child health and nutrition outcomes (Dror & Allen 2012). In this meta-analysis based on three small studies, vitamin B<sub>6</sub> supplementation had a significant positive effect on birth weight; however, there were no significant effects on other neonatal outcomes, including preterm birth, low birth weight and perinatal morbidity and mortality.

### Homocysteine and recurrent miscarriages

A 2012 study assessed homocysteine levels and pregnancy outcomes in 50 cases of recurrent miscarriage. Active treatment consisted of B<sub>12</sub> 1500 mcg, vitamin B<sub>6</sub> 10 mg and folic acid 5 mg daily taken throughout the pregnancy ( $n = 25$ ) or during the first trimester only ( $n = 25$ ). Following treatment with the B group vitamins, homocysteine levels decreased by 37%. Miscarriage rate in patients with hyperhomocysteinaemia was 26.6% compared with 11.4% in patients with normal homocysteine. The authors concluded that hyperhomocysteinaemia was associated with a 2.5-fold increased risk of miscarriage (Agarwal et al 2012).

### Morning sickness

A systematic review investigated the effectiveness and safety of a range of treatments for nausea and vomiting in early pregnancy and suggested there was low-quality evidence to support B<sub>6</sub> versus placebo for nausea but not vomiting (Festin 2009). A Cochrane review in 2010 of 27 trials with 4042 women investigated the outcomes of vitamin B<sub>6</sub> supplementation, ginger and conventional drug therapy in reducing nausea and vomiting in early pregnancy (Matthews et al 2010). Two studies of 416 women compared vitamin B<sub>6</sub> with placebo (Sahakian et al 1991, Vutyavanich et al 1995) and showed that vitamin B<sub>6</sub> supplementation reduced nausea after 3 days. A well-designed, double-blind, randomised, controlled trial had similar results but over a 3-week period (Smith & Crowther 2005). It is unclear whether vomiting frequency also reduced, due to the heterogeneity of studies.

In the same review, the comparative effectiveness of ginger and vitamin B<sub>6</sub> for nausea and vomiting in early pregnancy found both interventions significantly reduced nausea and vomiting scores ( $P < 0.05$ ,  $P < 0.001$  respectively) (Chittumma et al 2007, Sripramote & Lekhyananda 2003). Two other studies (Ensiyeh & Sakineh 2009, Smith et al 2004) report improvements in vomiting frequency, nausea and retching (Matthews et al 2010). In an experimental study of 60 pregnant women experiencing nausea and/or vomiting (prior to the 12th week of gestation), 30 women were given 10 mg of vitamin B<sub>6</sub> and 30 were given 1.28 mg for 2 weeks to investigate the outcome on Pregnancy-Unique Quantification of Emesis and nausea (PUQE) score. Plasma B<sub>6</sub> concentration was significantly increased in both groups ( $P < 0.05$ ), and the higher supplementation group had a greater decrease in PUQE score (Wibowo et al 2012), suggesting that the 10 mg dose of vitamin B<sub>6</sub> is effective in reducing both nausea and vomiting in early-stage pregnancy.

Another study (Bsar et al 2001) looked at the effectiveness of three different antiemetics (metoclopramide with vitamin B<sub>6</sub>, prochlorperazine and promethazine). The authors report that approximately 65%, 38% and 40% of women in each group, respectively, responded that they felt better on the third day of treatment. The authors conclude that their results favour pyridoxine-metoclopramide over the other two regimens.

Based on current research, vitamin B<sub>6</sub> appears to be effective in reducing both nausea and vomiting in early stages of pregnancy in a number of individual clinical trials. Its effectiveness is equivalent to that of ginger and may occur within 3 days of starting supplementation. Furthermore, the combination of metoclopramide with vitamin B<sub>6</sub> appears to be more effective than other conventional treatment (prochlorperazine and promethazine), and this effect may also begin within 3 days of treatment. Although a number of the trials showed benefit of B<sub>6</sub> overall, the authors concluded there was limited evidence from trials to support the use of pharmacological agents, including vitamin B<sub>6</sub> (Matthews et al 2010).

### Heart disease

A growing body of evidence in contemporary studies has suggested a subtle relationship between heart failure and micronutrient status (McKeag et al 2012). While the authors state the results are inconclusive, one recent study reviewed by them showed potentially significant results. This observational study measured riboflavin and pyridoxine levels in 100 patients (mean age 67.1 years, 58% males) with heart failure (as defined by Framingham criteria). It was found that the percentage of patients with evidence of pyridoxine deficiency was significantly higher in patients with heart failure (38.0% vs 19.0%;  $P = 0.02$ ) (Keith et al 2009). Whether low B<sub>6</sub> is a causative factor or consequence of disease remains to be clarified.

### Elevated homocysteine levels

In practice, the relative safety and affordability of combined vitamin B supplementation (B<sub>12</sub>, folic acid and B<sub>6</sub>) make it an attractive recommendation in people with familial hyperhomocysteinaemia. Whether lowering total homocysteine improves cardiovascular mortality and morbidity is questionable, as recent large-scale clinical trials and meta-analyses have failed to demonstrate any benefits for B group vitamins (including B<sub>6</sub>) in reducing overall cardiovascular risk, despite showing a reduction in homocysteine levels (Albert et al 2008, Clarke et al 2007, CTSUESU 2006, den Heijer et al 2007, Mann et al 2008, Marcus et al 2007, Ray et al 2007). Negative results were obtained yet again in a 2013 Cochrane intervention review which evaluated the clinical effectiveness of homocysteine-lowering interventions (in the form of supplements of vitamin B<sub>6</sub>, B<sub>9</sub> and B<sub>12</sub>) at reducing the incidence of myocardial infarction, stroke or all-cause mortality as compared to placebo.

Twelve randomised controlled trials involving 47,429 participants both with and without pre-existing cardiovascular disease were included in the review, which concluded that the interventions did not significantly affect non-fatal or fatal myocardial infarction (pooled relative risk [RR] 1.02), stroke (pooled RR 0.91) or death by any cause (pooled RR 1.01) as compared with placebo (Martí-Carvajal et al 2013).

Failure of combined B vitamin therapy to reverse inflammatory processes associated with atherogenesis may partly explain the negative results (Bleie et al 2007). The consistent findings of an association between elevated plasma total homocysteine levels and vascular risk are yet to be fully explained; however, it is possible that the association is a consequence rather than a cause of disease (Toole et al 2004).

### Venous thrombosis (VT)

A systematic review and meta-analysis investigated the association between B group vitamins and VT (Zhou et al 2012), given that a homocysteine-independent role for B group vitamins on VT development has been reported. In this review, significant standardised mean differences were obtained for plasma folic acid and vitamin B<sub>12</sub>, suggesting that reduced levels of folic acid and vitamin B<sub>12</sub> may be independent risk factors of VT. Moreover, a qualitative systematic review indicated that low level of vitamin B<sub>6</sub> was an independent risk factor of VT (Zhou et al 2012). Further prospective clinical studies are needed to provide additional evidence on the clinical benefits of B group vitamin supplementation for VT.

### IN COMBINATION

In a 12-week, open-label, randomised, placebo-controlled trial, 85 hypertriglyceridaemic (triglycerides >150 mg/dL) males were randomised to one of five

groups and given lysine (1 g/day), vitamin B<sub>6</sub> (50 mg/day), lysine (1 g/day) plus vitamin B<sub>6</sub> (50 mg/day), carnitine (1 g/day) or placebo for 12 weeks. Results showed that nutritional supplementation was associated with a significant reduction in total cholesterol by 10%. Additionally, plasma triglycerides were reduced by 36.6 mg/dL at 6 weeks compared with an increase of 18 mg/dL in the placebo group, although not statistically significant (Hlais et al 2012). The role of B<sub>6</sub> itself is unclear in achieving this result.

### Reducing thromboembolism

A prospective cohort study of 757 patients experiencing first venous thromboembolism found that patients with lower plasma B<sub>6</sub> had a 1.8-fold higher risk of recurrence than those with higher levels of B<sub>6</sub> (Hron et al 2007). In contrast, no risk reduction was found in a secondary analysis of the HOPE-2 trial, which included over 5000 individuals with known cardiovascular disease or diabetes who were given a daily supplement of folic acid (2.5 mg), B<sub>6</sub> (50 mg) and B<sub>12</sub> (1 mg) or a placebo for 5 years. In this analysis, vitamin therapy reduced homocysteine levels; however, it did not reduce the risk of venous thromboembolism, deep-vein thrombosis or pulmonary embolism (Ray et al 2007).

### Improving outcomes after heart transplantation

Cardiac transplantation represents a potentially life-saving procedure for patients with end-stage cardiac disease. Short-term survival is improving because of improved immunosuppression, but long-term survival remains limited by an aggressive form of atherosclerosis known as transplant coronary artery disease (Miner et al 2001).

A randomised, double-blind placebo-controlled study showed that pyridoxine supplementation (100 mg/day) taken for 10 weeks improved endothelial function as assessed by flow-mediated dilatation in cardiac transplant recipients (Miner et al 2001). Interestingly, homocysteine levels remained unchanged with treatment, suggesting that other mechanisms are responsible.

### IN COMBINATION

A randomised, double-blind, placebo-controlled study of 50 patients who were perceived to be at risk of cerebral ischaemia received B<sub>6</sub> (25 mg), folate (2.5 mg) and B<sub>12</sub> (0.5 mg) or a placebo daily for a year. The study found that supplementation significantly reduced carotid intima-media thickness, which is a marker of atherosclerotic changes (Till et al 2005). In contrast, another small, double-blind, randomised and placebo-controlled trial of 30 individuals with a history of ischaemic stroke found that long-term treatment over 3.9 years with similar dosages of B<sub>6</sub> and B<sub>12</sub> to the previous trial and slightly less folate (2 mg) produced no differences in carotid intima-media thickness and endothelial function (Potter et al 2007).

## Cancer

A number of studies have investigated whether low B<sub>6</sub> may be associated with a higher prevalence of certain cancers and if higher levels have a chemopreventive effect. Some studies have focused on B<sub>6</sub> alone but often it is included as part of an investigation into the effects of folic acid, B<sub>12</sub>, methionine and B<sub>6</sub> as a combination.

Theoretically, adequate B<sub>6</sub>, B<sub>12</sub>, folate and methionine might have a chemopreventive effect due to their roles in the one-carbon metabolism pathway, which is critical for DNA synthesis, methylation and repair (Harris et al 2012), and by reducing inflammation, cell proliferation and oxidative stress (Zhang et al 2013).

### Ovarian cancer

The association between folate, methionine, vitamin B<sub>6</sub>, vitamin B<sub>12</sub> and alcohol among 1910 women with ovarian cancer and 1989 controls from a case-control study was conducted. An inverse association between dietary vitamin B<sub>6</sub> (covariate-adjusted odds ratio [OR] 0.76, 95% confidence interval [CI] 0.64–0.92;  $P_{\text{trend}} = 0.002$ ) and methionine intake (covariate-adjusted OR 0.72, 95% CI 0.60–0.87;  $P_{\text{trend}} < 0.001$ ) and ovarian cancer risk was found. The association with dietary vitamin B<sub>6</sub> was strongest for serous borderline (covariate-adjusted OR 0.49, 95% CI 0.32–0.77;  $P_{\text{trend}} = 0.001$ ) and serous invasive (covariate-adjusted OR 0.74, 95% CI 0.58–0.94;  $P_{\text{trend}} = 0.012$ ) subtypes. The authors concluded that methionine and especially vitamin B<sub>6</sub> may lower ovarian cancer risk (Harris et al 2012).

### Breast cancer

The association of prediagnostic plasma concentrations of PLP with postmenopausal breast cancer risk was investigated in a case-control study of 706 cases and 706 controls. Women with higher plasma PLP concentrations had a 30% reduced risk of invasive breast cancer (CI 0.50–0.98) as compared with women with low PLP ( $P_{\text{trend}} = 0.02$ ). The results suggest that higher circulating levels of vitamin B<sub>6</sub> are associated with a reduced risk of invasive postmenopausal breast cancer. The authors suggest a role for vitamin B<sub>6</sub> in the prevention of postmenopausal breast cancer, although further research is required (Lurie et al 2012).

The majority of studies investigating the protective role of B vitamins in breast cancer have focused on folate, B<sub>6</sub> and B<sub>12</sub>. Several case-controlled studies have reported protective associations (Chen et al 2005, Larsson et al 2007, Lajous et al 2006, Yang et al 2013) while cohort studies have shown inconsistencies in results (Cho et al 2007, Ericson et al 2007, Shrubsole et al 2011, Stevens et al 2010). One investigated the association between dietary intakes of folate, B<sub>2</sub>, B<sub>6</sub>, B<sub>12</sub> and methionine for breast cancer risk in Hispanic and non-Hispanic white women in the United States. Higher intakes of folate, B<sub>12</sub> and methionine were associated with

a lower risk of breast cancer; however there was no risk reduction with vitamin B<sub>6</sub> or B<sub>2</sub> (Yang et al 2013).

Other researchers, using the prospective cohort Shanghai Women's Health Study (1997–2008), including 718 Chinese breast cancer cases, investigated folate, B<sub>6</sub>, B<sub>12</sub>, niacin, riboflavin and methionine intakes and their association with breast carcinogenesis and again found no specific benefit from vitamin B<sub>6</sub> (Shrubsole et al 2011).

### Bladder cancer

In an attempt to find a link between dietary components and incidence of bladder cancer, diet was assessed for 912 patients with bladder cancer and 873 controls by Garcia-Closas et al (2007). Individuals in the highest quintile for B<sub>6</sub> intake had a 40% reduced risk of bladder cancer compared with those in the lowest quintile.

### Colorectal cancer

Current evidence suggests high dietary vitamin B<sub>6</sub> intake is associated with a reduced risk of colorectal cancer. One large longitudinal population study ( $n = 61$ ; 433 women aged 40–76 years) used a food frequency questionnaire with a follow-up over 14.8 years and found that high dietary vitamin B<sub>6</sub> was associated with lower colorectal cancer risk, with protective effects most notably seen in women who drank alcohol (Larsson et al 2005). Similarly, a case-control study of 2028 people with colorectal cancer and 2722 controls confirmed a dose-dependent protective effect of B<sub>6</sub>, with strongest protective effects observed for the highest intake and in people aged over 55 years (Theodoratou et al 2008). Another large population study of both men and women further confirmed that low dietary B<sub>6</sub> was associated with an increased risk in colorectal cancer, but the effect was specific for men and not for women. Protective effects were strongest in men with higher alcohol intake. These findings were from the large Japan Public Health Center-based Prospective Study, from which there were 526 cases of colorectal cancer (Ishihara et al 2007). A randomised controlled trial also found that high levels of plasma B<sub>6</sub> may be protective against colorectal adenomas (Figueiredo et al 2008).

A systematic review with meta-analysis of prospective studies assessed the association of vitamin B<sub>6</sub> intake or blood levels of PLP (the active form of vitamin B<sub>6</sub>) with risk of colorectal cancer (Larsson et al 2010). Nine studies focused on vitamin B<sub>6</sub> intake and four studies on blood PLP levels. The pooled RRs of colorectal cancer for the highest vs lowest category of vitamin B<sub>6</sub> intake and blood PLP levels were 0.90 (95% CI 0.75–1.07) and 0.52 (95% CI 0.38–0.71), respectively. There was heterogeneity among studies of vitamin B<sub>6</sub> intake but not among studies of blood PLP levels. The risk of colorectal cancer decreased by 49% for every 100 pmol/mL increase in blood PLP levels (RR 0.51). Vitamin B<sub>6</sub> intake and blood PLP levels were

inversely associated with the risk of colorectal cancer in this meta-analysis (Larsson et al 2010).

Another later study evaluated whether higher vitamin B<sub>6</sub> intake in the remote past is strongly associated with a lower risk of colorectal cancer than intake in the recent past. Vitamin B<sub>6</sub> intake was assessed every 4 years for up to 28 years using validated food frequency questionnaires from 86,440 women in the Nurses' Health Study and 44,410 men in the Health Professionals Follow-up Study. Total vitamin B<sub>6</sub> intake was significantly associated with an approximately 20–30% lower risk of colorectal cancer in age-adjusted results but these significant associations became attenuated and non-significant after adjustment for other colorectal cancer risk factors. Additionally, results did not differ by cancer subsite, source of vitamin B<sub>6</sub> (food or supplement) or intake of alcohol and folate (Zhang et al 2012).

Conversely, a randomised, double-blind, placebo-controlled trial of 5442 female health professionals at high risk for cardiovascular disease examined the effect of a combination pill of folic acid (2.5 mg), vitamin B<sub>6</sub> (50 mg) and vitamin B<sub>12</sub> (1 mg) or placebo on the occurrence of colorectal adenoma. This study included 1470 participants who were followed up for as long as 9.2 years and underwent an endoscopy at any point during follow-up. The results indicated no statistically significant effect of the combination treatment on incidence of colorectal adenoma among this population. The risk of colorectal adenoma was similar among participants receiving treatment (24.3%, 180 of 741 participants) vs placebo (24.0%, 175 of 729 participants) (multivariable adjusted RR 1.00) (Song et al 2012).

Observational studies of dietary or dietary plus supplementary intake of vitamin B<sub>6</sub> and colorectal cancer risk have been inconsistent, with most studies reporting non-significant positive or inverse associations (Zhang et al 2013). However, a 30–50% reduction in colorectal cancer risk has been consistently reported in published studies where high circulating plasma levels of active vitamin B<sub>6</sub> (plasma POP) have been found. Zhang et al (2013) suggest that the discrepancy in the results may be due to dietary-based versus plasma-based studies, but why this is the case remains elusive. The age of vitamin B<sub>6</sub> repletion and the effect of repletion at different life stages, suboptimal levels, differing subtypes of colorectal cancer and genetic variants may also influence the results and explain such variations (Zhang et al 2013).

#### Lung cancer prognosis and vitamin B<sub>6</sub>

The bioactive form of B<sub>6</sub>, produced by pyridoxal kinase, has been found to exacerbate cisplatin- (cytotoxic agent used to treat non-small-cell lung cancer) mediated DNA damage and sensitise cancer cell lines to apoptosis, both in vitro and in vivo. Furthermore, low pyridoxal kinase activity, and thus low bioactive vitamin B<sub>6</sub>, has been associated with poor disease outcome. The authors suggest

pyridoxal kinase expression may be a marker for risk stratification in non-small-cell lung cancer patients (Galluzzi et al 2012).

#### Carpal tunnel syndrome (CTS)

It has been suspected that vitamin B<sub>6</sub> deficiency may play a role in the development of CTS, as several studies have found that patients with CTS and pyridoxine deficiency respond to supplementation (Ellis et al 1991). More recent evidence now casts doubt on the usefulness of B<sub>6</sub> supplementation in CTS. A 2002 review found no benefit with pyridoxine treatment in CTS (Gerritsen et al 2002). Similarly, a 2007 systematic review of treatments for CTS concluded that there was moderately strong evidence to suggest that B<sub>6</sub> was ineffective in the treatment of the condition (Piazzini et al 2007).

#### Autism

Overall, there is some research which suggests that supplementation with pyridoxine in combination with other nutrients, mainly magnesium, may improve some features of autism (Kuriyama et al 2002, Mousain-Bosc et al 2006, Pfeiffer et al 1995); however, larger trials with rigorous methodology are required before a more definitive conclusion can be made.

In 1997, a small, 10-week, double-blind, placebo-controlled trial found that an average dose of 638.9 mg pyridoxine and 216.3 mg magnesium oxide was ineffective in ameliorating autistic behaviours (Findling et al 1997). More recently, combination treatment with magnesium and B<sub>6</sub> was shown to improve symptoms such as social interaction, communication and general behaviour in autism (Mousain-Bosc et al 2006).

In a 2006 Cochrane systematic review, one study (Kuriyama et al 2002) concluded that pyridoxine was associated with improvement in verbal IQ scores; however it only included eight subjects and was a short-term study for 4 weeks. Overall, the review found that the quality and small sizes of the studies posed problems in evaluating the evidence that led to their conclusion that B<sub>6</sub>-Mg therapy could not be recommended (Nye & Brice 2005). This review has been edited with no change to conclusions and republished in 2009. However, more current research needs to be conducted, including investigations on the clinical significance of the reduction in urinary dicarboxylic acid in autism.

Several studies have sought to explain how vitamin B<sub>6</sub> supplementation may provide benefits in this population.

Several studies have observed dietary deficiencies of vitamin B<sub>2</sub>, vitamin B<sub>6</sub> and magnesium in autism (Kałuzna-Czapłinska et al 2009, Lakshmi Priya & Geetha 2011, Marlowe et al 1984, Xia et al 2010).

Increased homocysteine levels have been associated with autism (Kałuzna-Czapłinska et al 2013) as well as high levels of urinary dicarboxylic acids (an important marker of metabolism, energy

production, intestinal dysbiosis and nutritional status in autistic children) (Kaluźna-Czaplińska et al 2011). Homocysteine levels can be lowered with a combination of vitamins B<sub>6</sub>, B<sub>12</sub> and folate; however it remains unclear whether this effect translates into a clinical benefit. Supplementation with magnesium (200 mg/day), pyridoxine (500 mg/day) and riboflavin (20 mg/day) for 3 months is able to reduce excretion of urinary dicarboxylic acid according to a study of 30 autistic children (Kaluźna-Czaplińska et al 2011). In this study, parents of the children being treated observed improvements in eye contact and the ability to concentrate, suggesting a possible clinical improvement.

Adams et al (2006) found that children with autism spectrum disorder had very high plasma levels of B<sub>6</sub> (without supplementation) compared to other children and suggested this may have occurred because of low activity of pyridoxal kinase to convert pyridoxine into PLP, which is the active cofactor for dozens of enzymatic reactions, including the formation of neurotransmitters. This may explain why high doses of B<sub>6</sub> seem necessary to produce benefits.

#### IN COMBINATION

A Cochrane review of vitamin B complex for treating peripheral neuropathy, which included 13 studies (11 parallel randomised controlled trials and two quasi-randomised trials) involving 741 participants (488 treated with vitamin B complex and 253 treated with placebo or another substance) with alcoholic or diabetic neuropathy, concluded there are only limited data, and the evidence is insufficient to determine whether vitamin B complex is beneficial or harmful (Ang et al 2008). Within this review, however, one trial suggested that 4-week treatment with high doses of oral vitamin B complex (thiamin 25 mg/daily and pyridoxine 50 mg/daily) was more efficacious than lower doses (1 mg each of thiamin and pyridoxine) in short-term reduction of pain, composite impairments, paraesthesiae and neuropathic symptoms (Abbas & Swai 1997). It is not clear if the results were due to the thiamin or pyridoxine or the combination. Given the age of this study, further investigations need to be conducted to attempt to elucidate similar findings.

#### Seizures

A study found that vitamin B<sub>6</sub>-responsive seizures decrease or disappear following high-dose oral B<sub>6</sub> treatment (Ohtahara et al 2011). Vitamin B<sub>6</sub>-responsive seizures or epilepsy are associated predominantly with West syndrome, but may also include Lennox-Gastaut syndrome, grand mal or partial motor seizures. In the study, 216 consecutive cases of West syndrome in children aged from 3 months to 5 years with both idiopathic and symptomatic seizures with organic brain lesions were administered high-dose B<sub>6</sub> and had an overall response rate of 13.9%. In responsive patients, long-term seizure and mental outcomes were noted. An increasing dose of 30 to 50–100 mg daily showed a

slight clinical response, while doses of 100–400 mg/daily showed dramatic clinical improvements, with effects being noted within 1 week of treatment (Ohtahara et al 2011). In some cases the need for conventional antiepileptic medication was reduced.

This latter finding increases in significance and relevance in the clinical management of seizure control. A study found that 16/33 patients (48%) taking inducing antiepileptic drugs (AED) (phenytoin and carbamazepine) developed a vitamin B<sub>6</sub> deficiency compared with 9% in the control group. Of those that switched to non-inducing AED (levetiracetam, lamotrigine or topiramate), 21% were B<sub>6</sub>-deficient (Mintzer et al 2012). The authors concluded that treatment with inducing AEDs commonly causes vitamin B<sub>6</sub> deficiency that is often severe.

#### Convulsions during a febrile episode

Two randomised trials have been conducted in children, producing conflicting results. One study of 65 children who had been admitted to hospital with febrile convulsions showed that a dose of 2–10 mg/kg PLP daily (orally or intravenously) produced a 100% success rate, whereas 43% in the control group experienced repeated convulsions (Kamiishi et al 1996). A second randomised trial found that a lower dose of 20 mg twice daily did not alter the incidence of febrile convulsions compared with placebo (McKiernan et al 1981).

#### Symptomatic treatment for stress

The term 'stress', as used by the public, is a subjective one and often described in different ways. One theoretical model that has been developed to predict psychological stress includes measures of life stressors, social support and coping style. Using this model, pyridoxine deficiency has been identified as a significant predictor of increased overall psychological stress during bereavement. More specifically, pyridoxine deficiency is significantly associated with increases in depression, fatigue and confused mood levels, but not with those of anxiety, anger or vigour (Baldewicz et al 1998).

One explanation is that pyridoxine is involved in neurotransmitter biosynthesis, such as GABA and serotonin, and therefore deficiency states that are associated with mood disturbances are improved with consequent supplementation (McCarty 2000).

#### Cognitive performance/Alzheimer's disease

Whether vitamin B<sub>6</sub> supplementation provides benefits in cognitive function and Alzheimer's disease (AD) remains to be clarified. It has gained some attention as a cheap and safe method of reducing homocysteine, which is implicated in the aetiology of AD and cognitive dysfunction; however, findings are equivocal.

One systematic review evaluated data from 16 studies that investigated the association between cognitive function in the elderly and B<sub>6</sub>, folate and B<sub>12</sub>. An association was found between folate and

cognition in AD, but no association was found for vitamins B<sub>6</sub> or B<sub>12</sub>. However, the authors suggested that heterogeneity in the methodology of the studies made interpretation problematic (Raman et al 2007).

A similar research group doing a systematic review of 14 trials found that most studies were small and of low quality. They found that three studies of B<sub>6</sub> and six trials of combined B vitamins revealed no effect, despite different dosages, on cognitive function. Only one of the trials found a significant improvement using B<sub>6</sub> to improve long-term memory. The review concluded that there was insufficient evidence to support a positive effect of B<sub>6</sub> on cognition. The reviewers suggested that larger, well-designed trials are needed to assess different groups of the population for any association between B<sub>6</sub> and cognitive function (Balk et al 2007).

A Cochrane systematic review on vitamin B<sub>6</sub> and cognition found no evidence for short-term benefit of vitamin B<sub>6</sub> in improving mood (depression, fatigue and tension symptoms) or cognitive functions (Malouf & Grimley Evans 2003). The review included two trials only (Bryan et al 2002, Deijen et al 1992) that used a double-blind, randomised, placebo-controlled design and involved 109 healthy older people. No trials of vitamin B<sub>6</sub> involving people with cognitive impairment or dementia were found, which may explain the negative results.

The development of cognitive impairment has been linked to elevated plasma homocysteine (Ford & Almeida 2012). A systematic review and meta-analysis of 19 randomised controlled trials was conducted to determine the effects of vitamins B<sub>6</sub>, B<sub>12</sub> and folic acid (commonly recognised homocysteine-lowering B vitamins) in individuals with and without cognitive impairment. It was found that these B vitamins, either alone or in combination, did not show an improvement in cognitive function for individuals with or without cognitive impairment. It remains to be established if prolonged treatment with B vitamins can reduce the risk of dementia in later life (Ford & Almeida 2012).

### Homocysteine and Alzheimer's disease

According to one systematic review published in 2008, evidence is strong to suggest high homocysteine is a risk factor for AD and further randomised controlled trials are warranted to evaluate the association between B<sub>6</sub>, folate, B<sub>12</sub>, homocysteine levels and AD (Van Dam & Van Gool 2008).

### Brain matter

Investigation of a healthy elderly population found a relationship between greater B<sub>6</sub> supplement intake and greater grey-matter volume (Erickson et al 2008). Another study with Alzheimer's patients found that low B<sub>6</sub> levels in patients were associated with white-matter lesions in the brain (Mulder et al 2005). The clinical significance of these findings remains to be clarified.

It has also been theorised that inflammation may be implicated in AD and dementia and that C-reactive protein, as a marker for systemic inflammation, may be a risk factor. A study of 85 individuals discovered that, where C-reactive protein was elevated, this was related to low B<sub>6</sub> levels and cerebral atrophy (Diaz-Arrastia et al 2006). This anti-inflammatory effect of B<sub>6</sub> may explain its possible role in neurodegenerative diseases; another interesting observation came from a study with older men, where levels of beta-amyloid levels were reduced with B<sub>6</sub>, folate and B<sub>12</sub> (Flicker et al 2008).

### Schizophrenia

It has been suggested that high levels of homocysteine contribute to the pathogenesis of schizophrenia and the complex metabolic regulation of homocysteine that could be disrupted in schizophrenia (Petronijevic et al 2008).

To test whether supplementation could benefit this population, Levine et al (2006) conducted a randomised controlled trial of 42 schizophrenic patients with plasma homocysteine levels > 15 micromol/L. Treatment with oral folic acid, vitamin B<sub>12</sub> and pyridoxine for 3 months reduced homocysteine and, more importantly, significantly improved clinical symptoms as measured by the Positive and Negative Syndrome Scale and neuropsychological tests overall, in particular the Wisconsin Card Sort (Levine et al 2006).

### Tardive dyskinesia (TD)

TD is a significant clinical problem. Vitamin B<sub>6</sub> is a potent antioxidant and has a role in almost all of the possible mechanisms that are thought to be associated with the appearance of TD (Lerner et al 2007). To test whether supplementation would have any benefits, a 26-week, double-blind, placebo-controlled trial was conducted with 50 inpatients who had DSM-IV diagnoses of schizophrenia or schizoaffective disorder and TD. The randomised study found treatment with vitamin B<sub>6</sub> (1200 mg/day) significantly reduced symptoms of TD compared to a placebo.

### Parkinson's disease (PD)

A higher dietary intake of vitamin B<sub>6</sub> was associated with a significantly decreased risk of PD, probably through mechanisms unrelated to homocysteine metabolism, according to findings from the Rotterdam Study — a prospective, population-based cohort study of people aged 55 years and older (de Lau et al 2006). The association between dietary intake of folate, vitamin B<sub>12</sub> and vitamin B<sub>6</sub> and the risk of incident PD among 5289 participants was evaluated. After a mean follow-up of 9.7 years, the authors identified 72 participants with incident PD. Stratified analyses showed that this association was restricted to smokers. No association was observed for dietary folate and vitamin B<sub>12</sub>.

Hyperhomocysteinaemia has been reported repeatedly in PD patients; the increase, however,

seems mostly related to the methylated catabolism of L-dopa, the main pharmacological treatment of PD (Martignoni et al 2007).

### OTHER USES

Vitamin B<sub>6</sub> supplements are effective for treating hereditary sideroblastic anaemia and refractory seizures in newborns, caused by pyridoxine withdrawal after delivery. Vitamin B<sub>6</sub> supplements have been used to prevent diabetic retinopathy and kidney stones, and to treat symptoms of vertigo, allergy to monosodium glutamate, asthma, photosensitivity and pervasive developmental disorders with hypersensitivity to sound. Women taking the oral contraceptive pill sometimes use supplemental B<sub>6</sub> to relieve mood disturbances and restore vitamin status. Whether supplementation has benefits in these circumstances remains unknown.

A small trial has shown some future potential clinical use in renal transplant patients with high homocysteine levels and endothelial dysfunction. A dose of folate (5 mg/day), B<sub>6</sub> (50 mg/day) and B<sub>12</sub> (1000 mcg/day) was given to stable renal transplant patients for 6 months and homocysteine levels decreased and endothelial function was improved compared to the control patients (Xu et al 2008). Further trials are needed to confirm this finding.

### Dream states

Many have suspected that pyridoxine supplements taken at night are able to influence dream states and sleep, causing disruption in some people. The results of a 2002 double-blind, placebo-controlled crossover study support this observation (Ebben et al 2002). Pyridoxine supplementation (250 mg) taken before bedtime was shown to significantly influence dream salience scores (a composite score containing measures for vividness, bizarreness, emotionality and colour), starting on the first night of treatment.

### Leg cramps during pregnancy

A study of 84 pregnant women with leg cramps found that a combination of vitamin B<sub>1</sub> (100 mg/day) and B<sub>6</sub> (40 mg/day) improved symptoms 7.5-fold, and this was a better result than given by treatment with calcium carbonate (Sohrabvand et al 2006).

### Irritable bowel syndrome (IBS)

In a cross-sectional study, IBS symptom score and dietary intake were assessed in 17 subjects with diagnosed IBS according to the Rome II criteria. The mean dietary intake was found to be 0.9 mg/day, below the recommended intake of 1.6 mg daily for men and 1.2 mg daily for women. The results indicated a high symptom score was associated with low vitamin B<sub>6</sub> intake ( $P = 0.0002$ ) (Ligaarden & Farup 2011). This was a preliminary study, and the authors recognise the possibility of a type II error due to the small study group. However,

this study may have clinical implications in the treatment and improvement of IBS symptoms with B<sub>6</sub> therapy, especially if given at therapeutic doses (minimum 5–25 mg to improve deficiency states). Further investigations need to be conducted to ascertain such possibilities.

### Mortality in the elderly

A recent study identified that higher intakes of vitamins B<sub>1</sub> and B<sub>6</sub> observed among Taiwanese elders were associated with increased survival rates in this population by up to 10 years (Huang et al 2012). The Taiwanese Elderly Nutrition and Health Survey (1999–2000) provided data from 1747 participants 65 years and older. Dietary and biochemical data were collected at baseline and survivorship was determined until 31 December 2008. After controlling for confounders, a significant difference in mortality was found when comparing people in the lowest tertile to the highest tertile for both B<sub>1</sub> and B<sub>6</sub> dietary intakes (hazard ratios 0.74 and 0.74 respectively). The authors concluded that deficiencies of vitamin B<sub>1</sub> and B<sub>6</sub> were found to be clearly predictive of mortality in elderly Taiwanese.

### DOSAGE RANGE

- Prevention of deficiency: Australian RDI for adults and children > 8 years: 1–1.7 mg/day.
- Treatment of deficiency: 5–25 mg/day.
- Morning sickness: 30–75 mg/day, sometimes taken as 25 mg three times daily. In clinical practice, monitored doses of 150 mg daily are often used.
- Symptoms of PMS: 100–500 mg/day.
- Elevated homocysteine levels: 100 mg/day (usually taken with B<sub>12</sub> and folic acid).
- Leg cramps in pregnancy: vitamin B<sub>1</sub> 100 mg/day and B<sub>6</sub> 40 mg/day.
- Schizophrenic people with TD: vitamin B<sub>6</sub> (1200 mg/day).

### TOXICITY

Symptoms of toxicity include paraesthesia, hyperaesthesia, bone pain, muscle weakness, numbness and fasciculation, most marked at the extremities (Dalton & Dalton 1987, Diegoli et al 1998). Some symptoms include unsteady gait, numbness of the hands and feet and impaired tendon reflexes. Excessive doses of vitamin B<sub>6</sub> cause degeneration of the dorsal root ganglia in the spinal cord, loss of myelination and degeneration of sensory fibres in the peripheral nerves.

The dose and time frame at which toxicity occurs vary significantly between individuals. Studies involving large population groups using 100–150 mg/day have shown minimal or no toxicity in 5–10-year studies, whereas studies of women self-medicating for PMS, taking  $117 \pm 92$  mg for  $2.9 \pm 1.9$  years, have reported increased incidence of peripheral neuropathy (Bernstein 1990, Dalton & Dalton 1987).

## ADVERSE REACTIONS

Pyridoxine is considered non-toxic, although nausea and vomiting, headache, paraesthesia, sleepiness and low-serum folic acid levels have been reported.

Supplements taken at night may result in more vivid dreams and, for some individuals, disrupted sleep (Ebben et al 2002).

## SIGNIFICANT INTERACTIONS

### Amiodarone

Pyridoxine may increase the risk of drug-induced photosensitivity. Exercise caution with patients taking pyridoxine and amiodarone concurrently.

### Antibiotics

Destruction of gastrointestinal flora can decrease endogenous production of vitamin B<sub>6</sub>. Increase intake of vitamin B<sub>6</sub>-rich foods or consider supplementation with long-term drug treatment.

### Hydralazine

Hydralazine may induce B<sub>6</sub> deficiency according to a clinical study. Increased intake may be required with long-term drug therapy.

### Isoniazid

Isoniazid increases vitamin B<sub>6</sub> requirements. Increase intake of vitamin B<sub>6</sub>-rich foods or consider supplementation with long-term drug treatment.

### L-dopa (without carbidopa)

In people with PD, L-dopa can cause hyperhomocysteinaemia, the extent of which is influenced by B vitamin status. To maintain normal plasma homocysteine concentrations, the B vitamin requirements are higher in L-dopa-treated patients than in those not on L-dopa therapy. B vitamin supplements may be warranted for PD patients on L-dopa therapy (Miller et al 2003).

### Oral contraceptives

Oral contraceptives increase vitamin B<sub>6</sub> requirements. Increase intake of vitamin B<sub>6</sub>-rich foods or consider supplementation with long-term drug treatment.

### Penicillamine

This drug increases vitamin B<sub>6</sub> requirements. Increase intake of vitamin B<sub>6</sub>-rich foods or consider supplementation.

### Phenobarbitone, phenytoin

Vitamin B<sub>6</sub> supplements may lower plasma levels and efficacy of these drugs. Monitor for drug effectiveness, and exercise caution when these drugs are being taken concurrently.

### Theophylline

May induce pyridoxine deficiency. Increased intake may be required with long-term drug therapy.

## CONTRAINDICATIONS AND PRECAUTIONS

Monitor long-term use of high-dose pyridoxine supplements (>100 mg, although this level varies between individuals).

## PREGNANCY USE

Pyridoxine supplements are commonly used during pregnancy to reduce symptoms of morning sickness, suggesting safety when used in appropriate doses.

### Practice points/Patient counselling

- Vitamin B<sub>6</sub> is available in many foods; however, several surveys suggest that inadequate intakes are common.
- Deficiency can manifest with psychological symptoms of depression, irritability and confusion, and physical symptoms of lethargy, dermatitis, angular stomatitis, glossitis and impaired immunity.
- Overall, clinical research supports the use of vitamin B<sub>6</sub> supplements in relieving mild to moderate symptoms of PMS (particularly breast tenderness and mood disturbance), nausea in pregnancy and as a treatment for hyperhomocysteinaemia (usually with folate and B<sub>12</sub>).
- Preliminary evidence suggests regular high dietary B<sub>6</sub> intake may have a protective effect in colorectal, breast, bladder and ovarian cancer risk, incidence of improvement of IBS symptomatology and possibly all-cause mortality.
- There is conflicting evidence as to whether vitamin B<sub>6</sub> supplements improve symptoms of CTS and autism (combined with magnesium), and whether they prevent febrile convulsions in children.
- Pyridoxine should not be used in high doses for the long term, as this can induce toxicity.

## ! PATIENTS' FAQs

### What will this vitamin do for me?

Vitamin B<sub>6</sub> is essential for the body's normal functioning. It has been used to treat many different conditions; however, scientific evidence generally supports its use in only a few conditions (e.g. morning sickness, mild to moderate PMS and elevated homocysteine levels).

### When will it start to work?

This will depend on what is being treated. With regard to PMS symptoms, effects may take two to three menstrual cycles, whereas for morning sickness effects can be seen within 2–3 days.

### Are there any safety issues?

High doses should not be taken for the long term, as this can cause toxicity.

## Vitamin B<sub>12</sub>

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin B<sub>12</sub> (cobalamin) is a water-soluble vitamin obtained mostly from animal protein products in the diet. In the stomach gastric acid is required to liberate protein-bound cobalamin, which is then immediately bound to R-binders (glycoproteins) that protect it from being denatured. When the contents of the stomach reach the duodenum, the R-binders are partially digested by pancreatic proteases, releasing them to bind to intrinsic factor (a glycoprotein), which is secreted by the parietal cells of the gastric mucosa. This complex is then absorbed in the terminal ileum and transported to cells, where it carries out its metabolic function, or to the liver, where it is stored until required (FAO/WHO 2002, Oh & Brown 2003). An alternative method of absorption, which is independent of intrinsic factor, also appears to exist and accounts for the absorption of approximately 1% of large oral doses (> 300 mcg) of B<sub>12</sub> (Elia 1998). Absorption via intrinsic factor is limited to about 1.5–2.0 mcg/meal owing to limited receptor capacity (FAO/WHO 2002).

### CHEMICAL COMPONENTS

Vitamin B<sub>12</sub> is the largest of the B vitamins and is a complex structure containing a central cobalt atom. There are five forms of B<sub>12</sub>: cyanocobalamin (a synthetic form that has a cyanide attached to the cobalt), hydroxycobalamin (hydroxyl group attached to the cobalt; it is produced for parenteral administration), aquacobalamin (water group bound to the cobalt) and the coenzymatically active forms (methylcobalamin and 5-deoxyadenosylcobalamin), in which a methyl group or a 5-deoxyadenosyl

#### **Clinical note — Nori: a source for vegetarians**

While the majority of non-meat sources of vitamin B<sub>12</sub> do not contain the biologically active form, it is possible to get B<sub>12</sub> from some non-meat foods. In fact, improvements in B<sub>12</sub> status have been observed following the ingestion of nori (seaweed). Nori is said to contain as much B<sub>12</sub> as liver (Croft et al 2005), approximately 55–59 mcg/100 g dry weight. Five different biologically active vitamin B<sub>12</sub> compounds have been identified in nori: cyanocobalamin, hydroxycobalamin, sulfitocobalamin, adenosylcobalamin and methylcobalamin (Takenaka et al 2001); the source of B<sub>12</sub> appears to be bacteria (Croft et al 2005).

group is bound to the cobalt atom (FAO/WHO 2002, Freeman et al 1999).

### FOOD SOURCES

Vitamin B<sub>12</sub> is found in lamb's liver, sardines, oysters, egg yolk, fish, beef, kidney, cheese and milk. Up to 10% is lost in cooking (Wahlqvist 2002). Fortified breakfast cereals are also available.

Vitamin B<sub>12</sub> bioavailability significantly decreases with increasing intake as the intrinsic factor-mediated intestinal absorption system is estimated to be saturated at about 1.5–2.0 mcg/meal for healthy adults with normal gastrointestinal function. The bioavailability of vitamin B<sub>12</sub> from different sources is variable: fish (42%), lamb (56–89%), chicken (61–66%) and eggs (<9%) (Watanabe 2007).

Plants do not contain B<sub>12</sub> because they have no cobalamin-dependent enzymes (Croft et al 2005). Most microorganisms, including bacteria and algae, synthesise B<sub>12</sub>, which then makes its way into the food chain (FAO/WHO 2002). Human intestinal bacteria also synthesise B<sub>12</sub>, but this is not absorbed to any considerable extent (Wahlqvist 2002). Vegans living in situations with more stringent hygiene are therefore more likely to develop deficiencies.

### DEFICIENCY SIGNS AND SYMPTOMS

Vitamin B<sub>12</sub> deficiencies manifest primarily as haematological and neurological disturbances. The elderly are particularly at risk, with vitamin B<sub>12</sub> deficiency estimated to affect 10–15% of individuals over the age of 60 years (Baik & Russell 1999).

- Haematological: macrocytic (megaloblastic) anaemia, pancytopenia (leucopenia, thrombocytopenia); symptoms may include lethargy, dyspnoea, anorexia, weight loss and pallor (Wahlqvist 2002).
- Neurological disturbances: paraesthesias, ataxia, optic neuropathy (reversible), peripheral neuropathy and demyelination of the corticospinal tract and dorsal columns (subacute combined systems disease).
- Psychological disturbances: impaired memory, irritability, depression, personality change, dementia, delirium and psychosis (Lee 1999, Lindenbaum et al 1988). A case report of vitamin B<sub>12</sub> deficiency presenting as obsessive compulsive disorder has been described (Sharma & Biswas 2012).
- Various gastrointestinal symptoms can also develop, such as loss of appetite, intermittent constipation and diarrhoea, glossitis and abdominal pain.
- Folic acid supplementation may mask an underlying B<sub>12</sub> deficiency, leading to the progression of neurological symptoms.

### Primary deficiency

People at risk are those living in India, Central and South America, and selected areas in Africa (Stabler & Allen 2004), strict vegetarians and vegans, breast-fed infants of vegetarian mothers with low B<sub>12</sub> stores, elderly patients with 'tea and toast diets' and chronic alcoholics. Vitamin B<sub>12</sub> deficiency exists more commonly among vegans than vegetarians, with depletion or deficiency of vitamin B<sub>12</sub> found to occur irrespective of demographic, place of residency, age or type of vegetarian diet (Pawlak et al 2013). Approximately 62% of pregnant vegetarians are B<sub>12</sub>-deficient as are 25–86% of vegetarian children, 21–41% of vegetarian adolescents and 11–90% of elderly vegetarians.

As vitamin B<sub>12</sub> is stored to a considerable extent, even after complete depletion of food-ingested cobalamin, clinically relevant deficiencies will usually only develop after 5–10 years (Schenk et al 1999). This time frame increases to an average of approximately 18 years in strict vegetarians when intrinsic factor secretion is intact (Babior 1996). In this case, some enterohepatic recycling of cobalamin should occur in the distal ileum (Howden 2000).

### Secondary deficiency

Vitamin B<sub>12</sub> deficiency is more likely to result from inadequate absorption, defects in vitamin B<sub>12</sub> metabolism or gastrointestinal disorders than a lack of dietary intake.

- Pernicious anaemia: an autoimmune condition affecting gastric parietal cells that produce intrinsic factor; common cause of megaloblastic anaemia, especially in persons of European or African descent (Stabler & Allen 2004).
- Methylmalonic acidaemia: inherited defect in B<sub>12</sub> metabolism.
- Congenital absence of transcobalamin II.
- Medications that reduce gastric acidity (e.g. H<sub>2</sub> blockers and proton pump inhibitors [PPIs]).
- Atrophic gastritis/gastric atrophy: probably due to a decrease in acid output and intrinsic factor production (Schenk et al 1999). Gastric atrophy is more common in the elderly.
- Intestinal resection of the part of the ileum where absorption takes place or gastric resection, which affects the parietal cells and in turn production of intrinsic factor.
- Achlorhydria (Termanini et al 1998).
- Pancreatic insufficiency: the cobalamin-R-protein complex is split by pancreatic enzymes in the duodenum (Festen 1991).
- Ileal dysfunction (Howden 2000): may affect absorption at this site.
- Crohn's disease, irritable bowel disease, coeliac disease: reduced absorption.
- Bacteria and parasites in the intestine may also compete for B<sub>12</sub>.
- Radiotherapy for rectal cancer: causes a rapid and persistent decrease in B<sub>12</sub> status, as reflected by reduced serum B<sub>12</sub> combined with increased serum methylmalonic acid (MMA) (Gronlie Guren et al 2004).
- Nitrous oxide may induce or potentiate B<sub>12</sub> deficiency myelopathy (Hathout & El-Saden 2011).

The elderly deserve a separate mention as a population at risk of deficiency because of both primary and secondary causes, such as poor dietary intake, failure to separate vitamin B<sub>12</sub> from food protein, inadequate absorption, utilisation and storage, as well as drug–food interactions leading to malabsorption and metabolic inactivation (Bradford & Taylor 1999, Dharmarajan et al 2003). Subtle signs of deficiency may include lethargy, weight loss and dementia (Dharmarajan et al 2003).

### Elevated B<sub>12</sub> levels

Elevated levels of serum cobalamin may be a sign of a serious, even life-threatening, disease such as chronic myelogenous leukaemia, promyelocytic leukaemia, polycythaemia vera, hypereosinophilic syndrome, acute hepatitis, cirrhosis, hepatocellular carcinoma and metastatic liver disease. Elevated B<sub>12</sub> levels, therefore, warrant a full diagnostic workup to assess the presence of disease (Ermens et al 2003).

### Liver failure mortality

A prospective study of patients with acute-on-chronic liver failure ( $n = 105$ ) found that elevated vitamin B<sub>12</sub> levels on hospital admission were associated with increased severity of liver disease and 3-month mortality rate (Dou et al 2012).

#### Clinical note — Testing for vitamin B<sub>12</sub> deficiency

Numerous studies have indicated that serum B<sub>12</sub> levels are an inadequate guide to B<sub>12</sub> status (Briddon 2003, Carmel 1988, Kapadia 2000, Karnaze & Carmel 1990, Termanini et al 1998). The use of this test has led to poorly defined reference intervals for serum B<sub>12</sub> (Briddon 2003), potentially delaying the diagnosis and allowing the progression of B<sub>12</sub> deficiency. Approximately 50% of patients with subclinical disease have normal serum B<sub>12</sub> levels and older patients present with neurological and psychiatric symptoms without haematological findings. In addition, use of the oral contraceptive pill may affect test results (Bor 2004). As a result, this method of testing has lost favour as an adequate measure of B<sub>12</sub> status. A combination of two tests appears to be more conclusive. Elevated levels of total homocysteine in serum and plasma reflect deficiencies of either folate or B<sub>12</sub>. MMA is a more specific marker of cobalamin function, but renal insufficiency may affect the results of this test. Therefore, a combination of the two is probably the clearest indicator (Bjorke Monsen & Ueland 2003, FAO/WHO 2002, Kapadia 2000). Preliminary evidence also suggests that overnight fasting urinary MMA concentrations correlate strongly with serum MMA; however, further investigations are required to confirm the application of this test in various populations (Kwok et al 2004). While the use of such markers may improve the assessment of B<sub>12</sub> deficiency, establishing the cause of deficiency should also be part of the diagnostic approach (Schneede & Ueland 2005).

## MAIN ACTIONS

### Important cofactor

Vitamin B<sub>12</sub> is essential for the normal function of all cells. It affects cell growth and replication, the metabolism of carbohydrates, lipids and protein and is involved in fatty acid and nucleic acid synthesis. It is also involved in the production of red blood cells in bone marrow, and activates folacin coenzymes for red blood cell production.

### Homocysteine reduction

Methylcobalamin aids in the conversion of homocysteine to methionine by the action of methionine synthase, transferring a methyl group from methylfolate (folic acid).

After conversion from homocysteine, methionine is then converted to *S*-adenosyl-L-methionine (SAME), important for methylation reactions and protein synthesis. An increase in homocysteine levels and decrease in SAME levels have been implicated in depression and may also contribute to the neurological symptoms seen in pernicious anaemia (IMG 2003).

### Nervous system

Vitamin B<sub>12</sub> is involved in the synthesis of protein structures in the myelin sheath and nerve cells. As methylation is required for the production of myelin basic protein, a reduction in B<sub>12</sub> and SAME will result in demyelination of peripheral nerves and the spinal column (subacute combined degeneration; FAO/WHO 2002).

### Immune system

Vitamin B<sub>12</sub> acts as an immunomodulator for cellular immunity (Tamura et al 1999).

### Liver

Vitamin B<sub>12</sub> deficiency results in decreased serine dehydratase (SDH) and tyrosine aminotransferase activities in rat livers (Ebara et al 2008). In dimethylnitrosamine-induced liver injury in mice, vitamin B<sub>12</sub> decreased the blood levels of aspartate aminotransferase and alanine aminotransferase, suggesting a possible hepatoprotective effect (Isoda et al 2008).

### Antioxidant capacity

Recent studies have identified that vitamin B<sub>12</sub> and its cobalamin-based derivatives are powerful antioxidants at pharmacological concentrations (Birch et al 2009, Moreira et al 2011, Weinburg et al 2009).

## CLINICAL USE

Vitamin B<sub>12</sub> supplementation is administered using various routes, such as intravenous and oral doses. This review will focus on oral supplementation as this is the form generally used by the public and is available over the counter. It is sometimes used in combination with other B group vitamins, in particular B<sub>6</sub> and folate.

### Deficiency: treatment and prevention

Traditionally, vitamin B<sub>12</sub> supplementation has been used to treat deficiency or prevent it in conditions such as pernicious anaemia and atrophic gastritis, but special consideration should be given to the elderly, who are at high risk.

### Pernicious anaemia

Pernicious anaemia is caused by a deficiency of intrinsic factor, leading to malabsorption of vitamin B<sub>12</sub>. Signs and symptoms include pallor, glossitis, weakness and neurological symptoms, including paraesthesias of the hands and feet, decreased deep-tendon reflexes and loss of sensory perception and motor controls (neurological symptoms may be

irreversible). In more progressed conditions confusion, memory loss, moodiness, psychosis and delusional behaviour may be present. Achlorhydria and gastric mucosal atrophy may also occur, further complicating the condition.

Uncomplicated pernicious anaemia is characterised by mild or moderate megaloblastic anaemia without leucopenia, thrombocytopenia or neurological symptoms. In more advanced cases urgent parenteral administration of vitamin B<sub>12</sub> and folic acid (typically 100 mcg of cyanocobalamin and 1–5 mg of folic acid) is given intramuscularly, as well as blood transfusions.

### Atrophic gastritis

Elderly patients with atrophic gastritis appear to have higher rates of vitamin B<sub>12</sub> deficiency ( $P < 0.01$ ) which responds to B<sub>12</sub> supplementation (Lewerin et al 2008).

### Infants

In infants, severe vitamin B<sub>12</sub> deficiency can cause neurological symptoms, including irritability, failure to thrive, apathy, anorexia and developmental regression which responds well to supplementation (Dror & Allen 2008). A large cohort study ( $n = 2001$ ) found that vitamin B<sub>12</sub> levels at birth did not affect asthma or eczema-related outcomes between birth and age 6 (van der Valk et al 2013).

### Elderly

Vitamin B<sub>12</sub> deficiency is common in the elderly, with estimates as high as 43% (Wolters et al 2004). Poor vitamin B<sub>12</sub> status has been associated with vascular disease, depression, impaired cognitive performance and dementia. Elderly patients (>60 years) should be monitored for evidence of B<sub>12</sub> deficiency (a minimum threshold of 220–258 pmol/L [300–350 pg/mL] is desirable in the elderly) and general supplementation with vitamin B<sub>12</sub> (> 50 mcg/day) should be considered (Wolters et al 2004). Significantly higher doses may be required to correct deficiency. A randomised, parallel-group, double-blind, dose-finding trial found that the lowest dose of oral cyanocobalamin required to normalise mild vitamin B<sub>12</sub> deficiency in the elderly is 647–1032 mcg/day, more than 200-fold the recommended dietary allowance (Eussen et al 2005). Conversely another randomised controlled trial (RCT) reported that even low doses of B<sub>12</sub> could improve the vitamin status in elderly people with food-bound vitamin B<sub>12</sub> malabsorption. The dose required to increase mean serum vitamin B<sub>12</sub> by 37 pmol/L was 5.9 mcg/day (95% confidence interval [CI] 0.9–12.1) (Blacher et al 2007). In another study of elderly people with malabsorption taking 1000 mcg/day of crystalline cyanocobalamin for 1 month, 85% of subjects normalised their serum cobalamin concentrations, and all subjects corrected their initial macrocytosis and had medullar regeneration with a mean increase in reticulocyte count (Andres et al 2006). While hearing loss has been associated with

poor B<sub>12</sub> status in the elderly, short-term supplementation has so far failed to show benefits (Park et al 2006).

### Pemetrexed treatment

To reduce the incidence of adverse effects, pretreatment with folate and vitamin B<sub>12</sub> is recommended prior to treatment with pemetrexed, an antifolate chemotherapeutic used in non-small-cell lung cancer (Molina & Adjei 2003). No significant difference in adverse effects was noted in a trial which compared duration of folate and vitamin B<sub>12</sub> (5–14 days versus less than 4 days: Kim et al 2013).

### Hyperhomocysteinaemia

Vitamin B<sub>12</sub> alone may not be sufficient to normalise elevated homocysteine levels (Yajnik et al 2007). As a result, vitamin B<sub>12</sub> is often recommended in combination with folic acid and vitamin B<sub>6</sub> in conditions for which homocysteine is implicated as a possible causative factor.

#### **Clinical note — Oral forms are effective**

Vitamin B<sub>12</sub> is often given parenterally as an intramuscular injection, based on the understanding that oral doses will not be efficacious in cases of malabsorption.

There is now considerable evidence that oral vitamin B<sub>12</sub> therapy is comparable in efficacy to parenteral therapy, even when intrinsic factor is not present or in other diseases affecting absorption (Andres et al 2005a, 2005b, Castelli et al 2011, Delpre et al 1999, Oh & Brown 2003, Roth & Orija 2004, Vidal-Alaball et al 2005, Wellmer et al 2006). A 2005 Cochrane review suggested that 2000 mcg/day of oral vitamin B<sub>12</sub> or 1000 mcg initially daily then weekly and monthly may be as effective as intramuscular injections in obtaining short-term haematological and neurological responses in vitamin B<sub>12</sub>-deficient patients (Vidal-Alaball et al 2005). As rare cases of anaphylaxis may occur with parenteral administration, oral therapy is also considered a safer option with improved cost and compliance (Bilwani et al 2005, Bolaman et al 2003). At doses of 500 mcg/day, correction of serum B<sub>12</sub> levels is likely to occur within 1 week to 1 month, with correction of haematological abnormalities after at least 3 months (Andres et al 2005b).

### Cardiovascular protection

In practice, the relative safety and affordability of combined vitamin B supplementation (B<sub>12</sub>, folic acid and B<sub>6</sub>) make it an attractive recommendation in people with familial hyperhomocysteinaemia. Whether lowering total homocysteine improves cardiovascular mortality and morbidity is questionable, as large-scale clinical trials and meta-analyses have

failed to demonstrate any benefits for either B<sub>12</sub> alone or in combination for reducing overall cardiovascular risk, despite showing a reduction in homocysteine levels (Albert et al 2008, Clarke et al 2007, Mann et al 2008, Marcus et al 2007, Ray et al 2007). Furthermore, a 2013 Cochrane systematic review concluded that there was insufficient evidence to support the use of homocysteine-lowering interventions, including vitamin B<sub>12</sub>, to prevent cardiovascular events (Martí-Carvajal et al 2013).

Failure of combined B vitamin therapy to reverse inflammatory processes associated with atherogenesis may partly explain the negative results (Bleie et al 2007). The consistent findings of an association between elevated plasma total homocysteine levels and vascular risk is yet to be fully explained; however it is possible that the association is a consequence rather than a cause of disease (Toole et al 2004).

### Cardiovascular disease

There is very limited evidence from cohort studies that vitamin B<sub>12</sub> deficiency predisposes for cardiovascular disease or diabetes according to a systematic review (Rafnsson et al 2011). As such, current data do not support the use of vitamin B<sub>12</sub> supplementation to reduce the risk of either of these diseases. An intervention study, VITATOPS, was a randomised, double-blind, placebo-controlled trial ( $n = 8164$ ), which also found that daily administration of B<sub>12</sub> in combination with folic acid and vitamin B<sub>6</sub> did not reduce the incidence of major vascular events such as stroke or transient ischaemic attacks (TIAs) in elderly patients with a recent history of stroke or TIA (VITATOPS Trial Study Group 2010).

### Renal transplant recipients

Although studies investigating the effects of vitamin B<sub>12</sub> as a stand-alone treatment in this condition are not available, several clinical studies have produced conflicting evidence for the use of combination vitamin B treatment (vitamin B<sub>12</sub>, folic acid and B<sub>6</sub>).

An RCT involving 56 renal transplant patients found that vitamin supplementation with folic acid (5 mg/day), vitamin B<sub>6</sub> (50 mg/day) and vitamin B<sub>12</sub> (400 mcg/day) for 6 months reduced the progression of atherosclerosis. Patients taking the vitamin combination experienced a significant decrease in homocysteine levels and carotid intima media thickness, which is reflective of early atherosclerosis (Marcucci et al 2003). In another trial, 36 stable renal transplant recipients with hyperhomocysteinaemia received a similar combination of 5 mg folic acid and 50 mg B<sub>6</sub>, in addition to either 1000 mcg B<sub>12</sub> or placebo per day for 6 months. Supplementation decreased blood homocysteine and improved endothelium-dependent and independent vasodilation responses (Xu et al 2008). Despite these preliminary findings, combined therapy using even higher doses (40 mg folic acid, 100 mg B<sub>6</sub> and 2 mg B<sub>12</sub>) did not improve survival (448 vitamin

group deaths vs 436 placebo group deaths) (hazard ratio 1.04; 95% CI 0.91–1.18) or reduce the incidence of vascular disease (myocardial infarct, stroke and amputations) in patients with advanced chronic kidney disease or end-stage renal disease (Jamison et al 2007).

### Restenosis after percutaneous coronary intervention

An RCT found that vitamin B<sub>12</sub> (cyanocobalamin, 400 mcg/day), folic acid (1 mg/day) and vitamin B<sub>6</sub> (pyridoxine hydrochloride, 10 mg/day) taken for 6 months significantly decreased the incidence of major adverse events, including restenosis after percutaneous coronary intervention (Schnyder et al 2002).

### Neural tube defects

Vitamin B<sub>12</sub> is required to cleave folate, without which folate is not effective, and postpartum analysis of serum B<sub>12</sub> levels has shown an increased risk of neural tube defects in women with low B<sub>12</sub> status (Groenen et al 2004, Ray & Blom 2003, Suarez et al 2003). Some authors have called for combined fortification of food with folic acid and vitamin B<sub>12</sub> because there are concerns about masking B<sub>12</sub> deficiency (Czernichow et al 2005).

### Noise-induced hearing loss

Homocysteine levels are significantly higher in subjects with noise-induced hearing loss as compared to healthy controls (Gok et al 2004) and elevated plasma B<sub>12</sub> levels appear to play a protective role (Quaranta et al 2004).

### Recurrent abortion

There appears to be a correlation between low serum B<sub>12</sub> levels, increased homocysteine levels and early or very early recurrent abortion in some women (Reznikoff-Etievant et al 2002, Zetterberg et al 2002). One small study of five women with a history of very early recurrent abortion found that vitamin B<sub>12</sub> supplementation resulted in four normal pregnancies (Reznikoff-Etievant et al 2002). Further research is required to investigate possible benefits.

### Osteoporosis — inconclusive

Elevated homocysteine levels have been suggested as a risk factor for osteoporosis (Herrmann et al 2005); however, this remains uncertain. A meta-analysis of six studies identified that vitamin B<sub>12</sub> and homocysteine levels were significantly increased in postmenopausal osteoporotic women compared to controls (Zhang et al 2014), whereas a more recent meta-analysis found no association between homocysteine, folate or vitamin B<sub>12</sub> with bone mineral density in women (van Wijngaarden et al 2013). A small intervention study of women over 65 years of age ( $n = 31$ ) with elevated homocysteine levels found that treatment with the combination of vitamin B<sub>12</sub> and folate had no significant effect on bone turnover or bone health (Keser et al 2013).

## Depression

Elevation of homocysteine and low levels of vitamin B<sub>12</sub> and folate are commonly seen in depression (Coppen & Bolander-Gouaille 2005). Observational studies have found as many as 30% of patients hospitalised for depression to be deficient in vitamin B<sub>12</sub> (Hutto 1997). A cross-sectional study of 700 community-living, physically disabled women over the age of 65 years found that vitamin B<sub>12</sub>-deficient women were twice as likely to be severely depressed as non-deficient women (Penninx et al 2000). Similarly, a recent Finnish study found that, in subjects aged 45–74 years, vitamin B<sub>12</sub> level was associated with melancholic depressive symptoms, but not with non-melancholic depressive symptoms (Seppälä et al 2013).

A study of 225 hospitalised acutely ill older patients receiving 400 mL of an oral nutritional supplement (106 subjects) or placebo (119 subjects) daily for 6 weeks reported significant increases in plasma vitamin B<sub>12</sub> concentrations and red cell folate, and a decrease in depression scores (Gariballa & Forster 2007). Whether the study cohort were B<sub>12</sub>-deficient at baseline was not clear.

## AIDS and HIV

Low vitamin B<sub>12</sub> levels are often observed in patients infected with HIV type 1 (Remacha & Cadafalch 1999, Remacha et al 1993). One study identified deficiency in 10–35% of all patients seropositive for HIV, presumably as a result of decreased intake, intestinal malabsorption and/or abnormalities in plasma-binding proteins or antagonism by the drug azidothymidine. Importantly, as serum cobalamin levels declined, progression to AIDS increased and neurological symptoms worsened.

## Adjuvant treatment in hepatitis C infection

The combination of vitamin B<sub>12</sub> with standard treatment significantly improved viral response compared to standard treatment only in antiviral-naïve patients with chronic hepatitis C virus infection (Rocco et al 2013).

## Cognitive impairment and dementia

More than 77 cross-sectional studies including more than 34,000 subjects have reported a significant association between low blood levels of folate and B<sub>12</sub> (or high levels of homocysteine) and prevalent dementia. The association has been described for different types of cognitive impairment, including vascular dementia, Alzheimer's disease and mild cognitive impairment; however, it is not clear whether low B<sub>12</sub> was a cause or consequence of dementia (Vogel et al 2009). A positive association between serum homocysteine levels and incidence of dementia has also been described in a recent meta-analysis of eight cohort studies ( $n = 8669$ ; odds ratio 1.50; 95% CI 1.13–2.00) (Wald et al 2011).

Despite this possible association, few interventional studies using B<sub>12</sub> supplementation have been conducted. A systematic review reports on six

RCTs utilising B<sub>12</sub> supplementation for effects on cognitive function; however, the range of doses and administration forms together with cognitive status of volunteers and measures used make interpretation difficult (Vogel et al 2009). Overall, the review concludes that there is insufficient evidence to suggest vitamin B<sub>12</sub> supplementation to improve cognitive decline or incidence of dementia but also states there are several confounding factors to consider. Unfortunately, few studies considered taking fasting B<sub>12</sub> blood samples at baseline: the possibility of misclassification of study subjects as cognitive-impaired (or demented) or healthy and classing subjects with normal scores on cognitive tests as healthy even though they have Alzheimer's disease at the preclinical state are other confounding factors.

This is important to bear in mind when considering that, while some interventional studies are negative, there are also positive studies showing that supplementation with vitamin B<sub>12</sub> significantly reversed impaired mental function in individuals with pre-existing low levels (Healton et al 1991, Miller 2003, Refsum & Smith 2003, Tripathi et al 2001, Weir & Scott 1999).

Interestingly, women in the highest quartile of plasma vitamin B<sub>12</sub> levels during midlife scored significantly higher on cognitive function tests in later years and were cognitively equivalent to those 4 years younger (Kang & Grodstein 2005). Another study of 370 non-demented 75-year-olds found a twofold increased risk of developing Alzheimer's dementia in subjects with low serum levels of vitamin B<sub>12</sub> and folate over a 3-year period (Wang et al 2001).

## Diabetic neuropathy

According to a 2005 review of seven RCTs, vitamin B<sub>12</sub> supplementation may improve pain and paraesthesia in patients with diabetic neuropathy (Sun et al 2005). The studies cited, however, were generally of low quality and more research is required to confirm these results and determine whether positive effects are due to the correction of deficiency or to alteration of abnormal metabolism.

## Sleep disorders

A preliminary study investigated the effects of randomly assigned methyl- and cyanocobalamin on circadian rhythms, wellbeing, alertness and concentration after 14 days in 20 healthy subjects (Mayer et al 1996). Methylcobalamin supplementation led to a significant decrease in daytime melatonin levels, improved sleep quality, shorter sleep cycles, increased feelings of alertness, better concentration and a feeling of waking up refreshed in the morning. It appeared that methylcobalamin was significantly more effective than cobalamin.

## Tinnitus

A group of 113 army personnel (mean age 39 years) exposed to military noise was studied, of which 57 had chronic tinnitus and noise-induced hearing loss

(Shemesh et al 1993). Of this subset, 47% also had vitamin B<sub>12</sub> deficiency. Treatment with vitamin B<sub>12</sub> supplementation produced some improvement in tinnitus and associated symptoms.

### OTHER USES

Human trials have shown vitamin B<sub>12</sub> levels to be low in people with recurrent aphthous stomatitis, suggesting a possible aetiological factor (Piskin et al 2002). An inhalation of vitamin B<sub>12</sub> mixed solution has been shown to be effective for the treatment of acute radiation-induced mucosal injury (Chen & Shi 2006).

### Prostate cancer risk — no association

A large-scale population-based study ( $n = 317,000$ ) found no association with vitamin B<sub>12</sub> levels and prostate cancer risk (de Vogel et al 2013).

### Erythema nodosum

A case report exists of a 38-year-old female diagnosed with erythema nodosum and B<sub>12</sub> deficiency whose symptoms resolved completely without recurrence following vitamin B<sub>12</sub> therapy (Volkov et al 2005). Testing for deficiency may be advised in such cases.

### Atopic dermatitis

A novel use for B<sub>12</sub> in a topical cream for atopic dermatitis was tested in a prospective, randomised, placebo-controlled phase III multicentre trial involving 49 patients. Subjects applied the B<sub>12</sub> cream twice daily to one side of the body and a placebo cream to the contralateral side, according to the randomisation scheme, for 8 weeks. The B<sub>12</sub> cream was reported to significantly improve the extent and severity of atopic dermatitis and was considered safe and very well tolerated (Stucker et al 2004).

### Multiple sclerosis

Multiple sclerosis (MS) and vitamin B<sub>12</sub> deficiency share common inflammatory and neurodegenerative characteristics and low or decreased levels of vitamin B<sub>12</sub> have been demonstrated in MS patients and may correlate with early onset (<18 years) (Miller et al 2005). Considering vitamin B<sub>12</sub> is a cofactor, and myelin formation has important immunomodulatory and neurotrophic effects (Loder et al 2002, Miller et al 2005, Sandyk & Awerbuch 1993), a theoretical basis exists for its use in MS.

### Amyotrophic lateral sclerosis (ALS)

Early evidence suggests a possible benefit for long-term ultra-high-dose methylcobalamin (administered intravascularly or intramuscularly) for sporadic or familial cases of ALS (motor neuron disease) (Izumi & Kaji 2007); however, large-scale clinical trials are required to assess the efficacy and safety of this treatment.

### Schizophrenia

An improvement in the negative symptoms of schizophrenia was seen following daily vitamin B<sub>12</sub>

(400 mcg) and folic acid (2 mg) supplementation during a 16-week multicentre RCT (Roffman et al 2013). Treatment response was affected by genetic variation in folic acid absorption. The effect of vitamin B<sub>12</sub> in the absence of folic acid was not investigated.

### DOSAGE RANGE

#### Australian recommended daily intake

- Adult >13 years: 2.4 mcg/day.
- Pregnancy: 2.6 mcg/day.
- Lactation: 2.8 mcg/day.
- Requirements may be higher for elderly people with impaired digestion or absorption.
- Sublingual cyanocobalamin: 1000–2000 mcg/day taken 30 min before breakfast.
- Pernicious anaemia: generally, vitamin B<sub>12</sub> 1000 mcg intramuscularly 2–4 times weekly is given until haematological abnormalities are corrected, and then it is given once monthly. Alternatively, oral B<sub>12</sub> can be given in very large doses (0.5–2 mg/day). Correction of haematological abnormalities usually occurs within 6 weeks of treatment, but neural improvement may take up to 18 months.
- Homocysteine lowering: 0.5 mg/day (Dusitanond et al 2005).

Note: Sublingual cobalamin is the preferred oral form for many practitioners, with methylcobalamin also becoming available in some regions.

### ADVERSE REACTIONS

Although adverse effects to parenteral cobalamin have been reported, oral supplements appear to be well tolerated (Branco-Ferreira et al 1997, Hillman 1996).

### SIGNIFICANT INTERACTIONS

#### Carbamazepine

In studies with children, long-term carbamazepine use led to a decrease in vitamin B<sub>12</sub> levels (Karabiber et al 2003) — observe for signs and symptoms of B<sub>12</sub> deficiency. Increased intake may be required with long-term therapy.

#### Colchicine

The use of colchicine may reduce the absorption of orally administered vitamin B<sub>12</sub> — monitoring of serum B<sub>12</sub> concentration is recommended, particularly if there is a history of deficiency.

#### Gastric acid inhibitors: PPI and H<sub>2</sub> receptor antagonists

Gastric acid is required to liberate protein-bound cobalamin. Therefore, vitamin B<sub>12</sub> concentration may be decreased when gastric acid is markedly suppressed for prolonged periods (Laine et al 2000, Schenk et al 1999, Termanini et al 1998). Studies have shown that omeprazole therapy acutely decreases cyanocobalamin absorption in a dose-dependent manner

(Marcuard et al 1994, Saltzman et al 1994) and deficiency may occur with long-term use (Valuck & Ruscini 2004). Additionally, a large-scale 2013 case-control study found that use of PPIs or H<sub>2</sub> receptor antagonists for 2 years or more was associated with an increased risk of vitamin B<sub>12</sub> deficiency (Lam et al 2013). It should be noted that vitamin B<sub>12</sub> supplements do not suffer the same fate, as they are not bound to protein — observe for signs and symptoms of B<sub>12</sub> deficiency; vitamin B<sub>12</sub> supplements may be required with long-term therapy.

### Hydrochlorothiazide

There are a number of medications that have the ability to increase homocysteine levels, such as hydrochlorothiazide (Westphal et al 2003), therefore concurrent use of vitamin B<sub>12</sub> (with folic acid) may be a useful adjunct — potential beneficial interaction.

### Lithium

Lithium administration may result in a decrease in serum B<sub>12</sub> concentration; however, the clinical significance of these findings is not yet clear (Cervantes et al 1999). Beneficial interaction is possible.

### Metformin

In patients with type 2 diabetes, metformin has been shown to reduce levels of vitamin B<sub>12</sub> (and folate) and increase homocysteine (Sahin et al 2007). This effect was not demonstrated in women with polycystic ovary syndrome who were taking metformin and receiving vitamin B<sub>12</sub> and folate substitution, a daily oral multivitamin tablet, and dietary and lifestyle advice (Carlsen et al 2007). Supplementation may be beneficial.

### Oral contraceptive pill

Users of the oral contraceptive pill showed significantly lower concentrations of cobalamin than controls in a 2003 clinical study (Sutterlin et al 2003). However, it would appear that this may be due to an effect on B<sub>12</sub>-binding proteins in serum affecting test results, because total homocysteine and MMA markers were unchanged and no symptoms of deficiency were present (Bor 2004) — observe for signs and symptoms of B<sub>12</sub> deficiency and conduct testing if deficiency is suspected.

### Phenobarbitone and phenytoin

One clinical study reports that combined long-term use of phenobarbitone and phenytoin resulted in significantly increased serum levels of vitamin B<sub>12</sub> (Dastur & Dave 1987) — observe patients taking this combination.

### Prednisolone

Decreased vitamin B<sub>12</sub> levels have been reported in the cerebrospinal fluid and serum of MS patients following high-dose (1000 mg daily for 10 days) intravenous methylprednisolone (Frequin et al 1993). Given the suggested importance of B<sub>12</sub> in MS sufferers, a beneficial interaction is possible.

### Sodium valproate

Administration of sodium valproate has been shown to increase plasma vitamin B<sub>12</sub> concentrations, with one study citing increases of over 50% of baseline (Gidal et al 2005).

### Tetracycline antibiotics

B complexes containing B<sub>12</sub> may significantly reduce the bioavailability of tetracycline hydrochloride (Omray 1981) — separate doses by at least 2 hours.

#### Practice points/Patient counselling

- Vitamin B<sub>12</sub> (cobalamin) is a water-soluble vitamin obtained mostly from animal protein products in the diet.
- There is considerable evidence that oral vitamin B<sub>12</sub> therapy is comparable in efficacy to parenteral therapy, even when intrinsic factor is not present or in other diseases affecting absorption.
- As numerous studies have indicated that serum B<sub>12</sub> levels are an inadequate guide to B<sub>12</sub> status, a combination of total homocysteine and MMA is probably the clearest indicator, although discrepancies can still occur.
- Vitamin B<sub>12</sub> deficiencies manifest primarily as haematological and neurological disturbances and are estimated to affect 10–15% of individuals over the age of 60 years.
- Traditionally, supplementation is recommended to treat deficiency states or prevent them in people at risk, such as in pernicious anaemia or atrophic gastritis.
- When administered together with folic acid and vitamin B<sub>6</sub> (pyridoxine), vitamin B<sub>12</sub> is used to reduce homocysteine levels. In this way, vitamin B<sub>12</sub> is sometimes recommended in conditions where homocysteine is implicated as a possible causative factor.
- Some evidence has shown supplementation can be useful in HIV and AIDS, depression, tinnitus and cognitive impairment when low vitamin B<sub>12</sub> levels are also present. Preliminary evidence also suggests a possible role for supplementation in diabetic retinopathy and sleep disturbances.
- There are several commonly prescribed pharmaceutical medicines that can reduce vitamin B<sub>12</sub> absorption when used long-term.

#### ❓ CONTRAINDICATIONS AND PRECAUTIONS

- Parenteral cyanocobalamin given for vitamin B<sub>12</sub> deficiency caused by malabsorption should be given intramuscularly or by the deep subcutaneous route — never intravenously.
- Folic acid supplementation may mask a B<sub>12</sub> deficiency.
- Treatment with cyanocobalamin should be avoided in cases of altered cobalamin metabolism or deficiency associated with chronic cyanide intoxication (Freeman et al 1999).

## PREGNANCY USE

Vitamin B<sub>12</sub> is considered safe in pregnancy. Low-dose vitamin B<sub>12</sub> (1–18 mcg/day) does not appear to impact on the circulating level of serum cobalamins or its binding proteins in lactating women (Morkbak et al 2007). If required, higher doses may need to be utilised.

## PATIENTS' FAQs

### *What will this vitamin do for me?*

Vitamin B<sub>12</sub> is essential for healthy growth, development and health maintenance. It will reverse signs and symptoms of deficiency and can alleviate symptoms of tinnitus, poor memory, depression and HIV and AIDS when low vitamin B<sub>12</sub> levels are also present. There is also some research suggesting some positive effects in diabetic retinopathy and sleep disturbances.

### *When will it start to work?*

In cases of pernicious anaemia, the classical deficiency state, correction of blood abnormalities occurs within 6 weeks; however, correction of nervous system changes is slower and may take up to 18 months.

### *Are there any safety issues?*

Vitamin B<sub>12</sub> is considered a very safe nutrient.

## Vitamin C

**HISTORICAL NOTE** Vitamin C deficiency has been known for many centuries as scurvy, a potentially fatal condition, dreaded by seamen in the 15th century, who were often forced to subsist for months on diets of dried beef and biscuits. It was also described by the European crusaders during their numerous sieges. In the mid-1700s Lind was the first doctor to conduct systematic clinical trials of potential cures for scurvy, identifying oranges and lemons as successful treatments (Bartholomew 2002). However, it was not until 1928 that vitamin C (then known as antiscorbutic factor) was isolated, leading to mass production in the mid-1930s.

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin C is an essential water-soluble nutrient for humans and required in the diet on a regular basis, as we are one of few species of animals that cannot synthesise it. This is because humans lack the enzyme L-gulonolactone oxidase, which is required for the conversion of glucose into vitamin C (Braunwald et al 2003).

The bioavailability of ascorbic acid is dependent on both intestinal absorption and renal excretion. Vitamin C, consumed either in the diet or as dietary supplements, is absorbed by the epithelial cells of the small intestine by the sodium vitamin C co-transporter 1 (SVCT1) and subsequently diffuses into the surrounding capillaries and then passes into the circulatory system (Li & Schellhorn 2007). Ultimately, the degree of absorption depends on the dose ingested and decreases as the dose increases.

**Clinical note — Differences between major forms of vitamin C supplements**

Here is a brief summary of the most common forms found in over-the-counter supplements.

- Ascorbic acid. The major dietary form of vitamin C.
- Mineral ascorbates (also known as non-acid vitamin C). These are buffered forms of vitamin C and believed to be less irritating to the stomach than ascorbic acid. Sodium ascorbate and calcium ascorbate are the most common forms. When mineral salts are taken, both the ascorbic acid and the mineral are absorbed. For example, sodium ascorbate generally provides 131 mg of sodium per 1000 mg of ascorbic acid, and calcium ascorbate provides 114 mg of calcium per 1000 mg of ascorbic acid.
- Vitamin C with bioflavonoids. Many bioflavonoids are antioxidant substances and are added to some vitamin C preparations in the belief that this increases the bioavailability or efficacy of vitamin C. Typically, the bioflavonoids are sourced from citrus fruits.
- Ascorbyl palmitate. A fat-soluble form of vitamin C formed by esterification with palmitic acid and most often used in topical creams.

This is because, at low concentrations, most vitamin C is absorbed in the small intestine and reabsorbed from the renal tubule, but at high concentrations SVCT1 becomes saturated, which, combined with ascorbate-mediated SVCT1 downregulation, limits the amount of ascorbic acid absorbed from the intestine and reabsorbed from the kidney (Li & Schellhorn 2007). For this reason, oral vitamin C is best absorbed when it is ingested in small doses at regular intervals. Complete plasmatic saturation occurs at 1000 mg daily with a concentration of around 100 microM (Verrax & Buc Calderon 2008). Pectin and zinc are also able to impair oral absorption. These limitations are bypassed with the use of intravenously administered vitamin C, which can achieve much higher plasma levels than oral administration.

Following its absorption, ascorbic acid is ubiquitously distributed in the cells of the body. Within the body, the highest levels of ascorbic acid are found in the adrenal glands, the white blood cells, skeletal muscles and the brain, especially in the pituitary gland (Verrax & Buc Calderon 2008). Interestingly, the brain is the most difficult organ to deplete of ascorbate. As a polar compound with a relatively large molecular weight, vitamin C cannot readily cross the cell membrane by simple diffusion. The flux of vitamin C in and out of the cell is controlled by specific mechanisms, including facilitated diffusion and active transport, which are mediated by distinct classes of membrane proteins such as facilitative glucose transporters (GLUT) and SVCT

respectively (Li & Schellhorn 2007). Once in cells, dehydroascorbic acid (the oxidised form of ascorbate) is rapidly reduced to ascorbate (Harrison & May 2009). Eventually it is metabolised in the liver, filtered by the kidneys and excreted in the urine. The biological half-life of vitamin C is 8–40 days (NHMRC 2006).

**Clinical note — Deficiencies in smokers**

It is well established that smokers have lowered vitamin C status than non-smokers and therefore have higher requirements for vitamin C. Vitamin C status is inversely related to cigarette use (Cross & Halliwell 1993). The depletion of plasma ascorbic acid associated with cigarette smoking was first described in the late 1930s. Reports have shown that low ascorbic acid concentrations in the plasma, leucocytes and urine of both male and female cigarette smokers are associated with increased numbers and activity of neutrophils, which suggests increased utilisation and lower intake, or reduced bioavailability, of vitamin C in smokers than in non-smokers (Northrop-Clewes & Thurnham 2007).

**CHEMICAL COMPONENTS**

Vitamin C exists as both its reduced form (L-ascorbic acid) and its oxidised form (L-dehydroascorbic acid). The two forms interchange in the body in a reversible equilibrium.

**FOOD SOURCES**

Vitamin C is found in many different fruits and vegetables. The most concentrated food sources are blackcurrants, sweet green and red peppers, hot red peppers, green chilli peppers, oranges and fresh orange juice, and strawberries. Other good sources are watermelon, papaya, citrus fruits, cantaloupe, mango, cabbage, cauliflower, broccoli and tomato juice. In practice, vegetables may be a more important source of vitamin C than fruits because they are often available for longer periods during the year.

The vitamin C content of food is strongly influenced by many factors, such as season, transportation, shelf-life, storage conditions and storage time, cooking techniques and chlorination of water (FAO/WHO 2002). Cutting or bruising food will reduce its vitamin C content; however, blanching or storing at low pH will preserve it.

Up to 100% of the vitamin C content of food can be destroyed during cooking and storing because the vitamin is sensitive to light, heat, oxygen and alkali (Wahlqvist 2002). Additionally, using too much water during cooking can leach the vitamin from food and further reduce its vitamin C content.

**DEFICIENCY SIGNS AND SYMPTOMS**

In adults, scurvy remains latent for 3–6 months after reducing dietary intake to less than 10 mg/day

(Beers & Berkow 2003). It manifests when the body pools fall below 300–400 mg (NHMRC 2006). Many of the features of frank vitamin C deficiency (scurvy) result from a defect in collagen synthesis.

Early symptoms are:

- weakness
- fatigue and listlessness
- muscular weakness
- petechial haemorrhages and ecchymoses (bruising)
- swollen gums
- poor wound healing and the breakdown of recently healed wounds
- poor appetite and weight loss
- emotional changes such as irritability and depression
- vague myalgias and arthralgias
- congested hair follicles.

Symptoms of more severe deficiency are:

- fever
- drying of the skin and mucous membranes
- susceptibility to infection
- bleeding gums and loosening of teeth
- oedema of the lower extremities
- anaemia
- joint swelling and tenderness, due to bleeding around or into the joint
- oliguria
- pain in the extremities
- haemorrhage
- convulsions
- shock
- eventually death if left untreated.

Although frank deficiency is uncommon in Western countries, marginal deficiency states are not uncommon.

### Primary deficiency

This occurs if there is an inadequate dietary intake, which is often caused by a combination of poor cooking and eating habits. It occurs in areas of urban poverty, during famine and war, in young children fed exclusively on cow's milk for a prolonged period, in the institutionalised or isolated elderly, and in chronic alcoholics (Pimentel 2003, Richardson et al 2002). One Australian hospital identified that 73% of all new admissions had hypovitaminosis C and 30% had levels suggestive of scurvy (Richardson et al 2002).

### Secondary deficiency

Factors that increase nutritional requirements include cigarette smoking, pregnancy, lactation, thyrotoxicosis, acute and chronic inflammatory diseases, major surgery and burns, infection and diabetes (Beers & Berkow 2003, FAO/WHO 2002, Hendler & Rorvik 2001, Wahlqvist 2002). Decreased vitamin C absorption in achlorhydria and increased excretion in chronic diarrhoea also increase the risk of deficiency, particularly when combined with poor dietary intake.

### MAIN ACTIONS

Vitamin C is an electron donor (reducing agent or antioxidant), and this accounts for most of its biochemical and molecular functions. It is involved in many biochemical processes in the body, such as:

- energy release from fatty acids
- metabolism of cholesterol
- reduction of nitrosamine formation in the stomach
- formation of thyroid hormone
- carnitine biosynthesis
- modulation of iron and copper absorption
- corticosteroid biosynthesis
- protection of folic acid reductase, which converts folic acid to folinic acid
- collagen biosynthesis
- tyrosine biosynthesis and catabolism
- neurotransmitter biosynthesis.

The main actions of vitamin C are summarised below.

### Antioxidant and pro-oxidant

At physiological concentrations, vitamin C is the most effective aqueous antioxidant in plasma, interstitial fluids and soluble phases of cells. As such, it is one of the most important water-soluble antioxidant substances in the body, acting as a potent free radical scavenger in the plasma, protecting cells against oxidative damage caused by reactive oxygen species (ROS). It scavenges free radical oxygen and nitrogen species such as superoxide, hydroxyl, peroxy and nitroxide radicals and non-radical reactive species such as singlet oxygen, peroxyxynitrite and hypochlorite (FAO/WHO 2002, Hendler & Rorvik 2001). Besides having a direct antioxidant function, it also indirectly increases free radical scavenging by regenerating vitamin E (Vatassery 1987) and maintaining glutathione in reduced form. Much of the vitamin's physiological role stems from its very strong reducing power (high redox potential) and its ability to be regenerated using intracellular reductants such as glutathione, nicotinamide adenine dinucleotide and nicotinamide adenine dinucleotide phosphate (Chaudière & Ferrari-Iliou 1999).

In the presence of oxidised metal ions (e.g. Fe<sup>3+</sup>, Cu<sup>2+</sup>), high concentrations of ascorbic acid can have pro-oxidant functions at least in vitro, thereby promoting oxidative damage to DNA. The effect does not appear to be significant under normal physiological conditions in vivo; however, when used at higher pharmacological concentrations (0.3–20 mmol/L), ascorbic acid displays transition metal-independent pro-oxidant activity, which is more profound in cancer cells than healthy cells and causes cell death (Li & Schellhorn 2007).

Whether vitamin C functions as an antioxidant or pro-oxidant is determined by at least three factors: (1) the redox potential of the cellular environment; (2) the presence/absence of oxidised metal ions; and (3) the local concentrations of ascorbate (Li & Schellhorn 2007).

### Maintenance of connective tissue

Vitamin C maintains the body's connective tissue and is essential for the formation of collagen, the major fibrous element of blood vessels, skin, tendon, cartilage and teeth (Morton et al 2001). If collagen is produced in the absence of vitamin C, it is unstable and cannot form the triple helix required for normal tissue structure. Vitamin C is involved in the biosynthesis of other substances important for connective tissue, such as elastin, proteoglycans, bone matrix, fibronectin and elastin-associated fibrillin (Hall & Greendale 1998).

These effects have been harnessed by the dermatological and cosmetic industries and are the rationale for producing topically applied products containing vitamin C.

### Collagen stability

Vitamin C is necessary for the synthesis of collagen proteins, whereby it is involved in the hydroxylation of specific prolyl and lysyl residues of the unfolded procollagen chain. These reactions are catalysed by the enzymes prolyl 4-hydroxylase and prolyl 3-hydroxylase, which stabilise collagen molecules, and lysyl hydroxylase enzyme, responsible for collagen molecule cross-linking (Ochiai et al 2006, Traikovich 1999). In vivo and in vitro studies have explored topical vitamin C effects on melanogenesis and ageing.

### Brain and nerve function

Ascorbate is involved in neurotransmitter synthesis. It is a cofactor required for the biosynthesis of nor-adrenaline from dopamine and hydroxylation of tryptophan to produce serotonin. It also acts as a modulator of glutaminergic, cholinergic and GABAergic transmission (Bornstein et al 2003, FAO/WHO 2002, Harrison & May 2009). Furthermore, it is involved in neural maturation and acts as a neuroprotective agent (Harrison & May 2009),

### Immunostimulant

Ascorbic acid affects the immune system in several different ways and there is abundant evidence that the immune system is sensitive to circulating levels of vitamin C. Ascorbic acid modulates T-cell gene expression, specifically affecting genes involved with signalling, carbohydrate metabolism, apoptosis, transcription and immune function. It can also stimulate the production of interferons, the proteins that protect cells against viral attack and stimulate the synthesis of humoral thymus factor and antibodies of the immunoglobulin G (IgG) and IgM classes (Combs 2012).

Both in vivo and in vitro studies provide evidence of immunostimulant effects, generally at doses beyond recommended dietary intake (RDI) levels (Hendler & Rorvik 2001). In high doses, it is a potent immunomodulator and is preferentially cytotoxic to neoplastic cells. Vitamin C enhances the activity of natural killer cells in vivo and also both B- and T-cell activity (Drisko et al 2003).

Leucocytes maintain high levels of ascorbate which are correlated with their function. In fact, leucocyte ascorbate levels are 20–100 times higher than plasma levels. The uptake occurs via active transport which is temperature- and energy-dependent. Many infections and inflammatory diseases lower plasma and neutrophil ascorbate levels. Clinically, an association exists between recurrent infections and impaired neutrophil function. Adequate ascorbate nutrition improves several aspects of neutrophil activity, especially chemotaxis, proliferation and motility. Vitamin C can enhance neutrophil chemotaxis and motility, even in healthy individuals (Combs 2012, Muggli 1998).

In addition to these direct effects on the immune system, the antioxidant properties of vitamin C play a role. When neutrophils are activated during infection, they release free radicals. However, neutrophils are susceptible to free radical damage themselves. Protection against auto-oxidation is afforded by ascorbic acid together with other antioxidants and is essential during the mobilisation of host defences. Apart from its own effects, vitamin C helps immune function indirectly by protecting the antioxidant capacity of vitamin E, which is an immune-enhancing nutrient in its own right (Muggli 1998).

### Antihistamine

Ascorbic acid is involved in histamine metabolism, acting with  $\text{Cu}^{2+}$  to inhibit its release and enhance its degradation (Combs 2012).

An inverse association has been identified between blood histamine levels and vitamin C status in humans (Johnston et al 1996). In that study, increasing vitamin C status with supplements (up to 250 mg/day) over 3 weeks was shown to decrease histamine levels. It is unclear whether single, high-dose supplementation also affects histamine levels, as two studies using 2 g doses have produced conflicting results (Bucca et al 1990, Johnston et al 1992).

### Anticancer

In millimolar concentrations, vitamin C is selectively cytotoxic to many cancer cell lines and has in vivo anticancer activity when administered alone or together with other agents (Hoffer et al 2008). Importantly, pharmacological concentrations of ascorbic acid (0.3–20 mmol/L) are required to find evidence of cytotoxicity in vitro and in vivo, whereas physiological concentrations of ascorbic acid (0.1 mmol/L) do not have any effect on either tumour or normal cells (Li & Schellhorn 2007). The most reliable method of achieving these high doses is with intravenous (IV) administration of vitamin C and not via the oral route, which has limited absorption (Padayatty et al 2006). The effect is clearly dose-dependent and mediated via several mechanisms, such as immunomodulation, inhibition of cell division and growth, gene regulation and induction of apoptosis. One mechanism of cytotoxicity demonstrated in several models is the ability of ascorbate at pharmacological concentrations to exert

pro-oxidant activity, generating hydrogen peroxide-dependent cytotoxicity towards a variety of cancer cells *in vitro* and *in vivo* without adversely affecting normal cells (Chen et al 2008, Tamayo & Richardson 2003).

Much investigation has been undertaken to understand how preferential cytotoxicity is achieved; however, the mechanisms are still largely unknown. For example, studies with radioactive-labelled vitamin C have found that tumour cells accumulate more vitamin C than healthy cells, whereas other studies have reported no differences in intracellular concentrations (Prasad et al 2002). There is also some preliminary evidence of synergistic cytotoxic effects and decreased drug toxicity with some pharmaceutical anticancer agents (Giri et al 1998).

One theory proposed to explain the preferential targeting of tumour cells relates to their overexpression of facilitative GLUTs (Gatenby & Gillies 2004) and dehydroascorbic acid, transported by GLUTs, accumulating within the tumour cells, which enables intracellular hydrogen peroxide levels to increase (Chen et al 2005, Verrax & Buc Calderon 2008, Zhang et al 2001). Other intrinsic properties of cancer cells may also be involved, such as reduced concentrations of antioxidant enzymes (e.g. catalase and superoxide dismutase) and increased intracellular transitional metal availability, both of which further augment free radical production (Li & Schellhorn 2007). Alternatively, it has been suggested that extracellular ascorbate is the source of this anticancer effect and is more important than intracellular vitamin C.

There are a number of factors that may be contributing to the inconsistent results obtained to date, such as the variable characteristics of the subjects studied, type of infecting virus, lack of control for dietary vitamin C intake and differences in measures of outcomes. Clearly, further investigation is required to clarify many issues surrounding the use of vitamin C supplements for upper respiratory tract infections (URTIs). In practice, naturopaths often recommend megadoses of vitamin C (taken frequently, in small amounts), which are well beyond the doses investigated so far, and often report good results. Although anecdotal, it is interesting to note that little research has investigated this method.

### Modulation of gene expression

Many transcription factors, such as NF- $\kappa$ B, AP-1 or peroxisome proliferator-activated receptors, are redox-regulated, and moderate amounts of oxidative stress are known both to modulate gene expression and to signal transduction cascades by affecting kinases, phosphatases as well as Ca<sup>2+</sup> signalling. L-ascorbic acid may modulate relatively unspecific gene expression by affecting the redox state of transcription factors and of enzymes involved in signal transduction (Table 1).

### OTHER ACTIONS

High oral doses (4–12 g/day in divided doses) can acidify urine.

Ascorbic acid greatly enhances iron bioavailability from food. Within the body, ascorbic acid promotes the utilisation of haem iron, which appears to involve enhanced incorporation of iron into its intracellular storage form, ferritin. This effect involves facilitation of ferritin synthesis and enhanced ferritin stability (Combs 2012).

Vitamin C can also interact with other nutritional metals, reducing their toxicity, such as selenium, nickel, lead, vanadium and cadmium. This is achieved by interacting with them to create a reduced form which is poorly absorbed or more rapidly excreted (Combs 2012).

### CLINICAL USE

Vitamin C is an important biological antioxidant and has been a popular nutritional supplement for decades. It is administered as intramuscular or IV injections and used topically and orally. This review will chiefly focus on oral and topical use, as these are the forms of vitamin C most commonly used by the public.

#### Deficiency: prevention and treatment

Traditionally, vitamin C supplements are used both to treat and to prevent deficiency. Treatment may include 250 mg vitamin C daily and encouragement to eat fresh fruits and vegetables on a regular basis (Kumar et al 2002), or 100 mg taken 3–5 times daily until 4000 mg has been reached (Braunwald et al 2003). Some deficiency symptoms start to respond within 24 hours, although most take from several weeks to months to resolve completely.

#### Iron-deficiency anaemia

Ascorbic acid is a potent enhancer of iron absorption. Vitamin C facilitates iron absorption by forming soluble complexes and may be used with an iron supplement and nutritious diet in the treatment of iron-deficiency anaemia. It is specifically helpful in increasing absorption of iron from plant-based foods. It is also recommended for women with menorrhagia in order to reduce the risk of iron deficiency.

#### Dermatological uses

Vitamin C is used as an oral supplement or topical application in a number of dermatological conditions.

#### Wound healing

Vitamin C is important for effective wound healing, as deficiency contributes to fragile granulation tissue and therefore impairs the wound-healing process (Russell 2001).

*In vitro* studies with skin graft samples have demonstrated that vitamin C extends cellular viability, promotes formation of an epidermal barrier and promotes engraftment (Boyce et al 2002). In this way, vitamin C is used to enhance wound healing before surgery has commenced.

TABLE 1 KNOWN OR PUTATIVE GENES AND ENZYMATIC ACTIVITIES RESPONSIVE TO L-ASCORBIC ACID

Gene	Cellular process involved	Mechanism	Expression/activity with L-ascorbic acid
h1-Calponin	VSMC phenotypic modulation	?	↑
h-Caldesmon	VSMC phenotypic modulation	?	↑
SM22 $\alpha$	VSMC phenotypic modulation	?	↑
$\alpha$ -SM actin	VSMC phenotypic modulation	?	↑
Collagen I	Matrix production	Transcription, mRNA stability	↑
Collagen III	Matrix production	Transcription, mRNA stability	↑
Elastin	Elasticity of arterial wall, VSMC phenotypic modulation	mRNA stability	↓
MMP2	Matrix degradation	?	↓
TIMP1	Inhibits matrix degradation	?	↑
Calponin 1	VSMC phenotypic modulation	?	↑
Myosin heavy chain-1	VSMC phenotypic modulation	?	↑
GATA4	Cardiac development	?	↑
Nkx2.5	Cardiac development	?	↑
ANF	Regulation of cardiac and vascular tone	?	↑
eNOS	Vascular homeostasis	Increased intracellular Ca <sup>2+</sup>	↑
Prolyl hydroxylase	Stability and secretion of collagen	Cofactor	↑
ICAM-1	Cell adhesion	?	↓
Enzymes involved in carnitine synthesis	Fatty acid metabolism	Cofactor (epsilon-N-trimethyllysine hydroxylase and gamma-butyrobetaine hydroxylase)	↑

VSMC, vascular smooth-muscle cell.

Adapted from Villacorta et al (2007).

Numerous case reports of surgical and dental patients generally suggest a use for vitamin C supplementation in doses beyond RDI as a means of enhancing the rate of wound healing (Ringsdorf & Cheraskin 1982). One early double-blind study found that vitamin C (500 mg twice daily) resulted in a significant mean reduction in pressure sore area of 84% after 1 month compared with 43% in the placebo group (Taylor et al 1974). The mean rates of healing were 2.47 cm<sup>2</sup> for vitamin C and 1.45 cm<sup>2</sup> for the placebo.

### Photo-damaged skin

Two double-blind studies investigating the effects of topical preparations of vitamin C on photo-damaged skin have demonstrated good results after 3 months' use (Fitzpatrick & Rostan 2002, Humbert et al 2003). One study tested a topical application of 5% vitamin C in a cream base, whereas the other used a newly formulated vitamin C complex having 10%

ascorbic acid (water-soluble) and 7% tetrahexyldecyl ascorbate (lipid-soluble) in an anhydrous polysilicone gel base.

### Prevention of sunburn

One controlled study found oral vitamin C (2000 mg/day) in combination with vitamin E (1000 IU/day) had a protective effect against sunburn after 8 days' treatment in human subjects (Eberlein-Konig et al 1998). Similar results have been obtained for topical vitamin C preparations in several animal models (Darr et al 1992, 1996, JY Lin et al 2003) and a small human study (Keller & Fenske 1998). The latter found that application of an aqueous 10% L-ascorbic acid solution after ultraviolet B (UVB) radiation produced a significant reduction in the minimal erythema dose and a less intense erythematous response than controls.

As with many nutrients, studies associating dietary vitamin intake and disease risk are difficult

to interpret. This is because it is difficult to separate the effects of the individual vitamin from the effects of other components in the diet. Where possible, an effort has been made to include information that will help in the interpretation of this type of data.

### Hyperpigmentation

The beneficial effects of vitamin C on skin hyperpigmentation and ageing are mostly attributed to its antioxidant properties and key role in collagen production. The efficacy of vitamin C in hyperpigmentation disorders has been investigated in small studies, mostly as an adjunctive therapy. [Hwang et al \(2009\)](#) studied the efficacy of a formulation containing 25% L-ascorbic and a chemical penetration enhancer for the treatment of melasma. A 16-week open-label trial was conducted and 40 subjects were involved. The skin was assessed every month, and results showed significant decrease in pigmentation with the treatment. [Espinal-Perez et al \(2004\)](#) conducted a double-blind randomised trial comparing 5% L-ascorbic acid and 4% hydroquinone for melasma treatment. They concluded L-ascorbic acid to have beneficial effects on hyperpigmentation with minimal side effects, and therefore, to be a viable single or adjunctive long-term therapy for melasma ([Espinal-Perez et al 2004](#)). Results show that vitamin C has the ability to significantly improve abnormal skin pigmentation caused by chronic UV radiation exposure, including melasma.

### Antiageing

Vitamin C antioxidant properties contribute to its antiageing effect as well, since ROS are known to interfere with fibroblasts and to destroy collagen and connective tissue structures. Vitamin C is a well-known potential antiageing agent due to its antioxidant effect and major role in collagen production ([Humbert et al 2003](#), [Park et al 2009](#), [Taniguchi et al 2012](#), [Traikovich 1999](#)). A 3-month randomised double-blind vehicle-controlled study was conducted to determine the efficacy of topical vitamin C in photo-damaged skin. Clinical assessment showed significant improvement in many features, including fine wrinkles, tactile roughness, laxity and tone. Self-assessment questionnaire demonstrated that 84.2% of the subjects preferred the side treated with vitamin C. Photographic assessment showed vitamin C-treated skin to have 57.9% greater improvement compared to controls and optical profilometry analysis demonstrated improvement with active treatment up to 73.7% greater than control ([Traikovich 1999](#)).

### Upper respiratory tract infections

Vitamin C is widely used both to prevent and to treat common URTIs, such as the common cold and influenza, largely based on its effects on the immune system, its ability to reduce histamine levels and the observations that the gastrointestinal absorption of vitamin C increases in the common cold

(suggesting an increased demand for this nutrient) and that vitamin C concentrations in the plasma and leucocytes rapidly decline during infection ([Wilson et al 1976](#), [Wintergerst et al 2006](#)). Although extremely popular, its usefulness in these conditions is widely debated.

A meta-analysis of 29 trials involving 11,306 participants was undertaken to assess the risk ratio (RR) of developing a cold while taking vitamin C regularly over the study period ([Hemilä & Chalker 2013](#)). To be eligible for inclusion, at least 200 mg daily of vitamin C was required and each study needed to have a placebo arm. The most promising results were obtained for children and athletes. Five trials involving a total of 598 marathon runners, skiers and soldiers on subarctic exercises yielded a pooled RR of 0.48, indicating that regular vitamin C supplementation significantly reduced the incidence of the common cold in this population. For the studies involving children, using a dose of 1–2 g/daily, vitamin C shortened the duration of colds by 18% and also reduced the severity of the cold infection. In regard to the general adult community ( $n = 10708$ ), the pooled RR was 0.97, indicating similar effects to placebo and the duration was only slightly reduced, by 8% (3–12%), and in children by 14% (7–21%). Overall, the review concluded that routine vitamin C supplementation did not reduce the incidence of colds in the general population, yet vitamin C may be useful for people exposed to brief periods of severe physical exercise.

It has been suggested that the dose used may affect the magnitude of the benefit, there being on average greater benefit from  $\geq 2$  g/day compared to 1 g/day of vitamin C. In five studies with adults administered 1 g/day of vitamin C, the median decrease in cold duration was only 6%, whereas in two studies with children administered 2 g/day the median decrease was four times higher, 26% ([Hemilä 1999](#)).

Vitamin C taken in combination with zinc may be more successful, according to clinical trials. Both nutrients play a role in immune function and dietary intakes can be low. When the results of two double-blind, randomised, placebo-controlled trials utilising a combination of 1000 mg vitamin C plus 10 mg zinc in patients with the common cold are pooled together, the combination was significantly more efficient than placebo at reducing rhinorrhoea over 5 days of treatment. Furthermore, symptom relief was quicker and the product was well tolerated ([Maggini et al 2012](#)).

### Reduction in all-cause mortality

Several studies have identified an inverse association between plasma ascorbate levels, vitamin C intake and all-cause mortality. This means that low serum ascorbic acid levels are associated with higher all-cause mortality and in some studies, higher cardiovascular disease (CVD) mortality and cancer mortality.

In the Western Electric Company study, data on diet and other factors were obtained in 1958 and 1959 for a cohort of 1556 employed middle-aged men and an inverse association between vitamin C and mortality was identified (Pandey et al 1995). The next year, a prospective cohort study conducted with 725 older adults also identified an inverse relationship between vitamin C blood concentrations and total mortality during a 12-year follow-up (Sabyoun et al 1996). Similar results were obtained in the large European Prospective Investigation into Cancer and Nutrition (EPIC)-Norfolk study of 19,496 men and women aged 45–79 years (Khaw et al 2001). Plasma ascorbate concentration was inversely related to mortality from all causes, and from CVD and ischaemic heart disease in both men and women. Risk of mortality in the group with the highest intake was about half that of the low intake group and was independent of age, systolic blood pressure (SBP), serum cholesterol, cigarette smoking, diabetes or supplement use.

The Second National Health and Nutrition Examination Survey (NHANES II) mortality study further confirmed the inverse association between plasma ascorbate and risk of dying from all causes; however, this study identified a gender difference (Loria et al 2000). After adjustments for race, educational level, number of cigarettes smoked at baseline, serum total cholesterol, SBP, body mass index, diabetes status and alcohol consumption, men in the lowest serum ascorbate quartile (serum ascorbate concentrations <28.4 micromol/L) had a 57% higher risk of dying from any cause than did men in the highest quartile (>73.8 micromol/L). Additionally, men in the lowest serum ascorbate quartile had double the risk of dying from cancer than those in the highest quartile after adjustment for age. The dose corresponds to approximately 60 mg/day vitamin C. In contrast, among women no association was observed between quartiles of serum ascorbate concentration and total mortality or mortality from CVD or cancer.

As an extension to this, Simon et al (2001) identified that, amongst the 8453 Americans aged  $\geq 30$  years at baseline in the NHANES II, low serum ascorbic acid levels were marginally associated with an increased risk of fatal CVD and significantly associated with an increased risk for all-cause mortality (Simon et al 2001). Conversely, people with normal to high serum ascorbic acid levels had a marginally significant 21–25% decreased risk of fatal CVD ( $P$  for trend = 0.09) and a 25–29% decreased risk of all-cause mortality ( $P$  for trend < 0.001) compared to people with low level. Low serum ascorbic acid levels were also a risk factor for cancer death in men, but unexpectedly were associated with a decreased risk of cancer death in women. In other words, among men, normal to high serum ascorbic acid levels were associated with an approximately 30% decreased risk of cancer deaths, whereas such serum ascorbic acid levels were associated with

an approximately twofold increased risk of cancer deaths among women.

A gender difference was also reported in the NHANES I Epidemiologic Follow-up Study (NHEFS) (Enstrom et al 1992). Vitamin C intakes >50 mg/day plus regular supplement use were associated with reduced mortality, compared with intakes <50 mg/day in men, but apparently not in women.

### Prevention of cardiovascular disease

The association between vitamin C and CVD prevention is still unclear, although several themes are emerging as evidence accumulates.

In general, epidemiological studies show that low vitamin C intake is associated with higher CVD mortality and risk of heart failure and conversely higher levels are associated with lower risk, whereas interventional studies are less consistent (Carr & Frei 1999, Houston 2005, Khaw et al 2001, Knekt et al 2004, Kushi et al 1996, Lopes et al 1998, MRC/BHF 2002, Ness et al 1996, Nyyssonen et al 1997, Osganian et al 2003).

For example, subjects in NHANES I with the highest vitamin C intakes showed less cardiovascular death (standardised mortality ratio, 0.66; 95% confidence limits, 0.53–0.83) than subjects with lower estimated vitamin C intakes (Enstrom et al 1992). In the NHANES III survey of 8453 Americans, low serum ascorbic acid levels were marginally associated with an increased risk of fatal CVD (Simon et al 2001). A study by Toohey et al (1996) provides some rationale for the coronary heart disease (CHD)-preventive effects seen. In their trial, a significant inverse correlation was found between plasma ascorbic acid levels and both systolic ( $P < 0.0001$ ) and diastolic blood pressure (DBP) ( $P < 0.03$ ), and between plasma ascorbic acid and serum total cholesterol ( $P < 0.03$ ), low-density lipoprotein (LDL)-cholesterol (LDL-C) ( $P < 0.004$ ), and the ratio of LDL-cholesterol to high-density lipoprotein (HDL)-cholesterol (LDL-C:HDL-C) ( $P < 0.004$ ). Serum HDL-cholesterol was positively related to plasma ascorbic acid ( $P < 0.05$ ). When multiple regression analysis was applied, ascorbic acid was shown to be a significant independent contributor to the prediction of blood pressure and LDL-C concentration (Toohey et al 1996).

More recently, the European Prospective Investigation into Cancer and Nutrition study in Norfolk, United Kingdom, identified that the risk of heart failure decreased with increasing plasma vitamin C; the hazard ratios comparing each quartile with the lowest were 0.76 (95% confidence interval [CI] 0.65–0.88), 0.70 (95% CI 0.60–0.81) and 0.62 (95% CI 0.53–0.74) in age- and sex-adjusted analyses ( $P$  for trend < 0.0001) (Pfister et al 2011). This means that, for every 20 micromol/L increase in plasma vitamin C concentration, there was an accompanying 9% relative reduction in risk of heart failure after adjustment for age, sex, smoking, alcohol consumption, physical activity, occupational social class,

educational level, SBP, diabetes, cholesterol concentration and body mass index, with similar result if adjusting for interim CHD. The study analysed results from 9187 healthy men and 11,112 women aged 39–79 years.

### Possible mechanisms

Ascorbic acid is inversely related to several risk factors and indicators of atherosclerotic CVD, including hypertension and elevated concentrations of LDL, acute-phase proteins and haemostatic factors (Price et al 2001). More specifically, vitamin C inhibits oxidative modification of LDL cholesterol directly through free radical scavenging activity according to *in vitro* data, and indirectly by increasing glutathione and vitamin E concentrations within cell membranes. This has been demonstrated against the pro-oxidant combination of homocysteine and iron (Alul et al 2003) and may have implications for other diseases such as Alzheimer's dementia.

Other evidence suggests that other mechanisms are also likely to be involved. Vitamin C is linked to endothelial function and glucose metabolism. It improves endothelial dysfunction in smokers, renal transplant recipients, patients with CVD after a fatty meal, people with intermittent claudication diabetes and those with hypertension (Kaufmann et al 2000, Ling et al 2002, Silvestro et al 2002, Solzbach et al 1997, Williams et al 2001), but not in healthy elderly people (Singh et al 2002). It is also required for collagen synthesis and metabolism, and has been shown to reduce arterial stiffness and platelet aggregation in healthy male volunteers, smokers and non-smokers, and diabetics (Schindler et al 2002, Wilkinson et al 1999). These effects are often observed with doses several times higher than current RDI levels. *In vivo* studies further indicate that vitamin C decreases carotid wall thickness, downregulates inducible nitric oxide (NO) synthase expression, normalises gene expression of antioxidant enzymes and inhibits plaque maturation (Kaliora et al 2006).

A 1997 review of epidemiological studies showed some inverse associations between SBP, DBP or both and vitamin C plasma concentration or intake (Ness et al 1997). Three more recent studies have supported this finding (Bates et al 1998, Block 2002, Block et al 2001). Four intervention studies investigated the effects of vitamin C supplementation, with three producing positive results (Duffy et al 1999, Fotherby et al 2000, Galley et al 1997, Ghosh et al 1994). The doses used were typically 250 mg twice daily for a period of 6–8 weeks, although effects have been reported after 4 weeks' treatment. The negative study by Ghosh et al showed a significant reduction in both SBP and DBP with ascorbic acid. This became non-significant when compared with the placebo responses, although the placebo and ascorbic acid groups were not evenly matched for baseline plasma ascorbate concentration.

Additionally, plasma ascorbate concentrations have been shown to be inversely correlated to pulse rate in one cross-sectional study involving 500 subjects (Bates et al 1998).

### Nitrate tolerance

Preliminary studies seem to support the role of vitamin C in attenuating the development of nitrate tolerance. Three human studies have found that vitamin C administration prevents the development of nitrate tolerance (Bassenge et al 1998, Watanabe et al 1998a, 1998b). Although the mechanism responsible is not yet known, results from a double-blind study using an acute dose of 2 g have suggested that vitamin C is likely to protect NO from inactivation by oxygen free radicals (Wilkinson et al 1999), which could in part explain its observed effects.

### Myocardial infarction (MI)

Two prospective studies in men have suggested that ascorbic acid deficiency and marginal deficiency predict subsequent MI, independently of classical risk factors. The first, a 5-year prospective population study of 1605 middle-aged Finnish men, free of coronary disease at baseline, found that a significantly higher percentage (13.2%) of the 91 men with baseline plasma vitamin C concentrations less than 11.4 micromol/L (2.0 mg/L) experienced MI, compared with men with higher plasma vitamin C levels (Nyyssonen et al 1997). These results are particularly impressive because low plasma ascorbate was the strongest risk factor of all the measured factors. The second, a 12-year follow-up study, revealed a significantly increased relative risk of ischaemic heart disease and stroke at initially low plasma levels of vitamin C (<22.7 micromol/L), independently of vitamin E and of the classical cardiovascular risk factors (Gey et al 1993).

In contrast, one smaller study involving 180 male patients with a first acute MI, but no recent angina, failed to detect an association between low plasma concentration of vitamin C and the risk of acute MI (Riemersma et al 2000). Similarly, analysis from the NHANES III survey, which involved 7658 men and women, found that among participants who reported no alcohol consumption, serum ascorbic acid concentrations were not independently associated with CVD prevalence (Simon & Hudes 1999). Among participants who consumed alcohol, serum ascorbic acid concentrations consistent with tissue saturation (1.0–3.0 mg/dL) were associated with a decreased prevalence of angina (multivariate odds ratio (OR) 0.48; 95% CI 0.23–1.03%; *P* for trend = 0.06), but were not significantly associated with MI or stroke prevalence.

### Clinical studies involving vitamin C supplementation

Interventional studies with supplements have been performed; however, many use vitamin C in combination with other nutrients such as vitamin E,

making it difficult to assess the contribution of vitamin C alone.

One review which analysed studies that only used supplemental vitamin C produced encouraging results. [Knekt et al \(2004\)](#) analysed results from nine prospective studies and a 10-year follow-up whereby 4647 major incident CHD events occurred in 293,172 subjects who were free of CHD at baseline ([Knekt et al 2004](#)). They found that people with higher supplemental vitamin C intake had a lower CHD incidence. Compared with subjects who did not take supplemental vitamin C, those who took >700 mg supplemental vitamin C daily had a relative risk of CHD incidence of 0.75 (0.60, 0.93;  $P$  for trend < 0.001). Interestingly, dietary intake of antioxidant vitamins was only weakly related to a reduced CHD risk after adjustment for potential non-dietary and dietary confounding factors and, compared with subjects in the lowest dietary intake quintiles for vitamins E and C, those in the highest intake quintiles had relative risks of CHD incidence of 0.84 (95% CI 0.71–1.00;  $P$  = 0.17) and 1.23 (95% CI 1.04–1.45;  $P$  = 0.07), respectively.

#### IN COMBINATION

The Women's Antioxidant Cardiovascular Study tested the effects of vitamin C (500 mg daily), vitamin E (600 IU every other day) and beta-carotene (50 mg every other day) on the combined outcome of MI, stroke, coronary revascularisation or CVD death among 8171 female health professionals at increased risk. Participants were 40 years of age or older, with a prior history of CVD or three or more CVD risk factors, and were followed for an average 9.4 years. The study's factorial design enabled a comparison to be made between individual test agents as well as combination therapy. Overall, there was no significant effect for the individual nutrients vitamin C, vitamin E or beta-carotene on the primary combined end point, or on the individual secondary outcomes of MI, stroke, coronary revascularisation or CVD death. A marginally significant reduction in the primary outcome with active vitamin E was observed among the prespecified subgroup of women with prior CVD (RR = 0.89,  $P$  = 0.04). With regard to combination therapy, people receiving both vitamins C and E experienced fewer strokes ( $P$  = 0.03), but there were no other significant findings ([Cook et al 2007](#)).

#### Effects on blood pressure

Although epidemiological evidence and prospective clinical trials point strongly to a role of vitamin C in reducing blood pressure in hypertensive and normotensive subjects, controlled studies have been inconsistent ([Houston 2005](#)). Interpretation of these results is difficult, as some studies lack a control group, have no baseline readings, use variable vitamin C doses and population characteristics, and do not report serum vitamin C or oxidative stress status. Overall, it appears that doses between 100 mg and 1000 mg of vitamin C daily are required for a reduction in blood pressure, with greater reduction

in SBP than DBP and greater response in people with higher initial value.

There is a large body of evidence that ROS produced during myocardial ischaemia and reperfusion play a crucial role in myocardial damage and endothelial dysfunction. As a result, there has been some investigation to determine whether antioxidant supplementation (chiefly vitamins C and E) may improve the clinical outcome of patients with acute MI and limit the size of the infarct.

According to a large, randomised, double-blind, multicentre trial of 800 patients (mean age 62 years) with acute MI and receiving standard care, co-treatment with vitamin C (1000 mg/12 hours infusion) followed by 1200 mg/day orally and vitamin E (600 mg/day) for 30 days resulted in significantly less frequent incidence of reinfarction and other post-MI complications compared to a placebo (14% versus 19% respectively) ([Jaxa-Chamiec et al 2005](#)). Another randomised, double-blind, placebo-controlled study of 37 patients with acute MI investigated the effects of starting supplementation with vitamins C and E (600 mg/day each) on the first day of symptoms and continuing for a further 14 days ([Bednarz et al 2003](#)). Active treatment resulted in significantly lower exercise-induced QT-interval dispersion compared to a placebo, although baseline QT dispersion was similar in both groups. A prospective, randomised study of 61 patients further suggests that oral vitamin C administration (1 g/day) could be beneficial for patients at higher thrombotic risk post-MI, such as those with diabetes ([Morel et al 2003](#)).

#### Postmenopausal cardiovascular health

Across multiple large clinical trials, vitamin C supplementation, alone or in combination with vitamin E and betacarotene, appears to be ineffective at secondary prevention of CHD in pre- and postmenopausal women ([Bjelakovic et al 2007](#), [Cook et al 2007](#), [Heart Protection Study Collaborative Group 2002](#), [Waters et al 2002](#)). However, observational studies evaluating vitamin C for primary prevention of CHD have found conflicting results in women ([Gale et al 1995](#), [Osganian et al 2003](#)).

#### Cancer: prevention and treatment

One of the most important modifiable determinants of cancer risk is diet. Several research panels and committees have independently concluded that high fruit and vegetable intake decreases the risk of many types of cancer and, because vitamin C is present in large quantities in these foods, it is plausible that the reduction in cancer risk associated with the consumption of fruits and vegetables may be, at least in part, attributable to dietary vitamin C ([Li & Schellhorn 2007](#)).

#### Prevention

Epidemiological evidence of a protective effect of dietary vitamin C for non-hormone-dependent cancers is strong ([Block 1991a, 1991b](#)). The majority

**Clinical note — Vitamin C for cancer: a historical perspective**

More than three decades ago, the well-known team of Ewan Cameron and Linus Pauling started investigating the effects of high doses of continuous IV vitamin C and oral supplements in treating advanced, incurable cancer. The idea of using vitamin C was born out of the recognition that the outcome of every cancer is determined to a significant extent by the individual's inherent resistance, which in turn is influenced by the availability of certain nutritional factors such as ascorbic acid (Cameron 1982). They have published the results of several trials that have shown enhanced quality of life for some terminal patients and also improvements in objective markers. As a result, a protocol for the use of vitamin C in the treatment of cancer has been developed at the Vale of Leven Hospital, Scotland, the chief site of Cameron and Pauling's investigations (Cameron 1991). The protocol emphasises the importance of using an initial course of IV ascorbate, followed by a maintenance oral dose. Although their results are encouraging, they have been criticised because randomised double-blind principles were not adopted.

of studies in which a dietary vitamin C intake was calculated have identified a statistically significant protective effect, with high intake conferring approximately a twofold protective effect compared with low intake. In general, most have shown that higher intakes of vitamin C are associated with decreased incidence of cancers of the mouth, throat and vocal cords, oesophagus and stomach, pancreas, colon, rectum, renal cell and lung (Cohen & Bhagavan 1995, FAO/WHO 2002, Jenab et al 2006, Negri et al 2000, You et al 2000). More recently, a case-control study of men in New York found that a higher intake of vitamin C was associated with reduced risk of prostate cancer (McCann et al 2005).

Two other large studies have identified inverse associations between dietary vitamin C and breast cancer risk (Michels et al 2001, Zhang et al 1999). More specifically, the Nurses' Health Study, which involved 83,234 women, detected a strong inverse association between total vitamin C from foods and breast cancer risk among premenopausal women with a positive family history of breast cancer (Zhang et al 1999). Those who consumed an average of 205 mg/day of vitamin C from foods had a 63% lower risk of breast cancer than those who consumed an average of 70 mg/day. A large Swedish population-based prospective study that comprised 59,036 women found that high dietary intakes of ascorbic acid (mean intake 110 mg/day) reduced the risk of breast cancer among women who were overweight and/or had a high intake of linoleic acid (Michels et al 2001).

More recently, a case-control study nested within the EPIC study identified an inverse risk of gastric cancer in the highest versus lowest quartile of plasma vitamin C (Jenab et al 2006). The inverse association was more pronounced in subjects consuming higher levels of red and processed meats, a factor that may increase endogenous *N*-nitroso compound production. It has been proposed that vitamin C protects against gastric cancer because it inhibits carcinogenic *N*-nitroso compound production in the stomach and acts as a free radical scavenger.

Overall, it appears that the protective effect is dose-dependent, with studies finding significant cancer risk reductions in people consuming at least 80–110 mg of vitamin C daily in the long term (Carr & Frei 1999).

**Clinical studies**

One of the first published studies by Cameron and Pauling (1974) was a phase I–II study in 50 patients with advanced, untreatable malignancies, in which both subjective and objective markers were evaluated. They observed that 27 patients failed to respond to treatment; however, three patients experienced stabilisation of disease, tumour regression occurred in five patients and tumour haemorrhage and necrosis occurred in four patients. Two years later, the same research team published a report that compared the survival rates of 100 terminal cancer patients given supplemental ascorbate as part of their routine management with 1000 patients who were not given the supplement, and observed the mean survival time to be more than 4.2 times longer for the ascorbate subjects (>210 days) than for the controls (50 days) (Cameron & Pauling 1976).

In subsequent years, two randomised, placebo-controlled studies investigating the effects of oral vitamin C supplementation (10 g/day) in terminal cancer patients failed to detect a significant difference in outcome (Creagan et al 1979, Moertel et al 1985). These two studies are often cited as evidence disproving the benefits of vitamin C in cancer treatment; however, the different routes of administration investigated in these studies is an important factor central to the discrepant results (Padayatty & Levine 2000). Maximal plasma vitamin C concentrations achievable by oral administration are limited by the kidney, which eliminates excess ascorbic acid through renal excretion, whereas IV injection bypasses the renal absorptive system, resulting in elevated plasma concentrations to high levels. As such, it has been argued that only IV administration of high-dose ascorbate can produce millimolar plasma concentrations that are toxic to many cancer cell lines.

Scientific interest in the interaction between ascorbic acid and cancer has been reawakened in recent years, with new evidence that in millimolar concentrations (only achievable after parenteral administration) vitamin C is selectively cytotoxic to many neoplastic cell lines, potentiates cytotoxic agents and demonstrates anticancer activity alone and in

combination with other agents in tumour-bearing rodents (Hoffer et al 2008). Simultaneously, theoretical interest has arisen in the potential of redox-active molecules like menadione, trolox and ascorbic acid to modify cancer biology, especially when administered with cytotoxic drugs.

### Intravenous vitamin C

IV administration of vitamin C achieves much higher plasma and urine concentrations than oral dosing and has been proposed as the only viable means of achieving the high concentrations required to induce the antitumour effects exhibited by the vitamin (Padayatty et al 2004). Case studies suggest that this approach can improve patient wellbeing and, in some cases, reduce tumour size and improve survival (Padayatty et al 2006, Riordan et al 2005).

A safety study conducted in 2005 involved 24 late-stage terminal cancer patients who were administered continuous vitamin C infusions of 150–710 mg/kg/day for up to 8 weeks (Riordan et al 2005). This treatment regimen increased plasma ascorbate concentrations to a mean of 1.1 mmol/L and was considered relatively safe. The most common side effects reported were nausea, oedema and dry mouth or skin, and two 'possible' adverse events occurred. One was a patient with a history of renal calculi who developed a kidney stone after 13 days of treatment, and another was a patient who experienced hypokalaemia after 6 weeks. Interestingly, the majority of patients were vitamin C-deficient before treatment.

Clinical trials for phases I and II are currently being conducted using intravenously administered vitamin C in patients with solid tumours. The phase I study was primarily conducted to determine a recommended phase II dose, with secondary objectives to define any toxic effects, detect any preliminary antitumour effects and monitor for preservation of or improvement in quality of life. In the first phase I trial published in 2008, patients with advanced cancer or haematological malignancy were assigned to sequential cohorts infused with 0.4, 0.6, 0.9 and 1.5 g ascorbic acid/kg body weight three times weekly, delivered intravenously (Hoffer et al 2008). This protocol achieved plasma ascorbic acid concentrations of >10 microM for more than 4 hours, which is considered sufficient to induce cancer cell death according to *in vitro* research. In addition, all patients were provided with a daily multivitamin tablet (Centrum Select, Wyeth) and 400 IU D-alpha-tocopherol twice daily with meals, and, on non-infusion days, 500 mg ascorbic acid twice daily to obviate large shifts in plasma ascorbic acid concentrations. No unusual biochemical or haematological abnormalities were observed, and there were no changes in the social, emotional or functional parameters of quality of life in any cohort. Unlike in the previous case series by Cameron and Pauling (1974), in which acute tumour haemorrhage and necrosis were reported, these effects were not seen in this study (Hoffer et al 2008).

Researchers concluded that the promise of ascorbic acid in the treatment of advanced cancer may lie in its combination with cytotoxic agents, where high concentrations might modify either toxicity or response. A phase I–II clinical trial is being planned that will combine IV ascorbic acid with chemotherapy as a first-line treatment in advanced-stage non-small-cell lung cancer, using the dose determined from this study.

Based on the available evidence of antitumour mechanisms and these case reports, further research into this approach is clearly warranted.

### Adjunct to oncology treatments

Whether vitamin C improves or hinders responses to standard oncology treatment has been the focus of intense debate for many decades. There are *in vitro* studies showing that vitamin C can enhance the antitumour activity of cisplatin and doxorubicin (Abdel-Latif et al 2005, Kurbacher et al 1996, Reddy et al 2001, Sarna & Bhola 1993). *In vivo* evidence shows vitamin C enhances the effectiveness of 5-fluorouracil, doxorubicin, cyclophosphamide and vincristine (Lamson & Brignall 2000, Nagy et al 2003), whereas other studies find no change in drug effect. Although these results are promising, no large randomised studies are available to confirm their significance in humans.

Most recently, vitamin C inactivated the effects of bortezomib, a new proteasome inhibitor approved by the US Food and Drug Administration for the treatment of patients with relapsed multiple myeloma (Zou et al 2006). Interestingly, drug inactivation was not achieved through antioxidative mechanisms.

Evidence from experimental models suggests that vitamin C may also reduce drug toxicity in a dose-dependent manner (Giri et al 1998, Greggi Antunes et al 2000).

### Breast cancer

There is limited evidence to support the use of vitamin C in the primary prevention of total cancer incidence, including breast cancer (Lin et al 2009, Moorman et al 2001, Poulter et al 1984). One of the largest studies in women found that vitamin C (500 mg daily) had no effect on the incidence of cancer after 9.4 years of follow-up (Lin et al 2009).

While vitamin C may not significantly reduce the risk of breast cancer, reduced risk of mortality was reported for vitamin C supplements taken after diagnosis, according to a recent meta-analysis of 10 prospective studies (Harris et al 2014). Harris et al (2014) found that postdiagnosis vitamin C supplement use was associated with a reduced risk of mortality. Dietary vitamin C intake was also statistically significantly associated with a reduced risk of total mortality and breast cancer-specific mortality. The studies involved 17,696 breast cancer cases and found the summary RR for postdiagnosis vitamin C supplement use was 0.81 for total mortality (95% CI 0.72–0.91) and 0.85 for breast cancer-specific

mortality (95% CI 0.74–0.99). The summary RR for a 100 mg/day increase in dietary vitamin C intake was 0.73 for total mortality (95% CI 0.59–0.89) and 0.78 for breast cancer-specific mortality (95% CI 0.64–0.94) (Harris et al 2014).

### Oral cancer

A recent systematic review showed that the pro-oxidant activity of pharmacological ascorbic acid is a part of its dose-dependent bimodal activity and is a result of the proposed Fenton mechanism. In vitro, animal and ex vivo studies of pharmacological ascorbic acid have yielded meritorious results proving vitamin C as an effective cytotoxic agent against oral neoplastic cells with potentially no harming effects on normal cells (Putchala et al 2013).

#### **Clinical note — The debate continues ... to vitamin C or not?**

One research group based at the University of Colorado has produced evidence that suggests that vitamin C and other antioxidant nutrients may not only protect healthy cells from damage, but also improve the antitumour effects of standard treatment (Gottlieb 1999). They are currently conducting further research to identify how cell selectivity occurs, but propose that cancer cells may have lost the normal homeostatic regulatory mechanism that stops excessive concentrations of antioxidants from entering the cell. As intracellular levels rise, a series of reactions occurs, resulting in growth inhibition and cell death. Another group at Memorial Sloan Kettering Cancer Center (Gottlieb 1999) argues that tumours already contain higher levels of ascorbic acid than normal cells and have identified a mechanism to explain this observation. As such, they advocate against the use of vitamin C when cytotoxic agents that rely on free radical production are being used (see Chapter 10 for further discussion).

### Prevention of cataracts

Ascorbate has long been known to accumulate in tears and other biofluids, such as cerebrospinal fluid relative to plasma (Patterson & O'Rourke 1987), and lowered levels of vitamin C in the eye have been associated with increased oxidative stress in the human cornea (Shoham et al 2008). Ascorbic acid is thought to be a primary substrate in ocular protection because of its high concentration in the eye. Within the cell, vitamin C helps to protect membrane lipids from peroxidation by recycling vitamin E (May 1999). It is present at high concentrations in vitreous humour (Hanashima & Namiki 1999), cornea (Brubaker et al 2000) and tear film (Dreyer & Rose 1993).

Numerous observational and prospective clinical studies have been performed to examine the effect on cataracts of vitamin C alone or in combination

with other antioxidants. Several epidemiological studies have identified an association between vitamin C and cataract incidence (Ferrigno et al 2005, Jacques & Chylack Jr 1991, Jacques et al 1988, Valero et al 2002); however, studies investigating whether supplementation is protective have produced mixed results (Chasan-Taber et al 1999, Chylack et al 2002, Hammond & Johnson 2002, Jacques et al 1997, 2001, Kuzniarz et al 2001, Seddon et al 1994, Taylor et al 2002).

Results from the Harvard Nurses' Health Study, Physicians' Health Study, the Beaver Dam Eye Study and the Australian Blue Mountains study suggest that if protective effects are to be seen, they are most likely when vitamin C is taken for a long period (5–10 years or more) and/or used as part of a multivitamin combination (Kuzniarz et al 2001, Mares-Perlman et al 2000, Seddon et al 1994, Taylor et al 2002).

It is suspected that vitamin C protects the lens of the eye from oxygen-related damage over time by both direct free radical scavenging activity and indirect activity. This is achieved primarily by protecting endogenous alpha-tocopherol (the major lipid-soluble antioxidant of retinal membranes) against oxidation induced by UV radiation and by regenerating it (Stoyanovsky et al 1995).

### Diabetes

Vitamin C has several actions that provide a basis for its use in diabetes. It has been reported to lower erythrocyte sorbitol concentrations (important for preventing complications in type 1 diabetes), improve endothelial function (important for slowing atherosclerosis) and reduce blood pressure (Beckman et al 2001, Cunningham 1998). Plasma vitamin C levels seem to play a role in the modulation of insulin activity in aged healthy or diabetic subjects (Paolisso et al 1994) and are inversely related to glycosylated haemoglobin. Additionally, increased free radical production has been reported in patients with diabetes mellitus as a result of hyperglycaemia, which directly induces oxidative stress (Ceriello et al 1998).

### Blood glucose

At this stage there are few studies that test the effects of supplemental vitamin C on plasma glucose levels directly. Although one early study demonstrated that an oral dose of 1500 mg vitamin C reduces plasma glucose levels in patients with type 2 diabetes (Sandhya & Das 1981), no further published studies confirm this result.

### Endothelial function

The results of studies investigating the role of vitamin C on endothelial function in diabetes have attracted interest.

A double-blind, placebo-controlled study demonstrated that chronic oral vitamin C supplementation (500 mg/day) in type 2 diabetes significantly lowered arterial blood pressure and improved

arterial stiffness compared with a placebo (Mullan et al 2002). After 1 month's treatment, SBP fell from 142.1 to 132.3 mmHg, mean pressure from 104.7 to 97.8 mmHg, DBP from 83.9 to 79.5 mmHg and peripheral pulse pressure from 58.2 to 52.7 mmHg, whereas placebo had no effect.

A randomised study of women with a history of gestational diabetes showed that ascorbic acid supplementation resulted in a significant improvement of endothelium-dependent flow-mediated dilatation, with no effect seen for a placebo (Lekakis et al 2000).

However, a randomised, double-blind, placebo-controlled study of vitamin C (800 mg/day for 4 weeks) concluded that high-dose oral vitamin C therapy resulted in incomplete replenishment of vitamin C levels and does not improve endothelial dysfunction and insulin resistance in type 2 diabetes (Chen et al 2006).

The mechanism of action appears to involve several steps, such as reduction in LDL oxidation, enhanced endothelial NO synthase activity and NO bioavailability and reduced insulin resistance, which can cause endothelium-dependent, NO-mediated vasodilation.

### Eye health

Diabetes mellitus is associated with a number of ocular complications that can eventually lead to blindness. Vitamin C is found in high concentration in the eye and is thought to be important for protection against free radicals. This may have special significance for people with diabetes mellitus, as most studies have found that their circulating vitamin C levels are at least 30% lower than in people without the disease (Peponis et al 2002). Furthermore, a systematic review (Lee et al 2010) assessing five hospital-based, cross-sectional studies consistently reported that diabetic patients with retinopathy had lower vitamin C levels than those without retinopathy (Ali & Chakraborty 1989, Gupta & Chari 2005, Gurler et al 2000, Rema et al 1995, Sinclair et al 1992).

According to a 2008 Cochrane systematic review (Lopes de Jesus et al 2008) investigating the effectiveness of vitamin C in diabetic retinopathy, no research to date has adequately examined the treatment of diabetic retinopathy with vitamin C or superoxidase dismutase, so it remains unknown whether the intervention has a significant impact on the progress of this complication.

Because of its safety, cost-effectiveness and generally encouraging results, a strategy of adding 200–600 mg of vitamin C to a healthy diet is worth considering for individuals with diabetes type 1 or 2.

### Pneumonia

Three prophylactic trials found a statistically significant (80% or greater) reduction in pneumonia incidence in the vitamin C group. These trials were assessed in a recent Cochrane review, which

#### **Clinical note — Do asthmatic lungs need more antioxidant protection?**

In 1999, Kelly et al found that people with mild asthma have low levels of antioxidant nutrient vitamins E and C in their lung lining fluid, even though blood levels of these vitamins may be normal or increased. This observation, together with other factors, indicated that the asthmatic lung is exposed to greater oxidative stress in people with asthma than in non-asthmatics. The researchers suggested that the inflammatory cells in the lungs of asthmatic patients generate more free radical species than those in healthy people, adding to bronchoconstriction, increased mucus secretion and increased airways responsiveness. Given that oral supplementation in asthma has produced inconsistent results, chief researcher Frank Kelly suggests that future studies should focus on other administration forms, such as vitamin C inhalers (personal communication, Melbourne, 1998).

concluded that the prophylactic use of vitamin C to prevent pneumonia should be further investigated in populations who have a high incidence of pneumonia, especially if dietary vitamin C intake is low (Hemilä & Louhiala 2013).

### Asthma

Vitamin C is the major antioxidant present in the extracellular fluid lining of the lung, where it protects against both endogenous free radicals (produced as a byproduct of inflammation) and environmental free radicals (such as ozone in air pollution). Theoretically, it may be of benefit in reducing symptoms of inflammatory airway conditions such as asthma, and may also be beneficial in reducing exercise-induced bronchoconstriction.

According to many epidemiological studies, dietary intake of vitamin C-rich foods or serum ascorbate is associated with improved lung function in both asthmatic and normal subjects (Devereux & Seaton 2005, Kelly 2005, McDermoth 2000). Oxygen metabolites can play a direct or indirect role in the modulation of airway inflammation. Many studies suggest that superoxide dismutase and free radical scavengers in the blood are significantly lower in asthma, and document a correlation between asthmatic severity and ROS products in asthmatic subjects (Shanmugasundaram 2001, Vural 2000). Not surprisingly, low blood concentrations of vitamin C have been found in mildly asthmatic subjects (Rahman 2006).

Despite a theoretical basis for its use in lung diseases such as asthma, its value in this disease is controversial. A 2001 Cochrane review of three studies concluded that current evidence is insufficient to recommend a specific role for vitamin C in the treatment of asthma and that a large-scale randomised controlled trial (RCT) is required to

clarify its role (Kaur et al 2001). This was repeated in a Cochrane review published in 2004 that included new data from a study of 201 adults taking inhaled corticosteroids and came to a similar conclusion, stating that evidence is currently conflicting (Ram et al 2004).

A recent Cochrane review (Milan et al 2013) concluded that there is insufficient evidence to provide a robust assessment on the use of vitamin C in the management of asthma or exercise-induced bronchoconstriction. There was some indication that vitamin C was helpful in exercise-induced breathlessness in terms of lung function and symptoms; however, as these findings were provided only by small studies, more research is required before a conclusive recommendation can be made. Three human studies have produced positive results when vitamin C was used as pretreatment in doses ranging from 500 mg to 2000 mg (Cohen et al 1997, Miric & Haxhiu 1991, Schachter & Schlesinger 1982).

### Asthma and atopy in children

A systematic review and meta-analysis (Nurmatov et al 2011) assessed 14 papers reviewing the association between vitamin C and asthma or atopic outcomes in children. While some of the studies showed some improvement in wheeze or allergy symptomatology overall, the body of evidence was judged to be methodologically weak and the possible effectiveness of vitamin C to prevent atopic outcomes remains unclear.

### Bone mineral density (BMD)

Although the relationship between calcium, vitamin D and BMD is well known, other nutrients, such as vitamin C, are also critical for bone development, repair and maintenance (Ilich et al 2003). Epidemiological studies have demonstrated a positive association between BMD and intake of vitamin C (Hall & Greendale 1998, Leveille et al 1997). Low vitamin C intakes have been associated with a decline in BMD specifically at the femoral neck and total hip (Hall & Greendale 1998).

Data collected from 13,080 adults enrolled in NHANES III from 1988 to 1994 have identified an association between dietary and serum ascorbic acid, BMD and bone fracture (Simon & Hudes 2001). Dietary ascorbic acid intake was independently associated with BMD among premenopausal women and postmenopausal women without a history of smoking or oestrogen use. Additionally, fracture risk fell by 49% in postmenopausal women (with a history of smoking and oestrogen use) who had high serum vitamin C levels.

### Vitamin C supplementation

Two controlled studies have investigated the effects of long-term vitamin C supplementation in postmenopausal women and found that it increases BMD (Hall & Greendale 1998, Morton et al 2001). Both studies identified a positive association with BMD in postmenopausal women with dietary

calcium intakes of at least 500 mg or those taking calcium supplements. The effect was especially marked in those women taking calcium supplements and concurrent hormone replacement therapy.

The daily dose taken was generally in excess of the RDI and ranged from 100 mg to 5000 mg. More specifically, one study found that, for each 100 mg increment in dietary vitamin C intake, there was an associated increase of 0.017 g/cm<sup>2</sup> in BMD (femoral neck and total hip), and for those women with calcium intakes above 500 mg/day the increment increased to 0.019 g/cm<sup>2</sup> in BMD per 100 mg vitamin C.

An Australian study of 533 randomly selected women determined that vitamin C supplements may suppress bone resorption in non-smoking postmenopausal women (Pasco et al 2006).

In contrast to these results, no effect on BMD was observed for dietary or supplemental vitamin C in the Women's Health Initiative Observational Study and Clinical Trial, which involved 11,068 women aged 50–79 years (Wolf et al 2005). However, a significant beneficial interaction was observed between total vitamin C and hormone replacement therapy on total body, femoral neck, spine and total hip BMD.

Animal studies have detected an improved healing response in bone fractures with supplemental vitamin C, suggesting a further role in fracture healing (Yilmaz et al 2001).

### Sports

Vitamin C supplementation is often used by athletes in order to improve recovery, restore immune responses, enhance wound healing and counteract oxidative stress and changes to adrenal hormones and inflammatory responses. It is often taken together with other antioxidant vitamins and minerals, such as vitamin E and zinc. One placebo-controlled study has shown that 20 mg of ascorbic acid twice daily over 14 days has some modest beneficial effects on recovery from unaccustomed exercise (Thompson et al 2001); however, no studies have reported improved performance for vitamin C supplementation.

### Prevention of postendurance exercise infections

Athletes often use vitamin C supplements to prevent infections, as strenuous training and physiological stress appear to increase the body's need for vitamin C to a level above the usual RDI (Schwenk & Costley 2002). Additionally, the risk of infection after an intense aerobic training session or competition (such as a marathon) is increased (Jeurissen et al 2003).

A 2004 Cochrane review that analysed results from six trials involving a total of 642 marathon runners, skiers and soldiers on subarctic exercises found regular vitamin C supplementation significantly reduced the incidence of the common cold, supporting its use in this population (Douglas et al 2004).

### Alterations to neurotransmitters and adrenal hormones

Several studies have been conducted with ultramarathon runners to investigate whether vitamin C supplementation, usually in doses of 1500 mg/day, is able to restore exercise-induced changes to neurotransmitters, adrenal hormones or inflammatory responses (Nieman et al 2000, Peters et al 2001a, 2001b). Overall, it appears that high-dose vitamin C supplements taken at least 7 days before racing do have some effect.

One study involving 45 ultramarathon runners found that doses of 1500 mg vitamin C taken for 7 days before the race, on the day of the race and for 2 days following the race significantly attenuated exercise-induced elevations in cortisol, adrenaline and interleukin-10 (IL-10) and IL-1 receptor antagonist levels compared with a placebo (Peters et al 2001a); however, the effect was transient.

### Male infertility

A relationship between infertility and the generation of ROS has been established and extensively studied. Alterations in the testicular microenvironment and haemodynamics can increase production of ROS and/or decrease local antioxidant capacity, resulting in generation of excessive oxygen species. A large number of studies have elucidated the effects of increased oxygen species in the serum, semen and testicular tissues of patients.

Vitamin C (ascorbic acid), a major antioxidant found in extracellular fluid, is present in seminal fluid at a high concentration compared with that in blood plasma (364 versus 40 microM) and is present in detectable amounts in sperm (Patel & Sigman 2008). In infertile men, vitamin C has been found in reduced quantity in the seminal plasma (Lewis et al 1997). An association between oxidative stress and sperm DNA fragmentation has been identified and has led to studies looking for changes in semen DNA fragmentation as an outcome rather than just changes in semen parameters.

A review of the literature reveals that interventional studies have produced promising but inconsistent results and incomplete reporting of study outcomes. Sometimes changes to semen parameters are noted, but there is little or no information about successful pregnancies or characteristics of the study population, thereby hindering accurate interpretation of results. Clearly further research is required to better evaluate the effects of vitamin C in male fertility.

An RCT of 75 fertile, heavy smokers compared placebo to two different doses of vitamin C (200 mg and 1000 mg) and found that both supplemented groups experienced a significant improvement in sperm concentration, morphology and viability (Dawson et al 1992).

A randomised, placebo-controlled trial found that treatment with oral vitamin C and E of men with unexplained infertility associated with elevated

sperm DNA fragmentation led to decreased DNA fragmentation without a change in semen parameters (Greco et al 2005b).

In an uncontrolled study of 38 men with an elevated percentage of fragmented spermatozoa (15%) and one prior failed intracytoplasmic sperm injection (ICSI) attempt, oral supplementation with vitamins E and C demonstrated a significant improvement in pregnancy rate (48.2% vs 6.9%) and implantation rate (19.6% vs 2.2%) when compared with their prior ICSI attempt (Greco et al 2005a).

A systematic review on the effect of oral antioxidants on male infertility evaluated results from 17 RCTs including a total of 1665 men, which differed in the populations studied and type, dosage and duration of antioxidants used. None of the studies assessed vitamin C as a single oral agent; however, when reviewing the effectiveness of vitamin C in conjunction with other antioxidants, the results were as follows. Sperm motility improved in two out of five studies (Omu et al 2008, Scott et al 1998), sperm concentration improved in one out of five studies (Galatioto et al 2008) and sperm DNA fragmentation index was reduced in two out of two studies (Greco et al 2005a, Omu et al 2008). However, sperm morphology did not improve in any of the five studies. Pregnancy rate after ICSI was significantly improved in the treatment group in one study ( $P = 0.046$ ) (Tremellen et al 2007).

### Pregnancy

A Cochrane systematic review evaluated results from five RCTs involving 766 women in which vitamin C supplementation was used (Rumbold & Crowther 2005). No difference was seen between women supplemented with vitamin C alone or in combination with other supplements compared with placebo for the risk of stillbirth, perinatal death, birth weight or intrauterine growth restriction. In regard to preterm birth, women supplemented with vitamin C were at increased risk compared to placebo. No difference was seen between women supplemented with vitamin C compared with placebo for the risk of neonatal death whereas a reduced incidence of pre-eclampsia was found with supplementation when using a fixed-effect model.

More recently, another three systematic reviews and meta-analyses concluded that combined vitamin C and E supplementation did not decrease the risk of pre-eclampsia and should not be offered to gravidas for the prevention of pre-eclampsia or other pregnancy-induced hypertensive disorders (Ahmet et al 2010, Conde-Agudelo et al 2011, Rossi & Mullin 2011).

### Alzheimer's disease (AD)

A systematic review and meta-analysis reviewed eight RCTs, including a cohort of 223 people diagnosed with AD (da Silva et al 2013). Four studies showed statistically significantly lower plasma levels of vitamin C than in controls (unrelated to the classic malnourishment that is common in patients

with AD). However, whether this means AD patients have increased oxidative stress and therefore increased antioxidant requirements which would benefit from vitamin C supplementation remains to be tested.

### Periodontal disease

Nishida et al (2000) used data from the NHANES III study, which identified a statistically significant, albeit weak, association between decreased dietary vitamin C intake and increased risk of periodontal disease (OR 1.19). More recently, it was reported from the same NHANES III study that higher serum antioxidant levels were associated with lower ORs of severe periodontitis, with an OR of 0.53 for vitamin C (Chapple et al 2007). In a population of 413 non-institutionalised active older adults in Japan, a significant but weak association was found between serum vitamin C levels and clinical attachment loss (grade of severity of periodontal disease) (Amarasena et al 2005). Clinical attachment loss was 4% greater in subjects with lower serum vitamin C levels compared with subjects with higher serum vitamin C levels. The association was independent of other covariates, including smoking and random blood sugar levels. This result is in accordance with the findings from another study investigating the association of serum vitamin C levels with serology of periodontitis in a random subsample of Finnish and Russian men (Pussinen et al 2003).

### Complex regional pain syndrome (CRPS)

A 2013 systematic review and meta-analysis assessed the use of high-dose vitamin C for CRPS (Shibuya et al 2013). Use of high-dose vitamin C has been recommended by the Evidence Based Guidelines for Type 1 CRPS for wrist fractures (oral administration of 500 mg of vitamin C per day for 50 days from the date of the injury) (Perez et al 2010). Quantitative synthesis showed a relative risk of 0.22 when daily vitamin C of at least 500 mg was initiated immediately after the extremity surgery or injury and continued for 45–50 days. A routine, daily administration of vitamin C may therefore be beneficial in foot and ankle surgery or injury to avoid CRPS.

### Adjunct therapy for haemodialysis patients

Recent research highlights that vitamin C can potentiate the mobilisation of iron from inert tissue stores, and facilitates the incorporation of iron into protoporphyrin in haemodialysis patients being treated with epoetin. Eighteen published studies in the past decade have addressed this issue (Attallah et al 2006, Chan et al 2005, Deira et al 2003, Gastaldello et al 1995, Giancaspro et al 2000, Hörl 1999, Keven et al 2003, CL Lin et al 2003, Macdougall 1999, Mydlik et al 2003, Nguyen 2004, Sezer et al 2002, Taji et al 2004, Targ & Huang 1998, Targ et al 1999a, 1999b, 2004, Tovbin et al 2000).

Administration of IV vitamin C to haemodialysis patients with functional iron deficiency may promote

better anaemia control and iron utilisation and has also been used successfully in patients with iron overload (Targ & Huang 1998, Targ et al 1999a, 1999b). Current recommendations for maintenance of haemodialysis patients advise supplementation with ascorbic acid 75–90 mg daily (Fouque et al 2007) during dialysis. In addition to the potential benefits of vitamin C for anaemia management, the importance of adequate vitamin C with regard to improving cardiovascular outcomes in haemodialysis patients is also the subject of research. A study by Deicher and colleagues of 138 haemodialysis patients examined baseline levels of plasma vitamin C and followed the cohort for occurrence of cardiovascular events (Deicher et al 2005). Results showed that low total vitamin C plasma concentrations (less than 32 micromol/L) were associated with an almost fourfold increased risk for fatal and major non-fatal cardiovascular events compared with haemodialysis patients who had higher plasma vitamin C levels (greater than 60 micromol/L).

### OTHER USES

Vitamin C is used for numerous indications, although many have not been significantly studied, such as irritable bowel syndrome, osteoarthritis, menopausal hot flushes, cervical dysplasia, prevention of Alzheimer's dementia, allergies, treatment of lead toxicity and reducing delayed-onset muscle soreness.

Vitamin C supplements have also been used as part of antioxidant combination therapy in HIV. Preliminary research has shown that some antioxidant combinations reduce oxidative stress (Jaruga et al 2002), induce immunological and virological effects that might be of therapeutic value (Muller et al 2000) and produce a trend towards a reduction in viral load in HIV (Allard et al 1998).

For heroin withdrawal, high doses of oral ascorbic acid and vitamin E may ameliorate the withdrawal syndrome of heroin addicts after 4 weeks' treatment, according to one study (Evangelou et al 2000).

### DOSAGE RANGE

#### Australian and New Zealand RDI

##### Infants

- 0–6 months: 25 mg.
- 7–12 months: 30 mg.

##### Children

- 1–8 years: 35 mg.
- 9–18 years: 40 mg.

##### Adults

- >19 years: 45 mg.

##### Pregnancy

- <19 years: 55 mg.
- >19 years: 60 mg.

**Lactation**

- <19 years: 80 mg.
- >19 years: 85 mg.

**Deficiency**

- 100 mg taken 3–5 times daily until 4000 mg has been administered, followed by a maintenance dose of 100 mg/day and encouragement to eat a diet with fresh fruit and vegetables.
- In cases of acute infection, complementary and alternative medicine practitioners frequently recommend vitamin C in doses of 1000 g (or more), to be taken in divided doses every few hours until loose bowels are experienced, otherwise known as 'bowel tolerance'. The rationale behind this dosage regimen is that body requirements during infection are dramatically increased, and not only does high-dose vitamin C meet these needs, but also maximum vitamin C absorption is attained when it is taken in divided doses rather than one large amount.

**According to clinical studies**

- Asthma: 500–2000 mg before exercise.
- Cancer: 10–100 g/day IV.
- CVD prevention: up to 1000 mg/day long-term.
- BMD: 750 mg/day long-term.
- Cataract protection: 500 mg/day long-term.
- Diabetes: 0.5–3 g/day long-term.
- Histamine-lowering effects: 250 mg to 2 g/day for several weeks.
- Respiratory infection: at least 2 g/day.
- Sunburn protection: oral vitamin C (2000 mg/day) in combination with vitamin E (1000 IU/day).
- Urinary acidification: 4–12 g taken in divided doses every 4 hours.

**ADVERSE REACTIONS**

Adverse effects of oral vitamin C include loose bowels and diarrhoea with high-dose supplements; however, the dose at which this occurs varies between individuals and also varies for each individual at different times.

**SIGNIFICANT INTERACTIONS****Aluminium-based antacids**

Vitamin C increases the amount of aluminium absorbed. Separate doses by at least 2 hours.

**Aspirin**

Aspirin may interfere with both absorption and cellular uptake mechanisms for vitamin C, thereby increasing vitamin C requirements (observed in animal and human studies). Increased vitamin C intake may be required with long-term therapy (Basu 1982).

**Chitosan**

According to a preliminary study in rats, taking vitamin C in combination with chitosan might

**Clinical note — Is the kidney stone risk overstated?**

Most kidney stones consist of calcium oxalate, and higher urinary oxalate increases the risk of calcium oxalate nephrolithiasis (Taylor & Curhan 2007). Four mechanisms have been identified that account for increased oxalate excretion: increased dietary intake of oxalate, abnormally increased intestinal absorption of oxalic acid, a deficiency of oxalate-degrading bacteria (in particular *Oxalobacter formigenes*) and increased endogenous production of oxalate. Vitamins C and B<sub>6</sub> are both involved in the metabolic pathway of oxalate. While 40% of dietary vitamin C undergoes a non-enzymatic conversion to oxalate, vitamin B<sub>6</sub> has the opposite effect and metabolises oxalate (Gill & Rose 1985). Since vitamin C has been shown in some (but not all) studies to increase urinary oxalate, researchers speculated that it might have a detrimental role in increasing the risk of kidney stone formation.

Reports of a possible link between ascorbic acid and kidney stones started to appear in the literature in the 1980s (Griffith et al 1986, Power et al 1984). These findings have been challenged by several studies carried out in humans and in experimental animals since that time. In 1994, researchers discovered that vitamin C (in doses as high as 10 g/day) does not increase the amount of oxalate produced in the body in non-stone-forming people (Wandzilak et al 1994). Instead, urine tests used to detect oxalate levels were actually detecting oxalate formed by the conversion of ascorbate during the test procedure. As such, urine oxalate levels tested by this method do not genuinely represent in vivo oxalate when ascorbate is involved. Three studies that followed found no association between vitamin C intake and kidney stone risk. Two prospective studies of more than 85,000 women and 45,000 men found that doses ranging from less than 250 mg/day to more than 1500 mg/day taken over 6–14 years did not correlate with occurrence of kidney stones (Curhan et al 1996, 1999). The third was a controlled study measuring oxalate excretion and several other biochemical and physicochemical risk factors associated with calcium oxalate urolithiasis (Auer et al 1998, Curhan et al 1996, 1999).

Based on the available evidence, it appears unlikely that vitamin C supplements increase the risk of nephrolithiasis in the general population, particularly if they are used in the short to medium term.

provide additional benefit in lowering cholesterol. Potentially beneficial interaction.

**Cisplatin**

Vitamin C enhanced the antitumour activity of cisplatin in several in vitro tests (Abdel-Latif et al

2005, Reddy et al 2001, Sarna & Bhola 1993) and reduced drug toxicity in experimental models (Giri et al 1998, Gregg Antunes et al 2000). Potentially beneficial but difficult to assess.

### Corticosteroids

Corticosteroids may increase the requirement for vitamin C based on in vitro and in vivo data (Chowdhury & Kapil 1984, Levine & Pollard 1983). Increased intake may be required with long-term drug therapy.

#### **Clinical note — Does vitamin C interact with the oral contraceptive pill?**

In 1981 a case was reported of a woman who had experienced heavy breakthrough bleeding as a result of stopping vitamin C supplementation while taking the oral contraceptive pill (Morris et al 1981). At the time, it was suspected that vitamin C in high doses increases the bioavailability of oestrogen and raises blood concentrations due to competition for sulfation (resulting in reduced drug metabolism) (Back & Orme 1990). Therefore, ceasing supplement use would have the opposite effect and potentially cause breakthrough bleeding, as reported in this case. Since then, further investigation has been conducted to evaluate whether this interaction is clinically significant. In 1993 a placebo-controlled study was conducted with 37 women and found that 1000 mg of vitamin C does not lead to an increased systemic bioavailability of ethinyl oestradiol, and therefore the purported interaction is unlikely to be of any clinical importance (Zamah et al 1993).

### Cyanocobalamin

Vitamin C can reduce absorption of cyanocobalamin. Separate doses by at least 2 hours.

### Cyclophosphamide

Vitamin C enhanced the therapeutic drug effect in vivo (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

### Doxorubicin

Vitamin C enhanced the therapeutic drug effect and reduced drug toxicity in vivo (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

### Etoposide

Vitamin C enhanced the antitumour activity of etoposide in vitro (Reddy et al 2001). Potentially beneficial but difficult to assess.

### Fluorouracil

Vitamin C enhanced the antitumour activity of 5-fluorouracil in vitro and in vivo (Abdel-Latif et al 2005, Nagy et al 2003). Potentially beneficial but difficult to assess.

### Iron

Vitamin C increases the absorption of iron. Potentially beneficial interaction.

### L-Dopa

A case report of co-administration with vitamin C suggests this may reduce drug side effects (Sacks & Simpson 1975). Beneficial interaction.

### Tamoxifen

Vitamin C enhanced the antitumour activity in vitro (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

### Vincristine

Vitamin C enhanced the drug's effect in vivo (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

### PS-341 (bortezomib, Velcade)

This is a proteasome inhibitor approved by the US Food and Drug Administration for the treatment of patients with relapsed multiple myeloma. Vitamin C inactivated drug activity in vitro (Zou et al 2006). Avoid until safety can be established.

#### **? CONTRAINDICATIONS AND PRECAUTIONS**

In patients who are sensitive to iron overload, vitamin C supplementation may exacerbate iron toxicity by mobilising iron reserves. As such, vitamin C supplementation should be used with caution by people with erythrocyte glucose-6-phosphate dehydrogenase deficiency, haemochromatosis, thalassaemia major or sideroblastic anaemia.

### Intravenous vitamin C

A dose-response study involving patients with solid tumours receiving high-dose IV vitamin C found virtually all the side effects that occurred were consistent with the side effects attending the rapid infusion of any high-osmolarity solution. The symptoms were preventable by encouraging patients to drink fluids before and during the infusion. Indeed, rather than provoking fluid overload, ascorbic acid acted like an osmotic diuretic which could induce volume depletion if patients did not compensate by increasing their voluntary fluid intake. Therefore, contraindications to the infusion of very-high-osmolarity ascorbic acid infusions are the same as for other osmotic diuretics: anuria, dehydration, severe pulmonary congestion or pulmonary oedema and a fixed low cardiac output (Hoffer et al 2008).

### Laboratory tests

Supplemental vitamin C can affect the results of numerous laboratory tests and should be stopped prior to:

- carbamazepine
- lactate dehydrogenase

- serum aspartate transaminase
- serum bicarbonate
- serum cholesterol
- serum creatinine
- serum creatine kinase
- serum HbA<sub>1C</sub>
- serum phosphate
- serum triglycerides
- serum urea nitrogen
- stool guaiac
- theophylline
- urine 17-hydroxy corticosteroids
- urine 17-ketosteroids
- urine amphetamine
- urine and serum bilirubin
- urine and serum glucose
- urine and serum uric acid
- urine barbiturate

### Practice points/Patient counselling

- Vitamin C is an essential nutrient for humans, as we are one of the few animal species that cannot synthesise it endogenously.
- Although vitamin C is found widely in fruit and vegetables, up to 100% can be destroyed during cooking and storing, as it is sensitive to light, heat, oxygen and alkali.
- Although frank deficiency is uncommon in Western countries, marginal deficiency states are not uncommon, particularly in young children fed exclusively on cow's milk for a prolonged period, the institutionalised or isolated elderly, chronic alcoholics, the urban poor and cigarette smokers.
- Vitamin C generally acts as an antioxidant and is involved in a myriad of biochemical processes in the body, such as neurotransmitter and hormone synthesis, maintenance of connective tissue, immune function and adrenal function.
- Many, but not all, studies have found a protective effect for dietary vitamin C intake on CVD and cancer incidence, emphasising the importance of adequate dietary intake of fresh fruit and vegetables.
- Oral vitamin C supplements have been investigated in many different conditions. Positive results have been obtained in some of these studies, such as for reducing incidence of the common cold in children, CHD prevention, prevention of several CVDs and BMD. Positive effects on mortality have been reported when vitamin C intake is increased after a diagnosis of breast cancer; however, use as a cancer treatment remains controversial. There are also possible benefits for bone density and cataract incidence and increasing intake after a diagnosis of breast cancer.
- Research shows that long-term supplements do not increase the risk of kidney stones and do not interact with oral contraceptives.

- urine beta-hydroxybutyrate
- urine iodide
- urine oxalate
- urine paracetamol
- urine protein.

### PREGNANCY USE

Vitamin C is safe in pregnancy; however, it is recommended to not exceed the therapeutic dose nor abruptly cease supplementation.

### PATIENTS' FAQs

#### *What will this vitamin do for me?*

Vitamin C is necessary for health and wellbeing. Supplements have also been used for a variety of indications and in some cases shown to have benefits.

#### *When will it start to work?*

Studies have found that dietary or supplemental vitamin C may be required for at least 10 years before protection against heart disease or cancer incidence is detected. However, other benefits may be experienced more quickly, depending on the dose used and indication. Research also indicates that increasing vitamin C intake after a diagnosis of breast cancer may reduce mortality.

#### *Are there any safety issues?*

Vitamin C is considered very safe, although high doses may induce reversible loose bowels or diarrhoea. Supplements should be taken only under medical supervision by people with erythrocyte glucose-6-phosphate dehydrogenase deficiency, haemochromatosis, thalassaemia or sideroblastic anaemia.

# Vitamin D

**HISTORICAL NOTE** Vitamin D was identified as a nutrient in the early 1900s, when it was first realised that cod liver oil had an antirachitic effect in infants.

## *Is vitamin D really a vitamin?*

Many characteristics of the vitamin D molecules vary substantially from the orthodox definition of a vitamin (Dusso et al 2005, NHMRC 2006, Vieth 2006) in that they:

- are not essential in the diet of all individuals, given adequate sun exposure (Dusso et al 2005, Holick 2008, Nowson & Margerison 2001, Nowson et al 2012)
- are structurally steroid derivatives (Gropper et al 2009, Valdivielso et al 2009)
- are inherently biologically inactive and require hydroxylation to produce the active form (Holick 2005, Kemmis et al 2006, Prietl et al 2013)
- produce 1,25(OH)<sub>2</sub>D, which is a steroidal hormone (Dusso et al 2005)
- require vitamin D receptors (VDR) on cell surfaces, a member of the steroid receptor superfamily, to convey most, if not all, of their actions (Dusso et al 2005, Holick 2004, Hossein-nezhad & Holick 2013).

These discoveries and others have precipitated a revolution in vitamin D research over the last two decades (Dusso et al 2005, Holick 2004, 2005, Nowson et al 2012).

## BACKGROUND AND RELEVANT PHARMACOKINETICS

The name 'vitamin D' actually refers to several related fat-soluble vitamin variants, all of which are sterol (cholesterol-like) substances. It is a pleiotropic steroid hormone, with its role being in the regulation of calcium and phosphorus levels (Zittermann et al 2014), involvement in vascular biology (Valdivielso et al 2009), bone mineralisation (Nowson et al 2012) and immunomodulation (Clancy et al 2013, Prietl et al 2013). Research over the last two decades has suggested that vitamin D has a role in autoimmune disease, cardiovascular disease, certain cancers, cognitive decline, depression, pregnancy complications, allergy, frailty and potential fetal epigenetics and brain development (Abrams et al 2013, Eyles et al 2013, Hossein-nezhad & Holick 2013, Liu et al 2013).

Cholecalciferol (D<sub>3</sub>) is the form found in animal products and fish oils, whereas ergocalciferol (D<sub>2</sub>) is the major synthetic form of provitamin D typically found in supplements and fortified foods; however, other forms also exist. These ingested forms have 50–80% bioavailability and enter the lymphatic circulation from the small intestine following emulsi-

fication by bile salts, and promote the absorption of calcium and phosphate from the gut (Nowson et al 2012).

Vitamin D (D<sub>3</sub>) is also produced in the body through the conversion of a cholesterol-based precursor, 7-dehydrocholesterol, which is produced in the sebaceous glands of the skin. Exposure to sunlight (ultraviolet B [UVB]) converts this precursor into cholecalciferol over a 2–3-day period. Prolonged exposure to UVB can inactivate some of the newly formed vitamin D and its precursors, so that eventually a state of equilibrium is reached between vitamin D synthesis and catabolism. Therefore, short periods of sun exposure are considered more efficacious than long periods (Working Group 2005, 2012). Some vitamin D is stored in adipose tissue and can be mobilised during periods when exposure to sunlight is reduced or shortages develop (Nowson & Margerison 2002, Nowson et al 2012). This has implications for obesity research. Vitamin D and its metabolites are primarily excreted through bile, and the degraded active form is removed via the kidney. Losses are believed to be minor, owing to both reabsorption of vitamin D derivatives via the enterohepatic recirculation and limited filtration at the kidneys (Kohlmeier 2003). Parathyroid hormone (PTH), calcium, phosphorus and magnesium are involved in the regulation of vitamin D metabolism.

Traditionally associated with bone health, the identification of VDRs on a large and diverse number of cells has precipitated significant reconsideration of this nutrient (Dusso et al 2005, Holick 2004, 2006). VDRs are present in most tissues and cells in the body, including the brain, vascular smooth muscle, prostate, breast and macrophages (Hossein-nezhad & Holick 2013, Nowson et al 2012), and we now understand that vitamin D possesses two distinct action pathways dependent upon the site of bioactivation (Dusso et al 2005, Holick 2006). Renal hydroxylation of 25(OH)D produces 1,25(OH)<sub>2</sub>D, primarily responsible for its traditional endocrine actions. In this two-step process, high-capacity cytochromes in the liver convert initially to D's major circulating form, 25-hydroxycholecalciferol (inactive) — 25(OH)D, and then further hydroxylation in the proximal tubular epithelial cells of the kidneys, to the biological active form: 1,25-dihydroxycholecalciferol — 1,25(OH)<sub>2</sub>D, also known as calcitriol. This conversion is performed by CYP27B1 (25OH-1 $\alpha$ -hydroxylase) (Clancy et al 2013, Nowson et al 2012). By contribution to regulation of extracellular calcium and phosphate homeostasis and through interaction with PTH,

mineralisation of the skeleton is promoted, and regulation of muscle function (Angeline et al 2013). Importantly, as stated (Hossein-nezhad & Holick 2013, Nowson et al 2012), almost every nucleated cell expresses the VDR, and additionally, many extrarenal tissues have the capacity to make 1,25(OH)<sub>2</sub>D. This is suggestive that vitamin D not only operates by the classical endocrine pathways, but through autocrine and paracrine pathways as well, implying that there are local synthesis and actions. This extrarenal bioactivation, by immune, prostate, breast, colon, beta and skin cells, however, results in non-genomic responses, characterised as autocrine rather than endocrine effects (Dusso et al 2005, Holick 2006, Kemmis et al 2006, Valdivielso et al 2009). Production of 1,25(OH)<sub>2</sub>D at these sites does not fall under the same tight regulatory control as renal 1-alpha-hydroxylase (Dusso et al 2005, Kemmis et al 2006). This means that increasing concentrations of 25(OH)D provide a substrate for extrarenal bioactivation, with the rate of conversion mainly reliant upon local factors such as cytokines, which act to protect the internal cells from microbial invaders (Clancy et al 2013, Holick 2005, Lips 2006). Monocyte-macrophages contain CYP27B1, which enables intracellular production of active vitamin D, promoting an intracrine effect, which, by contrast to renal conversion, is not regulated by Ca<sup>2+</sup> levels (Clancy et al 2013). It is instead driven by immune components such as chemokines like interferon-gamma (IFN-gamma) and Toll-like receptors (TLRs), which gives vitamin D the ability to act independently on the immune system. Its destruction by catabolic enzyme 24-hydroxylase (CYP24A1) is also initiated by its activation to the active form, but not in macrophages, which results in a prolonged signalling of vitamin D, which may provide insight into the potential mechanism of action in fighting intracellular organisms such as tuberculosis (Clancy et al 2013).

## CHEMICAL COMPONENTS

Cholecalciferol (D<sub>3</sub>) is considered to be the most important dietary form and is identical to the form produced in the body. Ergocalciferol (D<sub>2</sub>) is produced by fungi and yeasts and is rare in the diet, but a common supplemental/fortificant form (Nowson & Margerison 2002, Nowson et al 2012). Some authors suggest that D<sub>2</sub> should not be classified as a nutrient, given that it has no natural place in human biology (Trang et al 1998, Vieth 2006) and, while both D<sub>2</sub> and D<sub>3</sub> were previously considered to be equipotent as supplements (FAO/WHO 2002, Nowson & Margerison 2002, Prietl et al 2013, Wahlqvist 2002), recent exploration of this issue points to marked discrepancies in favour of D<sub>3</sub>. D<sub>2</sub> also comes under the names 1-alpha-OHD<sub>2</sub>, calcifediol, calciferol, dihydrotachysterol, ergocalciferolum and ergosterol; D<sub>3</sub> may be referred to as 1-alpha-OHD<sub>3</sub>, alfalcidol, calcitriol or rocaltril (Micromedex 2003).

Quantification of any of the vitamin D forms is expressed in either international units (IU) or micrograms. The conversion is: 1 mcg = 40 IU.

## Are all vitamin D forms alike?

Coincident with the recognition of 25(OH)D as the key marker of individual vitamin D status, the ability of cholecalciferol (D<sub>3</sub>) and ergocalciferol (D<sub>2</sub>) to increase serum levels of this marker has been compared (Trang et al 1998). Results from these studies reveal a 70% greater increase in serum 25(OH)D in response to cholecalciferol (D<sub>3</sub>). Hypothesised reasons for this difference are based upon the distinct metabolic handling of the two different forms. D<sub>3</sub> demonstrates higher affinity for D-binding protein, making it less likely to be excreted in bile (Armas et al 2004, Dusso et al 2005, Hossein-nezhad & Holick 2013); D<sub>3</sub> produces more potent metabolites and is converted into 25(OH)D up to five times faster than D<sub>2</sub> (FSANZ 2007, Houghton & Vieth 2006, Trang et al 1998). The results of another study showed that serum 25(OH)D increases in response to D<sub>2</sub> supplementation were not sustained, and in fact fell below baseline values over 14 days, while the serum levels of those supplemented with D<sub>3</sub> continued to rise throughout the same period (Armas et al 2004). In addition to these concerns, the stability and purity of D<sub>2</sub> preparations are questionable (Houghton & Vieth 2006). This is confirmed by a recent systematic review reporting on 144 cohorts from 94 independent studies from 1990 to 2012. The review found that, in all four cohorts where D<sub>2</sub> was the supplement used, a decline in circulating 25(OH)D was observed. Further, in three of the four cohorts where D<sub>2</sub> and D<sub>3</sub> were reported separately, while an overall decline in 25(OH)D was noted, it is of interest that circulating 25(OH)D<sub>2</sub> increased significantly, but seemingly at the expense of 25(OH)D<sub>3</sub>, which showed a marked decline (Zittermann et al 2014).

These findings have major ramifications for the interpretation of vitamin D research and the clinical implementation of such protocols. Every piece of vitamin D research must now be considered in the light of the supplemental form used. Clinically D<sub>3</sub>'s improved potency translates to significantly lower dose requirements, in the vicinity of 2.5–10 times less (FSANZ 2007, Houghton & Vieth 2006), compared with a D<sub>2</sub>-based product (Glendenning 2002). Zittermann et al's (2014) review calculated that D<sub>3</sub> supplementation, compared with D<sub>2</sub>, corresponded to an average increase of 20.19 nmol/L in circulating 25(OH)D. The review also found that concomitant calcium supplementation incurred a significant decrease in circulating 25(OH)D levels by an average of 6.34 nmol/L. Body weight, age and baseline circulating levels of 25(OH)D also impacted on circulating levels of 25(OH)D, with 54% of variability in levels being explained by these factors. Body weight was the main factor contributing more than one-third of the variance; however all these variables should be considered when

reviewing or implementing the evidence, or planning new trials. The Working Group (2012) also discusses the concern of the effect of obesity on dosage regimens. Vitamin D enters adipose tissue and may not be readily available unless there is fat breakdown, which may result in lower circulating vitamin D following oral supplementation.

### FOOD SOURCES

Small amounts are found in fatty fish, such as herring, salmon, tuna and sardines, beef and liver, butter, eggs and fortified foods such as margarine and milk (Gropper et al 2009). Cod liver oil is also a good source. Notably, meat products also contain some 25(OH)D, which is five times more active than D<sub>3</sub> (Nowson & Margerison 2001); however, the vitamin D content of all animal products is dependent upon the individual animal's vitamin D status and the use of fortified feed (Mattila et al 2004). There is therefore concern that, as a consequence of modern agricultural and aquacultural practices, vitamin D content is in decline, as demonstrated by a study which revealed a 75% decrease in the vitamin D content of farmed compared to wild salmon (Lu et al 2007). Naturally occurring D<sub>2</sub> is found only in mushrooms.

Current vitamin D fortification practices in Australia provide very little supplementation of D<sub>3</sub> in mandatory fortification (including edible oil spreads and table margarine) and voluntary fortification (modified and skim milks, powdered milk, yoghurt, cheese, butter, legume- and cereal-based analogue beverages) (FSANZ 2011, Nowson & Margerison 2001). There is one specially supplemented milk product in Australia that provides 200 IU per 250 mL serving. However dietary fortifications are not mandated as they are in other countries such as the United States and Canada, and remain an inadequate source of supplementation (Working Group 2012). Australian diet studies reveal that fortified margarine and edible oil spreads make the largest single contribution to vitamin D consumption (28–53%) (NHMRC 2006, Nowson & Margerison 2001). An Australian study found that average dietary consumption of vitamin D was 1.2 mcg/day and that only 7.9% of this sample took vitamin D supplements (van der Mei et al 2007).

### DEFICIENCY SIGNS AND SYMPTOMS

Although the traditional understanding of hypovitaminosis D revolves around its critical role in calcium metabolism, the extensive presence of VDR throughout the body is providing the impetus for further research into actions, deficiency states and therapeutic applications (Gropper et al 2009). Its role in vascular biology and cardiovascular health in particular has been a focus of clinical studies in recent years. Some clinical studies have linked low levels of vitamin D metabolites with higher incidence of congestive heart failure and increases in mortality (Valdivielso et al 2009). Several studies have looked into the relationship between chronic

kidney disease and vitamin D status (Palmer et al 2007). However, in the expert opinion piece by Valdivielso et al (2009), the importance of vitamin D research in relation to vascular effects has been highlighted. The authors state that a causal relationship has been established in several basic science experiments between vitamin D and cardiovascular diseases (atherosclerosis, hypertension, arterial dysfunction, left ventricular hypertrophy). Equally, nephrology research has shown a great deal of interest due to the low levels of calcidiol and calcitriol seen in patients with chronic kidney disease, and with a higher mortality rate. With targeted trials to evaluate therapeutic levels of vitamin D to control secondary hyperparathyroidism, and cardiovascular disease, which is the major cause of death, vitamin D status is an important marker for these two patient populations (Valdivielso et al 2009). These authors, however, caution against the routine use of vitamin D supplementation in healthy humans where no deficit exists, with the idea of a U-shaped curve of benefit in metabolite levels for individuals.

### Primary deficiency

Unlike many other vitamins, vitamin D is not only ingested through the diet but also produced and stored in the body. As such, endogenous production, which is reliant on adequate exposure to sunlight, will greatly influence whether deficiency states develop. It has been estimated that exposing the skin to UVB radiation produces approximately 90% of the vitamin D<sub>3</sub> (cholecalciferol) that is bioavailable in the body. Currently, the National Health and Medical Research Council (NHMRC) reports that it is almost impossible to get sufficient vitamin D from dietary sources alone, stressing the importance of UVB exposure (NHMRC 2006, Working Group 2012).

### Deficiency more prevalent than once thought

Inadequate vitamin D among Australians is now recognised as a substantial concern, given the significant percentage demonstrating a combination of poor dietary intake and inadequate sun exposure, according to the 2012 position statement released by the Working Group of the Australian and New Zealand Bone and Mineral Society, Endocrine Society of Australia and Osteoporosis Australia. This working group cites epidemiological data that estimate 31% of adults in Australia have inadequate vitamin D status, which they define as <50 nmol/L, and up to 50% of women during winter and spring (Nowson et al 2012).

Ongoing epidemiological research in Australia supports this view and has identified the wider community at risk of mild deficiency, with the results of numerous studies supporting this proposition. Using a cut-off of ≤50 nmol/L for serum 25(OH)D, vitamin D insufficiency has been found to affect >40% of healthy adults in Queensland (Kimlin et al 2007, van der Mei et al 2007), >65% Tasmanians (van der Mei et al 2007) and up to 74% of general

medical inpatients (Chatfield et al 2007) — including 54% of the last group, who were taking vitamin D supplements. A study of maternal and neonatal levels in Sydney revealed that 15% of mothers (at 23–32 weeks' gestation) and 11% of neonates met the criteria for overt vitamin D deficiency ( $\leq 25$  nmol/L) (Bowyer et al 2009). These rates increase dramatically if the reference range for optimal serum 25(OH)D is raised, as has been proposed in the scientific literature (Dawson-Hughes et al 2005, Vieth et al 2001, 2004). One group of researchers reanalysed population data based on the proposed cut-off of  $\leq 80$  nmol/L (Dawson-Hughes et al 2005, Heaney 2006, Holick 2005) and found that 70% of their sample of healthy Australians would, using this definition, be below optimal (van der Mei et al 2007).

More recently, in 2014, a cohort of community-dwelling elective cardiothoracic surgical patients attending the Alfred Hospital in Melbourne, Australia, was found to have a high prevalence of sub-optimal vitamin D (Braun et al 2014). When fasting serum samples were taken on the day of surgery, 92.5% of patients had vitamin D levels  $< 75$  nmol/L, 67.5% had levels  $< 60$  nmol/L, 52.5% had levels between 30 and 59 nmol/L and 15% had levels  $< 30$  nmol/L (Braun et al 2014). The implications for surgical outcomes, healing and future cardiovascular events remain to be investigated.

Factors associated with lower 25(OH)D levels in Australia include:

- seasonal effects, with winter–early spring demonstrating peak incidence (Bowyer et al 2009, Chatfield et al 2007, Kimlin et al 2007, McGillivray et al 2007, van der Mei et al 2007)
- increasing latitude (Angeline et al 2013, Nowson et al 2012, van der Mei et al 2007)
- increasing skin pigmentation (Kimlin et al 2007, Nowson et al 2012), with one study calculating an odds ratio (OR) of 2.7 for dark skin (Bowyer et al 2009)
- non-Australian birthplace: OR 2.2 (Erbas et al 2008)
- hospitalisation, and institutionalisation and age (Bruyere et al 2009).

The institutionalised elderly are of particular concern, as their exposure to sunlight is often restricted and they have an estimated twofold reduction in capacity of the skin to produce  $D_3$  (Wilson et al 1991), compromised final conversion in the kidneys, reduced tissue response and further reductions to calcium absorption independently of these pathways (Bouillon et al 1997, FAO/WHO 2002). The increasing risk with age is clearly demonstrated by the results of a Tasmanian study, which revealed that, although only 8% of 8-year-olds were considered vitamin D-deficient, deficiency escalated with increasing age to peak at 85% for people aged 60 years (RACGP 2003).

At the other end of the age spectrum, a 2-year surveillance of infants presenting with vitamin D deficiency-related problems at the Monash Medical Centre in Clayton, Victoria, found that the 13 infants admitted to hospital all had migrant parents

and were predominantly or exclusively breastfed (Pillow et al 1995). This is a dangerous combination, with dark-skinned migrants at a significantly greater risk of deficiency (Bowyer et al 2009, Erbas et al 2008), particularly women who are veiled (OR 21.7) (Bowyer et al 2009, Grover & Morley 2001, Nowson & Margerison 2002, Wigg et al 2006), and breast milk is recognised as a poor source of vitamin D (Andiran et al 2002). Australian research demonstrates that recently immigrated infants or first-generation offspring of immigrant parents, especially Indian, Middle Eastern, African and Polynesian, are a key at-risk group: 40% of infants aged 4–12 months were found to be deficient (Nozza & Rodda 2001, Robinson et al 2006) and 87% of sampled East African children (0–17 years) living in Melbourne recorded serum 25(OH)D levels  $\leq 50$  nmol/L (McGillivray et al 2007).

Other populations at risk include obese individuals (Arunabh et al 2003, Blum et al 2008, Harris & Dawson-Hughes 2007, Hossein-nezhad & Holick 2013), psychiatric patients (Berk et al 2007), individuals with an intellectual disability (estimated deficiency prevalence 50–60%) (Vanlint et al 2008) and those observing requirements of modest clothing (Zittermann et al 2014).

### Secondary deficiency

Malabsorption states such as coeliac disease, Crohn's disease, gastrectomy, intestinal resection, chronic cholestasis, cystic fibrosis and pancreatic disorders increase the risk of deficiency (Hendler & Rorvik 2001, Kumar & Clark 2002, Nowson et al 2012).

The use of certain anticonvulsants and chronic administration of glucocorticoids increase the risk of vitamin D deficiency. Several rare hereditary forms of rickets develop because the body cannot process (metabolise) vitamin D normally (Beers & Berkow 2003). Chronic liver disease will obstruct the first hydroxylation reaction, and end-stage kidney disease results in negligible conversion of 25(OH)D into 1,25(OH)D (Kumar & Clark 2002, Micromedex 2003). One large study also demonstrated that levels of serum 25(OH)D are inversely correlated with percentage of body fat and, as such, morbidly obese individuals have increased requirements (Arunabh et al 2003).

### Signs and symptoms of deficiency

The previously determined serum concentrations of 25(OH)D believed to be indicative of deficiency ( $< 20$ – $25$  nmol/L) are considered outdated (Gomez et al 2003). It is now apparent that much higher concentrations, deemed 'suboptimal' status, have deleterious effects (Dawson-Hughes et al 2005, Heaney 2006, Holick 2005, Nowson & Margerison 2002). Indications of deficiency include:

- alopecia with dilated hair follicles and dermal cysts (Dusso et al 2005)
- anaemia, decreased bone cellularity and extramedullary erythropoiesis (Brown et al 1999)
- cardiomegaly (Dusso et al 2005, Holick 2005, Valdivielso et al 2009)

**Clinical note — The vitamin D dilemma**

Between 80% and 100% of our vitamin D needs can be met through adequate sun exposure, with dietary intake only required to meet the shortfall (Nowson & Margerison 2001, 2002, Nowson et al 2012, Samanek et al 2006). Quantifying this shortfall, however, is complex and individualistic, as multiple variables influence the rate of endogenous production, such as age, weight, season, latitude, time of day, part of body exposed to sunlight and use of sunscreen. Researchers estimate that full-body sun exposure in Australia, sufficient to induce mild erythema (minimal erythemal dose), is equivalent to consuming 15,000 IU orally, and that exposure of around 15% of the body surface (arms and hands or equivalent) for a third of a minimal erythemal dose, near the middle of the day, will produce about 1000 IU (25 mcg) (Working Group 2005, 2012). Hence, we have the dilemma: while the majority of public health messages continue to promote sun protection, there is growing media coverage of the negatives associated with this and advocacy for exposure to UVB in order to prevent vitamin D deficiency (Scully et al 2008). The successful Slip Slop Slap campaign in Australia, which encourages covering up and reduced sun exposure, appears at odds with the vitamin D message and may have put many Australians at risk of poor vitamin D status. Australian research concurs with this, indicating that the public health message battle is currently being won by 'sun protection', with only 15% of surveyed Australians agreeing with the statement that 'sun protection may result in not having enough vitamin D' (Janda et al 2007).

Clearly, revision of the current public health messages regarding both vitamin D and safe sunlight exposure has been required for some time.

In response, work has been undertaken to develop a message of compromise (Nowson & Margerison 2002, Working Group 2005, 2012), and the development of a vitamin D index, similar to a UV index, has been proposed (van der Mei et al 2007). Evidence from a study by Samanek et al (2006) supports the concept that safe sun exposure can yield vitamin D adequacy. Their research concluded that from October to March only 10–15 minutes of unprotected exposure to 15% of the body outside of the hours of 10 a.m. to 3 p.m. was sufficient; however, during other seasons, up to 1 hour of exposure was required. In addition to this, the authors themselves acknowledge that calculations were based on existing serum values, which have been widely contested by other researchers (Gomez et al 2003). In view of some of these concerns, the new NHMRC vitamin guidelines released in 2006 are now recommending an increased adequate intake of vitamin D, particularly for adults aged over 50 years. The guidelines also suggest varying lengths of time for sun exposure for different skin types in order to achieve adequate levels. Whether these initiatives are sufficient to prevent deficiency in the community remains to be seen. The Working Group (2012) recommendations range from 5 minutes exposure in Townsville, 7 minutes in Sydney, to 9 minutes in Hobart over the summer, and 16 min to 29 min for the rest of the year. They state that those with darker skin are likely to require exposure three to six times longer than suggested values, and those at risk of deficiency include very fair-skinned people who avoid exposure, those who may have clothing that blocks exposure, as well as those with chronic illness, or who are confined indoors.

- cardiovascular disease (atherosclerosis, hypertension, arterial dysfunction, left ventricular hypertrophy) (Valdivielso et al 2009)
  - chronic kidney disease increased mortality from cardiovascular causes (Valdivielso et al 2009)
  - chronic fatigue syndrome (deficiency may be misdiagnosed as this) (Holick 2004, Schinchuk & Holick 2007)
  - chronic lower-back pain (Al Faraj & Al Mutairi 2003)
  - excess PTH secretion and parathyroid hyperplasia
  - fibromyalgia (it is estimated that 40–60% of patients diagnosed with this condition are actually suffering from vitamin D deficiency) (Holick 2004, 2005, Schinchuk & Holick 2007)
  - hypertension (Dusso et al 2005, Forman et al 2007, Holick 2005)
  - impaired glucose-mediated insulin secretion (Brown et al 1999)
  - increased risk of fracture in the elderly (not limited to vitamin D's influence on bone mass)
  - increased susceptibility to mycobacterial and viral infections (Dusso et al 2005)
  - peripheral vascular disease with claudication (may be misdiagnosed or confounding factor) (Holick 2005)
  - rickets and osteomalacia
  - osteopenia and osteoporosis
  - sarcopenia — skeletal muscle weakness and atrophy (Dusso et al 2005, Visser et al 2003)
  - stunting.
- Deficiency also significantly increases the risk of:
- autoimmunity, including multiple sclerosis (MS) (including increased severity of pre-existing cases) (Dusso et al 2005, Hall & Juckett 2013, Holick 2004), diabetes type 1 (Clancy et al 2013, Cooper et al 2011, Holick 2006) and inflammatory bowel disease (Hewison 2011, Holick 2004)
  - cancer — breast, prostate, colon and skin cancers are among the 20 different cancer types demonstrating an inverse relationship with vitamin D levels (Holick 2004)
  - heart failure in patients with cardiovascular disease (Holick 2005, Valdivielso et al 2009)

- non-insulin-dependent diabetes mellitus in high-risk populations — some studies (Pittas et al 2007), but not all (Reis et al 2007), show positive association
- pre-eclampsia — particularly if hypovitaminosis D is present at <22 weeks (Bodnar et al 2007, Hossein-nezhad & Holick 2013).

## MAIN ACTIONS

Whereas vitamin D is considered a fat-soluble vitamin, its active metabolite  $1,25(\text{OH})_2\text{D}_3$  is considered to be more like a steroid hormone, because it can be produced by the body and moves through the systemic circulation to reach target tissues via receptors both at the cell membrane and at the nuclear receptor proteins. Vitamin D possesses two distinct action pathways dependent upon the site of bioactivation (Clancy et al 2013, Dusso et al 2005, Holick 2006). Renal hydroxylation of  $25(\text{OH})\text{D}$  produces  $1,25(\text{OH})_2\text{D}$ , primarily responsible for its traditional endocrine actions mentioned, as well as playing a role in intestinal detoxification and calcium absorption (Kutuzova & DeLuca 2007, Nowson et al 2012), healthy insulin secretion (Brown et al 1999, Dusso et al 2005, Mathieu & Badenhop 2005) and blood pressure control, via inhibition of renin production and blunting cardiomyocyte hypertrophy (Dusso et al 2005, Holick 2005, Simpson et al 2007, Valdivielso et al 2009).

Extrarenal bioactivation, by immune, prostate, breast, colon, beta and skin cells, however, results in non-genomic responses characterised as autocrine rather than endocrine effects (Dusso et al 2005, Hewison 2011, Holick 2006, Kemmis et al 2006). These autocrine effects include controlling immune function (especially anti-inflammatory), cellular growth, maturation, differentiation and apoptosis (Dusso et al 2005, Hewison 2011, Holick 2005, Kemmis et al 2006, Lips 2006) as well as photoprotection (Dixon et al 2007), explaining vitamin D's role in immune function and cancer prevention.

### Regulation of calcium and phosphorus levels

In conjunction with PTH, which is released under conditions of low calcium levels, vitamin D can stimulate calcium and phosphorus absorption in the intestines, reabsorption in the kidneys and release of calcium from the bones back into the blood.  $1,25(\text{OH})_2\text{D}_3$  in turn is regulated by PTH, calcium, phosphorus and  $1,25(\text{OH})_2\text{D}_3$  itself (Wahlqvist 2002). To achieve the maximal efficiency of vitamin D-induced intestinal calcium transport, the serum  $25(\text{OH})\text{D}$  concentrations must be at least 78 nmol/L (30 ng/mL). In deficiency, intestinal absorption of calcium can be halved in adults (Hossein-nezhad & Holick 2013, Holick 2004).

### Modelling and remodelling of bone

Besides influencing bone by maintaining calcium and phosphorus homeostasis, vitamin D may also contribute to bone health in other ways.

One pathway involves binding of  $1,25(\text{OH})_2\text{D}_3$  to DNA to promote transcription of specific mRNA, which codes for osteocalcin. Osteocalcin is then secreted by the osteoblasts, which bind calcium in new bone (Groppe et al 2009). Vitamin D also appears to play a role in oestrogen biosynthesis by increasing expression of the aromatase enzyme gene. It has demonstrated a synergistic effect in select tissues with the phyto-oestrogen genistein, with co-administration leading to a prolonged half-life of active vitamin D (Harkness & Bonny 2005, Swami et al 2005).

### Cell differentiation, proliferation and growth

Some of the actions already described are the result of the vitamin's capacity to affect cell differentiation, proliferation and growth in many tissues (e.g. differentiation of stem cells into osteoclasts to facilitate bone resorption). Alternatively,  $1,25(\text{OH})_2\text{D}_3$  can inhibit proliferation in many cells, including lymphocytes, keratinocytes, mammary, cardiac and both skeletal and smooth-muscle cells. This ability has led to its investigation as a treatment for proliferative disorders such as cancer (Brown et al 1999, Groppe et al 2009, Hossein-nezhad & Holick 2013, Kohlmeier 2003).

### Reduction of PTH and regulation of growth of the parathyroid gland

Although PTH regulates the levels of  $1,25(\text{OH})_2\text{D}$ , its secretion is regulated by vitamin D, calcium and phosphorus. In deficiency, hypersecretion of this hormone can cause excessive growth of the parathyroid gland and secondary hyperparathyroidism (Brown et al 1999, Hewison 2011).

### Immunomodulation

Increasing evidence for vitamin D's importance outside its classical role in bone metabolism is emerging. However the use of vitamin D to treat diseases has been used since Hippocrates first prescribed sunlight for tuberculosis (Clancy et al 2013). Vitamin D enhances the immune system's response to both bacterial and viral agents (Grant 2008c), primarily through promoting differentiation and activity of the macrophages, which means that immune responses can be tailored through the appropriate cell response (Brown et al 1999), but also through the induction of cathelicidin (Maalouf 2008). Vitamin D influences the cytokine production of immune cells, suppressing the release of interleukin-2 (IL-2), IFN-gamma and TNF-alpha, products of the Th1 line of cells, thereby reducing the propensity for a range of autoimmune conditions (Thien et al 2005). This reflects its propensity for inhibiting adaptive immunity while potentiating the innate response (Bikle 2008). There is speculation that, through this mechanism, vitamin D will promote a Th2 dominance and may predispose to the atopic diathesis. Supporting evidence comes from two studies that reveal supplementation with vitamin D in early life to be a potential

precipitator of allergic disease (Hyppönen et al 2001); however, in other scenarios (e.g. autoimmunity) this effect would be considered to be therapeutic (Smolders et al 2008). In recent years, data have increasingly linked vitamin D deficiency with Th1 autoimmune disorders (Clancy et al 2013), such as MS, type 1 diabetes and Crohn's disease, suggesting a significant impact of vitamin D on immune function. Even increased susceptibility to infectious diseases, such as tuberculosis, is thought to have a link to low vitamin D levels (Hewison 2012). In a symposium paper from the Proceedings of the Nutrition Society, Hewison (2012) discusses that cells from the immune system are capable of converting the precursor 25-hydroxyvitamin D to the active 1,25-dihydroxyvitamin D, which stimulates a macrophage response to this active form in an antimicrobial fashion. Additionally, regulation of the maturation of antigen-presenting dendritic cells (DCs) occurs, from which vitamin D may control T-lymphocyte (T-cell) function. T cells, however, also have a direct response capacity to the active form of vitamin D in the activation of suppressor regulatory T cells. This suggests an immune adaptive response as well as innate immunity. Its influence on cytokine inflammatory markers, as mentioned above, may indicate a protective effect by reducing prolonged exposure to inflammation (Hewison 2012). Priet et al (2013) also suggest that vitamin D-metabolising enzymes and VDRs, present in many cell types, are expressed extensively in immune cells, including antigen-presenting cells, T cells, B cells and monocytes, and purport that this not only modulates innate immune cells, but promotes a more tolerogenic immunological state.

## OTHER ACTIONS

Our current understanding of the role of vitamin D appears to be only part of the picture. Ongoing discovery of previously unidentified receptors on tissues continues to broaden our understanding of its diverse effects. Recently, Nowson et al (2012), in the Working Group paper, state that almost every nucleated cell expresses the VDR, and that many extrarenal tissues have the capacity to make 1,25(OH)<sub>2</sub>D. This suggests evidence for not only classical endocrine operation, but also autocrine and paracrine pathways, which suggests vitamin D's role and importance in local synthesis and actions. This has major implications for vitamin D research and therapeutic value.

## Haematopoietic tissues

VDRs have been identified on haematopoietic and lymphoid cells, suggesting the role of vitamin D in blood cell development and immune system function. The biologically active form of vitamin D, calcitriol, exerts an effect on erythropoiesis and bone cellularity. Calcitriol activates the VDRs, which appear to be the mediator of vitamin D's action, and may have a role in homing lymphoid cells to

specific tissues. It has been found that VDRs are ubiquitous in human tissue, and that the gene for VDR, with its various polymorphisms (encoded on chromosome 12) and differences in transcription effects, is responsible for at least some of the variability among individuals, not only in vitamin D absorption and status, but in biologically diverse ways, such as adult height, bone mineral density and susceptibility to diseases such as tuberculosis (Hall & Juckett 2013).

Vitamin D has also been shown to inhibit clonal cell proliferation in some leukaemia lines and to promote leucocyte differentiation (Brown et al 1999). VDRs are expressed in various cells such as monocytes, thymocytes, activated B and T lymphocytes, as well as haematopoietic precursors in the haematopoietic system. The presence on activated lymphocytes suggests that there is an immune modulation role on differentiated cells. Changes in inflammatory cytokine profiles in VDR knockout mice suggest vitamin D's role in mediating inflammation (Hall & Juckett 2013). The expression of VDR on isolated DCs from lymphoid tissue further confirms the role of vitamin D in immunoregulation (Hewison 2012). DCs are critical in the adaptive immune response, in the establishment of immunological memory, and have the ability to induce a primary immune response in T lymphocytes (Wieder 2003). Treatment with 1,25(OH)<sub>2</sub>D has been shown to suppress DC maturation, specifically in the myeloid DC, which is responsible for T-cell activation, and promote the more tolerogenic plasmacytoid DC (Hewison 2012).

## Muscle function

Vitamin D maintains muscle strength and has an effect on skeletal muscle and smooth muscle, with proximal muscle weakness being a common feature of deficiency (Hossein-nezhad & Holick 2013). Early work performed in 1975 demonstrated a relationship between vitamin D and muscle function. Birge and Haddad found that phosphate regulation within the muscle cell promoted maintenance of muscle metabolism and function. In 2004, Holick suggested a link between fibromyalgia and vitamin D deficiency, with 40–60% of cases presenting with generalised muscle weakness and pain being estimated as undiagnosed hypovitaminosis. More recently, with VDR being identified on smooth-muscle cells, and with vitamin D's classic role in calcium and phosphate homeostasis, there are major implications for skeletal muscle function as well as smooth muscle in the respiratory, cardiovascular and reproductive systems. Cannell and colleagues (2009) describe the binding of 1,25(OH)<sub>2</sub>D<sub>3</sub> to the VDR, leading to gene transcription and increased cell protein synthesis and growth. Further, Bischoff-Ferrari et al (2004) show an age-related decline of VDR expression in muscle tissue, and abnormal development of muscle fibres and maturation have been demonstrated in VDR knockout mice (Minasyan et al 2009).

The cellular effect of vitamin D can be seen in a variety of cellular signalling cascades. Principal among them is the mitogen-activated protein kinase signalling pathway, which initiates muscle tissue cell genesis, proliferation and differentiation (Angeline et al 2013). Disruption of this pathway in deficient murine models and subsequent supplementation showed an increase in muscle mass through increased protein synthesis. Interestingly, however, exercise-induced muscle cell apoptosis was reduced in these animals (Cannell et al 2009, Ceglia 2009). Further clinical trials should be implemented to elucidate the implications of this effect.

The US Preventive Services Task Force report concluded that vitamin D supplementation is effective in preventing falls in community-dwelling adults over 65 years, but the evidence is less convincing about primary fracture prevention (Moyer 2013). With a demonstrated age-related decline in VDR expression (Bischoff-Ferrari et al 2004), and Minasyan et al's (2009) finding that their VDR knockout mice with abnormal muscle fibre development and maturation also showed poorer motor and balance function, the role of vitamin D in muscle health and strength may play at least a part in falls prevention and therefore fracture risk reduction in the elderly.

### Vascular function

Local production of calcitriol acts as a regulator of certain cell functions. In both endothelial and vascular smooth muscle, the VDR activity suggests that vitamin D acts via an endocrine pathway as a regulator of vascular function. VDR is expressed in cells throughout the vascular system, including vascular smooth-muscle cells, endothelial cells and cardiomyocytes, which all produce CYP27B1 to convert into the active form calcitriol. Calcitriol has been shown to exhibit anti-inflammatory properties, through local control of cytokines, and also exhibit an inhibitory effect on vascular smooth-muscle cell proliferation, and help to regulate the renin-angiotensin system (Shapses & Manson 2011). Vitamin D has been found to exert a direct effect on the myocardium: 1,25(OH)<sub>2</sub>D<sub>3</sub> controls hypertrophy in cardiac monocytes and, together with 25(OH)D, improves the left ventricular function in patients with cardiomyopathies (Brown et al 1999). Cardiovascular pathology is the leading cause of death in patients with chronic kidney disease, and there is a relationship between cardiovascular health and vitamin D status. Metabolite levels are associated with a higher incidence of congestive heart failure and increases in mortality (Valdivielso et al 2009). Vitamin D deficiency has also been linked to an increased risk of developing incident hypertension (Forman et al 2007, Wang et al 2008). Observational studies have suggested considerable benefits from vitamin D dietary intake and supplementation; however, clinical trial evidence for hypertension and diabetes is inconsistent, and in subanalysis potentially suggests a benefit for those with the lowest levels of circulating vitamin D, and a potential detriment for

normotensive individuals, or those with adequate circulating 25(OH)D levels, suggesting a U-shaped curve of benefit. While biological plausibility exists, the data have been less compelling in human subjects compared with animal models (Shapses & Manson 2011, Valdivielso et al 2009). Confounding factors such as obesity, age and exercise levels need to be considered in conducting robust large-scale randomised controlled trials (RCTs) with cardiovascular outcomes as the primary measure.

### Pancreatic function

Vitamin D is essential for normal insulin secretion, as demonstrated in both animals and humans, and VDRs have been found in pancreatic beta cells, whose function improves following vitamin D repletion (Alemzadeh et al 2008, Mathieu & Badenhop 2005, Palomer et al 2008). Enhanced insulin synthesis may be due to vitamin D's role in controlling intracellular calcium flux in islet cells which facilitates conversion of proinsulin to insulin, exocytosis of insulin and beta-cell glycolysis (Brown et al 1999, Palomer et al 2008). Vitamin D also modulates insulin receptor gene expression (Palomer et al 2008).

### Brain function

Evidence over the past 10–15 years confirms that the steroid hormone vitamin D is essential for normal homeostasis and development of the brain (Eyles et al 2013). The data implicate 1,25(OH)<sub>2</sub>D in the biosynthesis of neurotrophic factors, contribution to brain detoxification pathways with increased glutathione and reduced nitric oxide, neuroprotective effects, induction of glioma cell death and involvement in neurotransmitter synthesis, including acetylcholine and the catecholamines (Garcion et al 2002). The VDR and 1-alpha-hydroxylase activity has been demonstrated in specific brain regions (e.g. the hypothalamus), implying a potential role for vitamin D as a neuroactive hormone (Berk et al 2007, Eyles et al 2014, Obradovic et al 2006, Vieth et al 2004). There is also increasing evidence of vitamin D's modulation of several neurotransmitters, such as acetylcholine, catecholamines and serotonin (Jorde et al 2006, Obradovic et al 2006). Preliminary studies in rats have demonstrated an antiepileptic action (Kaluff & Tuohimaa 2005). Tentative links are being made between the aetiology/pathophysiology of Parkinson's disease and poor vitamin D status (Johnson 2001, Kim et al 2005). The extensive and interesting work of the Australian group of Eyles and colleagues has been presented in a series of papers, and has outlined the varied and far-reaching implications of vitamin D deficiency and absence in the developing fetal brain (Byrne et al 2005, Cui et al 2010, Eyles et al 2003, 2011, 2013, 2014, Harms et al 2011). Vitamin D affects an array of cellular functions, and the group has described in experimental mouse and rat models the effects of induced extreme deficiency, and developmental absence of vitamin D. These models show: a less differentiated brain;

changes to neurotrophic factor expression; cytokine regulation; neurotransmitter synthesis; intracellular calcium signalling; antioxidant activity; greater number of proliferating cells (which elongates the shape of the developing brain); less apoptosis (further influencing distribution and shape of brain); expression of genes/proteins; structure and metabolism; and a reduction in factors associated with neuronal maturation (Eyles et al 2003, 2011, 2014). Additionally the group has demonstrated a persistent effect into adulthood of altered brain anatomy in structure and function (Eyles et al 2013), and neurochemistry (Eyles et al 2012) for fetuses exposed to deficiency or absence of vitamin D.

VDRs are shown to be nucleic in fetal life and readily apparent in the brain, although in lower amount than the more usual target organs of the gut and kidneys. However, in adulthood VDRs are demonstrated to be in the plasma membrane and more prominent in the gut and kidney, suggesting a change in function with maturation of the organs (Eyles et al 2014). Vitamin D deficiency has been linked to developmental psychiatric disorders, such as autism spectrum disorder, schizophrenia and Parkinson's disease, in observational and epidemiological studies (Eyles et al 2014). Correlations with greater risk associated with increasing latitude, seasonal variation as well as darker skin pigmentation in migrant groups have been well established for risk of schizophrenia (Cantor-Graae & Selten 2005, Davies et al 2003), depression (Byrne et al 2005), and are emerging for autism spectrum disorder (Cannell 2008, Grant & Soles 2009).

## CLINICAL USE

Vitamin D is administered using various routes and can be prescribed as either a supplement or a drug, largely depending on dose and administration route. This review will focus on oral supplementation of D<sub>2</sub> or D<sub>3</sub> only and will not cover the variety of analogues that continue to be extensively studied. For many conditions that appear to require high doses, the race is on to develop and trial pharmaceutical analogues that retain, in particular, the anti-proliferative nature of the vitamin, but are low-calcaemic in order to minimise the associated toxicity seen at such doses.

## Deficiency states

Frank vitamin D deficiency in infancy or childhood produces rickets, which results from reduced sun exposure, deficient diet or metabolic or malabsorptive diseases. Vitamin D deficiency results in inadequate calcium and phosphorus levels for bone mineralisation (Beers & Berkow 2003). Diagnosis is confirmed with X-ray and serum assay of 25(OH)D. When occurring in adults, it is called osteomalacia, and its first presentation is often as chronic lower-back pain (Al Faraj & Al Mutairi 2003).

Defective vitamin D metabolism may be another cause, and consequently deficiency will not respond to standard oral treatment. In this situation, extremely high doses may be required, which should

be monitored carefully for toxicity (Beers & Berkow 2003).

## Pregnancy and lactation supplementation

Vitamin D's role in pregnancy is extremely complex, and points to its importance not only in establishing a pregnancy, but also in fetal and neonatal growth and development (Hossein-nezhad & Holick 2013). Vitamin D appears to be critical both to musculoskeletal and neurological growth and to the development of the infant. A recent Cochrane review, including six trials and reporting on a total of 1023 women, concluded that supplementation with vitamin D significantly improved women's vitamin D levels. The clinical significance of this finding and the potential use of vitamin D supplementation as a part of routine antenatal care are yet to be determined. (De-Regil et al 2012). The authors reported that data from three trials indicated that women who received vitamin D supplementation were slightly less likely to have a low-birth-weight (<2500 g) baby. However, no difference was apparent with regard to: pre-eclampsia; gestational diabetes; impaired glucose tolerance; caesarean section; gestational hypertension; or death in the mothers. For the newborns there was no difference in: preterm birth; stillbirth; neonatal death; neonatal admission to intensive care unit; low Apgar score; or neonatal infection (De-Regil et al 2012). In a study by Merewood and colleagues (2009), a strong association was found between vitamin D deficiency and increased risk of caesarean section. When all other factors were controlled for, having serum 25(OH)D <37.5 nmol/L increased the odds of having a caesarean delivery by 3.84. Women who had the highest serum 25(OH)D levels had the lowest risk of requiring a caesarean delivery. The authors hypothesise that, given that muscles contain VDRs, and that suboptimal muscle performance and weakness are associated with low serum 25(OH)D, this may be responsible for a potential failure to spontaneously begin labour or failure to progress in labour. Also, given the role of 25(OH)D in calcium regulation, this may also affect the action of smooth muscle required for efficient labour initiation and effective contractions (Merewood et al 2009).

An Australian study investigated the well-documented seasonal variation in birth weight to determine the parameters of anthropometric changes associated with this seasonal variation (McGrath et al 2005). Comparison of over 350,000 mean monthly birth weights of neonates at more than 37 weeks' gestation revealed that overall size, length, head size and skinfold thickness all display seasonal variation, but in particular greater limb length occurred with winter/spring births. Earlier animal studies imply that this may be a consequence of hypertrophy of the cartilage growth plates due to prenatal hypovitaminosis D (McGrath et al 2005).

Whether pregnant women require additional supplementation has been investigated in some studies. Trials involving more than 500 women

conducted by [Marya et al \(1981, 1987\)](#), not included in the Cochrane Register review, have demonstrated statistically significant increased fetal birth weight, reduced prevalence of hypocalcaemia and hypophosphataemia, detected in both maternal and cord blood, and reduced blood pressure in non-toxaemic women. Additional evidence suggests a preventive role for a range of autoimmune conditions in the offspring when prenatal vitamin D levels are adequate ([Holick 2004](#)).

There is greater consensus regarding the need for vitamin D supplementation during lactation; breast milk is recognised as a poor source of this vitamin and infants are largely dependent on stored vitamin D acquired in utero ([Andiran et al 2002](#), [De-Regil et al 2012](#)).

### Children

The optimal regimen in relation to both route and dose of vitamin D for at-risk children remains controversial and is based on studies of limited size ([Huh & Gordon 2008](#)). The most common recommendation for infants is to supplement with D<sub>2</sub> or D<sub>3</sub> at 1000–2000 IU/day and up to 4000 IU/day in children older than 1 year. The US Institute of Medicine released a report in 2010 recommending dietary intakes of 400 IU/day for healthy infants and 600 IU for healthy children. The target circulating level of 25(OH)D was set at 50 nmol/L. This does not take into account the requirements for acutely or chronically unwell infants and children ([Abrams et al 2013](#)).

### Treatment of deficiencies secondary to malabsorptive syndromes

Numerous studies have confirmed a high prevalence (25–75%) of hypovitaminosis D in patients with coeliac disease, Crohn's disease, small-bowel resection or cystic fibrosis. A positive correlation between low vitamin D status and clinical consequences, such as reduced bone mineral density and osteopenia, has been demonstrated in most studies. Interestingly, trials investigating the benefits of oral vitamin D supplements (400–800 IU/day) found limited success in patients. Owing to the theoretical advantage of supplementation in conditions associated with poor nutrient absorption, larger trials involving higher doses or different forms are expected to determine the most effective treatment ([Abrams et al 2013](#), [Buchman 1999](#), [Congden et al 1981](#), [Hanly et al 1985](#), [Hoffmann & Zeitz 2000](#), [Jahnsen et al 2002](#)). A study of children with cystic fibrosis demonstrated 25(OH)D levels that were consistently >50 nmol/L with an average dose of 1405 IU/day.

### Reducing all-cause mortality

Several large studies have identified an association between serum 25(OH)D concentrations and all-cause and cause-specific mortality, finding that, in particular, vitamin D deficiency (25(OH)D concentration <30 nmol/L) mortality was strongly associated with mortality from all causes, cardiovascular

diseases, cancer and respiratory diseases ([Schottker et al 2013, 2014](#)). One German study investigated concentrations of 25(OH)D in 9578 people who were followed up over 9.5 years. For those people with vitamin D deficiency (<30 nmol/L) or insufficiency (30–50 nmol/L) was significantly increased (1.71 [1.43, 2.03] and 1.17 [1.02, 1.35], respectively) compared with that of subjects with sufficient 25(OH)D concentrations (>50 nmol/L). Vitamin D deficiency was also associated with increased cardiovascular mortality (1.39: 95% CI 1.02–1.89), cancer mortality (1.42: 95% CI 1.08–1.88) and respiratory disease mortality (2.50: 95% CI 1.12–5.56). The association of 25(OH)D concentrations with all-cause mortality proved to be a non-linear inverse association with risk that started to increase at 25(OH)D concentrations <75 nmol/L ([Schottker et al 2013](#)). [Chowdery et al \(2014\)](#) also concluded that evidence from observational studies indicates inverse associations of circulating 25-hydroxyvitamin D with risks of death due to cardiovascular disease, cancer and other causes. In particular, supplementation with vitamin D<sub>3</sub> significantly reduces overall mortality among older adults ([Chowdhury et al 2014](#)). The conclusion was based on study-specific relative risks from 73 cohort studies (849,412 participants) and 22 randomised controlled trials (vitamin D given alone versus placebo or no treatment; 30,716 participants). These were meta-analysed using random effects models and grouped by study and population characteristics.

The same group continued to explore the relationship in a larger study that involved a meta-analysis of individual participant data of eight prospective cohort studies from Europe and the United States. This involved data from 26,018 men and women aged 50–79 years. Comparing bottom versus top quintiles for vitamin D, a pooled risk ratio of 1.57 (95% CI 1.36–1.81) for all-cause mortality was observed. Risk ratios for cardiovascular mortality were similar in magnitude to that for all-cause mortality in subjects both with and without a history of cardiovascular disease at baseline. With respect to cancer mortality, an association was only observed among subjects with a history of cancer (risk ratio, 1.70: 1.00–2.88). Interestingly, no strong age, sex, season or country-specific differences were detected. The authors concluded that, despite levels of 25(OH)D strongly varying with country, sex and season, the association between 25(OH)D level and all-cause and cause-specific mortality was remarkably consistent ([Schottker et al 2014](#)).

### Cancer prevention

In the 1930s it was reported that US navy personnel exposed to high-level UVB showed higher rates of skin cancer but lower rates of cancer malignancies ([Giovannucci 2008](#), [Grant 2008a](#)). World Health Organization data from as early as 1955 have demonstrated latitudinal gradients in cancer mortality rates for breast, colon, lung, prostate, rectal and renal cancer ([Grant 2008a](#)); however, the hypothesis

linking UVB, vitamin D and cancer was not formally proposed until 1980. Since this time, ongoing epidemiological evidence has demonstrated in both single and multiple-country studies that there is increasing cancer incidence or mortality with increasing distance from the equator (Garland et al 1999, Grant 2008a). Both advancing age and ethnicity have also been positively correlated with these cancers and this has been similarly explained in relation to reduced UVB exposure. Further epidemiological support comes from the inverse relationship between prospective serum 25(OH)D levels and cancer risk, season of cancer diagnosis and survival time and lower rates of cancer in high fish-consuming countries such as Iceland and Japan (Giovannucci 2008, Grant 2008a). In 2002 Grant identified 14 cancers for which there was strong evidence to support vitamin D sensitivity, including breast, colon, ovarian, prostate and rectal forms. Recently, Hossein-nazhad & Holick (2013) have outlined evidence to support the hypothesis of vitamin D's ability to regulate microRNA and its effect in several cancer cell lines, tissues and sera. They also suggest that local conversion of 25(OH)D in healthy cells in the colon, breast and prostate can help prevent malignancy. This prevention may occur due to 25(OH)D's capacity to induce cellular maturation, induce apoptosis and inhibit angiogenesis (Hewison 2011). Additionally, 25(OH)D may act to enhance the genes which control cellular proliferation and active detoxifying enzymes (Eyles et al 2013, Hossein-nazhad & Holick 2013).

Evidence from an interventional study of calcium (1400–1500 mg/day), alone or with vitamin D<sub>3</sub> (1100 IU/day), versus a placebo over 4 years supports a chemoprotective role for vitamin D (Lappe et al 2007). The study, involving 1179 women >55 years old, was primarily designed to assess reductions in fracture incidence, but upon further analysis also demonstrated significant risk reduction (relative risk [RR] 0.40) for all cancer incidence in the combined calcium and vitamin D group. When the analysis was restricted to those cancers diagnosed only after the first year of treatment, the RR became 0.23. While the group receiving calcium alone also demonstrated a reduced risk, the researchers speculate that this may not be robust and conclude that vitamin D is the key variable in reduced incidence of all cancer. Given the ability of vitamin D to inhibit abnormal proliferation, facilitate apoptosis, attenuate growth signals and reduce angiogenesis around tumours, its chemoprotective potential continues to be enthusiastically investigated through both *in vitro* studies and RCTs (Giovannucci 2008, Grant 2008a, Hossein-nazhad & Holick 2013). Risk reduction via protection against viral infections has also recently been hypothesised (Grant 2008b, Hewison 2012).

### Improving cancer prognosis

According to a systematic review of 26 clinical studies, evidence now suggests that circulating

25-OHD levels may be associated with better prognosis in patients with breast and colorectal cancer (Toriola et al 2014).

### Colorectal cancer and prevention of adenomatous polyps

Evidence of vitamin D's chemoprotective effect is strongest in relation to colorectal cancer (Giovannucci 2008) and comes from several different lines of investigation (Garland et al 1991, Giovannucci 2008, Grant & Garland 2004, Holt 2008, Holt et al 2002, Theodoratou et al 2008). A 2004 review of more than 20 epidemiological studies of vitamin D and colorectal cancer concluded that the overwhelming majority of studies have demonstrated an inverse relationship between dietary intake, serum 25(OH)D and incidence (Garland et al 2004). An estimate of daily requirements needed for prevention has been formulated using the data from the studies, suggesting that an oral intake of >1000 IU/day of vitamin D or serum 25(OH)D levels of >33 ng/mL (82 nmol/L) could reduce the risk of colorectal cancer by as much as 50%. Most intervention studies to date, however, have focused on calcium supplementation. Interestingly, some of these show that calcium's protective effect against recurrent adenomas is largely restricted to individuals with baseline serum 25(OH)D above the median ( $\approx$  29 ng/mL). These data, together with later findings (Mizoue et al 2008), strongly point to a synergism between calcium and vitamin D for colorectal cancer and recurring adenoma risk reduction (Grau et al 2003, Holt 2008, Oh et al 2007, Theodoratou et al 2008).

An often-cited negative finding comes from the Women's Health Initiative (WHI), in which women supplemented with 1000 mg calcium and 400 IU vitamin D per day failed to demonstrate reduced cancer rates; however, several authors have published major criticisms of the study that include the inadequate dose of vitamin D administered and the time frame (Giovannucci 2008, Grant 2008a, Holt 2008). Reanalysis of the WHI findings has also elucidated oestrogen's critical modifying effect upon both nutrients, whereby higher oestrogen levels of both menstruating and postmenopausal women taking hormone replacement therapy negate calcium's otherwise protective effect (Ding et al 2008). Explanations for this phenomenon include competitive binding between vitamin D and oestrogen (Ding et al 2008, Oh et al 2007). Two recent meta-analyses reporting on more than 2000 participants each have shown a significant decrease in the risk of colorectal and rectal cancer in an inverse relationship with circulating levels of 25(OH)D (Chung et al 2011, Lee et al 2011). Stubbins et al (2012) show that the active form of vitamin D targets a  $\beta$ -catenin pathway by upregulating key tumour suppressor genes, which promote an epithelial phenotype. This is only possible when there is adequate VDR expression. This could provide useful targets for therapeutic administration.

Current evidence for a combined protective role of calcium, either dietary or supplemental, and vitamin D, particularly in men and postmenopausal women not taking hormone replacement therapy, is strong and further elucidation of the independent and combined effects of these nutrients will assist in the development of preventive protocols. Stubbins et al (2012) suggest that the recommended dietary intake should be increased to 2000 IU to target and increase serum 25(OH)D levels to above 30 ng/mL.

### Prostate

Vitamin D's relationship to cancer is least clear with respect to prostate cancer, with inconsistent findings from numerous studies (Giovannucci 2008, Li et al 2007, Mucci & Spiegelman 2008). The belief that increased calcium, dairy consumption and vitamin D levels could increase risk has dominated, with epidemiological evidence from a number of substantial studies, including the Helsinki Heart Study, involving 19,000 men. This study showed that increased levels of circulating 1,25(OH)<sub>2</sub>D<sub>3</sub> and low levels of 25(OH)D are inversely associated with prostate cancer, in both incidence and aggressiveness, and are associated with an earlier age of onset (Chen & Holick 2003, Mucci & Spiegelman 2008). However, evidence of the potentially protective effects of increased serum 25(OH)D and 1,25(OH)<sub>2</sub>D continue to emerge (Li et al 2007), while more comprehensive investigations of the relationship between dietary vitamin D intake and risk fail to show any effect (Huncharek et al 2008), largely due to globally poor intakes. Several explanations for these contrasting findings have been proposed, including that vitamin D status many years prior to diagnosis may be more predictive and relevant than levels just before or following diagnosis (Giovannucci 2008, Mucci & Spiegelman 2008). In a recent review of ecological studies, there was strong evidence for a correlation with solar UVB irradiance and 15 types of neoplasms, and weaker, but significant, evidence of nine other types of cancer, including prostate (Grant 2012).

Experimental research with vitamin D has produced interesting results. Prostate cancer cells in vitro respond to vitamin D<sub>3</sub> with reduced proliferation, increased differentiation and apoptosis. More recently, reduced activity of the 1- $\alpha$ -hydroxylase enzyme in cancerous prostate cells when compared to healthy prostate tissue was discovered, resulting in a reduced ability to convert vitamin D to its active form. Therefore, prostates with cancer display partial resistance to the tumour-suppressing activity of 1,25(OH)<sub>2</sub>D<sub>3</sub> (Ma et al 2004). Clinical trials using supplemental vitamin D at various stages of prostate cancer have yielded inconsistent results (Miller 1999).

### Breast

Normal breast cells produce 1,25(OH)<sub>2</sub>D, which in turn may contribute to healthy mammary function, inducing differentiation, inhibiting proliferation and

modulating immune responses (Perez-Lopez 2008). VDRs in mammary tissue have also been shown to oppose oestrogen-driven proliferation of cells (Welsh et al 2003). In addition, there is growing epidemiological evidence to suggest an inverse association between vitamin D and breast cancer (Grant 2006, 2008c, 2012, Mohr et al 2008, Perez-Lopez 2008), with increasing UVB exposure reported to produce a RR of between 0.67 and 0.85 (Perez-Lopez 2008). One study that involved 179 breast cancer patients and 179 controls assessed vitamin D status of patients and polymorphisms of vitamin D, and identified an inverse relationship, possibly as high as sevenfold, between 25(OH)D levels and breast cancer risk (Lowe et al 2005). Interestingly, from a population-based case-control study in Ontario, there is evidence to suggest that sun exposure between the ages of 10 and 19 years is particularly protective against subsequent breast cancer diagnoses (Perez-Lopez 2008). This implies that vitamin D status may be especially important during breast development.

A more recent investigation of the effect of UVB exposure on breast cancer incidence in 107 countries also confirmed that increased UVB exposure is independently protective, with age-standardised incidence rates substantially higher at latitudes distant from the equator (Mohr et al 2008). The same study demonstrated that the protective effect was evident at serum levels above 22 ng/mL. Another study revealed that women with serum 25(OH)D  $\geq$  50 ng/mL halve their risk of breast cancer compared to those below this cut-off level (Perez-Lopez 2008).

A large meta-analysis of dietary studies initially failed to find a relationship between vitamin D intake and breast cancer risk. Restricting studies to only those with intakes > 400 IU/day, however, revealed a trend towards risk reduction with increasing vitamin D intake (RR 0.92) (Gissel et al 2008).

### Autoimmune diseases

Autoimmune status is affected by multifactorial inputs: environmental contribution, as well as a genetic predisposition, and exposure to epidemiological risk factors are all key influencers of a person's immune state. Increasing prevalence of autoimmune disorders as well as geographical and seasonal variations have led to investigations of vitamin D insufficiency as a potential key factor. Autoimmune diseases such as type 1 diabetes mellitus (T1DM), MS, systemic lupus erythematosus (SLE), rheumatoid arthritis, Crohn's disease and other inflammatory bowel disease have been linked to significant epidemiological data which suggest associations with vitamin D (Hewison 2011, Prietl et al 2013). Treatment with calcitriol in animal models has shown to have preventive effects, or amelioration of disease (Bock et al 2012; Hewison 2011). Further, Bock et al (2012) present animal data from vitamin D-deficient or VDR knockout mice, showing increased inflammation and increased susceptibility to autoimmune disorders such as

T1DM and Crohn's disease. Interestingly, they also demonstrate disturbed T-cell function, such as homing, and a lack of host protection from bacterial invasion and infection. [Hall and Juckett \(2013\)](#) elucidate the mechanism of action. Inflammatory cytokines, such as IL-2 and IFN- $\gamma$ , stimulate a cellular immune response termed Th1, whereas IL-4, IL-6 and IL-10 drive a humoral immune response, termed Th2. Stimulation of VDR tends to favour the inflammatory mediating Th2 response by suppressing IFN- $\gamma$ , which is implicated in innate and adaptive immunity, as well as autoimmune disease, when uncontrolled. [Hewison \(2011\)](#) also discusses regulation of cytokine synthesis and apoptosis of inflammatory cells with therapeutic administration of calcitriol in MS model mice.

### Type 1 diabetes mellitus

Vitamin D deficiency has been linked to both types of diabetes mellitus, but the largest volume of evidence relates to an inverse association between prenatal and infant vitamin D levels and a child's overall risk of developing T1DM ([Bailey et al 2007](#), [Hypönönen et al 2001, 2010](#), [Littorin et al 2006](#), [Priest et al 2013](#), [Zipitis & Akobeng 2008](#)). Incidence rates vary widely according to geographical location related to latitude. It is hypothesised that vitamin influences T1DM pathogenesis by reducing lymphocyte proliferation and cytokine production through immunomodulatory actions ([Melamed & Kumar 2010](#)). International epidemiological data confirm this marked geographical pattern of increasing incidence with increasing latitudes, together with significantly greater rates of diagnosis in autumn and winter ([Svensson et al 2009](#), [Zipitis & Akobeng 2008](#)). In addition, assessment of T1DM patients reveals significantly lower 25(OH)D than age-matched controls. Given that the beta-cell destruction of T1DM frequently begins in infancy, with diagnosis typically occurring when 80% of cells have already been destroyed, much focus has been placed on the environmental and nutritional influences in early life as potential aetiological factors. [Greer et al \(2007\)](#) found in Australia that adolescents with newly diagnosed T1DM had a three times higher risk of having levels below 20 ng/mL than controls.

One birth cohort study published in the *Lancet* in 2001 involved the offspring of 12,055 pregnant Finnish women who gave birth in 1966. The families were assessed for vitamin D supplementation in the infant's first year of life and then the child was followed until 31 years of age to account for subsequent diagnoses of T1DM. It was shown that treatment of children with 2000 IU/day vitamin D from 1 year of age decreased the risk of developing the disease by 80% through the next 20 years; furthermore, children from the same cohort who were vitamin D-deficient at 1 year old had a fourfold increased risk of developing T1DM ([Hypönönen et al 2001](#)). Similar findings have been demonstrated in animal models, with pretreatment with 1,25(OH) $_2$ D being effective in mitigating or preventing the onset of T1DM ([Palomer et al 2008](#)).

A case-control study conducted in Norway that involved 545 Norwegian children up to 15 years old with T1DM retrospectively assessed their cod liver oil and vitamin D use from birth to 12 months old. Children who had been given cod liver oil five times a week had a 26% lower incidence of the disease, whereas other forms of vitamin D appeared to bear no relationship ([Stene & Joner 2003](#)). Although this does not adequately assess vitamin D as a sole treatment agent and is not conclusive, it adds to the growing body of evidence implicating vitamin D in a preventive role against diabetes.

A meta-analysis of five studies of vitamin D supplementation in infancy, including the above two, concluded that supplementation during an infant's first year appears to be associated with a significant risk reduction for the development of T1DM later in life (OR 0.71) ([Zipitis & Akobeng 2008](#)). Current evidence points to the superiority of cod liver oil as a delivery form, but a lack of specific detail in many of the studies means that optimal dose, duration of supplementation and timing cannot currently be elucidated.

Research into the role of vitamin D metabolism genes demonstrates a consistent genetic predisposition to lower vitamin D metabolism and the risk of T1DM. [Cooper and colleagues \(2011\)](#) have shown consistent results indicating that circulating levels of calcitriol vary seasonally and are under the same genetic control as the normal population, but three key metabolism genes (CYP27B1, DHCR7 and CYP2R1) are much lower in those with T1DM. This indicates that there is a genetic role leading to vitamin D deficiency in T1DM, which has implications for the efficacy of supplementation and the dosages required in this population.

Seasonal variation suggests that the pathophysiology is multifactorial. [Hewison \(2011\)](#) indicates that low vitamin D status is linked to risk of developing T1DM, and that supplementation provides a protective effect. In knockout model mice, those under dietary restriction of vitamin D showed increased severity of disease. Further, genetic investigation reveals that polymorphic variations in genes for various aspects of vitamin D metabolisms and signalling affect diabetes susceptibility. In particular, the presence of specific VDR gene alleles is protective ([Ramos-Lopez et al 2006](#)), and variations in CYP27B1 (conversion enzyme) impacts on susceptibility ([Bailey et al 2007](#)).

### Type 2 diabetes mellitus (T2DM)

Epidemiological studies suggest that vitamin D deficiency places some populations (e.g. non-Hispanic blacks) at a higher risk of insulin resistance, impaired glucose homeostasis and metabolic syndrome ([Palomer et al 2008](#)). The mechanisms for this effect remain speculative, including suppression of PTH, reducing calcium influx and therefore limiting lipogenesis. Other theories relate to vitamin D's immunomodulatory actions. A range of elevated inflammatory markers has been identified to predate

the onset of T2DM and many of these appear to be downregulated by vitamin D, but direct evidence of this pathogenetic path is currently lacking (Palomer et al 2008, Shapses & Manson 2011). The relationship between diabetes and vitamin D, however, is likely to be a bidirectional one, with low levels of functioning insulin impairing bioactivation of vitamin D, and poor vitamin D status impeding correct insulin release and function.

Consistent evidence of an inverse relationship between serum 25(OH)D and adiposity highlights another domain of potential overlap and potential confounding between hypovitaminosis D and T2DM (Alemzadeh et al 2008, Palomer et al 2008). Consequently, vitamin D deficiency is common in T2DM patients (Sugden et al 2008). One study revealed that three-quarters of obese adolescents had levels <50 nmol/L, with a positive correlation between poor vitamin D status and glucose dysregulation (Alemzadeh et al 2008), while 49% of adult T2DM patients in another study demonstrated vitamin D deficiency (Sugden et al 2008). A meta-analysis concurs with these findings, while also adding calcium to the equation; it calculates an OR of 0.82 for incident T2DM among individuals with low vitamin D status, calcium or dairy intake (Pittas et al 2007).

Vitamin D supplementation in patients with mild T2DM and in non-diabetic patients with vitamin D deficiency can improve insulin secretion in response to oral glucose loads, but it is ineffective in patients with established or severe T2DM (Palomer et al 2008). In one clinical trial, 1332 IU/day oral vitamin D was administered for 1 month to 10 adult women with T2DM. Corresponding changes were observed in first-phase insulin secretion (34.3% increase) and serum 25(OH)D levels. Improvements observed in second-phase insulin secretion and insulin resistance were deemed non-significant (Borissova et al 2003). A more recent pilot study employed a single high dose of D<sub>2</sub> (100,000 IU) to vitamin D-deficient T2DM patients; this resulted in improved endothelial function, as evidenced by a highly significant reduction in systolic blood pressure. The proposed mechanisms for this effect are many and varied but remain hypothetical at this time (Sugden et al 2008). Intravenous administration of vitamin D to patients with gestational diabetes produces a transient reduction in both fasting glucose and insulin, suggesting improved insulin sensitivity rather than secretion (Palomer et al 2008).

It is important to note that single high-dose vitamin D actually increases blood glucose levels in patients with diabetes (Palomer et al 2008). While there is some biological plausibility for the role of vitamin D in the treatment of T2DM, and positive findings from observational studies, the results from clinical studies have been inconsistent, and insufficient to make recommendations (Maxwell & Wood 2011, Shapses & Manson 2011, Valdivielso et al 2009). There is some evidence to support a

beneficial effect in people with very low levels of circulating 25(OH)D, but some evidence also points to a potential increase in risk at the highest levels, representing a U-shaped curve of effect (Shapses & Manson 2011). Pooled analysis shows inconsistent results; however results for insulin sensitivity seem to be more positive (Maxwell & Wood 2011, Shapses & Manson 2011). Well-designed large RCTs, with prespecified outcomes for T2DM, insulin resistance and cardiovascular outcomes, are required to establish whether vitamin D is effective for the treatment of these metabolic disorders.

### Hypoparathyroidism

Vitamin D in combination with calcium has established benefits in the treatment of hypoparathyroidism, by promoting homeostasis of calcium, phosphorus, 25(OH)D and PTH levels (Hewison 2011, Mimouni et al 1986, Nowson et al 2012).

### Secondary hyperparathyroidism

In a controlled study of 100 postmenopausal women with confirmed vitamin D deficiency (<18 nmol), supplementation with combination calcium and low-dose vitamin D showed more significant reductions in PTH levels over the 90-day trial period than supplementation with calcium alone (Deroisy et al 2002).

### Hypophosphataemia

A combination of high-dose vitamin D and phosphorus results in improved phosphorus and calcium balance in these patients (Lyles et al 1982).

### Osteoporosis and fracture prevention

One of the main functions of vitamin D is to maintain serum calcium and phosphorus levels in order to maintain healthy metabolic functions, transcription regulation and bone metabolism (Hosseinezhad & Holick 2013). Both serum 25(OH)D and 1,25(OH)<sub>2</sub>D levels are low in osteoporotic patients (Cranney et al 2008, Hunter et al 2000, Wilson et al 1991); however, conclusions regarding improvement of bone health with vitamin D supplementation alone have been mixed and largely hampered by methodological issues (e.g. accurate vitamin D assessment, accounting for and discriminating between different vitamin D sources, extricating effects of vitamin D from those of calcium) (Cranney et al 2008). A 2008 systematic review that included 17 RCTs of either D<sub>2</sub> or D<sub>3</sub> supplementation (300–2000 IU/day) in postmenopausal women or older men has found consistent evidence of a protective effect of D<sub>3</sub> at doses of ≥700 IU/day in combination with calcium (500–1200 mg/day) (Cranney et al 2008). Notably, however, vitamin D at these doses provided no additional benefits in black populations. A meta-analysis of 29 RCTs conducted in 63,897 individuals ≥50 years over an average of 3.5 years also concluded that calcium alone (≥1200 mg/day) or in combination with vitamin D (≥800 IU/day) reduced the risk of

fracture by 12–24%, and reduced bone loss by 0.54% at the hip and 1.19% at the spine (Tang et al 2007). The greatest improvements were noted specifically in the elderly, institutionalised, underweight and calcium-deficient. In addition, an Australian trial that investigated the administration to 120 women aged 70–80 years of 1200 mg/day of calcium alone or in combination with 1000 IU vitamin D over 5 years yielded beneficial effects on bone mineral density and bone turnover markers for both treatment groups, with evidence of more sustained improvements in those also taking vitamin D (Zhu et al 2008). In a recent pooled analysis of the evidence, Bischoff-Ferrari et al (2012) state that doses of 20–50 mcg/day (800–2000 IU/day) have been demonstrated to prevent osteoporotic fractures in the elderly, and recommendations from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis state that up to 250 mcg (10,000 IU) daily is considered to be safe in this patient population (Rizzoli et al 2013).

Another study comparing the combined effects of calcium (500 mg/day) with either oral vitamin D<sub>2</sub> (700 IU/day) or calcitriol over 3 years demonstrated a protective effect of vitamin D<sub>2</sub> on the spine but not on the hip (Zofkova & Hill 2007).

Serum 25(OH)D levels in postmenopausal women are inversely associated with fracture risk, independent of number of falls, physical functionality, frailty and other associated risks (Cauley et al 2008). These data reveal that individuals with baseline serum levels <47.5 nmol/L have an increased risk of hip fracture rate over the next 7 years of 1.71 compared to those with values >70.7 nmol/L. Other studies of similar design concur with these results, while producing different cut-off values. Studies investigating vitamin D supplementation for fracture prevention in osteoporosis have produced some positive results. In the context of adequate or supplemented calcium, a 60% reduction in the incidence of peripheral fractures was observed by Cosman (700–800 IU/day), with a 40% reduction in hip fracture incidence specifically (Cosman 2005). A systematic review of 15 RCTs involving mostly D<sub>3</sub> supplementation (300–800 IU/day) found a non-significant reduction in fractures; however, methodological limitations, including the relatively low dose, could be a confounding issue (Cranney et al 2008).

One study has investigated the bone mineral density effects of co-supplementing silicon with calcium and vitamin D. In an RCT of 136 predominantly postmenopausal osteopenic women, 1000 mg calcium, 20 mcg vitamin D and 3 mg, 6 mg or 12 mg silicon in the form of orthosilicic acid was administered daily for 12 months to the treatment group. These subjects demonstrated significantly greater type I collagen, indicative of increased bone synthesis, compared to those receiving the placebo (Spector et al 2008). There was also a trend of decreasing resorption with increasing silicon dose.

The mechanisms behind vitamin D's bone actions are not limited to the suppression of PTH and improved calcium balance alone; evidence also exists of direct inhibition of bone resorption and reduced inflammatory markers. The active calcitriol interacts with its VDR in the small intestine to increase the efficiency of intestinal calcium and phosphorus absorption. It also interacts with VDR in osteoblasts to stimulate a receptor activator of the ligand of NF- $\kappa$ B, which works to produce immature preosteoclasts, stimulating them to become mature bone-resorbing osteoclasts, which then remove calcium and phosphorus from the bone to maintain blood calcium and phosphorus levels. In the kidneys, calcitriol stimulates calcium reabsorption from the glomerular filtrate (Hosseini-nezhad & Holick 2013). There is also speculation regarding vitamin D's potentially positive effects on lean body mass, which would then convey an anabolic effect via increased mechanical load (Cauley et al 2008, Zofkova & Hill 2007).

### Reducing falls in the elderly

The most recent recommendations from the Australian Working Group recognise vitamin D deficiency as an independent predictor of falls in older people, and have summarised the evidence for insufficient vitamin D and its association with impaired balance, increased muscle mass loss, lower-extremity muscle weakness, and impaired strength and physical function (Nowson et al 2012). Poor vitamin D status (e.g. low serum 25(OH)D, compromised VDR numbers or binding affinity, colder seasons) is independently associated with an increased risk of falling in the elderly, particularly in those aged 65–75 years (Prince et al 2008, Richey et al 2008, Snijder et al 2006) and in some studies with poorer physical performance generally (Brunner et al 2008). A 2004 review of double-blind RCTs of vitamin D in elderly populations concluded that vitamin D supplementation reduced the risk of falling by more than 20%. The results were significant only in women and appeared to be independent of calcium administration, type of vitamin D and duration of therapy (Bischoff-Ferrari et al 2006). More recent research has suggested an even greater effect, but the degree of risk reduction varies between studies. According to a double-blind randomised trial involving 64 institutionalised elderly women (age range 65–97 years; mean 25(OH)D levels 16.4 ng/mL), treatment with 1200 mg/day calcium plus 800 IU/day D<sub>3</sub> over 3 months reduced the rate of falls by 60% compared with calcium supplementation alone (Bischoff-Ferrari et al 2006). An Australian study of community-based women aged 70–90 years with baseline serum 25(OH)D < 24 ng/mL found that D<sub>2</sub> (1000 IU/day) in combination with 1000 mg calcium citrate over 1 year reduced falls by 19% (Prince et al 2008). An interesting finding was the marked seasonal variation in efficacy, with vitamin D's protective effect evident in winter/spring (months exhibiting increased risk of falls

generally) but not in summer/autumn. This has been attributed to the decline in serum 25(OH)D during these months and has also been postulated as an explanation for the lack of effect seen in some larger long-term studies. The researchers also concluded that a serum level of <24 ng/mL is predictive of individuals who may benefit from vitamin D supplementation in this context.

In 2007 a pilot study of an osteopenic/osteoporotic elderly female population ( $\geq 65$  years) investigated the possible additional clinical benefits of 3 months' exercise training and increased protein intake on top of year-long calcium and vitamin D supplementation (500–1000 mg/day and 400–800 IU/day, respectively) (Swanenburg et al 2007). Although the number of falls reduced dramatically in both groups, the group undertaking exercise training demonstrated greater and more sustained risk reduction (e.g. 100% at 6 months versus 40%). This multi-pronged approach appears promising and warrants further investigation. A systematic review funded by the US Office of Dietary Supplements of the National Institute of Health and the Agency for Healthcare Research and Quality included 14 RCTs of vitamin D for fall prevention and concluded that there was consistent evidence of benefit (OR 0.89) (Cranney et al 2008).

As a result of the accumulating evidence, routine vitamin D administration has been recommended for those institutionalised or housebound elderly who are already at risk of deficiency (Nowson et al 2012, Sambrook & Eisman 2002). The findings of an Australian study, however, suggest there are a significant number of community-dwelling elderly with sufficiently low vitamin D status who might also benefit from routine vitamin D (Prince et al 2008). One additional consideration is the best delivery form, with a comparative meta-analysis demonstrating superior results from vitamin D analogues, e.g. alfacalcidol and calcitriol, when compared to oral vitamin D (Richy et al 2008). These analogues, which override renal regulation of vitamin D bioactivation, may be particularly indicated in individuals who take high-dose glucocorticoids, exhibit impaired renal function or chronic inflammation, or who have T1DM.

In a recent systematic review on vitamin D supplementation on muscle strength, gait and balance in older adults, Muir and Montero-Odasso (2011) found that there was a significant improvement in postural sway, time to complete the timed up-and-go test for lower-extremity strength and balance with 800–1000 IU supplementation per day. They conclude that there were consistently demonstrated beneficial effects of vitamin D supplementation on strength and balance; however, gait was not affected.

In 2013, the American Geriatrics Society Workgroup on Vitamin D supplementation for Older Adults (American Workgroup) has recommended supplementation at 4000 IU/day to reduce the risk of falls and fractures for those with no underlying risk of hypercalcaemia. This larger dose

recommendation is based on: the population's potential decreased adherence compared with trial participants, and increased requirement due to age and sun exposure likelihood.

### Anticonvulsant-induced osteomalacia

Preliminary evidence has shown vitamin D to be an effective treatment for this condition; however, much emphasis has been placed on establishing the most superior form of D, D<sub>2</sub> or D<sub>3</sub>, as they exhibit important metabolic differences in these patients (Hartwell et al 1989, Tjellesen et al 1985, 1986). More recent evidence suggests that the resultant bone disease in patients treated with anticonvulsant drugs mostly demonstrates bone remodelling rather than decreased mineralisation, some with significant turnover of bone, with manifest features of osteomalacia. Prophylactic vitamin D<sub>3</sub> supplementation of up to 2000 IU/day is recommended, and up to 2000–4000 IU/day in patients exhibiting osteopenic/osteoporotic disorders (Drezner 2004).

### Hepatic and renal osteodystrophy

Both chronic liver disease and those conditions exhibiting end-stage renal disease result in compromised hydroxylation of vitamin D to produce its active metabolite. It has been reported that 50% of patients with chronic liver disease, especially those with primary or secondary biliary cirrhosis, present with associated osteodystrophy. This frequently leads to a vitamin D deficiency and manifests most commonly as metabolic bone disorders, hypocalcaemia and secondary hyperparathyroidism (Wills & Savory 1984). The resultant hypovitaminosis D can result in bone loss, cardiovascular disease, immune suppression and increased mortality in patients with end-stage kidney failure (Andress 2006). Consequently, correction of this deficiency has been one of many first-line treatments in these situations.

Although vitamin D<sub>2</sub> supplementation in combination with calcium, phosphorus and magnesium (where indicated) has shown some success in those patients with hepatic osteodystrophy (Compston et al 1979, Long & Wills 1978), recent trials and emerging research implicate other factors in the aetiology of these sequelae (Klein et al 2002, Suzuki et al 1998). As such, therapy with D<sub>2</sub> may need to be reviewed.

The treatment of renal osteodystrophy is reliant upon only the active forms or analogues of vitamin D, and natural supplementation is ineffective because of the inability to convert these precursors into 1,25-alpha-(OH)<sub>2</sub>D (Kim & Sprague 2002). In a recent Cochrane review of vitamin D for chronic kidney disease, it was found that, although the evidence was insufficiently powered to make clear recommendations, it did seem that vitamin D suppresses PTH in people with chronic kidney disease, but treatment was associated with clinically relevant serum elevations in both phosphorus and calcium. Observational data suggest improved survival rates in this population, but large RCTs are required to confirm these results.

### Localised and systemic scleroderma

Although patients suffering from scleroderma do not show compromised D synthesis (Matsuoka et al 1991), vitamin D<sub>3</sub> has been investigated as a therapeutic agent to moderate the excessive proliferation and collagen production typically seen in this condition. An in vitro study assessing the action of vitamin D<sub>3</sub> on the behaviour of affected fibroblasts has confirmed a non-selective antiproliferative action (Boelsma et al 1995).

To date, clinical studies have produced mixed results. Clinical trials focusing on generalised scleroderma have involved small numbers and produced promising results, such as increased joint mobility, reduced induration and increased extensibility of the skin, with benefits lasting at least 1 year after discontinuation of treatment (Caca-Biljanovska et al 1999, Hulshof et al 1994). However, the largest RCT involving 27 patients (the majority of whom suffered a localised condition) found that treatment over 9 months with a similar dose of D<sub>3</sub> failed to produce any significant changes in any of the assessment criteria (Hulshof et al 2000). These results suggest that different therapies may be required for the two conditions; however, larger controlled studies are needed to confirm those positive results from the preliminary open trials. Pelago et al (2010) have criticised previous trials for dosage regimens being too low (40 IU/day) to demonstrate the potential benefits. Larger well-controlled randomised studies are required.

### Prevention and treatment of infections and tuberculosis

The potential immune-enhancing effect of vitamin D was first described indirectly in 1849, when cod liver oil was attributed with being one of the most efficacious agents in the treatment of pulmonary tuberculosis (Maalouf 2008). However, the treatment of tuberculosis with sunlight was prescribed by Hippocrates. It is now understood that 1,25(OH)<sub>2</sub>D is a potent suppressor for *Mycobacterium tuberculosis* proliferation in human monocytes (Hewison 2011). It was demonstrated under gene array analysis that macrophage expression of the converting enzyme CYP27B1 and the VDR was induced by the activation of TLR 2/1, which is a pathogen recognition receptor for Gram-positive bacteria and *M. tuberculosis* (Liu et al 2006). This antibacterial activity is, however, not restricted to macrophages and monocytes. Vitamin D-mediated induction by intracrine synthesis also induces the expression of the gene for cathelicidin (LL-37), which is an antimicrobial peptide that produces 1,25(OH)D only in primates (Hewison 2011, Reinholz et al 2012). The production or transcription of LL-37 is stimulated by the 1,25(OH)<sub>2</sub>D<sub>2</sub>-VDR complex, and its bacterial killing response can be enhanced by simply increasing the precursor 25(OH)D. Studies conducted by Liu et al (2006) demonstrate this capacity, where the serum from vitamin D-deficient individuals produced lower levels of LL-37 following activation by TLR 2/1

compared with individuals who were vitamin D-sufficient.

Hewison (2011) describes the role of vitamin D, which has also been shown to promote increased levels of autophagy, and the formation of associated autophagosomes. These are known to be important for intracellular isolation of pathogens and their subsequent eradication by antibacterial proteins (Hewison 2011).

Remarkably, in spite of mounting evidence regarding the vast and potent immunomodulatory effects of vitamin D, the evidence supporting its use in the prevention and treatment of infections has not progressed substantially and the small number of in vivo studies conducted in this area possess marked methodological weaknesses. The most robust evidence to date comes from a small study of 67 patients with pulmonary tuberculosis, who received 10,000 IU/day in addition to standard antimycobacterial treatment and showed higher rates of sputum conversion and radiological improvement as a result. Several post hoc analyses of vitamin D supplementation studies using other primary outcomes (e.g. fracture) have revealed trends of decreasing infections, colds and flu for those individuals taking a minimum of 800 IU/day (Grant 2008b, Maalouf 2008). In a recent Australian study (D-Health), in a secondary analysis it was found that there was a 28% non-significant reduction in antibiotic use in the vitamin D group compared to the placebo group during the study period. When the data were stratified for age, there was a significant reduction in antibiotic use in the high-dose >70-year-old group, with an RR of 0.53. Dosages were high, at 60,000 IU/month (Tran et al 2014).

This is an area of potential growth and promise. Large clinical trials with primary antibacterial outcomes are required.

### Depression

Patients with primary hyperparathyroidism, which secondarily impedes the bioactivation of vitamin D and raises serum calcium, frequently present with depressive disorders that normalise following successful PTH lowering (Hoogendijk et al 2008). Rodents deficient in VDR demonstrate mood abnormalities that include increased anxiety (Hoogendijk et al 2008, Jorde et al 2006, Obradovic et al 2006), and the presence of both VDR and 1-alpha-hydroxylase activity in specific brain regions (e.g. hypothalamus) implies a potential role for vitamin D as a neuroactive hormone (Berk et al 2007, Obradovic et al 2006, Vieth et al 2004). There is also increasing evidence of vitamin D's modulation of several neurotransmitters, such as acetylcholine, catecholamines and serotonin (Jorde et al 2006, Obradovic et al 2006). Yet in spite of such strong theoretical underpinning, concerted research into the links between vitamin D and mood has only recently begun in earnest.

Recent epidemiological data reveal a strong independent inverse relationship between serum 25(OH)D and both depression scores and cognitive

impairment in elderly subjects (Hoogendijk et al 2008, Johnson et al 2008, Wilkins et al 2006), premenstrual syndrome, seasonal affective disorder, non-specific mood disorder and major depressive disorder in women (Murphy & Wagner 2008), depression and anxiety in fibromyalgia patients (Armstrong et al 2007), depression rating scores on the Beck Depression Inventory in overweight and obese patients (Jorde et al 2008) and significantly lower vitamin D levels in patients with uni- and bipolar depression compared with matched controls (Berk et al 2007).

Initial interventional studies of vitamin D supplementation produced mixed findings in depression, seasonal affective disorder and general wellbeing; however, notably low doses were used (400 IU/day over short durations and in small samples), which may partly explain this lack of effect in some studies (Berk et al 2007, Hoogendijk et al 2008, Lansdowne & Provost 1998). More recent study designs have attempted to account for such shortcomings and have produced more consistent results (Jorde et al 2008, Vieth et al 2004). In two studies, thyroid outpatients with low vitamin D status during summer received either 600 or 4000 IU/day over the following 6 months (a placebo treatment was deemed unethical, given confirmation of hypovitaminosis D of all subjects at baseline). When vitamin D status and wellbeing questionnaires were repeated the following winter, improvements in mood and self-reported health were noted, particularly in those patients taking 4000 IU/day and those with the lowest serum concentrations at baseline. Another study of 441 overweight and obese individuals, only some of whom had vitamin D deficiency, found that supplementation with either 40,000 IU/week or 20,000 IU per week in combination with 500 mg/day calcium over 1 year produced significant reductions in depression rating scores (Jorde et al 2008). The greatest effects were evident in those with higher depression scores at baseline and were independent of both body mass index and initial serum 25(OH)D values. Another study of elderly women supplemented with 800 IU/day and 1000 mg/day calcium, however, failed to produce improvements on mental health scores (Dumville et al 2006).

Vieth et al (2004) comment that previous studies have suggested gender-specific mood effects of vitamin D, with women being more susceptible to seasonally-dependent mood lability and more responsive to supplementation. They also identify many potential modulating influences upon vitamin D's mood effects, which future researchers must take into consideration in addition to baseline 25(OH)D: season, dose, duration, age and sex. More well-designed research is needed in this area to clarify the real therapeutic potential of vitamin D in depressed mood.

In a systematic review of the evidence to date, while high-quality trial data are still largely unavailable, the authors conclude that this is an association evident between vitamin D deficiency

and depression. They examined a total of 31,424 participants in case-control, cross-sectional and cohort studies, and found lower vitamin D levels in depressed individuals compared with controls (standard mean difference = 0.60), and an increased OR of depression in the group with the lowest vitamin D levels versus the highest group in the cross-sectional studies of 1.31, or an increase of 31%, and an increase in the hazard ratio of lowest versus highest in the cohort studies (hazard ratio = 2.21). However, for establishing more robust causal relationship data, RCTs are needed (Anglin 2013).

#### **Clinical note — A link between vitamin D and schizophrenia?**

The epidemiological correlation between babies born in winter and spring and an increased prevalence of schizophrenia has been a long-established phenomenon and presented many riddles for researchers (Eyles et al 2013, Kendell & Adams 2002). The association has also been observed in cities where air pollution reduces UV irradiation, and, more recently, a 7–10-fold increased risk has been identified in second-generation dark-skinned migrants. These observations have led to the emergence of a neurodevelopmental theory of schizophrenia, which suggests that low prenatal vitamin D interferes with brain development by interacting with D-responsive/susceptible genes to create the currently recognised polygenic effects of schizophrenia (Mackay-Sim et al 2004).

A significant progression of this theory was made at the Queensland Centre for Schizophrenic Research, led by Professor John McGrath. The centre's work has taken the level of evidence beyond the early epidemiological findings, with research being conducted to assess the impact of vitamin D deficiency on animal brains and in vitro cultures. Research has also been conducted to measure third-trimester serum 25(OH)D levels in schizophrenic and schizoaffective mothers, while investigating the impact of vitamin D supplementation prior to 1 year of age in the infants and the subsequent risk reduction for the disease in later life (McGrath et al 2003, 2004a, 2004b). Subsequent investigations from the same group (Eyles et al 2013) have furthered the basic science evidence for the developmental basis of vitamin D deficiency and its association with schizophrenia. The evidence to date shows support for this hypothesis, with a consistent positive relationship appearing for males, and evidence pointing towards a stronger relationship in dark-skinned populations compared to fairer-skinned populations.

## **OTHER USES**

### **Multiple sclerosis**

There is strong evidence that vitamin D status is associated with risk of MS (Grant 2006, Kampman

& Brustad 2008, Kragt et al 2009, Hewison 2011, Munger et al 2006, Niino et al 2008, Smolders et al 2008). A variety of observational studies illustrate a relationship between MS incidence and geographical location, with very low prevalence in the equatorial regions and increasing risk with increasing latitude in both hemispheres. Other demonstrated associations with MS incidence include the level of outdoor activity in adolescents and risk of onset later in life, while there is evidence of lower 25(OH)D levels in newly diagnosed patients when compared to controls and in relapsing patients compared to those in remission (Kampman & Brustad 2008, Niino et al 2008, Smolders et al 2008). Evidence is more mixed regarding VDR polymorphisms, month of birth and season of diagnosis.

In spite of these findings, strong evidence linking vitamin D to modulation of MS is currently lacking. A limited number of interventional studies using vitamin D also leave us without a firm conclusion. Some studies, including the Nurses' Health Study, point towards a protective effect in the years following regular supplement use, but the effects of vitamin D are difficult to extricate from other supplemented nutrients. In an open and uncontrolled study of 39 MS patients treated with 1000 IU/day for 6 months, changes in inflammatory markers were observed but clinical benefits were not investigated. The most promising study to date was conducted in 12 patients administered 1000 IU/day over 28 weeks, which reduced the number of gadolinium-enhancing lesions on the magnetic resonance imaging of one subject (Smolders et al 2008).

In the latest Cochrane review of vitamin D for the management of MS (Jagannath et al 2010), only one study was of sufficient quality to be included in the review. The results of this review suggest that there is some evidence of a beneficial effect of vitamin D supplementation, and a relative absence of any adverse events or risk of high serum calcium levels. A single trial assessed outcomes for 49 participants over a 52-week period. The study group ( $n = 25$ ) were administered with escalating doses of vitamin D, and demonstrated a relative benefit in outcomes such as annualised relapse rate, suppression of T-cell proliferation and higher satisfaction scores. Hewison (2011) reviews evidence for the experimental autoimmune encephalomyelitis mouse model of MS, that shows an increased severity of disease under dietary restrictions of vitamin D, and a protective effect against symptoms when used therapeutically.

### **Crohn's disease and other inflammatory bowel disease**

Crohn's disease is an autoimmune disease marked by an aberrant colonic immune response to enteric bacteria (Hewison 2012). Epidemiological evidence suggests that incidence of Crohn's disease and other inflammatory bowel diseases, in adult and paediatric patients, is related to levels of circulating vitamin D (Vagianos et al 2007). Research by Liu et al (2013)

has identified that VDR expression on the intestinal epithelium is substantially reduced in patients with Crohn's disease or ulcerative colitis, and that in the knockout mouse model, gut epithelial VDR signalling has potent anticolic activity that can be differentiated and is independent of non-epithelial immune VDR actions. Elevation of VDR expression by an approximate factor of 2 was protective against many experimental colitis models.

In another VDR gene knockout mouse study, aberrant gut migration of a specific cytotoxic T cell appears to be linked to an increased risk of inflammatory bowel disease (Yu et al 2008). In a study of vitamin D status in a paediatric population with inflammatory bowel disease, the prevalence of deficiency was reported to be 34.6%. Deficiency was more pronounced in children with darker skin, in winter months and in those not taking vitamin D supplementation (Pappa 2006). Hewison (2012) elucidates the aberrant or inadequate innate immune response of enteric microbiota as initiating an inflammatory adaptive immune response and its consequent damage. The effectiveness of vitamin D therapeutics may well function to both stimulate the innate immune response and suppress the inflammatory adaptive immune response.

### **Lupus (SLE)**

There is growing evidence suggesting an aetiological role for vitamin D in SLE, as in MS and other autoimmune diseases. In addition to epidemiological studies showing low 25(OH)D in SLE patients compared to healthy controls, and inverse correlations between vitamin D status and disease severity, individuals with this condition are identified as being at high risk of vitamin D deficiency because of a range of factors (Cutolo & Otsa 2008, Kamen & Aranow 2008). These factors include increased photosensitivity, renal involvement impeding bioactivation and evidence of anti-D antibodies in select patient subsets. Data from animal and in vitro studies also point to vitamin D as an effective treatment, in particular reversing the characteristic immune abnormalities, while experimentally-induced deficiencies exacerbate clinical features. Additionally, given that SLE is a B-cell-related disorder, studies demonstrating the effect of 1,25(OH)D on VDR-expressing B cells indicate a suppression of proliferation and immunoglobulin production, and with the identification that B cells have a capacity to express CYP27B1 to activate conversion of vitamin D, this highlights the potential role of vitamin D in disorders such as SLE (Hewison 2012). Interventional studies in SLE patients are now required to confirm this indication.

### **Psoriasis**

As a regulator of cellular growth and differentiation in various tissues, vitamin D has been investigated in psoriasis. The active form of vitamin D and its analogues have been found to suppress growth and stimulate the terminal differentiation of

keratinocytes. [Schauber et al \(2011\)](#) have found that vitamin D may ameliorate the symptoms of psoriasis when treated with the antimicrobial peptide cathelicidin, whose production in the skin is stimulated by vitamin D.

### Vaginal atrophy

Animal studies have revealed the presence of VDR in the cells lining the vagina ([Yildirim et al 2004a](#)). Given the established role of vitamin D in regulating growth and differentiation of tissues, especially those lining stratified squamous epithelium, a possible role for vitamin D in the prevention and treatment of vaginal atrophy associated with menopause is being considered ([Yildirim et al 2004b](#)). A number of studies involving co-administration with calcium have produced some positive results; however, a trial of calcium and D<sub>3</sub> (500 mg/day and 400 IU/day, respectively) used as a replacement for transdermal oestrogen replacement therapy in menopausal women over 1 year revealed an objective worsening of vaginal atrophy ([Checa et al 2005](#)). Dose, however, may be an issue.

### DOSAGE RANGE

#### Acceptable daily intake (ADI)

The NHMRC vitamin guidelines released in 2006 make the following recommendations for ADI:

- Children and adults < 50 years: 200 IU/day.
- Adults 51–70 years: 400 IU/day.
- Adults over 70 years: 600 IU/day.

The ADI is based on the amount of vitamin D required to maintain serum 25(OH)D at a level of at least 27.5 nmol/L with minimal sun exposure. The level has been raised in the 51–70-year age group to account for the reduced capacity of the skin to produce vitamin D with ageing. The higher level recommended in the over-70-years group was made because this group tends to have less exposure to sunlight.

In a recent systematic review, recommendations were made on a 'per kg of body weight' dosage. The review found that up to 34.5% of variation in circulating 25(OH)D could be explained by body weight. The authors also found that type of supplement (D<sub>3</sub> or D<sub>2</sub>), age, concomitant calcium intake and baseline 25(OH)D could explain further variations in circulating levels ([Zittermann et al 2014](#)).

#### According to clinical studies

(D<sub>3</sub> supplemental form unless otherwise indicated.)

- Uncomplicated rickets: 1600 IU/day for the first month, gradually reducing the dose to 400 IU.
- Osteomalacia: 36,000 IU/day with calcium supplementation.
- Rickets and osteomalacia due to defective metabolism: 50,000–300,000 IU/day.
- Pregnancy supplementation: two large doses of 600,000 IU in the seventh and eighth months ([Marya et al 1981](#)).
- Reduction in fractures associated with osteoporosis: prevention of fractures has resulted from as

little as 200 IU/day in combination with calcium, but the most effective dose is ≥800 IU/day in combination with ≥1200 mg/day calcium.

- Reduction in falls: 1000 IU/day in combination with 1000 mg/day calcium.
- Hyperparathyroidism: 2.5–6.25 mg/day.
- Hepatic osteodystrophy: 4000 IU/day.
- Anticonvulsant osteomalacia: 4000 IU D<sub>2</sub>/day for 105 days, followed by 1000 IU/day.
- Systemic scleroderma: 0.75–1.25 mcg D<sub>3</sub>/day for 6 months.

### TOXICITY

Toxic ingestion of prescribed forms of vitamin D or excessive dietary consumption of either D<sub>2</sub> or D<sub>3</sub> has been reported in the vicinity of 50,000–100,000 IU/day or 10,000 IU/day taken routinely for several months. Obtaining such enormous amounts from unfortified foods is improbable. Traditionally the toxicity picture of vitamin D has been attributed to a secondary hypercalcaemia, which manifests as anorexia, nausea, vomiting, polyuria, muscle pain, unusual tiredness, dry mouth, persistent headache and secondary polydipsia. Over extended periods of time, this state of hypervitaminosis can result in metastatic calcification of soft tissues, including kidney, blood vessels, heart and lungs. Symptoms and signs at this later stage include cloudy urine, pruritus, drowsiness, weight loss, sensitivity to light, hypertension, arrhythmia, fever and abdominal pain. Toxic levels cannot be obtained from excessive sun exposure ([FAO/WHO 2002](#), [Groppe et al 2009](#)). More recent research into vitamin D pharmacokinetics, however, points towards 25(OH)D's ability at high doses to displace 1,25(OH)<sub>2</sub>D from VDR, therefore increasing free concentrations of the active form and subsequent gene transcription ([Jones 2008](#)).

### ADVERSE REACTIONS

High doses of supplements may induce the following:

- arterial calcification
- arrhythmia
- gastrointestinal distress, including nausea, vomiting and constipation
- hypercalcaemia
- nephrotoxicity, manifesting as polyuria, polydipsia and nocturia.

### SIGNIFICANT INTERACTIONS

Only those interactions relevant to the oral supplemental forms of vitamin D will be reviewed.

A number of pharmacokinetic and pharmacodynamic interactions are possible with vitamin D and a range of medicines and minerals.

#### Antituberculosis drugs

Drugs such as rifampicin and isoniazid have been reported to induce catabolism of vitamin D and in some cases manifest as reduced levels of metabolites. This may represent a concern in those patients already at risk of poor vitamin D status ([Harkness & Bratman 2003](#)).

### Calcium channel blockers

Vitamin D supplementation may reduce the effectiveness of these drugs. Use with caution unless under medical supervision (Harkness & Bratman 2003).

### Glucocorticoids

In high doses, these drugs directly inhibit vitamin D-mediated calcium uptake in the gastrointestinal tract and through unknown mechanisms may deplete levels of active vitamin D (Wilson et al 1991). During long-term therapy with either oral or inhaled corticosteroids, calcium and vitamin D supplementation should be considered.

### Ketoconazole

This drug reduces the conversion of vitamin D to its active forms. Increased vitamin D intake may be required with long-term drug use.

### Lipid-lowering drugs

Drugs such as cholestyramine and colestipol may compromise the absorption of all fat-soluble vitamins. To avoid the interaction, administer the supplement at least 1 hour prior to or 4–6 hours after ingestion of the drug (Harkness & Bratman 2003). Conversely, long-term use of statins is associated with increased 25(OH)D levels via an unknown mechanism (Aloia et al 2007).

### Magnesium

Either an excess or inadequate level of magnesium can impact on vitamin D status. The final hydroxylation step to 1,25(OH)<sub>2</sub>D<sub>3</sub> is dependent upon magnesium and a deficiency would compromise this. However, high levels of magnesium, mimicking calcium, can suppress PTH secretion, also suppressing the activation phase (Groff & Gropper 2005). Therefore magnesium levels within the normal range will enhance activation of vitamin D to its active form.

### Mineral oil

Mineral oil impairs absorption of all fat-soluble nutrients and may therefore deplete oral intake of vitamin D sources. Separate doses by at least 2 hours.

### Oestrogens

Vitamin D works synergistically with oestrogens to prevent bone loss. Interaction is beneficial.

### Orlistat

Although orlistat has been shown to reduce the absorption of some fat-soluble nutrients, its effect on vitamin D specifically remains unclear. Concurrent supplementation of a multivitamin with D is advised. Separate doses by a minimum of 4 hours either side of ingestion of orlistat (Harkness & Bratman 2003).

### Phenytoin and valproate

The anticonvulsants induce catabolism of vitamin D through liver induction and prolonged use is

associated with increased risk of developing rickets and osteomalacia.

### Practice points/Patient counselling

- Vitamin D has a critical role in bone growth and development, but also has diverse roles throughout the body, including inhibiting abnormal proliferation of cells.
- Most vitamin D is endogenously produced through sun exposure and an activation process that involves both the liver and the kidneys; food sources represent a secondary and often unreliable source. Those groups in the community who have restricted sun exposure are at the greatest risk of a deficiency, including the elderly, newborns, institutionalised, adolescents and young children with marginal calcium intake during rapid growth periods, and those with dark skins.
- In the prevention of falls and prevention or treatment of osteoporosis, vitamin D supplements are most commonly given in combination with other nutrients, such as calcium.
- Other uses for vitamin D include: supplementation during pregnancy to increase fetal levels; correction of deficiencies that may result from medications or malabsorptive diseases such as coeliac disease, Crohn's disease and cystic fibrosis; as a protective agent against breast, prostate and colorectal cancer; and for a variety of metabolic bone disorders. Evidence suggests that higher circulating vitamin D levels may also be associated with better prognosis in patients with breast and colorectal cancer and vitamin D supplementation, reducing mortality in the elderly.

### CONTRAINDICATIONS AND PRECAUTIONS

- Hypersensitivity to vitamin D.
- Hypercalcaemia.
- Not to be taken in sarcoidosis or hyperparathyroidism without medical supervision.
- Possible interference with the action of calcium channel blockers.
- High doses require medical supervision in patients with arteriosclerosis and heart disease.
- High doses capable of inducing hypercalcaemia may precipitate arrhythmias in patients taking digitalis.

### PREGNANCY USE

Vitamin D supplements as either D<sub>2</sub> or D<sub>3</sub> are exempt from pregnancy classification by the Therapeutic Goods Administration, which reflects their safety in pregnancy and lactation (Australian Drug Evaluation Committee 1999).

## **!** PATIENTS' FAQs

### *What will this vitamin do for me?*

Vitamin D is essential for health and wellbeing. It plays a critical role in regulating calcium and phosphorus levels in the body, and is important for healthy bones and preventing abnormal cell changes, which may increase the risk of some cancers. Optimal levels of vitamin D appear to be associated with reduced mortality and supplementation for reducing mortality in the elderly.

### *When will it start to work?*

This will depend on the condition being treated. In uncomplicated rickets, serum levels should begin to rise in 1–2 days, and after 3 weeks signs of calcium and phosphorus mineralisation appear on X-ray. For disease prevention, long-term adequate vitamin D status is recommended.

### *Are there any safety issues?*

Vitamin D is considered a safe supplement when used in the recommended doses; however, it may interact with some medicines.

## Vitamin E

**HISTORICAL NOTE** Vitamin E was first discovered in 1922 at the University of California in Berkeley, when it was observed that rats required the nutrient in order to maintain their fertility (Evans 1925). In this way, vitamin E became known as the antisterility vitamin, which is reflected in its name, as *tokos* and *pherein* are the Greek words for 'offspring' and 'to bear or bring forth' (Saldeen & Saldeen 2005). Although considered an essential nutrient, it was not until the mid-1960s that deficiency states in humans were first identified (McDowell 2000). More specifically, deficiency was detected in children with fat malabsorption syndromes, and defects in genetic hepatic alpha-tocopherol transfer protein (Shils 1999, Traber et al 2006, Wahlqvist 2002). Most fat-soluble vitamins (A, D and K) have defined roles in human metabolism. However, vitamin E does not present an actual role; rather it is utilised in deficiency states, and is seen in malabsorptive and in genetic disorders. It is an antioxidant functioning via peroxy radical-scavenging actions protecting membranous lipoproteins and polyunsaturated fats. Vitamin E depends on a complex network of other antioxidants and antioxidant enzymes to maintain efficacy and therefore rarely acts alone, as demonstrated by many journal papers (Blaner 2013, McDowell 2000, Saldeen & Saldeen 2005). Most of the research regarding vitamin E has been on alpha-tocopherols, with approximately 1% investigating tocotrienols (Wong 2012). This makes vitamin E as a single prescriptive supplement difficult to evaluate in human studies, rendering many studies equivocal (Blaner 2013, Traber et al 2006).

## BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin E is a collective term relating to all antioxidant activities of tocol and tocotrienol derivatives (Blaner 2013). Alpha-tocopherol is absorbed from the intestinal lumen and is dependent upon adequate fat digestion. After micellisation, it enters the lymphatic circulation and then the systemic circulation, where it is transported in chylomicrons. Breakdown of chylomicrons in the blood releases some vitamin E, which is then taken up by circulating lipoproteins such as low-density lipoprotein (LDL) and high-density lipoprotein (HDL). The remaining vitamin E is transported via chylomicron remnants to the liver. Here, the RRR alpha-tocopherol form is preferentially secreted back into the circulation in very-low-density lipoprotein (VLDL). It is suspected that hepatic alpha-tocopherol transfer protein is responsible for discriminating between the different types of tocopherol at this point (with the natural form preferentially taken up). Vitamin E is ultimately delivered to tissues when chylomicrons and VLDL are broken down by lipoprotein lipase. Vitamin E transported by LDL is also taken up by tissues via the LDL receptor. The bulk of vitamin E is stored in adipose tissue, although some storage also occurs in cell membranes, such as the plasma mitochondrial and microsomal membranes of the heart, muscles, testes, uterus, adrenal and pituitary glands, and blood (Borel 2013). Vitamin E molecules cannot be recycled. The inactive oxidated end product conjugates entering bile, and is mainly excreted in the faeces and urine, although the skin has also been implicated in its evacuation via sebaceous secretions (Shils 1999, Traber et al 2006). The efficiency of vitamin E absorption varies from 17% to roughly 79%, has an unknown saturation point, is enhanced by the presence of dietary lipids and is dependent upon adequate fat digestion, involving effective secretion of free fatty acids, monoglycerides and bile acids (Traber et al 2006).

## CHEMICAL COMPONENTS

To date, there are eight identified naturally occurring compounds — ‘tocochromanols’ — collectively known as vitamin E ‘vitamers’, that display the biological activity of RRR-alpha-tocopherol, alpha-, beta-, gamma- and delta-tocopherol; and alpha-, beta-, gamma- and delta-tocotrienol. They all share the same chromanol structure and are divided into two classes: tocopherols (saturated side chain with 16 carbons) and tocotrienols (unsaturated side chain with 16 carbons). The various vitamers cannot be interconverted by the body, and RRR-alpha-tocopherol is the most biologically active form meeting human requirements (Blaner 2013, Colombo 2010, Traber et al 2006). The human diet generally provides a mixture of compounds with vitamin E activity (Bender 2003). Natural vitamin E consists of four forms — alpha-, beta-, gamma- and delta-tocotrienol — and is labelled as ‘d’ forms.

The synthetic forms are labelled ‘dl’ or ‘all-*rac*’ for clarification (Colombo 2010).

## Relative strengths of the various forms of vitamin E

Natural vitamin E consists of four forms — alpha-, beta-, gamma- and delta-tocotrienol — and is labelled as ‘d’; the synthetic forms are labeled ‘dl’ or ‘all-*rac*’ for clarification. The relative strength of the different forms of vitamin E can be expressed as either alpha-tocopherol equivalents (alpha-TE) or international units (IU). One alpha-TE (IU) represents the activity of 1 mg RRR-alpha-tocopherol (D-alpha-tocopherol representing the highest biopotency), and the alpha-TE of natural forms of vitamin E can be calculated using mathematical calculations as follows. The number of milligrams of beta-tocopherol should be multiplied by 0.5, gamma-tocopherol by 0.1 and alpha-tocotrienol by 0.3, whereas any of the synthetic all-*rac*-alpha-tocopherols (DL-alpha-tocopherol) should be multiplied by 0.74 (FAO/WHO 2002).

More commonly, activity is described in terms of IU, where 1 mg of synthetic all-*rac*-alpha-tocopherol (DL-alpha-tocopherol) acetate is equivalent to 1 IU vitamin E. Relative to this, 1 mg of DL-alpha-tocopherol is equal to 1.1 IU, 1 mg of D-alpha-tocopherol acid succinate is equal to 1.21 IU and 1 mg of D-alpha-tocopherol acetate is equal to 1.36 IU (Table 1). The natural form of D-alpha-tocopherol has the highest biopotency, which is equal to at least 1.49 IU (Meydani & Hayes 2003).

## FOOD SOURCES

Vitamin E is found in various forms in both animal and plant foods. The richest food sources of vitamin E are cold-pressed vegetable oils, with safflower oil being the highest source. Good alternative sources are wheatgerm oil, sunflower oil, and nuts and seeds, particularly almonds and sunflower seeds. Non-lipid sources include spinach, kale, sweet potatoes, yams, egg yolk, liver, soya beans, asparagus and dairy products such as butter and milk. Higher tocopherol sources are found in olive oil, soya bean, corn and sunflower oils. Higher tocotrienol lipid sources include palm oil, coconut oil and cocoa butter, with non-lipid forms such as rice bran, legumes, and the bran and germ portions of cereal grains such as rice, barley and oats (Colombo 2010, NUTTAB 2010).

TABLE 1 EQUIVALENCE TABLE

1 mg	DL-alpha tocopherol — synthetic	1 IU
1 mg	DL-alpha-tocopherol	1.1 IU
1 mg	D-alpha-tocopherol acid succinate	1.21 IU
1 mg	D-alpha-tocopherol acetate	1.36 IU
1 mg	D-alpha-tocopherol	1.49 IU

Similar to all fat-soluble vitamins, vitamin E is susceptible to oxidation and destruction during food preparation and storage, frying, processing, bleaching, milling and freezing. Therefore processed foods may not confer adequate intakes (Whitney et al 2011).

### Fortified foods

Fortified foods contain esterified vitamin E (alpha-tocopherol acetate and succinate) prolonging the shelf-life and protecting its antioxidant property. It is suggested that the body efficiently hydrolyses and absorbs esters; however there is little supportive evidence (Leonard et al 2004).

#### **Clinical note — Free radicals, antioxidant recycling and the antioxidant network**

Oxygen-containing free radicals (such as the hydroxyl radical, superoxide anion radical, hydrogen peroxide, oxygen singlet and nitric oxide radical) are highly reactive species, capable of damaging biologically important molecules such as DNA, proteins, carbohydrates and lipids. Antioxidants can break the destructive cascade of reactions initiated by free radicals by converting them into harmless derivatives.

The term 'oxidative stress' refers to an imbalance of pro-oxidants over antioxidants. The term 'antioxidant capacity' is a measure of the sum of available endogenous and exogenous defence mechanisms that work synergistically to restore and maintain the oxidative balance. During the process of maintaining oxidative balance, antioxidants such as vitamin E become oxidised themselves. Other antioxidants, such as ubiquinone, ascorbate and glutathione, are then involved in recycling vitamin E back to its unoxidised state, allowing it to continue neutralising free radical molecules (Sen & Packer 2000). When these other antioxidants become oxidised in turn, they are also regenerated to their antioxidant forms by yet others, such as alpha-lipoic acid and cysteine. In this way, the recycling of various antioxidants occurs in an orchestrated manner. The interactions between antioxidant substances have been described as the 'antioxidant network', which comprises four parts that work together to provide a continuous defence against free radical damage (De Vita et al 2005). These are:

1. enzymes that destroy or detoxify common oxidants (e.g. catalase, glutathione peroxidase, which needs selenium)
2. antioxidant vitamins, notably vitamins E and C, and coenzyme Q10, which are continuously recycled, as discussed earlier
3. dietary antioxidants or phytochemicals (e.g. carotenoids, polyphenols and allyl sulfides).
4. proteins that sequester iron and copper so that free forms do not exist in the body.

The antioxidant network provides a basis for recommending combinations of foods and antioxidant nutrients to provide maximal benefits, rather than single entities in high doses.

### DEFICIENCY SIGNS AND SYMPTOMS

Owing to the widespread availability of vitamin E in the food chain, it is generally accepted that primary vitamin E deficiency is rare; however, due to alpha-tocopherol transfer protein deficiency it does occur in genetic abnormalities, lipoprotein synthesis defects, fat malabsorptive syndromes and possibly with total parenteral nutrition. It may also manifest in low-birth-weight infants given infant formula or cow's milk with low vitamin E levels, diseases such as cystic fibrosis, Crohn's disease, cholestatic liver disease, pancreatitis and biliary obstruction. Due to the malabsorption of fats, people with conditions such as those listed may sometimes require water-soluble forms of vitamin E, e.g. tocopherol polyethylene glycol-1000 succinate (NIH 2013). Individuals limiting their dietary fat intake thereby reduce both vitamin E availability and absorption (Shils 1999, Traber et al 2006).

Ultimately, it is tissue uptake, local oxidative stress levels and polyunsaturated fat content that influence whether symptoms of deficiency develop.

Symptoms of deficiency tend to be vague and difficult to diagnose because of the nutrient's widespread actions, but the following signs and symptoms have been reported in humans (FAO/WHO 2002, Meydani & Hayes 2003, Traber et al 2006):

- haemolytic anaemia
- immunological abnormalities
- neurological disturbances (e.g. peripheral neuropathies and ataxia)
- platelet dysfunction
- leakage of muscle enzymes such as creatine kinase and pyruvate kinase into plasma
- increased levels of lipid peroxidation products in plasma.

### Retinal degeneration

It is possible that there is an increased usage of vitamin E in intense physical training, in smokers and in polluted environments; however further research is needed (Dunford & Doyle 2012, Packer 2002).

### MAIN ACTIONS

Vitamin E is an electron donor (reducing agent or antioxidant), and many of its biochemical and molecular functions can be accounted for by this function. It is involved in many biochemical processes in the body, but its most important biological function is that of an antioxidant and working within the antioxidant network. The actions of the electron donor activity relate to maintenance of membrane integrity in body tissue, providing protection from destructive reactive oxidation species, particularly during inflammation and tissue injury (Mittal et al 2014, Traber et al 2006).

### Antioxidant

Vitamin E is considered to be one of the most important and potent lipid-soluble antioxidants, due to its oxidative inhibitory action, protecting cell membranes against lipid peroxidation. It prevents free radical damage to the polyunsaturated fatty acids (PUFAs) within the phospholipid layer of each cell membrane and oxidation of LDL. It has been estimated that, for every 1000–2000 molecules of phospholipid, one molecule of vitamin E is present for antioxidant defence (Rizvi et al 2014).

This is achieved by reacting with free radical molecules and forming a tocopheroxyl radical, which then leaves the cell membrane. Upon entering the aqueous environment outside the membrane, it reacts with vitamin C (or other hydrogen donors, such as glutathione) to become reduced and, therefore, regenerated (Vatassery 1987). In this way, vitamin E activity is influenced by what has been called the ‘antioxidant network’, which restores vitamin E to its unoxidised state, ready to act as an antioxidant many times over (see Clinical note for more information).

Taking a larger perspective, the collective antioxidant action at each cell membrane protects the body’s tissues and organs from undue oxidative stress. Prolonged and/or excessive exposure to free radicals has been implicated in many conditions, such as cardiovascular disease (CVD), cancer initiation and promotion, degenerative diseases and ageing in general (FAO/WHO 2002, Rizvi et al 2014).

### Regulates immunocompetence

Vitamin E increases humoral antibody production, resistance to bacterial infections, cell-mediated immunity, the T-lymphocyte response, tumour necrosis factor production and natural killer cell activity, thereby playing a role in immunocompetence. It also decreases prostaglandin E<sub>2</sub> production and therefore reduces its immunosuppressive effects and decreases levels of lipid peroxides that can adversely affect immune function. It is now considered an antiangiogenic vitamer due to the mediating effect on growth factor- $\alpha$ . Alpha, gamma and delta tocopherols have various actions in the inhibition of cancer, each having its own biochemical pathway in halting cancer growth (Meydani 1995, Rizvi et al 2014, Takahashi et al 2009).

### OTHER ACTIONS

- Regulates vascular smooth-muscle cell proliferation
- Inhibits smooth-muscle cell proliferation by inhibiting protein kinase C activity
- Inhibits phospholipase A<sub>2</sub> activity, suppressing arachidonic acid metabolism
- Antiplatelet activity has been demonstrated in vitro, but in vivo tests have been inconsistent for D-alpha-tocopherol

- Modulates vascular function by regulating the enzymatic activities of endothelial nitric oxide synthase and NAD(P)H oxidase (Ulker et al 2003)
- Analgesic activity: most likely mediated via inhibitory effects on cyclooxygenase-2 and 5-lipoxygenase
- Promotes wound healing
- Exerts neuroprotective effects
- Gene regulation. Vitamin E modulates genes involved in cholesterol homeostasis, atherosclerosis, inflammatory pathways and cellular trafficking, including of synaptic vesicular transport and the synthesis pathways of neurotransmitters (Brigelius-Flohe 2009, Munteanu et al 2004).

More specifically, vitamin E regulates genes encoding proteins involved in apoptosis (CD95L, Bcl2-L1), cell cycle regulation (p27, cyclin D1, cyclin E), cell adhesion (E-selectin, L-selectin, intercellular adhesion molecule-1, vascular cell adhesion molecule-1, integrins), cell growth (connective tissue growth factor), extracellular matrix formation/degradation (collagen alpha-1(1), glycoprotein IIb, matrix metalloproteinase-1 [MMP-1, MMP-19]), inflammation (interleukin-1 $\beta$  [IL-1 $\beta$ ], IL-2, IL-4, transforming growth factor- $\beta$ ), lipoprotein receptors (CD36, SR-BI, SR-AI/II, LDL receptor), transcriptional control (peroxisome proliferator-activated receptor- $\gamma$ ), metabolism (CYP3A4, HMG-CoA reductase, gamma-glutamylcysteine synthetase), and other processes (leptin, a beta-secretase in neurons, tropomyosin), activation of the cellular retinoic acid-binding protein II (Brigelius-Flohe 2009).

### Cell signalling

Under in vitro conditions efficiency of vitamin E is involved in the upregulation of Christmas factor, increasing blood coagulation and catalysing an increased conversion of testosterone to 5- $\alpha$ -dihydrotestosterone, simultaneously upregulating enzymatic activity involved in the rate limitation of glutathione synthesis (Rimbach et al 2010).

### Telomere length

In co-administration with vitamin C, vitamin E was associated with longer telomere production (in women), demonstrated by both foods containing the antioxidants and supplemental forms (Xu et al 2009).

### CLINICAL USE

Although vitamin E supplementation is used to correct or prevent deficiency states, most uses are based on the concept of high-dose supplements acting as therapeutic agents to either prevent or treat various health conditions. The Scientific Committee of Food set a tolerable upper intake level for D-alpha tocopherol of 300 mg/day in adults. However, there are numerous clinical trials which have used higher doses and not shown any serious adverse effects. The Joint Expert Committee on Food additives suggests an acceptable daily intake at 0.15–2.0 mg/kg/day. These intakes are likely to have individual response differences dependent on uptake

(Colombo 2010). In recent years, accumulating evidence has suggested that gamma tocopherol, mixed tocopherols and tocotrienols may have properties superior to alpha tocopherol and are being scientifically investigated.

### Deficiency: prevention and treatment

Traditionally, vitamin E supplementation has been used to treat or prevent deficiency in conditions such as genetic abnormalities with alpha-tocopherol transfer protein, apolipoprotein B, or microsomal triglyceride transfer protein; and to treat fat malabsorption syndromes (e.g. chronic cholestasis, cystic fibrosis, short-bowel syndromes such as Crohn's disease, chronic steatorrhoea, coeliac disease, chronic pancreatitis and total parenteral nutrition) (Traber et al 2006).

### Cardiovascular disease

Oxidative stress has been shown to play an integral role in the formation, progression and rupture of the atherosclerotic plaque via modification of proteins and DNA, alteration of gene expression, promotion of inflammation and endothelial dysfunction, enhancement of surface adhesion molecule expression, LDL oxidation, MMP production and consequently plaque rupture (Katsiki & Manes 2009). Vitamin E in the form of mixed tocopherols has an inhibitory effect on platelet aggregation and adhesion, and smooth-muscle cell proliferation has an anti-inflammatory effect on monocytes, improves endothelial function and decreases lipid peroxidation (Kaul et al 2001, Rizvi et al 2014). Based on these observations and evidence, largely from epidemiological studies, investigation of various antioxidant substances, in particular vitamin E, has been conducted to determine their role in primary and/or secondary prevention of CVD.

Vitamin E also modulates the expression of genes that are involved in atherosclerosis (e.g. scavenger receptors, integrins, selectins, cytokines, cyclins) (Munteanu et al 2004). Its ability to reduce oxidative stress, both directly and indirectly as part of the antioxidant network, is of particular importance as oxidation of LDL is a key process in atherogenesis, enhancing foam cell and early lesion formation (Terentis et al 2002).

In animal cell lines tocotrienols inhibit cholesterol synthesis, suppressing the key enzyme in sterologenic pathways 3-hydroxy-3-methylglutaryl CoA reductase enzyme. This has an effect of down-regulating cholesterol biosynthesis in the liver. In humans, a study of tocotrienols combined with lovastatin (cholesterol-lowering medication) lowered cholesterol through different mechanisms. The outcome suggested that the combined therapy was effective, avoiding some of the detrimental effects of statin medication (Colombo 2010, McAnally et al 2007).

Based on these observations and evidence, largely from epidemiological studies, investigation of various antioxidant substances, in particular vitamin

E, has been conducted to determine their role in primary and/or secondary prevention of CVD.

### Epidemiological and clinical studies

Many epidemiological studies have observed an inverse association between cardiovascular disease (CVD) and dietary intake of vitamin E that contains mainly gamma tocopherol and alpha tocopherol; however, the results from intervention studies are more controversial. In humans, some clinical trials have reported a clear association between the reduction in the relative risk of CVD with high intake or supplementation of Vitamin E, whereas others have shown no association. The genetic background, type of vitamin E and dose used, baseline levels and dietary habits of test volunteers may have contributed to the different results and deserve further study. It was back in 1946 when a Canadian doctors first reported that vitamin E could protect against coronary heart disease; however, it was not until the results of two very large human studies were published nearly 50 years later that the greater scientific community and the public started to take note of vitamin E. In 1993, the prospective Nurses' Health Study and the Health Professionals' Follow-up study both reported that, compared to non-users, vitamin E supplementation at a dose of at least 100 IU for at least 2 years significantly reduced the risk of coronary disease by an estimated 40% (Rimm et al 1993, Stampfer et al 1993).

The prospective Nurses' Health Study followed 87,245 women aged 34–59 years without known coronary disease over 8 years and found that those women with the highest intake of vitamin E had the lowest relative risk of non-fatal myocardial infarction (MI) or death from coronary disease, compared to those with the lowest intake (Stampfer et al 1993). Interestingly, short-term use or dietary intake alone did not produce the same significant reduction. The Health Professionals' Follow-up study observed 39,910 men aged 40–75 years over 4 years and produced similar results, finding that long-term vitamin E (at least 100 IU/day) significantly reduced the relative risk of coronary disease compared to non-users (Rimm et al 1993).

Subsequently, a double-blind study conducted at Cambridge University, UK, and published in 1996 supported these results, but further suggested that higher doses could produce benefits more quickly and more dramatically (Stephens et al 1996). The placebo-controlled randomised study known as the Cambridge Heart Antioxidant Study (CHAOS) involved 2002 patients with angiographically proven coronary atherosclerosis, and compared the effects of two different strengths of alpha-tocopherol supplementation (400 IU and 800 IU) and a placebo over a median of 510 days. Treatment with either dose of vitamin E was seen to reduce the risk of cardiovascular death and non-fatal MI by over 75%, with effects established after 12 months.

In 1999, results from the large Gruppo Italiano per lo Studio della Sopravvivenza nell'Infarto

miocardico (GISSI) trial were published, which were less convincing. However, the trial used synthetic vitamin E at a lower dose than the previously positive CHAOS study (Albert et al 1999, GISSI 1999). The trial, which involved 11,324 patients who had recently survived MI (<3 months), investigated the effects of three different treatment protocols compared to a placebo: 1 g omega-3 fatty acid/day, 300 IU synthetic vitamin E/day, fish oils plus vitamin E/day or a placebo. The four groups were observed for nearly 4 years for CVD morbidity and mortality. Results showed that the fish oil treatment groups had significantly decreased combined end points of death, non-fatal MI and stroke over this time, whereas the vitamin E treatment produced little effect. The trial has since been criticised because the form of vitamin E used was synthetic and the dose was relatively low compared to doses in other studies involving patients with pre-existing disease.

To date, 27 different randomised controlled trials (RCTs) in the peer-reviewed literature have evaluated the effects of vitamin E in people at risk of CVD or with clinically diagnosed CVD (Katsiki & Manes 2009). The larger studies — GISSI (1999), Women's Antioxidant Cardiovascular Study (WACS) and Alpha-Tocopherol Beta-Carotene (ATBC) cancer prevention study — have resulted in several published papers as researchers analyse effects in subgroups or results are re-evaluated using different models, with respect to the GISSI 2006 study, which tested the same daily intervention with slightly different patient characteristics (post-MI vs post-MI without congestive heart failure at baseline). Overall, eight RCTs have tested vitamin E as a sole treatment, five studies have studied vitamin E in combination with vitamin C supplementation, and 11 have used multiple vitamin combinations, which included vitamin E. Nine studies combined beta-carotene with vitamin E or in a multivitamin combination. The dose of vitamin E administered in the studies varies considerably, from 55 IU to 1,200 IU daily, and in at least nine studies, synthetic vitamin E was used. In general, studies using natural vitamin E tend to produce positive results, showing a benefit on cardiovascular outcomes, however, inconsistent results still remain. Additionally, RCTs conducted in people with established CVD were more likely to report a cardioprotective effect than primary prevention studies (Table 2). Most recently, new data has emerged that allows identification of a specific target population for vitamin E supplementation, namely patients with diabetes mellitus and the haptoglobin genotype 2-2 as being more likely to respond (Vardi et al 2013).

### Restenosis

Restenosis is a major limitation to the long-term success of angioplasty. Therefore, measures that prevent or delay this occurrence are being investigated to extend the beneficial effects of the procedure.

While studies in experimental models have shown that vitamin E helps to stabilise atherosclerotic plaque after angioplasty and favours vascular remodelling (Orbe et al 2003), clinical trials to date have produced disappointing results.

An early double-blind study using oral synthetic vitamin E (1200 IU) for 4 months found that treatment did not significantly reduce the rate of restenosis after percutaneous transluminal coronary angioplasty, with restenosis defined as >50%. However, minor reductions were noted (treatment group 35.5% vs control group 47.5%) which did not reach statistical significance (DeMaio et al 1992, Vardi et al 2013).

In the Multivitamin Prevention (MVP) trial, Tardif et al (1997) aimed to decrease the incidence and severity of restenosis after coronary angioplasty (317 patients). The patients were randomly assigned one of four different treatments: (1) a combination of vitamins, including vitamin E (30,000 IU beta-carotene, 500 mg vitamin C and 700 IU vitamin E 2000 IU); (2) placebo; (3) probucol and MVP combination; or (4) probucol 500 mg. Treatment was given 1 month prior to surgery and 6 months post-surgery at a dose of twice daily, unless procedure-related complications were noted. Additionally all patients received an extra 1000 mg of probucol, and 2000 IU of vitamin E or placebo 12 hours prior to angioplasty. It was found that probucol treatment was the most effective in reducing restenosis (mean  $\pm$  SD); there was a reduction in luminal diameter 6 months > angioplasty  $0.12 \pm 0.41$  mm in the probucol group,  $0.22 \pm 0.46$  mm in the combined treatment group,  $0.33 \pm 0.51$  mm in the multivitamin alone group, and  $0.38 \pm 0.50$  mm in the placebo group.

### Angina pectoris

Low-dose vitamin E supplements (50 mg/day) produce a minor decrease in the incidence of angina pectoris in smokers without previous coronary heart disease, according to an RCT (Rapola et al 1996). A smaller study of 29 subjects with variant angina identified six patients who did not respond to calcium channel blockers and had lower plasma levels than normal, but who responded positively to supplementation with 300 mg/day vitamin E. Treatment resulted in a significantly reduced incidence of angina episodes (Miwa et al 1996). Several years later, the same research group identified a transcardiac reduction in plasma vitamin E concentrations concomitant with lipid peroxide formation, suggesting that oxidative stress and vitamin E depletion may be involved in the pathogenesis of coronary artery spasm (Kusama et al 2011, Miwa et al 1999).

### Nitrate tolerance

Nitroglycerin (NTG) is utilised to prevent vasoconstriction in the acute treatment of angina, acute MI, pulmonary oedema and severe arterial hypertension. One limitation of treatment is that nitrate tolerance

**TABLE 2 SUMMARY OF POSITIVE FINDINGS FROM RANDOMISED STUDIES OF VITAMIN E IN PRIMARY OR SECONDARY CARDIOVASCULAR DISEASE (CVD) PREVENTION**

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Findings
CHAOS (Stephens et al 1996)	Secondary	2002	Coronary disease	Natural vitamin E (400 IU or 800 IU)	Vitamin E reduced risk of cardiovascular death and non-fatal MI by over 75%
SPACE (Boaz et al 2000)	Secondary	2198	End-stage renal disease — people on haemodialysis with pre-existing cardiovascular event	Natural vitamin E (800 IU)	Vitamin E caused a 50% reduction in cardiac events
CLAS (Azen et al 1996)	Secondary	146	Non-smoking 40–59-year-old men with previous coronary artery bypass graft surgery	Vitamin E (< or >100 IU) and vitamin C (< or >250 mg)	Higher vitamin E intake was associated with less carotid intima media thickness progression compared with low vitamin E users in people not treated with colestipol
DeMaio et al (1992)	Secondary	100	Restenosis	Dl tocopherol 1200 IU/day	35.5% reduction in restenosis versus 47.5% not statistically significant
ASAP (Salonen et al 2003)	Primary	520	Smoking/non-smoking men and postmenopausal women aged 45–69 years with elevated serum cholesterol	Twice daily either (136 IU) of D-alpha-tocopherol, 250 mg of slow-release vitamin C, a combination of these, or a placebo, for 3 years	The proportion of men with progression of carotid atherosclerosis was reduced by 74% with combination of vitamins E and C compared to the placebo; no significant effect was seen in women
ASAP follow-up (Salonen et al 2003)	Primary	520	Smoking/non-smoking men and postmenopausal women aged 45–69 years with elevated serum cholesterol	Twice daily (136 IU) D-alpha-tocopherol, 250 mg of slow-release vitamin C, or a placebo, for 6 years	Effect was still significant after a further 3 years: combined vitamins E and C continued to slow down atherosclerotic progression in hypercholesterolaemic men
ATBC (Rapola et al 1996)	Primary: incidence of angina pectoris	29,134	Finnish male smokers aged 50–69 years with no history of MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Vitamin E was associated with a minor decrease in incidence of angina pectoris
ATBC (Virtamo et al 1998)	Primary and secondary	29,134	Finnish male smokers aged 50–69 years with no history of MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Vitamin E decreased incidence of primary major coronary events by 4%; no effect on incidence of non-fatal MI; vitamin E decreased incidence of fatal coronary heart disease by 8%

**TABLE 2 SUMMARY OF POSITIVE FINDINGS FROM RANDOMISED STUDIES OF VITAMIN E IN PRIMARY OR SECONDARY CARDIOVASCULAR DISEASE (CVD) PREVENTION (continued)**

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Findings
ATBC (subset) (Leppala et al 2000)	Primary: prevention of incident and fatal subarachnoid, intracerebral haemorrhage, cerebral infarction and stroke	29,134	Finnish male smokers aged 50–69 years with no history of MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Vitamin E prevented ischaemic stroke in high-risk hypertensive patients
St Francis (Arad et al 2005)	Primary	1005	Asymptomatic calcium scores >80th percentile	Atorvastatin 20 mg/day, vitamin C 1 g/day, vitamin E 1000 IU/day, aspirin 81 mg/day	Arteriosclerotic CVD event rate decreased 6.9% vs 9.9%
VEAPS (Hodis et al 2002)	Primary	353	LDL >3.37 mmol/L	DL-alpha-tocopherol 400 IU/day	Coronary carotid intimal thickness did not change, circulating LDL reduced
ATIC (Nanyakkara et al 2007)	Primary	93	Mild to moderate chronic kidney failure	Alpha-tocopherol, pravastatin and homocysteine-lowering therapy, consecutively introduced	Significant decrease in intima media thickness, endothelial dysfunction, albuminuria; no effect on renal output
IEISS (Singh et al 1996)	Secondary	125	Patients with suspected acute MI	Vitamin E (400 mg), vitamin A (50,000 IU), vitamin C (1000 mg), beta-carotene (25 mg)	Treatment reduced mean infarct size, angina pectoris and total arrhythmias; poor left ventricular function occurred less often with antioxidants; cardiac end points were significantly less in the antioxidant group (20.6% vs 30.6%, respectively)
Fang et al (2002)	Secondary	40	After cardiac transplantation	Twice-daily vitamin C (500 mg) plus vitamin E (400 IU)	Supplementation with vitamins C and E retarded early progression of transplant-associated coronary arteriosclerosis compared to the placebo
WACS (Cook et al 2007)	Secondary	8171	Women with CVD or at least three risk factors	Vitamin C (500 mg/day), natural vitamin E (600 IU every other day) and beta-carotene (50 mg every other day)	Vitamin E significantly reduced incidence of stroke and produced a marginally significant reduction in the primary outcome (a combination of MI, stroke, coronary revascularisation or CVD death) in a prespecified subgroup of women with prior CVD

**TABLE 2 SUMMARY OF POSITIVE FINDINGS FROM RANDOMISED STUDIES OF VITAMIN E IN PRIMARY OR SECONDARY CARDIOVASCULAR DISEASE (CVD) PREVENTION (continued)**

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Findings
SPACE (Boaz et al 2000)	Secondary	196	-	DL-alpha-tocopherol 800 IU/day	Relative risk 0.46 in composite MI, ischaemic stroke, peripheral vascular disease and unstable angina

CHAOS, Secondary Prevention with Antioxidants of Cardiovascular disease in Endstage renal disease; MI, myocardial infarction; SPACE, Secondary Prevention with Antioxidants of Cardiovascular disease in Endstage renal disease; CLAS, Cholesterol Lowering Atherosclerosis Study; ASAP, Antioxidant Supplementation in Atherosclerosis Prevention; ATBC, Alpha-Tocopherol Beta-Carotene; VEAPS, Vitamin E Atherosclerosis Prevention Study; LDL, low-density lipoprotein; ATIC, Anti-oxidant Therapy in Chronic renal insufficiency; IEISS, Indian Experiment of Infarct Survival Study; WACS, Women's Antioxidant Cardiovascular Study; SPACE, Secondary Prevention with Antioxidants of Cardiovascular disease in Endstage renal disease.

develops with continuous use of NTG over time (Klemenska & Beresewicz 2009). Vitamin E supplements (200 mg three times daily) prevented nitrate tolerance when given concurrently with transdermal nitroglycerin (NTG 10 mg/24 hours) according to one randomised, placebo-controlled study in which 24 patients with ischaemic heart disease were compared with 24 healthy volunteers over a 6-day period (Watanabe et al 1997).

In animal studies of rats with angina pectoris, research indicates that continuous NTG infusion causes a time-dependent vitamin E depletion in plasma and tissue. Vitamin E dietary supplementation (0.5 g/kg) administered to the animals delayed the onset of, and extent of, tolerance, demonstrating vitamin E is beneficial in the prevention of nitrate tolerance (Minamiyama et al 2006). Yasue et al (2008) concur with animal study findings in that human trials demonstrate plasma vitamin E levels are low in coronary spasm disorders, with vasoconstriction causing oxygen free radical degradation. This suggests that vitamin E's antioxidant properties may be of use; however further trials are needed.

### Hypertension

Vitamin E supplementation may reduce blood pressure and LDL oxidation and improve endothelial dysfunction in hypertension, according to clinical research.

An early double-blind, placebo-controlled study found that DL-alpha-tocopherol nicotinate (3000 mg) significantly reduced systolic blood pressure (SBP) from 151.0 to 139.2 mmHg within 4–6 weeks in hypertensive subjects; however, diastolic blood pressure (DBP) remained unchanged (Iino et al 1977). More recently, long-term vitamin E (200 IU/day) was shown to decrease SBP by 24% in mildly hypertensive patients compared with a 1.6% reduction with a placebo, according to a triple-blind placebo-controlled study conducted over 27 weeks (Boshtam et al 2002). The study involved 70 hypertensive patients (SBP 140–160 mmHg; DBP 90–100 mmHg) aged 20–60 years without other cardiovascular risk factors. Besides reducing SBP,

DBP was reduced by 12.5% compared to 6.2% with a placebo.

Some studies have revealed that hypertensive patients have a higher susceptibility to LDL oxidation than normotensive subjects and, therefore, increased atherogenic potential. One study measured the effect of vitamin E (400 IU/day) on the resistance of LDL to oxidation in 47 volunteers (Brockes et al 2003). Comparisons made before and after 2 months' supplementation showed that vitamin E caused a significant increase in the lag time in normotensive and hypertensive patients, ultimately bringing hypertensive patients up to the same point as the healthy controls.

### All-cause mortality (ACM)

There is substantial research indicating benefits for vitamin E supplementation in the treatment and prevention of various diseases, but regardless of these benefits, three meta-analyses have drawn the conclusion that vitamin E supplementation increases ACM (Bjelakovic et al 2007, 2013, Miller et al 2005). These findings have been unexpected and widely criticised, as they are based on the results of smaller studies of variable quality, often involving people with chronic disease and sometimes testing vitamin E as part of a multinutritional intervention and not as a stand-alone treatment. Based on recent reanalysis of the data by Berry et al (2009) and Gerss and Kopcke (2009), which are discussed below, the evidence is not convincing that vitamin E supplementation increases mortality.

In 2005, Miller et al published a meta-analysis of the dose-response relationship between vitamin E supplementation and total mortality using data from 19 RCTs consisting of a large study population ( $n = 135,967$ ). A dose-response analysis showed a statistically significant relationship between vitamin E dosage and ACM. The authors suggested caution with doses of 400 IU/day or higher, while acknowledging that the high-dose studies ( $\geq 400$  IU/day) analysed in the report were often small and performed in patients with chronic diseases.

**TABLE 3 SUMMARY OF NEGATIVE FINDINGS FROM RANDOMISED STUDIES OF VITAMIN E IN PRIMARY OR SECONDARY CARDIOVASCULAR DISEASE (CVD) PREVENTION**

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Results
GISSI (Albert et al 1999)	Secondary	11,324	Post-MI	Synthetic vitamin E (300 mg/day), fish oils (1 g/day), combination of fish oil and vitamin E, or a placebo	There was no significant reduction in the combined end points of death, non-fatal MI and stroke
GISSI (Marchioli et al 2006)	Secondary	8415	Post-MI patients without CHF at baseline	Synthetic vitamin E (300 mg/day), fish oils (1 g/day), combination of fish oil and vitamin E, or a placebo	Vitamin E treatment was associated with a significant 50% increase of CHF in patients with left ventricular dysfunction (ejection fraction <50%)
HOPE (Yusuf et al 2000)	Primary and secondary	9541	2545 women and 6996 men 55 years of age or older who were at high risk of cardiovascular events because they had CVD or diabetes in addition to one other risk factor	Natural vitamin E (400 IU), and a placebo or angiotensin-converting-enzyme inhibitor (ramipril), or both	There was no significant effect on the primary outcome, which was a composite of MI, stroke and death from cardiovascular causes
MICRO-HOPE (Lonn et al 2005)	Secondary	3654	Middle-aged and elderly people with diabetes and CVD and/or additional coronary risk factor(s)	Vitamin E (400 IU) for an average of 4.5 years	Vitamin E had no effect on CV outcomes or nephropathy
PPP (de Gaetano 2001)	Primary	4495	Those at risk of CVD: people with hypertension, hypercholesterolaemia, diabetes, obesity, family history of premature MI or the elderly	Vitamin E (300 mg)	There was no significant reduction in CV events
ATBC (subset) (Rapola et al 1997)	Secondary	1862	Finnish male smokers with previous MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Risk of fatal coronary heart disease increased in groups receiving either beta-carotene or vitamin E and beta-carotene. There was a non-significant trend of increased deaths in the vitamin E group

This meta-analysis has several serious flaws and has been criticised on a number of accounts, inspiring over 40 letters to the journal's editor and hundreds of emails and telephone calls to the authors (Jialal & Devaraj 2005b). In summary, these responses centre on six major flaws. First, results from 12 clinical studies that reported fewer than 10 deaths each were excluded from the meta-analysis, which

created the appearance of bias and would have given an artificial weight to studies in which more people died. Second, the meta-analysis included trials of different designs, treatment times, doses, combinations and end points. Pooling information together from such heterogeneous studies was considered inappropriate. Third, subjects in many studies had significant chronic diseases, such as Parkinson's

**TABLE 3 SUMMARY OF NEGATIVE FINDINGS FROM RANDOMISED STUDIES OF VITAMIN E IN PRIMARY OR SECONDARY CARDIOVASCULAR DISEASE (CVD) PREVENTION (continued)**

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Results
HPS (Parkinson Study Group 2002)	Secondary	20,536	High CVD risk: coronary disease, other occlusive arterial disease, or diabetes	Vitamin E (600 mg), vitamin C (250 mg), beta-carotene (20 mg)	There were no significant differences in all-cause mortality, or in deaths due to vascular or non-vascular causes; no significant reduction in incidence of non-fatal MI, coronary death, non-fatal or fatal stroke or coronary or non-coronary revascularisation
MVP (Tardif et al 1997)	Secondary: aimed to decrease incidence and severity of restenosis after angioplasty	317	Before and after coronary angioplasty	One month before angioplasty and for 6 months afterwards: multivitamins (30,000 IU beta-carotene, 500 mg vitamin C, and 700 IU vitamin E) twice daily and/or probucol, or a placebo 12 hours before angioplasty given an extra 1000 mg probucol, 2000 IU vitamin E, or both, or a placebo	Multivitamin ineffective at reducing the rate of restenosis
WAVE (Waters et al 2002)	Secondary	423	Postmenopausal women	Vitamin E 400 IU/day plus vitamin C 500 mg BID, HRT or placebo	Increased risk of death, MI and stroke
SUVIMAX (Zureik et al 2004)	Primary	1162	Healthy population	Vitamin C (120 mg), vitamin E (30 mg), beta-carotene (6 mg), selenium (100 mcg), and zinc (20 mg)	There was no beneficial effect on carotid atherosclerosis and arterial stiffness
PHS 11 (Sesso et al 2008)	Primary	14,641	Male >50 years old /94.9% were CVD-free at enrolment	Alpha-tocopherol 400 IU every other day, vitamin C or placebo	No effect on CV outcomes: associated with increased risk of haemorrhagic stroke

GISSI, Gruppo Italiano per lo Studio della Sopravvivenza nell'Infarto miocardico; MI, myocardial infarction; CHF, congestive heart failure; HOPE, Heart Outcomes Prevention Evaluation; PPP, Primary Prevention Project; ATBC, Alpha-Tocopherol Beta-Carotene; HPS, Heart Protection Study; MVP, Multivitamin Prevention; WAVE, Women's Angiographic Vitamin and Estrogen; HRT, hormone replacement therapy; PHS 11, Physician's Health Study 11.

disease (PD), end-stage renal disease, coronary artery disease, diabetes mellitus and Alzheimer's dementia (AD), which would have influenced their mortality risk. This also means that the results do not necessarily apply to healthy adults taking these supplements. Fourth, studies used different forms of vitamin E (natural and synthetic) and sometimes used vitamin E in combination with other nutrients;

however, results of all these studies were pooled and not separated. Furthermore, subject adherence to the treatment protocol was considered in only one study (CHAOS). Lastly, the use of some statistical models has been questioned.

In 2007, Bjelakovic et al conducted a meta-analysis using data from 68 randomised trials involving 232,606 adults that compared beta-carotene,

**Clinical note — Confusing results for vitamin E**

To date, many in vitro, animal and epidemiological studies support the use of vitamin E in the prevention of CVD (Clarke & Armitage 2002). However, intervention studies are equivocal. Many factors could account for the lack of benefit on the primary end point in the majority of trials (Linus Pauling Institute 2008).

*Dose selection*

A closer look at the evidence shows that dose selection varies enormously, from levels just above the recommended dietary intake (RDI: 50 mg/day) to large doses of 2000 IU/day. Clinical research reveals that a daily dose of at least 400 IU is required for LDL to become less susceptible to oxidation (Brookes et al 2003, Miller et al 2005) and an effective threshold dose may be as high as 800 IU/day (Jialal & Devaraj 2005a, Traber et al 2006). However an RCT review suggests that a dose relationship with mortality exists with supplementation over 150 IU/day (Miller et al 2005). More recently, Colombo (2010) suggests a beneficial dose should reach 0.15–2.0 mg/kg body weight per day.

*Biomarkers of oxidative stress*

Just as the statin trials investigate subjects with high cholesterol levels rather than the general population, it can reasonably be assumed that antioxidant treatment is best suited to those people with increased oxidative stress rather than the general population, yet researchers consistently fail to consider this as a biochemical basis for patient inclusion (Meagher 2003). The levels of oxidised amino acids in urine and plasma can reflect those in tissues and identify people with high levels of oxidative stress; this may be one method of subject selection (Heinecke 2002). Brack et al (2013) suggest in both chronic and acute disease, such as CVD, amongst others, multiple abnormalities can be found, where a broad-spectrum approach to measuring numerous antioxidant profiles, including vitamin E status, is warranted (Niki 2014).

*Type of supplement*

In the specific case of vitamin E, the form of tocopherol used is crucial, as synthetic forms have less biological activity than RRR D-alpha-tocopherol. According to a 2002 FAO/WHO report, cross-country correlations between coronary heart disease mortality in men and the supply of vitamin E homologues across 24 European countries show a highly significant ( $P < 0.001$ ) correlation for D-alpha-tocopherol, whereas all other forms of vitamin E do not achieve statistical significance.

In the last few years, it has further been proposed that the lack of efficacy of commercial tocopherol preparations in some clinical trials may

be due to the absence of other natural tocopherols, primarily gamma- and delta-tocopherol. Preliminary studies provide some support for this view (Jialal & Devaraj 2005a, Saldeen & Saldeen 2005). Studies using different mixtures of alpha-, beta-, gamma- and delta-tocopherol have found that a mixture of gamma-, delta- and alpha-tocopherol with the ratio of 5:2:1 have a much better antioxidant effect than alpha-tocopherol alone. This mixture is similar to that found in nature. In human and animal studies, the mixed tocopherol preparation also had much more favourable effects on constitutive NO synthase and superoxide dismutase activity than alpha-tocopherol, and in a rat model was more effective in decreasing platelet aggregation and inhibiting thrombus formation. A mixed tocopherol preparation is also superior to alpha-tocopherol in terms of myocyte protection (Chen et al 2002). Similarly, Yoshida et al (2003) sustain a similar view. This view is not supported by Niki et al (2014) who remain steadfast in the view that alpha-tocopherol alone exerts antioxidant effects in vivo and in vitro. It is important to note that, in diets rich in mixed tocopherols such as Mediterranean diets, there is a lower incidence of heart disease; however this may be due to many other nutrient and lifestyle factors (Roehm 2009).

*Plasma vitamin E levels*

The measurement of plasma vitamin E levels in the supplemented groups has been inconsistent in studies, so it is uncertain whether levels significantly rose in response to treatment and subjects were compliant. For example, in the CHAOS, Antioxidant Supplementation in Atherosclerosis Prevention (ASAP), ASAP follow-up and Secondary Prevention with Antioxidants of Cardiovascular disease in Endstage renal disease (SPACE) studies, a significant increase in plasma antioxidant levels was reported and all studies found a benefit on the primary end point, whereas measurement of plasma levels has been inconsistent in the negative studies (Jialal & Devaraj 2005a).

Clearly, the optimal form/s, dosage regimen, duration of use and subpopulation best suited to primary and secondary preventive treatment still need to be clarified with future trials.

*Identifying responders*

New data is emerging to suggest that the specific target population for vitamin E supplementation appears to be patients with excessive oxidative stress, such as those undergoing haemodialysis and those with diabetes mellitus and the haptoglobin genotype 2-2 as likely responders (Vardi et al. 2013).

vitamin A, vitamin C (ascorbic acid), vitamin E and selenium, either singly or combined, to a placebo or to no intervention. When all trials of antioxidant supplements were pooled, there was no significant effect on mortality for vitamin E given singly in high ( $\geq 1000$  IU) or low dose ( $< 1000$  IU). After exclusion of high-bias risk (studies with heterogeneity) and selenium trials, vitamin E given singly or combined with other antioxidants significantly increased mortality, with an estimate of increased mortality of about 5%. A closer look at the details of the study reveals that, of the 815 trials originally identified, 405 trials were excluded from the meta-analysis because mortality was zero ( $n = 40,000$ ). Vitamin E was administered in doses ranging from 10 to 5000 IU daily, and populations studied were either healthy (primary prevention trials) or had a variety of established diseases such as cancer, CVD, renal disease, hepatitis, systemic lupus erythematosus, heart failure, cirrhosis, gastritis, MI or macular degeneration.

Gerss and Kopcke (2009) concur that the use of different methodological approaches yields contradictory results, with some statistical models finding an association and others not. They used the same data as that described in the Miller et al study (2005). The meta-analysis was augmented with 2495 additional participants receiving vitamin E doses from 136 to 5000 IU/day. Moreover in two of the originally included trials, the updated results of mortality at longer periods of follow-up were made available.

More specifically, hierarchical logistic regression analyses confirmed the former results, showing an increased mortality of patients receiving high-dose vitamin E, whereas application of a traditional methodological approach to meta-regression found that in certain trials increased mortality was not due to high-dose vitamin E, but could be explained by a higher proportion of male subjects in comparison to other trials (Gerss & Kopcke 2009). Overall, the causal relationship of vitamin E supplementation and increased ACM is questionable and, in particular, high-dose vitamin E supplementation cannot be regarded as 'proven' to increase mortality.

Similar findings were obtained by Berry et al (2009), who applied a Bayesian meta-analytical method to synthesise results from previous clinical trials of vitamin E. They used data from studies in the Miller et al (2005) meta-analysis, appended by 10 more recent studies, and concluded that vitamin E intake is unlikely to affect ACM, regardless of dose.

Re-evaluation of data from the original Framingham Heart Study has also failed to find an association between vitamin E supplementation and increased risk of ACM (Dietrich et al 2009). The Framingham Heart Study ( $n = 4270$ ) began enrolling in 1948 to investigate the association between supplemental vitamin E and the 10-year incidence of CVD and ACM. Eleven per cent of people participating in the study used vitamin E supplements

at baseline and the most commonly consumed dose was 300–500 IU/day. In all statistical models, age, diabetes and treatment for blood pressure were significant positive predictors of CVD and ACM, whereas no statistically significant associations were found between vitamin E supplement intake and CVD and ACM. In secondary analyses, the associations of vitamin E dose and duration of use with CVD and ACM were assessed. Once again, no statistically significant associations were observed in any of the analyses for CVD or ACM. The effects of potential confounders, such as use of aspirin, anticholesterol treatment and multivitamins, were minimised using multivariate models which did not change the results.

In a further attempt to suggest the effects of supplementation of beta-carotene, vitamin A, and vitamin E singly or in combination on increased ACM, Bjelakovic et al (2013) included 53 RCTs involving 241,883 participants. Meta-regression analysis revealed that doses of  $> 15$  mg of vitamin E increased mortality significantly. In rebuttal, Hemilä (2013: not peer-reviewed) states that the increase in ACM by 3% based on a pooling of studies does not correspond to an individual level analysis. The latest ATBC studies confirm the statement made by Hemilä casting doubt on the significance of the review by Bjelakovic et al (2013) (Kataja-Tuomola et al 2010, Lynch et al 2012).

#### **Clinical note — LDL oxidation and vitamin E**

Oxidative stress affects lipid metabolism by producing an oxidised LDL that has greater atherogenic potential than its original form. In the past, attention focused on investigating various antioxidants, such as vitamin E, for their ability to prevent LDL oxidation. In recent years, researchers have started to focus on identifying the biological oxidants responsible for initiating oxidation of LDL within the human arterial wall and on a better understanding of what makes oxidised LDL proatherogenic. In 2003, in vitro testing with LDL discovered that myeloperoxidase is a pathway that promotes LDL oxidation in the human artery wall, although others are also likely to exist. It is noteworthy that vitamin E failed to inhibit LDL oxidation by myeloperoxidase in vitro (Heinecke 2003), although it does reduce LDL oxidation in animals and humans when given in doses well above RDI (Brookes et al 2003). Oil palm vitamin E (tocopherols 70% and tocotrienols 30%) reduced atherogenesis in a recent animal model trial (Che Anishas et al 2014). In earlier studies the effect of palm oil vitamin E in humans suggests its use in lowering LDL and protecting HDL levels (Mukherjee & Mitra 2009). Supplemental forms of tocopherols are available from a palm oil source.

**Clinical note — Neurodegenerative disease and oxidative stress**

Neurodegenerative diseases are defined by the progressive loss of specific neuronal cell populations and are associated with protein aggregates. A growing body of evidence suggests that oxidative stress plays a key role in the pathophysiology of neurodegenerative disorders such as AD and PD. Reactive oxygen species are known to cause cell damage by way of three main mechanisms: lipid peroxidation, protein oxidation and DNA oxidation. Cells have developed several defence and repair mechanisms to deal with oxidative stress, and antioxidants such as vitamin E represent the first line of defence. In addition to its antioxidant properties, vitamin E can act as an anti-inflammatory agent, which may also be neuroprotective, and it regulates specific enzymes, thus changing the properties of membranes. The central nervous system is especially vulnerable to free radical damage because, compared to other tissues, it has a high oxygen consumption rate, abundant lipid content and a relative deficit in antioxidant systems. While it remains unclear whether oxidative stress is the primary initiating event associated with neurodegeneration or a secondary effect related to other pathological pathways, a growing body of evidence implicates it as being involved in the propagation of cellular injury (Ricciarelli et al 2007).

**Parkinson's disease**

Based on experimental and clinical data, it is well established that oxidative stress and lipid peroxidation are increased in the substantia nigra of people with PD and this may play an important role in the disease's aetiology. Vitamin E has therefore been the focus of research as a potential treatment. Using both in vitro and in vivo experimental model systems for PD, studies have demonstrated both vitamin E-mediated protection and lack of protection (Fariss & Zhang 2003). Similarly, inconsistent results have been obtained for vitamin E supplementation in the prevention and treatment of clinical PD. An open study using high doses of both tocopherol (3200 IU/day) and ascorbic acid (3000 mg/day) delayed the use of levodopa or dopamine agonists for 2 years in subjects with early PD (Fahn 1992). In contrast, the Deprenyl and Tocopherol Antioxidative Therapy of Parkinsonism (DATATOP) study found no effect on the progression of disability with a dose of alpha-tocopherol 2000 IU/day (Parkinson Study Group 1996). The same study found that vitamin E had no effect on mortality (Parkinson Study Group 1998). A meta-analysis six case-control, one cohort study and a cross-sectional study of several vitamins and the risk of PD found that vitamin E demonstrated a

protective role seen in both high (less significant and warranting further trials) and moderate intakes, suggesting that vitamin E has a neuroprotective role attenuating risk (Mahyar et al 2005).

**Alzheimer's dementia and cognitive decline**

Alzheimer's disease occurs due to protein oxidation and lipid peroxidation. Beta amyloid proteins undergo oxidative stress via hydrogen peroxide, leading to neuronal death and decline into the disease. Vitamin E may block hydrogen peroxide production, slowing progression of cytotoxicity, resulting in reduced beta amyloid cell death (animal studies) (Rizvi et al 2014). The current standard of care for pharmacological management of the cognitive and functional disabilities of AD consists of a cholinesterase inhibitor and sometimes the addition of high-dose vitamin E (Bonner & Peskind 2002). The inclusion of vitamin E is largely based on a 1997 double-blind study that compared a large dose of synthetic vitamin E (1000 IU twice daily) with selegiline (5 mg twice daily) and placebo in a group of patients with moderately severe AD. The 2-year study found that vitamin E significantly slowed down the progression of the disease, delayed institutionalisation and increased survival rate (Sano et al 1997). In contrast to the positive 1997 study, a study involving 769 subjects with possible or probable AD using the same dose found no significant effects in patients with mild cognitive impairment and no change in the rate of progression to AD over a 3-year period (Petersen et al 2005).

Despite this, positive results were again achieved in a double-blind RCT which found that supplementation with alpha-tocopherol in mild to moderate AD was effective in slowing functional decline and decreasing caregiver burden (Dysken et al 2014). The study involved 613 patients with mild to moderate AD who received 2000 IU/day of alpha-tocopherol ( $n = 152$ ), 20 mg/day memantine ( $n = 155$ ), the combination ( $n = 154$ ) or placebo ( $n = 152$ ). Over a mean follow-up of 2.27 years, Alzheimer's Disease Co-operative Study — Activities of Daily Living (ADCS-ADL) inventory scores declined by 3.15 units (95% confidence interval [CI], 0.92–5.39; adjusted  $P = 0.03$ ) less in the alpha-tocopherol group compared with the placebo group. In the memantine group, these scores declined 1.98 units less (95% CI, -0.24 to 4.20; adjusted  $P = 0.40$ ) than the placebo group's decline. This change in the alpha-tocopherol group translates into a delay in clinical progression of 19% per year compared with placebo or a delay of approximately 6.2 months over the follow-up period.

Recent research suggests that in fact gamma-tocopherol may be more important than previously suspected in AD. A study by Morris et al (2014) found gamma-tocopherol concentrations were associated with lower amyloid load ( $P = 0.002$ ) and lower neurofibrillary tangle severity ( $P = 0.02$ ), whereas concentrations of alpha-tocopherol were

not associated with AD neuropathology, except as modified by gamma-tocopherol. High alpha-tocopherol was associated with higher amyloid load when gamma-tocopherol levels were low and with lower amyloid levels when gamma-tocopherol levels were high ( $P$  for interaction = 0.03). Brain concentrations of gamma- and alpha-tocopherols may be associated with AD neuropathology in interrelated, complex ways (Morris et al 2014).

### Prevention

Higher plasma vitamin E levels are associated with a significantly reduced risk of cognitive impairment and dementia in older adults. Protection is most consistently seen with vitamin E from food sources, but not always from vitamin E supplements (Cherubini et al 2005, Engelhart et al 2002, Morris et al 2005). Intervention studies using supplements have produced mixed results and focus on alpha-tocopherol only. The Cache County Study was a large study of 4740 people aged 65 years or older that found a combination of vitamins E (400 IU/day) and C (500 mg/day) taken for at least 3 years was associated with a reduced incidence of AD (Zandi et al 2004). No protective effects were seen when vitamin E or C was taken alone. In the Honolulu/Asia Aging Study, long-term use of vitamin E and C supplements was associated with an 88% reduction in the frequency of subsequent vascular dementia and appeared to improve cognitive function in later life; however, a protective effect against AD was not observed (Masaki et al 2000). A lack of association between dietary or supplemental vitamin E and risk of AD in elderly subjects was also found in the Washington Heights/Inwood Columbia Aging Project (WHICAP), which involved 980 older subjects (Luchsinger et al 2003). It must be noted that dietary intakes were assessed in this study with a limited food frequency questionnaire, which is likely to be less accurate than the more detailed surveys used in some other studies.

### Immunity in the elderly

Immune cell function is influenced by the oxidant and antioxidant balance, so antioxidant supplements have been investigated clinically for their ability to enhance immune responses (Meydani et al 1998). Increased markers of T-cell-mediated immunity were enhanced with all doses of synthetic vitamin E tested, according to a randomised, double-blind study of 78 healthy elderly subjects. Doses used were 60, 200 and 800 mg/day for 4 months, with best overall responses obtained with the 200 mg dosage (Meydani et al 1997). Rizvi et al (2014) state that supplementation enhances immunity in the elderly, correlating higher plasma vitamin E levels with reduced number of infections over a 3-year period. Enhanced vaccine antibody response with no adverse side effects was also observed, with other authors stating that vitamin E improves

resistance to respiratory infections in the aged (Rizvi et al 2014, Wu & Meydani 2008).

### Common cold and respiratory disease

Low-dose vitamin E supplementation (50 mg/day) was found to reduce the incidence of the common cold by 28% in a subgroup of men enrolled in the ATBC cancer prevention study (Hemila et al 2006). Participants were older city-dwelling men ( $\geq$  65 years) who smoked only 5–14 cigarettes/day. More recently, researchers re-evaluated the data and found that the effect of vitamin E diverged, depending on location of dwelling and smoking status. Among city-dwelling men considered to be low-moderate-level smokers (5–14 cigarettes/day), vitamin E significantly reduced common-cold risk, whereas among those smoking more and living away from cities, vitamin E increased common-cold risk. It appears that different modifying factors have an influence on whether vitamin E supplementation has beneficial or harmful effects. The ATBC study correlated vitamin E with a 14% higher incidence of pneumonia in smokers of five cigarettes a day aged 50–69 years over a 6-year period (Hemila & Kaprio 2008).

### Haemodialysis (HD)

HD increases oxidative stress and triggers atherosclerosis and dialysis-related amyloidosis (Masatomi Sasaki 2006). Vitamin E supplementation may offer several benefits to patients on HD, who typically experience high levels of oxidative stress, as there is some evidence that supplementation reduces oxidative stress and LDL oxidability in this population (Badiou et al 2003, Diepeveen et al 2005, Galli et al 2001, Giray et al 2003). The SPACE study by Boaz et al (2000) found that high-dose vitamin E supplementation (natural vitamin E 800 IU/day) caused a 50% reduction in cardiac events. This is a highly significant outcome and worthy of further investigation.

HD patients also experience cramps, which appeared to respond to vitamin E supplementation according to a placebo-controlled, double-blind study of 60 subjects (Khajehdehi et al 2001). Treatment with a vitamin E dose of 400 mg/day for 8 weeks resulted in a 54% reduction in cramps, which increased to a 97% reduction when combined with vitamin C (250 mg/day). The benefits were not significantly associated with age, sex, aetiology of end-stage renal disease, serum electrolytes or HD duration, but showed a positive correlation ( $P = 0.01$ ) with the type of therapy used.

According to one small study, vitamin E supplementation (500 mg/day) allowed for a reduction in erythropoietin dose (from 93 to 74 IU/kg/week) while maintaining stable haemoglobin concentrations (Cristol et al 1997).

Intradialytic hypotension is a condition plaguing diabetic HD patients where SBP may drop by up

to 20% during treatment. In a small unrandomised trial of 62 diabetic HD patients, vitamin E-bonded polysulfone membrane dialysers were utilised to observe SBP. Two groups entered the trial. The groups were divided into those with very low SBP (28) requiring medication and those with low SBP (34) who were not medicated. Both groups demonstrated significantly improved SBP at 3 months (Koremoto 2012).

### Premenstrual syndrome (PMS)

Treatment with D-alpha-tocopherol (400 IU/day) over three menstrual cycles significantly alleviated some affective and physical symptoms of PMS according to one randomised double-blind study (London et al 1987). Symptoms of anxiety, food craving and depression responded to active treatment, whereas effects on other measured parameters such as weight gain were not significant.

An earlier study of 75 women with benign breast disease found that D-alpha-tocopherol (150–600 IU/day) significantly decreased some symptoms of PMS compared with placebo; however, the study involved subjective patient evaluation, which may have influenced the findings (London et al 1983). Women who suffer from PMS do not statistically differ from other women in regard to biochemical deficiency. In a study of 62 women who presented with moderate to severe forms of PMS, cohorts were given either vitamin E 400 IU/day or placebo and both groups demonstrated significant benefits in physical and mental symptoms. Further observation and cross-over studies are obviously needed (Mandana et al 2013).

### Dysmenorrhoea

According to two randomised placebo-controlled studies, taking 200 IU vitamin E twice daily or 500 IU daily, starting 2 days before menstruation and continuing for the first 3 days of bleeding, seems to reduce menstrual pain severity and duration and to decrease blood loss in teenage girls with primary dysmenorrhoea (Ziaei et al 2001, 2005). Beneficial effects can be seen after 2 months and reach maximal effect after 4 months.

### Intermittent claudication

A Cochrane review of five placebo-controlled studies including a total of 265 volunteers (average age 57 years) concluded that, although further research is required to determine its effectiveness, vitamin E may have beneficial effects in intermittent claudication with no serious side effects (Kleijnen & Mackerras 2000). Treatment duration varied from 12 weeks to 18 months, and dosage regimens varied between the studies, which were considered generally small and of poor quality. A closer look at the evidence suggests that doses of at least 600 IU/day for a minimum of 12 weeks are required.

Since then a double-blind RCT testing vitamin E (400 IU/day) found no beneficial effects on

perceived pain or treadmill-walking duration in people with claudication (Collins et al 2003).

A small study of 16 patients with stable claudication revealed that administration of vitamin E (200 mg/day) and vitamin C (500 mg/day) for 4 weeks reduces oxidative stress in this population, and therefore may also have an effect on the remote ischaemia-reperfusion damage (Wijnen et al 2001). Although mentioned as a possible supplement in the treatment of intermittent claudication, no further trials have been conducted (Brass 2013).

### Cancer

Most of the epidemiological evidence suggests that vitamin E and other antioxidants decrease the incidence of certain cancers. Based on these observations, numerous prospective and intervention studies have been conducted in various populations. Very often, vitamin E is used in combination with other antioxidant nutrients, and sometimes the form of tocopherol administered is not stated, making it difficult to interpret study findings.

A review that systematically evaluated the scientific literature using guidelines developed by the US Preventative Services Task Force concluded that there is evidence to suggest that those individuals with higher serum vitamin E levels or who are receiving vitamin E supplementation have a decreased risk of some cancers, including lung, prostate, stomach and gastrointestinal carcinoma (Sung et al 2003). As can be expected, study design, differing treatment dose (nutritional levels or higher), form of vitamin used and population studied (general or high-risk) had an influence on outcomes. Since then, several new studies have been published that cast doubt on the cancer-protective effects of vitamin E for the general population. However, it seems likely that certain subpopulations (e.g. the poorly nourished) may benefit, and that lifestyle factors modify responses to supplementation (e.g. smoking). Research further suggests that differences in telomere length may be another factor affecting individuals' responses to vitamin E supplements (Shen et al 2009).

The role of vitamin E in cancer prevention remains controversial. The Cancer Institute of New Jersey states that gamma- and delta-tocopherols are preventive in prostate, lung, breast and colon cancer. Alpha-tocopherols had no effect. The Heart Outcomes Prevention Evaluation — The Ongoing Outcomes (HOPE-TOO) trial and the Women's Health Study found no significant reduction in risk with daily doses of 400–600 IU (Rizvi et al 2014).

### All cancers

A large study of nearly 30,000 subjects was carried out in Linxian, China. It tested four combinations of vitamins and minerals (retinol and zinc; riboflavin and niacin; vitamin C and molybdenum; and beta-carotene, vitamin E and selenium) over a 5-year period in a population with a persistently low intake

of several micronutrients (Blot et al 1995). Although no statistically significant effect on cancer incidence was achieved by any intervention, secondary analysis showed that the combination of selenium, beta-carotene and alpha-tocopherol was associated with a statistically significant lower total mortality rate, a 13% reduction (borderline significant) in total cancer mortality rate and a statistically significant lower mortality rate from stomach cancer (a major cancer in Linxian).

Results from the SUVIMAX study suggest that the protective effects of vitamin E may be gender-specific (Zureik et al 2004). In this trial, antioxidant supplementation (vitamin C 120 mg, vitamin E 30 mg, beta-carotene 6 mg, selenium 100 mcg and zinc 20 mg) was associated with a lower cancer incidence in men, but not in women. It is possible that men in the SUVIMAX trial benefited from supplementation due to their lower baseline levels of antioxidants.

More recently four large studies have found that vitamin E supplementation has no protective effect against cancer incidence. The Medical Research Council/British Heart Foundation study of 20,536 UK adults aged 40–80 years with coronary disease, other occlusive arterial disease or diabetes found that a daily antioxidant supplement containing 600 mg vitamin E, 250 mg vitamin C and 20 mg beta-carotene produced no significant reduction in the incidence of cancer or ACM (Parkinson Study Group 2002). The HOPE-TOO study, which used long-term natural vitamin E (400 IU/day) as a stand-alone supplement, failed to find a protective effect against cancer incidence or cancer deaths in people with pre-existing vascular disease or diabetes mellitus (Lonn et al 2005). Long-term use of natural vitamin E (600 IU) taken on alternate days provided no overall benefit for cancer incidence or total mortality in a large randomised study involving 39,876 healthy women of at least 45 years of age (Lee et al 2005).

Results from 7627 women free of cancer at baseline in the WACS found that long-term use (average 9.4 years) of vitamin C (500 mg/day), natural vitamin E (600 IU every other day) and beta-carotene (50 mg every other day) was not significantly associated with lowered incidence of total cancer or cancer mortality for any of the tested antioxidants (O'Donnell et al 2009).

When data were evaluated for effects on site-specific cancers, women receiving vitamin E supplements had a reduced risk (but not statistically significant) for colorectal cancer compared with the placebo group. This was largely due to a reduced risk of colon cancer. However, there was no statistically significant association of vitamin E supplementation with rectal or other cancers. Further subgroup analysis revealed that women in the vitamin E supplement group who currently smoked or had smoked in the past had lower rates of cancer death than those who never smoked. The *Cancer Prevention Research Journal* suggests that, at a

nutritional level, all forms of vitamin E are protective against cancer. However supplementation has not been proven to reduce cancer incidence and supplementation did not alter cancer progression or prevention (Chung 2012). However in the Selenium and vitamin E Cancer Prevention Trial (SELECT 2008 and 2011 update) for prevention of prostate cancer, statistical significance was reached with a 17% relative increase in prostate cancer compared to placebo, whereas the selenium alone or E and selenium supplementation were not statistically significant (National Cancer Institute (NIH) 2014).

### Urinary tract cancer

Analysis of data from the ATBC cancer prevention study, which tested synthetic vitamin E (50 mg/day) and beta-carotene (20 mg/day) in male Finnish smokers aged 50–69 years ( $n = 29,133$ ), found neither supplement affected the incidence of urothelial cancer or of renal cell cancer (Virtamo et al 2000). Jacobs et al (2002) assessed the US Cancer Prevention Study II, where vitamin C and E supplements were trialled, to determine reduced risk in bladder cancer. In the E group regular supplementation use  $\geq 10$  years demonstrated a reduced risk of bladder cancer mortality whereas shorter-duration supplementation did not prove beneficial. In a large epidemiological study plasma alpha-tocopherol and gamma-tocopherol with vitamin A were assessed. Researchers from Texas University suggest that gamma-tocopherol is not protective in isolation (Hernandez et al 2004). In the groups where plasma levels of all three nutrients were higher there was a reduction in the risk associated with bladder cancer, leading to the conclusion that there is a potentially protective effect in combination treatment (Liang et al 2008).

### Respiratory tract cancers

Smoking and alcohol consumption are the major risk factors for upper aerodigestive tract cancers, and observational studies indicate a protective role for fruits, vegetables and antioxidant nutrients (Wright et al 2007). Analysis of data from the ATBC cancer prevention study testing long-term supplementation with synthetic vitamin E (50 mg/day) and beta-carotene (20 mg/day) in male Finnish smokers aged 50–69 years ( $n = 29,133$ ) found no effect of either agent on the overall incidence of any upper aerodigestive tract cancer nor any effect on mortality from these neoplasms. In animal models oesophageal squamous cell carcinoma was visibly reduced by supplementation of selenium and vitamin E (80 IU/kg) in diet; this has yet to be proven in human trials (Yang et al 2012).

### Breast cancer

Mixed results have been obtained for vitamin E in the primary prevention of breast cancer, although a 2003 study has detected a modest protective effect against recurrence of breast cancer and disease-related mortality in postmenopausal women

previously diagnosed with the disease (Fleischauer et al 2003). Protective effects were established after 3 years' use, according to the study.

In a single study Chamras et al (2005) found a dose-responsive inhibition of cell proliferation in oestrogen receptor-positive cells. This trial is hopeful as the cell proliferation was reduced by 69–84%; vitamin E altered the expression of oestrogen receptor cells. This suggests that vitamin E may inhibit oestrogen receptor-positive cell growth and alter cellular response to oestrogen.

#### Ovarian cancer

Vitamin E supplements were protective against the incidence of ovarian cancer whereas consumption of antioxidants from diet was unrelated to risk according to another study (Fleischauer et al 2001). In analyses combining antioxidant intake from diet and supplements, vitamins C (>363 mg/day) and E (>75 mg/day) were associated with significant protective effects. In a human case-controlled study in Korean ovarian cancer patients, women with the highest tertile group for both alpha-tocopherol and gamma-tocopherol plasma levels presented >72% overall reduced risk compared to the lowest tertile group (Jeong et al 2009).

#### Colorectal cancer

Colorectal cancers are highly prevalent, with Australian levels reaching >12,000 diagnosed per year (ABS 2005). Studies investigating the association between vitamin E and incidence of colorectal cancer have produced inconsistent results. Prospective studies have shown that high serum levels of vitamin E are protective; however, only one of three intervention studies has produced positive results (Stone & Papas 1997). These results are difficult to interpret, as the studies have been criticised for not adequately distinguishing between cancer incidence and adenoma recurrence.

In the WACS ( $n = 7627$ ), women receiving natural vitamin E (600 IU every other day) had a reduced risk (but not statistically significant) of colorectal cancer compared with the placebo group. This was largely because of a reduced risk of colon cancer; however, there was no statistically significant association of vitamin E supplementation with rectal or other cancers (O'Donnell et al 2009). The ATBC study also detected a somewhat lower incidence of colorectal cancer in the alpha-tocopherol arm compared with the no alpha-tocopherol arm, but this was not statistically significant (Virtamo et al 2000).

The World Cancer Research Fund (2011) suggests that vitamin E does not present with significant evidence of reduced incidence or prevalence of colorectal cancer. In a recent systematic review, although there was a concession that observational studies suggest vitamin E may be protective, experimental studies have had inconsistent results. From four studies Arain and Qadeer (2010) state that vitamin E as a primary prevention of colorectal

cancer does not reduce incidence. In another review of dietary supplements where two trials regarding vitamin E were assessed, the conclusion remains steadfast (Posadzki et al 2013).

#### Prostate cancer

The ATBC cancer prevention study provided information about the incidence of prostate cancer with long-term use of synthetic alpha-tocopherol (50 mg), beta-carotene (20 mg), both agents or a placebo daily for 5–8 years (Albanes et al 2000). One of the most striking outcomes was a 32% decrease in the incidence of prostate cancer for volunteers receiving vitamin E ( $n = 14,564$ ) compared to those not receiving it ( $n = 14,569$ ) and a 41% reduction in mortality among men using vitamin E. Neither agent had any effect on the time interval between diagnosis and death (Heinonen et al 1998). The preventive effect of vitamin E on prostate cancer incidence was observed to be long-term according to later analysis of postintervention effects (Virtamo et al 2003).

One study has identified a decrease in serum androgen concentrations associated with long-term alpha-tocopherol supplementation, suggesting this may be one of the factors contributing to the observed reduction in incidence and mortality of prostate cancer (Hartman et al 2001). In contrast, SELECT (National Cancer Institute (NIH) 2014) determined that, in combination with selenium, there was an increased risk of prostate cancer with vitamin E. More specifically, there were 17% more prostate cancer cases diagnosed in the group of men assigned to take 400 IU of vitamin E (and no selenium) daily compared to the men taking two placebos (no vitamin E and no selenium), after an average of 7 years — 5.5 of the years on supplements followed by 1.5 years not taking supplements. Importantly, the vast majority of all of the cancers that were screened were very early-stage disease, and the rate of advanced or aggressive cancers in the vitamin E group was no higher than in the placebo group. Several theories have been proposed to explain the differences in results, such as a U-shaped response curve, where very low or very high blood levels of a nutrient are harmful but more moderate levels are beneficial. In other words, while the ATBC dose may have been preventive, the SELECT dose may have been too large to have a prevention benefit (<http://www.cancer.gov/newscenter/qa/2008/selectqa>).

#### Pancreatic cancer

Higher alpha-tocopherol concentrations may play a protective role in pancreatic carcinogenesis in male smokers, according to the ATBC cancer prevention study, which found that men with the highest serum tocopherol levels had a lower pancreatic cancer risk (highest compared with lowest quintile) (Stolzenberg-Solomon et al 2009). Polyunsaturated fat, a putative pro-oxidant nutrient, modified the association such that the inverse alpha-tocopherol association was

most pronounced in subjects with a high polyunsaturated fat intake. [Gong et al \(2010\)](#) suggest that a positive association was noted in high intakes of monounsaturated palmitoleic and oleic fatty acids and polyunsaturated linolenic acid with vitamin C. In the study of a large population-based case-control study in San Francisco, it was found that vitamin C and vitamin E together or alone may reduce the risk of pancreatic cancer.

### Adjunct with cisplatin

[Bove et al \(2001\)](#) made the observation that the neurotoxic presentation associated with cisplatin use was similar to that of vitamin E deficiency. They hypothesised that cumulative cisplatin use could induce vitamin E deficiency if patients' levels were not sufficiently high throughout treatment. To test the theory they started by measuring vitamin E in the plasma of five patients who developed severe neurotoxicity after cisplatin treatment and in another group of five patients before and after two or four cycles of cisplatin treatment. This produced preliminary data that supported the theory that inadequate vitamin E due to cisplatin treatment could be responsible for the peripheral nerve damage induced by free radicals ([Bove et al 2001](#)). Following this, four clinical trials were conducted where it was concluded that the incidence of chemotherapy-induced peripheral neuropathy was significantly reduced with vitamin E supplementation ([Wolf et al 2008](#)). Oral vitamin E (300 mg/day), taken before cisplatin treatment and continued for 3 months after cessation of treatment, significantly reduced the incidence and severity of neurotoxicity according to a randomised study ( $n = 47$ ), in which the incidence of neurotoxicity was significantly lower in the group receiving vitamin E (30.7%) compared to those receiving the placebo (85.7%;  $P < 0.01$ ) ([Pace et al 2003](#)). Shortly afterwards, [Argyriou et al \(2005\)](#) conducted a randomised study of 31 patients with cancer treated with six courses of cumulative cisplatin, paclitaxel or their combination regimens. Only 25% of patients randomly assigned to receive oral vitamin E (600 mg/day) during chemotherapy and for 3 months after its cessation developed neurotoxicity, compared to 73% in the control group. A year later, in another randomised study, 30 patients scheduled to receive six courses of cumulative cisplatin-based regimens were randomly allocated to receive either vitamin E (600 mg/day) during chemotherapy and for 3 months after its cessation or no adjunctive therapy (controls). This study again found a significantly reduced incidence of neurotoxicity with vitamin E (21.4%) compared to controls (68.5%) ( $P = 0.026$ ) ([Argyriou et al 2006](#)).

While no data were included on the long-term survival of the patients involved, studies undertaken have failed to show a detrimental effect from combining vitamin E with chemotherapy ([Ladas et al 2004](#), [Pace et al 2003](#)).

### Arthritis

High-dose vitamin E supplements may be effective in relieving pain in osteoarthritis (OA) and rheumatoid arthritis (RA), according to several double-blind studies, with some studies finding that the effects are as strong as with diclofenac. Vitamin E supplements have been studied in people with OA, RA, spondylitis ankylosis, spondylosis and psoriatic arthritis. Comparisons have been made to placebos and non-steroidal anti-inflammatory drugs (NSAIDs).

### Osteoarthritis

According to an early crossover study ([Machtey & Ouaknine 1978](#)), 52% of OA patients experienced less pain when treated with vitamin E (600 mg/day) compared to a placebo. Several years later, a double-blind randomised study of 50 volunteers with OA confirmed these findings and showed that vitamin E (400 IU/day) was significantly superior to a placebo in relieving pain, increasing mobility and reducing analgesic requirements ([Blankenhorn 1986](#)). Symptoms of pain at rest, during movement or with applied pressure all responded to treatment with vitamin E.

Vitamin E supplementation (500 IU/day) did not alter the loss of cartilage volume in knee OA according to a 2-year, double-blind, randomised, placebo-controlled study of 138 patients (American College of Rheumatology clinical and radiographic criteria) ([Wluka et al 2002](#)). Additionally, symptoms did not improve. Vitamin E also failed to alleviate symptoms in a shorter, 6-month double-blind study using the same dose ([Brand et al 2001](#)) and symptoms of pain, stiffness and function did not change at the 1-, 3- or 6-month assessments.

Research has continued in recent years, so that by 2007 a systematic review by [Canter et al \(2007\)](#) identified a total of seven RCTs that tested vitamin E in OA: four trials compared the treatment with a placebo, two tested against diclofenac and one against vitamin A. Of these, two placebo-controlled trials demonstrated the effectiveness of vitamin E for pain. One trial was considered methodologically weak, but the second was more robust and indicated greater effectiveness both for the whole patient sample and for a subgroup with OA of the knee and hip. [Hafalah et al's \(2009\)](#) findings suggest that a dose of 400 mg/day has a potential role in reducing the symptoms of OA of the knee and may be as effective as glucosamine. This is in contrast to two earlier studies that involved patients with OA of the knee and produced largely negative results. Two equivalence trials comparing vitamin E to diclofenac produced more positive outcomes and suggested similar effectiveness for the two treatments, with one study reporting a statistically significant superiority of vitamin E over diclofenac ([Canter et al 2007](#)). The authors of the review have claimed that variable methodological rigour does not yet allow a definitive conclusion to be made about the effectiveness of vitamin E in OA. Further

trials are needed; however it appears that the supplement of palm vitamin E is safe to use.

### Rheumatoid arthritis

According to several double-blind studies, a dose of 1200 mg/day vitamin E significantly reduces pain symptoms in people with RA, but not always morning stiffness.

A double-blind study of 42 RA patients who received vitamin E (600 mg twice a day) over 12 weeks showed that pain parameters were significantly decreased with active treatment compared to a placebo (Edmonds et al 1997). The same study also found no change in the Ritchie Articular Index, duration of morning stiffness, swollen joint count or laboratory parameters with vitamin E supplementation compared to a placebo. A further study using the same dose detected a significant inverse correlation between vitamin E levels and pain score, whereas morning stiffness and sedimentation rate were not affected (Scherak & Kolarz 1991).

Edmonds et al (1997) enrolled 42 patients with RA in a double-blind randomised study in which alpha-tocopherol (600 mg twice a day) was compared to a placebo for 12 weeks. While laboratory measures of inflammatory activity and oxidative modification were unchanged with active treatment, pain parameters were significantly decreased after vitamin E treatment when compared with the placebo, suggesting that vitamin E may exert a small but significant analgesic activity independently of a peripheral anti-inflammatory effect. More recently, a combination of standard treatment (intramuscular methotrexate, oral sulfasalazine and indomethacin suppository at night) and vitamin E (400 mg three times daily) was compared to standard treatment and a combination of antioxidants or to standard treatment alone (Helmy et al 2001). Standard treatment started to produce tangible improvements after 2 months, whereas additional treatment with either vitamin E or antioxidants improved symptoms more quickly (after 1 month). Karlson et al (2008) suggest in a primary prevention Women's Health Study of females >45 years (randomised, double-blind, controlled) that, while inflammatory laboratory measures were unchanged in the active treatment group, pain parameters demonstrated significantly decreased levels after vitamin E treatment at 600 IU on alternate days. Although no significant associations were found in the primary end point in the prevention of RA, there was a suggestion of an inverse association with vitamin E treatment and seropositive RA; however it did not reach statistical significance. As seropositive RA is the more severe phenotype, this deserves further study. The limitations of the study were numerous, as discussed by the authors; larger numbers are needed to detect the risk reductions in seropositive and negative RA and inflammatory polyarthritis, due to previous findings of other authors reporting 28–56% reduction in risk with vitamin E supplement use (Cerhan et al 2003). In a systematic review of natural alternatives to RA

treatment, McFarlane et al (2010) also suggest that vitamin E alleviates pain with no reported changes in laboratory measures of inflammation.

### Comparisons with pharmaceutical medication

After 3 weeks' treatment with either high-dose vitamin E (400 mg RRR- $\alpha$ -tocopherol acetate three times daily) or diclofenac sodium, a significant improvement in all assessed clinical parameters was observed in hospitalised patients with established chronic RA ( $n = 85$ ), according to a randomised, double-blind parallel-group trial (Wittenborg et al 1998). Duration of morning stiffness, grip strength and the degree of pain, assessed by a 10-cm visual analogue scale, reduced significantly with vitamin E as well as with diclofenac. Both treatments were considered to be equally effective by patients and doctors.

### Menopausal symptoms

According to a review published by the Mayo Clinic in the United States, behavioural changes in conjunction with vitamin E (800 IU/day) are a reasonable initial approach for menopausal women with mild symptoms that do not interfere with sleep or daily function (Shanafelt et al 2002). The recommendation is based on a double-blind, randomised, placebo-controlled, crossover clinical trial that found that vitamin E (800 IU/day) was more effective than a placebo in controlling hot flushes in breast cancer survivors. Benefits have been confirmed in another double-blind, placebo-controlled trial, which found that treatment with 400 IU vitamin E daily significantly reduced hot flush severity and daily frequency as reported by participants (Ziaei et al 2007).

### Male infertility

Lipid-soluble antioxidants such as vitamin E have been studied for their effects in male reproductive physiology because the membranes of germ cells and spermatozoa are very sensitive to oxidation (Bhardwaj et al 2000, Bolle et al 2002).

According to three of four studies, oral vitamin E supplementation can effectively treat some forms of male infertility (Geva et al 1996, Kessopoulou et al 1995, Rolf et al 1999, Suleiman et al 1996). Doses varied from 200 to 800 mg/day.

Kessopoulou et al (1995) compared vitamin E (600 mg/day) to a placebo over 3 months in 30 healthy men with high levels of reactive oxygen species generation in semen and a normal female partner. The randomised, crossover study found that active treatment improved zona binding, thereby showing that vitamin E significantly improved the in vitro function of human spermatozoa. Geva et al (1996) studied men enrolled in an in vitro fertilisation program who previously had had low fertilisation rates, and treated them with oral vitamin E (200 mg/day) for 3 months. After the first month, fertilisation rates increased significantly, from 19% to 29%. The same year, Suleiman et al (1996)

treated asthenospermic patients with oral vitamin E, which significantly decreased the malondialdehyde concentration in spermatozoa and improved sperm motility. Of the 52 treated males, 11 (21%) impregnated their spouses; nine of the spouses successfully continued to have normal-term deliveries, whereas two aborted in the first trimester. No pregnancies were reported in the spouses of the placebo-treated patients.

The negative study used high-dose oral vitamin C (1000 mg/day), and vitamin E (800 mg/day) was tested over 56 days in 31 men with asthenozoospermia (<50% motile spermatozoa) and normal or only moderately reduced sperm concentration ( $>7 \times 10^6$  spermatozoa/mL) (Rolf et al 1999). Most recent studies combine vitamin E (400 IU/day) with selenium (and/or vitamin C) and are positively correlated with increased fertility and oligoasthenozoospermia syndrome; however it is not known whether vitamin E alone would have been just as effective (Kobori et al 2014, Moslemi & Tavanbakhsh 2011).

### Dermatological conditions

Vitamin E is used both as an oral supplement and as a topical preparation in a variety of dermatological conditions. It is a popular ingredient in many moisturising preparations used to: alleviate dry and cracked skin; assist in the repair of abrasions, burns, grazes and skin lesions; prevent stretch marks; and diminish scar tissue. Vitamin E oil is used as a stand-alone preparation or incorporated into a cream or ointment base for these purposes.

### Sunburn protection

Topical application of 1% alpha-tocopherol provided significant protection against erythema and sunburn in an experimental model. When combined with 15% ascorbic acid, the protective effect was enhanced (Lin et al 2003). Further improvements were seen when ferulic acid was added to the alpha-tocopherol (1%) and ascorbic acid (15%) solution, as this substance improves chemical stability of the antioxidants and doubles the photoprotective effect (Lin et al 2005).

Once again, it appears that not all forms of vitamin E exert a significant protective effect (McVean & Liebler 1999). According to an *in vivo* study, a 5% dispersion of alpha-tocopherol, gamma-tocopherol or delta-tocopherol in a neutral cream vehicle produced a statistically significant inhibition of thymine dimer formation, whereas alpha-tocopherol acetate and alpha-tocopherol methyl ether had no effect. Further research revealed that gamma-tocopherol and delta-tocopherol were five- to 10-fold less potent than alpha-tocopherol (McVean & Liebler 1997).

A comparison between topical vitamins E and C has demonstrated that vitamin E affords better protection against ultraviolet B radiation, whereas vitamin C is superior against ultraviolet A radiation (Baumann & Spencer 1999).

Although most research has focused on topical use, oral administration of a combination of high-dose vitamins E and C increases the threshold to erythema. The first study to show that the systemic administration of vitamins E and C reduces the sunburn reaction in humans was a small, double-blind, placebo-controlled trial that used ascorbic acid (2 g/day) combined with D-alpha-tocopherol (1000 IU/day) (Eberlein-Konig et al 1998). The effect was seen after 8 days. The next to show reduction of the sunburn reaction was a 50-day study of 40 volunteers (20–47 years old), which showed that supplemental vitamin E (2 g/day) and C (3 g/day) protected against sunburn and resulted in increased vitamin E levels in keratinocytes (Fuchs & Kern 1998). This was once again confirmed in a controlled study of 45 healthy volunteers (Mireles-Rocha et al 2002). The doses used were lower in this study: 1200 IU/day of D-alpha-tocopherol in combination with vitamin C (2 g/day).

### Scar tissue

Although vitamin E is widely used to diminish the appearance of scars, a small double-blind study of 15 patients who had undergone skin cancer removal found that applying an emollient preparation known as Aquaphor with added vitamin E after surgery either had no effect or worsened the appearance of scars compared to Aquaphor alone (Baumann & Spencer 1999). A larger study of 80 people with hypertrophic scars and keloids found that treatment with vitamin E and silicone gel sheets was successful in scar treatment (Palmieri et al 1995). After 2 months, 95% of patients receiving vitamin E and gel sheet treatment had improved by 50%, whereas 75% had improved by 50% without vitamin E.

### Type 1 diabetes

Although the Heart Outcomes Prevention Evaluation (HOPE) study involving 3654 people with diabetes failed to detect a preventive effect for long-term vitamin E (400 IU/day) on CVD outcomes or nephropathy (Jain et al 1996, Lonn et al 2002), it is known that both types of diabetes demonstrate increased free radicals. It could be rationalised that the antioxidant effect on lipid peroxidation would be of some use; however metabolic parameters do not appear to improve in type 1 patients after vitamin E supplementation. There are limited trials and cohorts are relatively small (Gupta et al 2011).

### Type 2 diabetes

In type 2 diabetes there is a similar increased production of free radicals as displayed in type 1 diabetes. Plasma measures of vitamin E are found to be lower in a small group of 52, with 36.2% diabetics with low alpha-tocopherol <12 micromol/L, 32.7% with a low alpha-tocopherol. Larger epidemiological and longitudinal studies are needed to confirm the use of vitamin E supplementation in this group (Illison et al 2011).

### Chronic hepatitis C

According to a 2004 systematic review, significant improvements in biochemical responses were seen for vitamin E compared to a placebo (Coon & Ernst 2004). The authors report on one placebo-controlled trial in which a statistically significant reduction in liver enzyme (alanine aminotransferase [ALT]) was observed during vitamin E treatment but reductions were not consistent for all patients and complete normalisation of ALT levels did not occur. In the Middle East, where hepatitis C genotype is prevalent, ribavirin when used with pegylated interferon induces anaemia. Supplemental vitamin E 1000 IU/day demonstrated a protective impact on neutrophils and platelet counts, ameliorating the effect of haemolysis associated with ribavirin administration (Assem 2011).

### Asthma and atopy

Studies have consistently demonstrated beneficial associations between dietary vitamin E and ventilatory function, and a few have demonstrated beneficial associations with asthma and atopy (Devereux & Seaton 2005). However, benefits do not extend to vitamin E supplements, as a randomised study ( $n = 72$ ) using natural vitamin E (500 mg/day) over 6 weeks found no clinical benefit in subjects with mild to moderate asthma (Pearson et al 2004).

### Age-related macular degeneration (AMD)

According to a review of RCTs comparing antioxidant vitamin and/or mineral supplement to controls, there is no evidence that antioxidant (vitamin E or beta-carotene) supplementation prevents AMD. However, there is evidence that supplementation with antioxidants (beta-carotene 15 mg, vitamin C 500 mg and vitamin E 400 IU) and zinc (elemental 80 mg) daily slows down the progression to advanced AMD and visual acuity loss in people with signs of the disease (Evans 2008). People with AMD, or early signs of the disease, may experience some benefit from taking supplements as used in the Age-Related Eye Disease Study (AREDS) (Sackett & Schenning 2002). Christen et al (2012) conducted an 8-year trial in well-nourished doctors of 400 IU every other day and vitamin C 500 mg/day. There appeared to be no beneficial or harmful effect on the risk of incidence of AMD. The dose for vitamin E was much lower than in the AREDS, at 400 IU/daily. Although this represents the largest study of its kind, it is not unreasonable to conclude that the dose was not high enough to exert effect and that the men were already nutritionally replete and perhaps at less risk.

### Neurogenerative disease

Vitamin E supplementation may slow the rate of motor decline early in the course of Huntington's disease, according to a randomised, double-blind, placebo-controlled study of high-dose D-alpha-tocopherol treatment (Peysers et al 1995). The study of 73 patients with Huntington's disease found that treatment with D-alpha-tocopherol had no effect on

neurological and neuropsychiatric symptoms in the treatment group overall; however, post hoc analysis revealed a significant selective therapeutic effect on neurological symptoms for patients early in the course of the disorder.

It now seems that the role of vitamin E has been established as essential for neurological function. In a recent review vitamin E was validated in the treatment of disorders of the central nervous system, specifically the use of vitamin E in the prevention or cure of Huntington's disease, tardive dyskinesia, amyotrophic lateral sclerosis (motor neuron disease [MND]), PD and AD (the last discussed earlier). Many trials for the use of vitamin E in the nervous system have been too small or the dose of vitamin E has been too low. Imounan et al (2012) suggest that in many neuropathic disorders vitamin E is revealing an important role.

### OTHER USES

Oral supplements have been used to prevent or treat many other conditions, such as exercise-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia.

Vitamin E prophylaxis in premature babies significantly reduces the risk of stage 3+ retinopathy by 52%, according to a 1997 meta-analysis of six randomised studies (Raju et al 1997).

Infusions of vitamin E are being investigated as a means of preventing ischaemic reperfusion injury in liver and heart surgery (Bartels et al 2004, Jaxa-Chamiec et al 2005).

### DOSAGE RANGE

The body's requirement for vitamin E changes according to the amount and type of fat eaten in the diet. For example, vitamin E requirements increase when there is a high intake of PUFAs (Wahlqvist 2002).

Many scientists believe it is difficult for an individual to consume more than 15 mg/day of alpha-tocopherol from food alone, without also increasing fat intake above recommended levels.

### Recommendations for adults (Australian adequate intake)

Adequate intake is used when there is insufficient scientific evidence derived from approximations of intakes in groups or a group of possibly healthy people (NHMRC 2014). It is at best a guide, not a therapeutic dose, and will not suffice where frank deficiency is observed.

- Men > 18 years: 10 mg/day alpha-tocopherol.
- Women > 18 years: 7 mg/day alpha-tocopherol.
- Upper level of intake: 300 mg/day alpha-tocopherol.
- Deficiency treatment: 800–1200 mg/day.

### According to clinical studies

Both natural and synthetic forms of vitamin E have been evaluated in clinical trials at different doses and durations, and sometimes in combination with other nutrients that also exhibit antioxidant properties.

Unless stated, dosages are for natural vitamin E (alpha-tocopherol).

- Alzheimer's disease: 2000 IU/day synthetic alpha-tocopherol.
- Anaemia in HD: 500 mg/day.
- Angina pectoris: 50–300 mg/day.
- Antioxidant effects: 400 IU/day.
- Cancer, to reduce cisplatin-induced neurotoxicity: oral vitamin E (600 mg/day) during chemotherapy and for 3 months after its cessation.
- Cerebral infarction prevention: 50 mg/day synthetic vitamin E.
- Colorectal cancer prevention: 50 mg/day long-term.
- CVD: primary prevention: 100–260 IU/day long-term (benefits uncertain with supplementation).
- CVD: secondary prevention: 100–800 IU/day long-term (benefits most likely in people with low baseline vitamin E and higher oxidative stress, e.g. people on haemodialysis and diabetics).
- Carotid atherosclerosis, slowing progression: 136 IU twice daily and vitamin C 250 mg (slow-release) twice daily.
- Dementia prevention: 400 IU/day alpha-tocopherol plus vitamin C 500 mg/day.
- HD, associated cramps: 400 mg/day alpha-tocopherol plus vitamin C 250 mg/day.
- Hypertension: 200 IU/day long-term.
- Immune system support in the elderly: 200 mg/day.
- Intermittent claudication: 600–1600 IU/day.
- Ischaemic stroke prevention in high-risk hypertension: 50 mg/day.
- Male infertility: 200–800 mg/day.
- Menopausal symptoms: 800 IU/day.
- Nitrate tolerance prevention: 200 mg three times daily.
- OA: 1200 IU/day.
- Ovarian cancer: >75 mg/day.
- Premenstrual symptoms: 400–600 IU/day.
- Prostate cancer prevention: 50 mg/day (200 mg detrimental).
- Retinopathy of prematurity: 100 mg/kg/day.
- RA: 1200 IU/day.
- Sunburn protection: 1000 IU/day up to 2000 mg/day plus vitamin C 2000–3000 mg/day.

## TOXICITY

Vitamin E is relatively non-toxic. It is not stored as readily in the body as other fat-soluble vitamins and up to 60–70% of a daily dose is excreted in the faeces. Doses as high as 3200 mg/day have been used for 12 years with few adverse effects (Fariss & Zhang 2003).

In April 2000, the Food and Nutrition Board of the *Institute of Medicine* in the United States set an upper tolerable limit of 1500 IU of RRR-alpha-tocopherol as the highest dose unlikely to result in haemorrhage in most adults.

## ADVERSE REACTIONS

Adverse effects are dose-related and tend to occur only at very high supplemental doses (>1200 IU/

day); they include diarrhoea, flatulence, nausea and heart palpitations. Doses above this level should be used only under professional supervision.

## SIGNIFICANT INTERACTIONS

Considering vitamin E is a fat-soluble vitamin, any medication that reduces the absorption of fats in the diet will also reduce the absorption of vitamin E. These include cholestyramine, colestipol, isoniazid, mineral oil, orlistat and sucralfate.

### Oral contraceptive pill

A very small cross-sectional study suggests the oral contraceptive pill significantly lowered coenzyme Q10, and alpha-tocopherol levels. Further studies are needed (Palan et al 2006).

### HMG-CoA reductase inhibitors (statins)

The effect of statins on lowering blood lipid levels of vitamin E has been suggested as a risk factor in the development of statin-associated myopathy. Further studies are warranted (Galli et al 2010).

### Chloroquine

According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts. The clinical significance of this observation is unknown. Observe patients taking this combination (Scuntaro et al 1996).

### Chlorpromazine

According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts. The clinical significance of this observation is unknown — observe patients taking this combination (Scuntaro et al 1996).

### Cisplatin

A review of four clinical trials testing the effects of the combination of vitamin E with cisplatin has shown that in all trials the incidence of chemotherapy-induced peripheral neuropathy was significantly reduced (Wolf et al 2008). Beneficial interaction, but should be used under professional supervision.

### Warfarin

Contradictory results have been obtained in clinical studies that have investigated whether vitamin E affects platelet aggregation or coagulation. A dose of 1200 IU/day (800 mg of D-alpha-tocopherol) taken for 28 days had no effect on platelet aggregation or coagulation according to one clinical study (Morinobu et al 2002). Similarly, a second clinical study found that a lower dose of 600 mg (900 IU) of RRR-alpha-tocopherol taken daily for 12 weeks did not alter coagulation activity (Kitagawa & Mino 1989). In contrast, increased risk of gingival bleeding at doses of 50 mg/day was found by another study (Liede et al 1998).

Overall, it appears that people with reduced levels of vitamin K may be more susceptible to the effects of vitamin E, potentiating warfarin activity.

**Practice points/Patient counselling**

- Vitamin E is actually a generic term used to describe any chemical entity that displays the biological activity of RRR- $\alpha$ -tocopherol, the most abundant form found in nature. The 'natural' form is the most potent of all eight forms of vitamin E, although there is evidence that other tocopherols also exhibit significant beneficial effects.
- It is involved in myriad biochemical processes such as immunocompetence and neurological function, but its most important biological function is that of an antioxidant.
- Vitamin E is used for many different indications. There is evidence to suggest that supplementation may be useful in:
  - secondary CVD prevention, although effects are inconsistent
  - slowing down progression of AD, although effects are inconsistent
  - enhancing immune function in the elderly\* preventing anaemia and treating cramps in patients on HD
  - reducing PMS, dysmenorrhoea and menopause symptoms
  - reducing pain in OA and RA
  - improving some forms of male infertility
  - reducing risk of stage 3+ retinopathy in premature babies
  - preventing ischaemic stroke in high-risk hypertensive patients
  - reducing incidence of some cancers, although effects are inconsistent
  - preventing sunburn (when used with vitamin C)
  - slowing down carotid atherosclerosis (when used with vitamin C)
  - reducing blood pressure
  - reducing nitrate tolerance
  - reducing cisplatin-induced neurotoxicity.
- Oral supplements have been used to prevent or treat many other conditions, such as exercise-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia.
- It is a popular ingredient in many moisturising preparations used to: alleviate dry and cracked skin; assist in the repair of abrasions, burns, grazes and skin lesions; prevent stretch marks; and diminish scar tissue. Vitamin E oil is used as a stand-alone preparation or incorporated into a cream or ointment base for these purposes.
- People with impaired coagulation, inherited bleeding disorders, a history of haemorrhagic stroke or vitamin K deficiency, or who are at risk of pulmonary embolism or thrombophlebitis should use high-dose supplements under medical supervision.

Until further research can clarify whether the interaction is clinically significant for most people, it is recommended that prothrombin time ratio, or international normalised ratio, should be closely monitored upon the addition and withdrawal of treatment with high-dose vitamin E supplements.

**Doxorubicin**

One study found that oral DL- $\alpha$ -tocopherol acetate (1600 IU/day) prevented doxorubicin-induced alopecia (Wood 1985). The same dose of oral DL- $\alpha$ -tocopherol acetate failed to prevent alopecia after doxorubicin treatment following mastectomy for breast cancer (Martin-Jimenez et al 1986). It also failed to prevent alopecia in a second study of 20 patients with different types of solid tumours (Perez et al 1986). Possible beneficial interaction but difficult to assess.

**Nitrates**

Oral vitamin E prevented nitrate tolerance when given concurrently with transdermal nitroglycerin (10 mg/24 hours), according to one randomised placebo-controlled study (Watanabe et al 1997). Beneficial interaction possible.

**NSAIDs and simple analgesics**

Vitamin E may enhance the pain-modifying activity of drugs. Beneficial interaction possible; drug dosage may require modification.

**Propranolol**

According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts. The clinical significance of this observation is unknown. Observe patients taking this combination (Scuntaro et al 1996).

**? CONTRAINDICATIONS AND PRECAUTIONS**

Vitamin E is considered to be a safe substance.

People with impaired coagulation, inherited bleeding disorders, a history of haemorrhagic stroke, vitamin K deficiency or at risk of pulmonary embolism or thrombophlebitis should use high-dose supplements under medical supervision.

Although it was thought that people with hypertension wanting to take supplements should start with low doses, evidence does not support the concern that high-dose supplements will significantly elevate blood pressure. Suspend use of high doses (>1000 IU/day) 1 week before major surgery.

**PREGNANCY USE**

Vitamin E is considered to be safe in pregnancy.

## ! PATIENTS' FAQs

### What will this vitamin do for me?

Vitamin E is essential for health and wellbeing. It is involved in many important biological processes in the body and may prevent serious diseases such as heart disease and some cancers; however, people with these conditions should seek professional advice. It is also used to reduce symptoms in common conditions such as arthritis, PMS and menopause. Vitamin E supplements enhance immune function in the elderly and may slow the progression of AD. Oral supplements have been used to prevent or treat many other conditions, such as exercise-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia.

### When will it start to work?

This depends largely on the reason for taking the supplement. In the case of disease prevention, studies suggest that long-term use is necessary (i.e. 2–3 years or longer). When using vitamin E to reduce symptoms, effects have generally been seen within 3 months.

### Are there any safety issues?

People with impaired coagulation, inherited bleeding disorders, a history of haemorrhagic stroke or vitamin K deficiency, or who are at risk of pulmonary embolism or thrombophlebitis should use high-dose supplements under medical supervision. Additionally, vitamin E can interact with some medicines, so professional advice is recommended when using high-dose supplements.

# Wild yam

**HISTORICAL NOTE** Wild yams have made a significant contribution as a root crop to tribal people in some parts of the world, such as Nepal. They are usually consumed boiled, steamed, baked or fried. Many different forms and cultivars of the wild edible yam species are available in different areas, and it is likely that these differ in composition and nutritional values. Traditionally, wild yams have also been used as medicine and are believed to exert antispasmodic, anti-inflammatory and autonomic nervous system-relaxant effects. Wild yam is a source of diosgenin, the raw material originally used to produce progesterone in the laboratory.

## COMMON NAME

Wild yam

## OTHER NAMES

Atlantic yam, barbasco, China root, colic root, devil's bones, Mexican yam, natural DHEA, rheumatism root, wild Mexican yam, yuma

## BOTANICAL NAME/FAMILY

*Dioscorea composita*, *D. floribunda*, *D. mexicana*, *D. macrostachya*, *D. villosa* (family Dioscoreaceae [yams])

## PLANT PART USED

Root and rhizome

## CHEMICAL COMPONENTS

The root of the wild yam contains diosgenin, dioscin, dioscorin and a range of vitamins and minerals such as vitamin C, beta-carotene, vitamins B<sub>1</sub>, B<sub>2</sub> and B<sub>3</sub>, iron, magnesium, potassium, selenium and zinc (USDA 2003), along with polyphenols (Bhandari & Kawabata 2004). Although diosgenin can be converted to dihydroepiandrosterone (DHEA) and other steroid compounds in the laboratory, and has been used for commercial production of these compounds, this conversion does not occur in the human body. Additionally, wild yam does not contain progesterone or any other active steroid hormones.

## MAIN ACTIONS

### Hormonal actions

The evidence of a hormonal action with wild yam varies. Wild yam extract may enhance oestradiol binding to oestrogen receptors and induce transcription activity in oestrogen-responsive cells (Park et al 2009), and diosgenin has been observed to have an oestrogenic action on mouse mammary epithelium (Aradhana Rao & Kale 1992). In contrast, in an oestrogen competition assay using human breast cancer cell, diosgenin was found to cause an acute, endothelium-independent coronary artery relaxation, but did not interact with oestrogen or progesterone receptors (Au et al 2004), and extracts with an upper limit of 3.5% diosgenin have been found to have no oestrogenic activity (Hooker 2004).

One study looking at steroid hormone-regulated gene expression using an in vitro tissue culture indicator system suggests that wild yam extract does not have significant oestrogenic or progesterone activity, but rather weak antioestrogenic and/or antiandrogenic activities (Rosenberg Zand et al 2001). A further study suggests that wild yam extract suppresses progesterone synthesis without direct effects on oestrogen or progesterone receptors (Zava et al 1998). In an in vivo study, supplementation with diosgenin protected the kidney from morphological changes associated with ovariectomy (Tucci & Benghuzzi 2003) and produced a significant decrease in the cortical and medullary adrenal areas of ovariectomised rats (Benghuzzi et al 2003).

There is in vitro evidence that diosgenin upregulates vascular endothelial growth factor A and promotes angiogenesis in pre-osteoblast-like cells via pathways involving oestrogen receptors (Men et al 2005).

### Cholagogue

There appears to be more consistent evidence for wild yam's effect on bile flow. Diosgenin has been shown to increase biliary secretion of cholesterol (Accatino et al 1998, Yamada et al 1997) and prevent oestrogen-induced bile flow suppression in rats (Accatino et al 1998), as well as increase elimination of indomethacin and reduce indomethacin-induced intestinal inflammation (Yamada et al 1997).

## OTHER ACTIONS

Traditionally, wild yam is also believed to exert antispasmodic, anti-inflammatory and autonomic nervous system-relaxant effects (Fisher & Painter 1996). Wild yam exhibits significant antioxidant activity (Bhandari & Kawabata 2004). Wild yam has also demonstrated potential cytotoxic action against certain cancer cell lines in animal and in vitro models (Saekoo et al 2010, Tong et al 2012).

## CLINICAL USE

The therapeutic effectiveness of wild yam has not been significantly investigated under clinical trial conditions, so evidence is derived from traditional, in vitro and animal studies.

**Clinical note — The major influence of wild yam on modern medicine**

The Mexican wild yam has had a major influence on drug development and modern medical practice, although few people are familiar with the story and misunderstandings abound.

In the late 1930s scientists entering the field of sex endocrinology were confronted with the sober reality that they were dealing with research materials (animal glands) that needed to be sourced from slaughterhouses and were not readily available in sufficient quantities (Soto Laveaga 2005). Eventually, female urine was identified as a better source of hormones and provided an alternative. As pharmaceutical companies embarked upon large-scale hormone production, it became apparent that a cheaper and more abundant source of raw materials would need to be found; hence, a search through the plant kingdom ensued.

The American chemist Russell Marker identified that saponins in plants could be chemically modified to produce steroids and that sex hormones could be synthesised using yams (Soto Laveaga 2005). For several years he tried unsuccessfully to direct pharmaceutical companies to use Mexico as a source of wild yams, but the general perception was that Mexico was too politically unstable and unsophisticated. Over time, changes in the infrastructure of the Mexican countryside coincided with further chemical discoveries, and wild yam root picking became a financial panacea to previously unemployed peasants in yam-rich areas. By the 1950s, scientists at the pharmaceutical company Upjohn had found a way to convert diosgenin to progesterone, then to hydrocortisone and finally cortisone, thereby reinforcing the importance of wild yam as a source of raw materials for steroid drugs. Considering the importance of these events, it could be said that wild yams revolutionised the world of modern medicine.

At one stage Mexican wild yams provided up to 90% of the world's raw material for steroid drug synthesis, but this has steadily fallen owing to the rapid increase in demand for larger quantities and Mexico's reduced ability to produce wild yam tubers (Soto Laveaga 2005).

**Menopausal symptoms and other female reproductive conditions**

Although wild yam has been a popular treatment for menopausal symptoms, there is scarce clinical research supporting its use for these indications.

Wild yam has been used as a 'natural alternative' to oestrogen replacement therapy, to treat postmenopausal vaginal dryness, premenstrual syndrome and osteoporosis, and to increase energy and libido in men and women, as well as for breast

enlargement. The use of wild yam as a natural progesterone appears misguided, because diosgenin is not converted to progesterone, DHEA or other steroid hormones in vivo. One small, double-blind, placebo-controlled crossover trial of topical wild yam extract showed no effect on menopausal symptoms (Komesaroff et al 2001). The study involved 23 healthy women suffering menopausal symptoms. Each woman was randomly assigned the active cream or matching placebo for 3 months, after which no significant changes to symptoms or physical health measurements were recorded.

It is possible that other yams have beneficial effects in treating menopausal symptoms. For example, a double-blind, placebo-controlled trial found that regular oral ingestion of purple yam (*Dioscorea alata*) significantly improved menopausal symptoms (Hsu et al 2011). The study involved 50 otherwise healthy symptomatic menopausal women, randomised to receive either 12 mg dried yam extract or placebo for a period of 12 months. The women were followed up at 1, 6 and 12 months; with improvement noted from 6 months and best results at 12 months. Significant improvements were noticed for symptoms of anxiety, insomnia, 'excitability' and musculoskeletal pain.

**OTHER USES**

Wild yam has been used traditionally as an antispasmodic for treating diverticulosis, gallbladder colic, painful menstruation, cramp, nausea in pregnancy and rheumatoid arthritis, and for increasing energy (Fisher & Painter 1996). It may also be useful when combined with other herbs for irritable bowel syndrome (Abascal & Yarnell 2005).

**DOSAGE RANGE**

- Decoction of dried root: 2–4 g three times daily.
- Tincture (1:5): 2–10 mL three times daily.
- Liquid extract (1:2): 3–6 mL/day.

**TOXICITY**

Considering that wild yams are widely consumed as food by several tribal groups, it appears that dietary ingestion is non-toxic. After assessment with short-term toxicity tests, dermal irritation tests, a sensitisation test, an ocular irritation test, a rat uterotrophic assay and genotoxicity tests, wild yam was deemed safe for use in cosmetic products (Hooker 2004). An in vivo study demonstrated that high doses of wild yam (0.79 g/kg/day) induced significant increases in kidney, and to a lesser extent liver, fibrotic markers (Wojcikowski et al 2008). While serological markers did not indicate decreased organ function, the researchers concluded that long-term use of wild yam would not be advisable in patients with compromised kidney function, or when taking nephrotic agents.

**ADVERSE REACTIONS**

In large doses, wild yam may cause nausea, vomiting and diarrhoea.

## SIGNIFICANT INTERACTIONS

Insufficient reliable data are available to determine whether interactions may occur.

### ❓ CONTRAINDICATIONS AND PRECAUTIONS

None known.

### 👤 PREGNANCY USE

Likely to be safe when consumed in dietary amounts; however, safety is not known when used in larger quantities.

## ! PATIENTS' FAQs

### What will this herb do for me?

Although wild yam has been used medicinally to treat menopausal symptoms, there is scientific evidence showing it is ineffective.

### When will it start to work?

This cannot be answered based on scientific evidence.

### Are there any safety issues?

Given that it is consumed as food, usual dietary intakes may be considered safe.

### Practice points/Patient counselling

- Wild yam is a popular root vegetable in some parts of the world.
- It was a popular ingredient in commercial herbal formulas for menopausal women; however, scientific research has since found it does not improve menopausal symptoms.
- Wild yam has been touted as having progestational and/or oestrogenic activity, but current evidence suggests this is unlikely.
- There is no clinical or scientific evidence to support the use of wild yam in the treatment of conditions of the female reproductive system.
- Wild yam root may be useful as an antispasmodic. Its use as a source of naturally occurring sex hormones appears misguided.

# Willow bark

W

**HISTORICAL NOTE** This herb has been used as a therapeutic agent since ancient times, with some reports of its use around 500 BC in ancient China as a treatment for pain and fever, and around 400 BC by Hippocrates, who recommended the bark be chewed for relief of fever and pain (Hedner & Everts 1998). Willow bark was also used traditionally as an anti-inflammatory agent (Drummond et al 2013). As centuries passed, herbalists continued to prescribe the bark for many conditions, and by the 18th century it was widely used as an antipyretic and analgesic (Hedner & Everts 1998). In a report published in 1763 (Stone 1763), willow bark (dried, pulverised and dispersed in

tea or water) was given to 50 patients. At a dose of 1 dram (1.8 g), it cured their fever. During the late 1820s, French and German scientists extracted the glycosidic constituents, including salicin (Hedner & Everts 1998). The oxidation of salicin yields salicylic acid, which was produced in the mid-1800s but had limited clinical use due to the gastric irritation it caused. In 1853 a French chemist neutralised salicylic acid to create acetylsalicylic acid, but had no interest in marketing it and abandoned his discovery. A Bayer chemist called Hoffmann rediscovered acetylsalicylic acid in 1897 as a better-tolerated treatment for his father's rheumatoid arthritis and within 2 years it was marketed by Bayer under the trade name of Aspirin (Setty & Sigal 2005). Since then it has become one of the most successful medicines in history. The health benefits may be due to the polyphenol constituents in willow bark. Polyphenols are known for their antioxidative and anti-inflammatory characteristics (Drummond et al 2013). Although many believe aspirin was synthesised from the salicin found in willow bark, it was actually from the salicin found in another herb, meadowsweet, that aspirin was developed.

## OTHER NAMES

White willow bark, brittle willow, bay willow, crack willow, purple willow, silberweide, violet willow

While white willow (*Salix alba*) is the willow species most commonly used for medicinal purposes, crack willow (*S. fragilis*), purple willow (*S. purpurea*) and violet willow (*S. daphnoides*) are all salicin-rich and are sometimes sold under the label of willow bark (Setty & Sigal 2005).

## BOTANICAL NAME/FAMILY

*Salix alba* (family Salicaceae)

## PLANT PART USED

Bark

## CHEMICAL COMPONENTS

The ethyl acetate fraction contains a high amount of polyphenols, whereas the ethanol fraction contains a high amount of salicin and salicin derivatives while having a comparatively low polyphenol content (Ulrich-Merzenich et al 2012), phenolic glycosides (mainly salicylates including salicin and its derivatives), tannins (mainly catechin, tannins, some gallotannins and condensed tannins [procyanidins]), lignans and flavonoids.

With polyphenols (e.g. proanthocyanidins) and flavonoids identified as fractions contributing to the efficacy of willow bark, future research should be directed towards the identification of the constituents or combination of constituents mainly responsible for the observed effects of willow bark (Nahrstedt et al 2007).

Two pharmacokinetic studies have been conducted and confirm that maximal serum levels of salicylic acid are reached within 2 hours of oral administration (Schmid et al 2001b). In one study, testing an oral willow bark extract containing 240 mg salicin, salicylic acid was the major metabolite of salicin detected in the serum (86% of total salicylates), as well as salicylic acid (10%) and gentisic acid (4%). In a second study testing a dose of willow bark extract (equivalent to 240 mg of total salicin), serum levels of catechol and salicylic acid were measured via high-performance liquid chromatography analysis with a peak concentration of 13.3 microM (1.5 mg/L) for catechol at 1.2 hours and no catechol after 24 hours. Maximum salicylic

acid concentrations of 24.5 microM (3.4 mg/L) were reached at 2.7 hours (Knuth et al 2013).

## MAIN ACTIONS

### Anti-inflammatory and analgesic effects

Clinical studies using willow bark preparations standardised to salicin content have shown anti-inflammatory and analgesic activity (Chrubasik et al 2000, 2001a, 2001b, Mills et al 1996, Schmid et al 2000). In vitro studies have demonstrated that *Salix* extract inhibits cyclooxygenase-2 (COX-2)-mediated prostaglandin E<sub>2</sub> release and that it is a weak inhibitor of proinflammatory cytokines (Fiebich & Chrubasik 2004). While salicin is considered the main analgesic constituent, it is now thought that other constituents, such as tannins, flavonoids and salicin esters, may contribute to its overall effect (Schmid et al 2001a). In addition, the flavonoids and polyphenols contribute to the potent willow bark analgesic and anti-inflammatory effect (Vlachoianis et al 2011).

The effect of a standardised willow bark extract (STW 33-I), containing 23–26% salicin and a high polyphenol content, and its fractions A–E was investigated in a rat model. Two dosage levels of STW 33-I were compared with anti-inflammatory doses of acetylsalicylic acid, as a non-selective COX inhibitor, and celecoxib, as a selective COX-2 inhibitor. On an mg/kg basis, the extract was at least as effective as acetylsalicylic acid in reducing inflammatory exudates and in inhibiting leucocytic infiltration as well as in preventing the rise in cytokines. In addition, STW 33-I was more effective than acetylsalicylic acid in suppressing leukotrienes, but equally effective in suppressing prostaglandins. STW 33-I was more effective than acetylsalicylic acid in reducing COX-2 (Khayyal et al 2005). STW 33-I was found to have in vitro anti-inflammatory effects on lipopolysaccharide-stimulated human monocytes and differentiated macrophages. In addition, there was a significant lowering of intracellular tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) content along with a proapoptotic effect in non-activated monocytes. Apoptosis in monocytes is inhibited by microbial products such as lipopolysaccharide, or by certain inflammatory cytokines such as interferon- $\gamma$ . Real-time polymerase chain reaction revealed

that 10 mcg/mL STW 33-I exhibited a significant inhibitory effect on the COX-2 (30–55%) and TNF- $\alpha$  expression (75–85%) ( $P < 0.01$ ) (Bonaterra et al 2010). An aqueous extract of willow bark showed significant reduction in TNF- $\alpha$ -induced adhesion molecule intercellular adhesion molecule-1 (ICAM-1) expression in human microvascular endothelial cells without showing cytotoxic effects. The ethyl acetate extract of willow bark, containing a variety of phenols from different structural classes (particularly catechol), exhibited the most pronounced reduction in ICAM-1 expression (Freischmidt et al 2012). It is suggested that willow bark extract does not damage the gastrointestinal mucosa, probably due to a gastroprotective constituent in the extract. An ethanol extract of willow bark containing 12% salicin in a dose of up to 120 mg/kg did not produce any mucosal lesions in rats, whereas 9 of 10 aspirin-treated rats (100 mg/kg aspirin) showed stomach lesions (Vlachojannis et al 2011).

### Antioxidant effects

A standardised willow bark extract (STW 33-I) was examined in a rat model. The extract raised GSH (reduced glutathione) levels, an effect which helps to limit lipid peroxidation. Higher doses of the extract also reduced malondialdehyde levels and raised superoxide dismutase activity (Khayyal et al 2005). Willow bark extract has been found to reduce oxidative stress in human umbilical vein endothelial cells as well as increase antioxidant enzyme expression by activating nuclear factor erythroid 2-related factor 2 (Ishikado et al 2013).

### Antidepressant effects

Ulrich-Merzenich and colleagues (2012) investigated whether a standardised willow bark preparation would have an effect in a standard model of depression, the forced swimming test in male Sprague-Dawley rats, compared to the tricyclic antidepressant imipramine. Studies were accompanied by gene expression analyses. The 4-week treatment of willow bark (15 and 60 mg/kg body weight) increased the serotonin concentration in the hippocampus significantly, whereas the concentration of 5-hydroxyindole acetic acid decreased (willow bark: 15 and 30 mg/kg body weight), showing a slower serotonin turnover (5-hydroxyindole acetic acid/serotonin [ $P < 0.05$ ]). Imipramine (15 mg/kg) also showed a slower serotonin turnover ( $P < 0.05$ ). In the willow bark group, the transcript for the 5-HT receptor 1A was downregulated, whereas in the imipramine group, the transcripts for the 5-HT receptors 1A, 1F, 3A and 5B were downregulated.

### OTHER ACTIONS

Heat shock protein (HSP) 47, derived from the serpin family of proteins, interacts transiently with procollagen during its folding, assembly and transport (Nizard et al 2004). An *in vitro* study tested the effect of willow bark on HSP 47 expression on old and young donor normal human fibroblasts. The

dermal cells were prepared by means of facial liftings from 20- and 70-year-old healthy female donors. Treatment with an aqueous solution of willow bark on young donor cells induced no clear increase of HSP 47 level. However, a significant increase was observed when treatment was performed on 70-year-old donor cells. This level was approximately similar to the level of control young donor cells.

### CLINICAL USE

In clinical practice, willow bark is generally used as a symptomatic treatment in osteoarthritic conditions and lower-back pain.

### Arthritis

#### Osteoarthritis

Four randomised double-blind trials have investigated the efficacy of willow bark in people with osteoarthritis, with the two earlier studies finding that herbal treatment produced symptom-relieving effects superior to a placebo (Biegert et al 2004, Mills et al 1996, Schmid et al 2000). Seventy-eight subjects were randomly assigned willow bark extract (240 mg salicin/day) or a placebo over a 2-week period, after which active treatment was found to produce a statistically significant improvement (Schmid et al 2000). Mills et al (1996), testing willow bark in 82 patients with chronic arthritic pain, also found active treatment produced a statistically significant alleviation of pain symptoms. The effectiveness and tolerance of willow bark extract compared to conventional therapies were tested in patients with knee or hip pain in a cohort study with a control group. This open, observational study included 90 patients treated with a standardised willow bark extract preparation (equivalent to 240 mg salicin daily) and a reference group of 41 patients with a standard therapy prescribed by a doctor, and 8 patients with a combination of the two. Both the doctors and the patients judged the effectiveness in both groups to be comparable. After 6 weeks, the effectiveness and tolerance of the willow bark extract were better than conventional therapy. No adverse events were recorded in the willow bark group (Beer & Wegener 2008).

These findings contrast with earlier studies in which willow bark failed to reduce Western Ontario and McMaster Universities Arthritis Index (WOMAC) pain scores better than a placebo in a trial on 127 outpatients with painful hip or knee osteoarthritis (Biegert et al 2004). Patients were randomised to receive willow bark extract, corresponding to 240 mg of salicin/day, diclofenac 100 mg/day or a placebo. Treatment with diclofenac produced the strongest pain-reducing effects (WOMAC scores decreased by 47%) compared with willow bark (17% reduction) and the placebo (10% reduction), with the difference between willow bark extract and placebo not statistically significant.

## Rheumatoid arthritis

Willow bark extract (corresponding to 240 mg salicin/day) failed to significantly reduce pain in people with active rheumatoid arthritis, according to a small, double-blind, randomised study of 26 volunteers (Biegert et al 2004). The main outcome measure used was each patient's assessment of pain rated on a 100-mm visual analogue scale.

### IN COMBINATION

A placebo-controlled, randomised, double-blind trial investigated the effects of a supplement on joint pain for 8 weeks (Nieman et al 2013). The daily supplement contained glucosamine sulfate (1500 mg), methylsulfonylmethane (500 mg), white willow bark extract (standardised to 15% salicin) (250 mg), *Boswellia serrata* extract (standardised to 65% boswellic acid) (125 mg), ginger root concentrate (50 mg), turmeric root extract (50 mg), cayenne 40 m HU (50 mg) and hyaluronic acid (4.0 mg). The subjects in the study reported knee pain (74.2%), upper-limb joint pain (55.7%), hip pain (41.2%), lower-limb joint pain (24.7%) and back pain (18.6%). Joint pain severity was assessed biweekly using the 12-point Likert visual scale from the symptom logs. Joint pain reduction became apparent by the fourth week in the supplement group. Furthermore, joint pain severity was significantly reduced in the supplement group compared to placebo at 8 weeks (WOMAC, interaction effect  $P = 0.025$ ). The most significant results were in subjects reporting knee pain. This was shown by reductions in joint pain symptom severity for the supplement compared to placebo (interaction effect,  $P = 0.0125$ ). Decreases in WOMAC total ( $P = 0.018$ ) and pain ( $P = 0.014$ ), function index ( $P = 0.027$ ), and stiffness ( $P = 0.081$ ) scores were greater for the supplement compared to placebo. Systemic inflammation biomarkers and the 6-minute walk test did not differ significantly between groups. The supplement had no adverse symptoms or negative effects on general metabolism and liver and kidney function.

## Lower-back pain

Two randomised studies have investigated the use of oral white willow bark in people with acute episodes of chronic non-specific low-back pain (Chrubasik et al 2000, 2001a). According to a 2006 Cochrane systematic review, there is moderate evidence that a daily dose of 240 mg salicin from an extract of *S. alba* reduces pain more than either a placebo or a daily dose of 120 mg of salicin in the short term for individuals with acute episodes of chronic non-specific low-back pain (Gagnier et al 2006).

One randomised, placebo-controlled study involving 210 patients with chronic lower-back pain found that 39% of those treated with 240 mg salicin became pain-free after 4 weeks compared with 6% in the placebo group. This response was achieved after 1 week (Chrubasik et al 2000). Similar results were achieved in an open trial conducted over 18 months that compared willow bark extract

containing 120 mg or 240 mg salicin with what the authors term 'conventional treatment' in 451 people with acute exacerbations of lower-back pain. Those receiving 240 mg salicin experienced the best results, with 40% becoming pain-free after 4 weeks, compared to 19% in the 120 mg salicin group and 18% in the control group (Chrubasik et al 2001b).

### Comparative trial with rofecoxib

No significant differences in pain-relieving effects were found between white willow bark, standardised to provide a daily dose of 240 mg salicin, and 12.5 mg of the synthetic COX-2 inhibitor rofecoxib according to a randomised trial of individuals with acute episodes of chronic non-specific low-back pain (Chrubasik et al 2001a). With regard to rescue treatments, the percentage of patients requiring non-steroidal anti-inflammatory drugs (NSAIDs), tramadol or both was 10% for the willow bark group and 13% for the rofecoxib group. Approximately 90% of doctors and patients rated either treatment as effective and close to 100% rated either treatment as acceptable.

Given that some pharmaceutical treatments used in the management of pain and inflammatory conditions are costly, such as the newer COX-2 inhibitors, Chrubasik et al (2001b) also compared the cost savings associated with the use of willow bark. A dose of 120 mg salicin/day from willow bark reduced overall patient spending on additional drugs by about 35–50%. In comparison, 240 mg salicin/day produced superior pain relief that resulted in even less reliance on supplementary treatments, but savings were outweighed by the extra cost of the higher dose.

In a systematic review of the same studies, Gagnier et al (2007) concluded there is moderate-level evidence to support the acute and short-term use of willow bark for pain at daily doses standardised to 120 mg or 240 mg salicin, where it has relative equivalence to 12.5 mg per day of rofecoxib. Most recently, a 2009 systematic review (Vlachojannis et al 2009) of studies ranging from 2 to 6 weeks in length concluded that ethanolic willow bark extract was a promising analgesic in the treatment of low-back pain with a low incidence of adverse events. There was a dose-dependent effect where an extract with 240 mg of salicin in the daily dosage was more effective than that of 120 mg.

## Musculoskeletal pain

In a multicentre study, a total of 436 patients with musculoskeletal disorders were treated with STW 33-I (daily administration of the equivalent of 240 mg salicylic alcohol derivatives) alone (61.5%) or in combination with other analgesics (28.9% of the patients received additional NSAIDs [mainly diclofenac and ibuprofen], 3.9% additionally NSAIDs and opioids and 5.7% additionally other medication). Of the 436 participants, 56% had osteoarthritis, 60% had back pain, 34% had osteoarthritis and back pain,

15% had fibromyalgia, 9% had osteoarthritis with back pain and fibromyalgia, 6% had soft-tissue rheumatism, 8% had rheumatoid arthritis and 18% reported other conditions. During the visits the global pain intensity was rated by patients on a visual analogue scale and the global efficacy of treatment was rated by doctors on a five-point Likert-scale. The mean reductions in the pain intensity scale were significant ( $P < 0.01$ ) after 3 weeks and clinically relevant at the end of the study. Of the patients available for the last rating after 24 weeks, 60% had a nearly complete or partial remission (rating 0–1) of their symptoms compared to 27.1% after 3 weeks. The relative reductions of the weekly means of the daily patient self-rated scores of the pain were between 33% and 44% of the baseline values during the course of the study (Uehleke et al 2013).

### Fever and headaches

The known activity of salicylate constituents in willow bark provides support for its use as symptomatic treatment in fever and headaches. Commission E has approved willow bark for these indications (Blumenthal et al 2000). Despite this, only one clinical study has been conducted exploring the effectiveness of willow bark for headaches, but it was used in combination with the herb feverfew, so the efficacy of stand-alone treatment remains unknown (Shrivastava et al 2006).

### IN COMBINATION

A prospective, open-label study was performed in 12 patients diagnosed with migraine without aura. Twelve weeks' treatment with feverfew (*Tanacetum parthenium*, 300 mg) plus willow bark (300 mg) twice daily was shown to reduce attack frequency and intensity, with 70% of patients having a reduction of at least 50%. Attack duration also decreased significantly in all patients. Self-assessed general health, physical performance, memory and anxiety also improved by the end of the study. The treatment was well tolerated and no adverse events occurred (Shrivastava et al 2006).

### OTHER USES

An in vitro study that examined the effects of the main groups of compounds (salicylalcohol derivatives, flavonoids, proanthocyanidins) and salicin isolated from willow bark extract BNO 1455 found that all compounds exerted antiproliferative activity, inhibited cell growth and promoted apoptosis in human colon and lung cancer cell lines, irrespective of their COX-selectivity (Hostanska et al 2007).

### DOSAGE RANGE

- Tincture (1:1): 1–2 mL three times daily.
- Decoction: 1–3 g finely chopped herb in 1 cup of cold water, brought to the boil then reduced to simmer for 5 minutes, drunk 3–4 times daily.
- The European Scientific Co-operative on Phyto-medicine (ESCoP) monograph recommends a daily dose of willow bark equivalent to 120–240 mg total salicin (Nahrstedt et al 2007).

### Clinical note — Lack of significant haematological effects

It has largely been assumed that willow bark alters platelet aggregation and increases bleeding time, in much the same way as aspirin. Whether this is in fact correct and clinically significant has been investigated by Krivoy et al (2001). The clinical study found that consumption of *Salicis cortex* extract (containing 240 mg salicin per daily dose) only minimally affected platelet aggregation compared to a cardioprotective dose of acetylsalicylate (up to 100 mg/day). The particular preparation studied produced a total serum salicylate concentration bioequivalent to only 50 mg acetylsalicylate.

### According to clinical studies

- Osteoarthritic joint pain and inflammation — willow bark preparations standardised to total salicin content and providing 240 mg daily in divided doses.
- Acute episodes of chronic non-specific low-back pain — willow bark preparations standardised to total salicin content and providing 240 mg daily in divided doses.

### ADVERSE REACTIONS

None reported. Theoretically, the tannin and salicylate content may cause gastrointestinal disturbances, but willow bark extract contains a gastroprotective principle (Vlachojannis et al 2011). In rare cases allergic skin reaction may occur (Cameron et al 2009).

### SIGNIFICANT INTERACTIONS

Controlled studies are not available, therefore interactions are based on evidence of pharmacological activity and clinical significance is uncertain.

### Anticoagulants

Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect. Exercise caution with high doses >240 mg salicin/day. In a prospective, longitudinal study, patients completed a 16-week diary by recording bleeding events and exposure to factors previously reported to increase the risk of bleeding and supratherapeutic international normalised ratios, including CM consumption. This study identified that the use of willow bark was associated with an increased risk of self-reported bleeding in patients using warfarin (Shalansky et al 2007). Controlled studies are now warranted to confirm whether oral willow bark preparations induce clinically significant changes to bleeding.

### Salicylate drugs

Theoretically, concurrent use may result in additive effects, although this has yet to be tested. Observe patients taking this combination.

## Aspirin

Theoretically, willow bark may enhance the anti-inflammatory and antiplatelet effects at doses above salicin 240 mg/day. Since salicylic acid concentrations after 100 mg aspirin impair platelet aggregation but those after willow bark with 240 mg salicin almost not, it remains to be established if salicylic acid derivatives have a different effect on blood clotting (Vlachojannis et al 2011). Observe patients taking this combination; beneficial interaction may be possible.

An increased risk of bleeding is theoretically possible with high doses >240 mg salicin. Observe.

## NSAIDs

A reduction in drug requirements may be possible with the use of white willow bark for lower-back pain. Beneficial interaction is possible.

### CONTRAINDICATIONS AND PRECAUTIONS

Commission E states that there is no evidence that willow bark preparations should be contraindicated in small children because of the risk of Reye's syndrome, as the salicylates in the herb are metabolised differently from those in aspirin.

Owing to the relatively high concentration of salicylates in this herb, it should not be used by people with salicylate sensitivity.

### PREGNANCY USE

It is generally not advised to recommend salicylate-containing medicines during pregnancy or lactation, although no restrictions are known for willow bark directly.

### Practice points/Patient counselling

- Evidence from several randomised controlled trials suggests that willow bark is an effective treatment for relieving pain in chronic backache and osteoarthritis.
- The results of one clinical study suggest it is as effective as 12.5 mg of the synthetic COX-2 inhibitor rofecoxib when used at a daily dose of 240 mg salicin.
- People using willow bark may find they have lowered requirements for traditional anti-inflammatory medicines such as NSAIDs.
- Currently, there is no evidence to suggest gastrointestinal side effects or significant platelet inhibition.
- Due to its salicylate content, people with salicylate sensitivity should avoid use of willow bark.

## PATIENTS' FAQs

### What will this herb do for me?

Scientific studies have found that willow bark is a useful treatment for relieving pain in osteoarthritis and chronic backache. It may also relieve symptoms of headache and fever.

### When will it start to work?

Studies using willow bark preparations in diseases characterised by joint pain have found that effects start within 1 week of use.

### Are there any safety issues?

Willow bark appears to be free of major side effects or drug interactions, but it should not be taken by people with salicylate sensitivity.

## Withania

**HISTORICAL NOTE** The name ashwagandha (one of the common names for this herb) comes from the Sanskrit, meaning 'horse-like smell'. Apparently, this name not only refers to the smell of the herb but also to its strengthening and aphrodisiac qualities. It is often referred to as 'Indian ginseng' because it is used in much the same way as *Panax ginseng* in traditional Chinese medicine, although it is considered less stimulating. In Ayurvedic medicine it is classified as a 'rasayana', used to promote physical and mental health and improve vitality and longevity (Kulkarni & Dhir 2008).

### OTHER NAMES

Ashwagandha (and a variety of spellings, including ashvagandha, ashwaganda, asvagantha), Ayurvedic ginseng, Indian ginseng, winter cherry.

### BOTANICAL NAME/FAMILY

*Withania somnifera* (family Solanaceae)

Sometimes confused with *Physalis alkekengi*, also known as winter cherry, and another related species with known medicinal properties, *Withania coagulans* (Mirjalili et al 2009).

### PLANT PARTS USED

Primarily root and leaves, although berry and bark are sometimes used.

### CHEMICAL COMPONENTS

Steroidal lactones (comprising 40 withanolides, e.g. withaferin A), 12 alkaloids (including withanine, somniferine, isopelletierine, anaferrine, tropine, pseudotropine), flavonoids, saponins, sitoindosides, iron, choline, acylsteryl glucosides, coumarins (scopoletin and aesculetin), triterpene (beta-amyrin), phytosterols (stigmaterol, stigmaterol glucoside, beta-sitosterol and beta-sitosterol glucoside), polysaccharides, Viscosa lactone B, alpha + beta glucose, essential oils (ipuranol, withaniol) (Abou-Douh 2002, Kulkarni & Verma 1993, Mills & Bone 2000, Mirjalili et al 2009, Misra et al 2008).

Plants sourced from Sardinia, Italy have significantly higher levels of withaferin A content than those sourced from India or Sicily (Scartezini et al 2007).

### MAIN ACTIONS

Withania and several of its key constituents have been subjected to scientific investigation in vitro and in vivo. While it is important to understand the pharmacological actions of individual components, clinical effects are difficult to predict from these studies as the ultimate effect of the herbal treatment will be a result of many intraherbal interactions.

#### Adaptogen (modulates stress responses)

Withania has been shown to attenuate the negative effects of chronic stress in rats, including hyperglycaemia, glucose intolerance, increase in plasma corticosteroid levels, gastric ulcerations, male sexual dysfunction, cognitive deficits, immunosuppression and mental depression (Bhattacharya & Muruganadam 2003, Kour et al 2009).

Animal trials have shown that a withanolide-free hydrosoluble fraction of withania reduces the stress response induced both chemically and physically (Singh et al 2003). It suppresses stress-induced increases in dopamine receptors in the corpus striatum and acts as a gamma-aminobutyric acid (GABA)-mimetic agent by binding to GABA receptors (Mehta et al 1991, Upton 2000). Animal studies also suggest an ability to reduce adrenal weight and plasma cortisol levels (Kurandikar et al 1986), thus potentially protecting against the negative effects of elevated cortisol levels in chronic stress and allostasis.

#### Cognitive enhancement

The potent acetylcholinesterase inhibitory activity of withania in vitro may help to explain its traditional

use for improving cognition (Vinutha et al 2007). Memory enhancement has been confirmed by animal studies and appears to be mediated by a cholinergic effect (Dhuley 2001). Increased cortical muscarinic acetylcholine receptor capacity has been observed in animals and humans with extracts of withania (Schliebs et al 1997). Several withanolides exert calcium antagonistic ability, together with anticholinesterase activity, by inhibiting butyrylcholinesterase and acetylcholinesterase enzymes (Choudhary et al 2004, 2005). The presence of choline in the herb may also contribute to the production of acetylcholine and further increase cholinergic effects. Withania extract is also protective of hypobaric hypoxia-induced memory loss and neurodegeneration in rats by modulation of corticosterone levels, via the nitric oxide pathway in the hippocampus (Baitheru et al 2013).

### Neuroprotective

Several animal studies indicate the potential for protection of neurons (Ahmed et al 2013, Jain et al 2001), including protection from neuronal injury in Parkinson's disease (Ahmad et al 2005, RajaSankar et al 2009) and promotion of dendrite formation (Tohda et al 2000). One possible explanation is due to the antioxidant properties of withania (Parihar & Hemnani 2003). More recently a mouse model of Parkinson's disease demonstrated the antioxidant actions of *Withania somnifera* root extract on nigrostriatal dopaminergic neurodegeneration and significant improvement in behavioural, physiological and biochemical irregularities (Prakash et al 2013).

In animal experiments withania has been shown to be useful for the treatment of drug-induced dyskinesia (chewing movements, tongue protrusion and buccal tremors) due to reserpine (an antihypertensive and antipsychotic agent no longer available in Australia) and haloperidol (an antipsychotic). In one study, *W. somnifera* root extract (50 and 100 mg/kg) was administered for 4 weeks and dose-dependently reduced reserpine-induced vacuous chewing movements and tongue protrusions, and memory retention deficits in rats. The effect was most likely due to reversal of the drug-induced depletion of glutathione, superoxide dismutase and catalase (Naidu et al 2006). Other researchers support the theory that benefits of withania appear to be due to its antioxidant rather than GABA-mimetic action (Bhattacharya et al 2002, Naidu et al 2003).

In vitro results suggest that withanolide A, withanoside IV and withanoside VI are involved in reconstructing neuronal networks, including axons, dendrites, pre- and postsynapses in the neurons (Kuboyama et al 2002, 2005, Tohda 2008). In vivo, oral withanolide A, withanoside IV and withanoside VI (10 micromol/kg/day for 12 days) have been shown to improve experimentally-induced memory impairment, neurite atrophy and synaptic loss in the cerebral cortex and hippocampus in mice; and withanoside IV (10 micromol/kg/day for 21 days)

improves locomotor functions in mice with spinal cord injury (Tohda 2008).

A rat model studying the effect of withanolides A and C in rat neurons with beta-amyloid proteins found they bind with the active motif of the protein, preventing the fibril formation common in Alzheimer's disease (AD) (Jayaprakasam et al 2010). This was confirmed for an aqueous *W. somnifera* extract in a second study in 2012 (Kumar et al 2012).

A 30-day course of a withania extract, semipurified to contain mostly withanolides and withanosides, was administered to middle-aged and old APP/PS1 AD transgenic mice, resulting in the eradication of behavioural deficits and amyloid plaque in the hippocampus and cortex of middle-aged mice and significant reductions of both in the old mice (Seghal et al 2011). In 2012 Patil et al demonstrated in rat cortical neurons that withanolide A and Asiatic acid modulated several targets associated with amyloid-beta protein and amyloid-beta precursor protein production, indicating they may be useful in the treatment of AD.

### Antioxidant

Withania exerts an indirect antioxidant action in vivo (Bhattacharya et al 1997, 2001). This mechanism is responsible for much of the herb's protective action against organ toxicity, degeneration or injury.

Daily administration of *W. somnifera* root extract increases hepatic glucose-6-phosphatase activity and decreases hepatic lipid peroxidation, most likely by increasing the activity of endogenous antioxidant enzymes (Panda & Kar 1997, 1998, 1999).

In vitro *W. somnifera* inhibits both the lipid peroxidation and the protein oxidative modification induced by copper (Gupta et al 2003). In animal studies the antioxidant actions have been proposed as a possible mechanism for withania, preventing the negative effects of stroke induced by middle cerebral artery occlusion in rats (Choudhary et al 2003). The antioxidant properties may also contribute to the anticataleptic effect noted in studies of haloperidol-induced catalepsy in albino mice (Nair et al 2008) and may protect against the genotoxic potency of commercial-grade malathion, a commonly used insecticide (Bernhardt et al 2011). Pretreatment with withania was also protective in radiation-induced hepatotoxicity in rats via antioxidant mechanisms (Mansour & Hafez 2012).

### Increases haematopoiesis

Animal trials indicate that the herb increases haemoglobin and red blood cell levels (Ziauddin et al 1996) and increases haematopoiesis (Aphale et al 1998). The iron content of the herb may further contribute to its role in red blood cell formation.

### Immunomodulation

Immunomodulating activity has been demonstrated in vivo for withania, including an increase in white blood cell, platelet and neutrophil counts (Agarwal et al 1999, Davis & Kuttan 2000, Gupta et al 2001,

Ziauddin et al 1996), proliferation of lymphocytes, increased interferon-gamma (Teixeira et al 2006, Yamada et al 2011) and interleukin-2 (IL-2) levels and a reduction in tumour necrosis factor (TNF) (Davis & Kuttan 1999, Yamada et al 2011). The effects on immune function have also been demonstrated clinically in a small study of 5 people who were given 6 mL of withania root extract twice daily for 96 hours, resulting in increases in lymphocytes and natural killer cells from baseline (Mikolaj et al 2009).

In animal studies, oral administration of a standardised fluid extract (1:1) of withania (30 mg/kg) for 15 days resulted in enhanced T-helper cell (Th1) immunity (increased expression of Th1 cytokines, interferon-gamma and IL-2) with a moderate decline in Th2 (decreased expression of Th2 cytokine IL-4). This effect appeared to be due to withanolide A. The extract also strongly activated macrophage function and no toxicity was noted (Malik et al 2007). Other studies have confirmed an increased expression of Th1 cytokines in chronically stressed (Khan et al 2006) and immunosuppressed mice (Bani et al 2006, Kour et al 2009, Malik et al 2009). Although human trials are required to confirm these effects, withania shows promise for selective Th1/Th2 modulation.

### Antibacterial and antifungal activity

Animal and in vitro studies have shown antibacterial effects against *Staphylococcus aureus* (Datta et al 2011), *Listeria monocytogenes*, *Bacillus anthracis*, *Bacillus subtilis*, *Salmonella enteridis* (Akin et al 1986) and *Salmonella typhimurium* (Owais et al 2005). The methanol and hexane extracts of both the leaves and the roots have potent antibacterial activity against *S. typhimurium* and *Escherichia coli* (Arora et al 2004); and the steroidal withanolides from the related species *W. coagulans* have been found to have antifungal activity against *Allescheria boydii*, *Aspergillus niger*, *Curvularia lunata*, *Drechslera rostrata*, *Epidermophyton floccosum*, *Microsporum canis*, *Nigrospora oryzae*, *Pleurotus ostreatus* and *Stachybotrys atra* (Choudhary et al 1995). *W. somnifera* glycoprotein exerts an antibacterial activity against *Clavibacter michiganensis* and a fungistatic effect against *Aspergillus flavus*, *Fusarium oxysporum* and *F. verticillioides* (by inhibiting spore germination and hyphal growth) (Girish et al 2006).

### Anti-inflammatory activity

Withania extract suppresses the production of pro-inflammatory molecules in many in vitro models. This is partly due to inhibition of transcription factors nuclear factor-kappa B (NF- $\kappa$ B) and activator protein-1 by withanolides (steroidal lactones) (Ichikawa et al 2006, Kaileh et al 2007, Maitra et al 2009, Mulabagal et al 2009, Oh et al 2008, Singh et al 2007). Several withanolides exert selective cyclooxygenase-2 (COX-2) enzyme inhibition (Jayaprakasam & Nair 2003) and withania has been found to decrease alpha-2-macroglobulin, a

liver-synthesised plasma protein that increases during inflammation (Anbalagan & Sadique 1985).

Withania rectal gel 1000 mg/kg was applied in an experimental inflammatory bowel disease rat model, resulting in highly significant protection compared to controls ( $P < 0.001$ ) upon histological examination (Pawar et al 2011). Additionally, withaferin A reduces the microglial inflammatory response via downregulation of lipopolysaccharide-induced COX-2 expression and prostaglandin E<sub>2</sub> production, believed to occur at least partially through STAT 1/3 inhibition (Min et al 2011). In pulmonary epithelial cells withaferin A inhibits TNF- $\alpha$ , downregulating NF- $\kappa$ B (Oh et al 2009). Withaferin A has also been compared to indomethacin in an experimental mouse model of induced inflammation, pyrexia and gastric ulceration. Withaferin A significantly reduced inflammation and pyrexia at 20/30 mg/kg and without causing gastric damage at 30/40 mg/kg, as compared to indomethacin 20 mg/kg, which caused significant gastric ulceration (Sabina et al 2009).

A reduction in the erythrocyte sedimentation rate has also been noted in a double-blind clinical trial of 50–59-year-old males (Kupparajan et al 1980).

### Chondroprotective

Withania root powder has demonstrated chondroprotective effects in vitro (human osteoarthritic cartilage matrix), inhibiting the gelatinase activity of collagenase type 2 enzyme and exerting a significant short-term chondroprotective effect in a subset (50%) of patient samples (Sumantran et al 2007). A more recent study had similar results (Ganesan et al 2011). In vivo the root powder rectified biochemical changes resulting from experimentally induced arthritis in rats (Rasool & Varalakshmi 2007). Associated with arthritis were increased levels of lipid peroxides, glycoproteins and urinary constituents; and depletion of antioxidant status and bone collagen. These biochemical alterations were ameliorated significantly by oral administration of *W. somnifera* root powder (1000 mg/kg body weight) in test animals. It should be noted, however, that the high dose used (1000 mg/kg body weight) is not likely to be reproducible in human trials.

### Anticancer (antineoplastic and chemoprevention)

Some research has been conducted with withania; however most has focused on the component withaferin A, which has multiple mechanisms of action.

In vitro studies have determined that withania extracts possess cell cycle disruption and antiangiogenic activity (Mathur et al 2006). Withania stimulates the production of cytotoxic T lymphocytes in vivo and in vitro, and may prevent or reduce tumour growth (Choudhary et al 2010, Davis & Kuttan 2002, Jayaprakasam et al 2003, Malik et al 2008). In animal models, withania was found to prevent skin carcinoma induced by ultraviolet B

radiation (Mathur et al 2004) and forestomach tumours (Padmavathi et al 2005); reduce the incidence, number and size of tumours; and counteract the associated decrease in body weight (Singh et al 1986).

The withaferin A fraction appears to exert anti-angiogenic activity (Mohan et al 2004) and antigenotoxic effects on bone marrow (Panjamurthy et al 2008), and may be partly responsible for the antineoplastic effects observed in both in vitro and in vivo studies (Uma Devi et al 1995, 1996). The antioxidant effects aid in the prevention of DNA damage by mutagens (Khanam & Devi 2005) and this, in combination with detoxifying properties, anti-inflammatory and immunomodulatory effects, determined in animal studies, is likely to contribute to its chemopreventive action (Prakash et al 2001, 2002).

Because several genes that regulate cellular proliferation, carcinogenesis, metastasis and inflammation are regulated by NF- $\kappa$ B, the ability of withanolides to inhibit activation of NF- $\kappa$ B and NF- $\kappa$ B-regulated gene expression may partly explain the role of withania in enhancing apoptosis and inhibiting invasion and osteoclastogenesis (Grover et al 2011b, Ichikawa et al 2006).

Further investigation of withaferin A in apoptosis demonstrates that it induces endoplasmic reticulum stress via mediation of reactive oxygen species (ROS) (Choi et al 2011) and the modulation of heat shock protein 90 client complexes involved in protein folding (Grover et al 2011a, Yu et al 2010), leading to protein disruption and apoptosis. Um et al (2012) have also demonstrated that the down-regulation of the STAT 3 signalling pathway may play a role in apoptosis, as might microtubule disruption (Grin et al 2012, Thaiparambil et al 2011). Withaferin A may also induce apoptosis in cervical cancer cells by downregulating human papillomavirus oncogenes E6/7 and restoring the p53 pathway (Munagala et al 2011). Breast cancer cell lines have also been studied with withaferin A, inducing apoptosis via ROS inhibition of mitochondrial respiration, survivin protein suppression, microtubule disassembly, inhibition of STAT 3 signalling pathways and antioestrogen effects (Hahm et al 2011, Lee et al 2010, Thaiparambil et al 2011). Additionally, studies have found that NOTCH2 and NOTCH4 involved in breast cancer cell migration were inhibited (Lee et al 2012).

### Anxiolytic and antidepressant

Animal studies have found that glycowithanolides exert anxiolytic effects comparable to those of lorazepam, and antidepressant effects comparable to those of the antidepressant drug imipramine (SK Bhat-tacharya et al 2000). Anxiolytic and antidepressant activities have also been demonstrated for the withania root extract (WS 100, 200 or 500 mg/kg) and potentiation of diazepam at subtherapeutic doses (WS 50 mg/kg) has been demonstrated (Gupta & Rana 2007). Recently, a double-blind, randomised study confirmed significant anxiolytic

and antidepressant activity after 60 days of treatment with an oral root extract standardised to at least 5% withanolide content (Chandrasekhar et al 2012).

### Blood glucose control

Withania extract (200 and 400 mg/kg) was administered orally once daily for 5 weeks in a type 2 diabetes experimental model. The treatment reduced elevated levels of blood glucose, HbA<sub>1c</sub> and insulin, and improved glucose tolerance and insulin sensitivity (Anwer et al 2008). Similar results have been seen in animal models that further suggest an antioxidant-related effect (Anwer et al 2012, Udayakumar et al 2009, 2010). In experimental in vitro models, withania (especially the ethanolic extract) has shown effects comparable to metformin in preventing the formation of advanced glycation end products, which are implicated in the pathogenesis of diabetes mellitus (Babu et al 2007).

### Cardioprotective

Cardioprotective effects have been noted in animal studies (Dhuley 2000, Mohanty et al 2004), significantly reducing myocardial injury after ischaemia and reperfusion (Gupta et al 2004). These effects are most likely to be due to restoration of the myocardial oxidant-antioxidant balance and the marked antiapoptotic properties of withania (Mohanty et al 2008). Cardioprotective effects were also observed against doxorubicin-induced cardiotoxicity in vivo when pretreatment with a standardised withania extract (300 mg/kg; 1.5% withanolides) was administered before drug exposure (doxorubicin 10 mg/kg) (Hamza et al 2008). The alkaloids are considered to be sedative and reduce blood pressure and heart rate (Chevallier 1996, Malhotra et al 1965a). The withanolides have a chemical structure similar to cardiac glycosides and have demonstrated mild inotropic and chronotropic effects on the heart (Roja et al 1991, Tripathi et al 1996).

### Antihypercholesterolaemic

High doses of withania root powder (0.75 and 1.5 g/day) produced significant decreases in total lipids (-40.54%; -50.69%), cholesterol (-41.58%; -53.01%) and triglycerides (-31.25%; -44.85%); and significant increases in high-density lipoprotein cholesterol levels (+15.10%; +17.71%) in an experimental model of hypercholesterolaemia. Additionally, treatment resulted in significant decreases in HMG-CoA reductase activity and bile acid content in the liver of these animals, and there was a trend towards increased excretion of bile acid (+22.43%; +28.52%), cholesterol (+14.21%; +17.68%) and neutral sterol (+12.40%; +18.85%). Lipid peroxidation also decreased significantly (-35.29%; -36.52%) (Visavadiya & Narasimhacharya 2007). The doses used in this study may not be feasible in humans.

### Thyroid modulating

An in vivo study reported that daily administration of *W. somnifera* root extract enhanced serum

thyroxine concentration (Panda & Kar 1998, 1999). Withania 1.4 g/kg returned triiodothyronine/thyroxine levels to normal in metformin-induced hypothyroidism in type 2 diabetic mice (Jatwa & Kar 2009). Note that this dose is unlikely to be safely achieved in practice. There is one case report of thyrotoxicosis in a 32-year-old woman attributed to a withania-containing herbal capsule (van der Hooft et al 2005), so caution is advised.

### Sexual enhancer

Traditionally used for this purpose, one double-blind clinical trial found that a dose of 3 g taken daily for 1 year improved the sexual performance of 71.4% of healthy ageing males (Kupparajan et al 1980). Alternatively, animal studies have indicated that very high doses (3000 mg/kg) result in reduced sexual performance (Ilayperuma et al 2002); however, in a randomised study of 95 men with psychogenic erectile dysfunction withania 500 mg given for 60 days was found to be no better than placebo in improving function (Mamidi & Thakar 2011).

## OTHER ACTIONS

### Hepatoprotective

Animal studies have demonstrated hepatoprotective effects (A Bhattacharya et al 2000, Sudhir et al 1986) and that withania inhibits phase I, and activates phase II and antioxidant enzymes in the liver (Padmavathi et al 2005).

### Anticonvulsant

Withania root extract (100 or 200 mg/kg orally) increases seizure threshold in mice. The effect is likely to be due to GABA-A modulation (Kulkarni et al 2008).

### Antitussive

A water extract polysaccharide fraction from withania showed reduced coughing efforts in guinea pigs in a manner similar to codeine (Sinha et al 2011).

### Blood pressure — no effects

A small, poor-quality study consisted of 51 hypertensive patients (presumed to be stress-related) sampled purposively into two groups: 2 g of withania powder was given in either milk (group I) or water (group II) for 3 months. While there were systolic decreases in group I and diastolic reductions in both groups, neither was statistically significant (Kushwaha et al 2012).

## CLINICAL USE

*W. somnifera* has not undergone significant scientific investigation in humans, therefore much of its use is based on pharmacological effects demonstrated in experimental models or traditional usage. In practice, it is often used in herbal combination treatments as part of the Ayurvedic system of medicine.

## Stress adaptation

The pharmacological effects of the herb, which have been well established in animal studies, provide a theoretical basis for its use in situations characterised by stress (Archana & Namasivayam 1999, Bhattacharya & Muruganandam 2003, Dhuley 2000, Grandhi et al 1994).

More specifically, oral administration of an aqueous, standardised extract of *W. somnifera* (in a dose extrapolated from the human dose) has been found to offer protection against experimentally induced biological, physical and chemical stressors (Rege et al 1999).

In one in vivo study, plasma cortisol levels and adrenal weight were significantly lower, while liver weight increased (Kurandikar et al 1986).

(For more information see Clinical note — Allo-stasis and adaptation to stress in the Siberian ginseng monograph.)

## Anxiety and depression

A daily dose of 300 mg of standardised root extract of *W. somnifera* root (KSM-66 ashwagandha extract, Ixoreal Biomed, Hyderabad, India, standardised to withanolide content of at least 5%) was investigated in a double-blind randomised controlled trial (RCT) involving 64 subjects over a period of 60 days. Active treatment resulted in a highly significant reduction in all measures compared to placebo; perceived stress scale 44% vs 5.5% ( $P < 0.0001$ ) and total score for depression anxiety stress scale and the subsets; depression 77% vs 5.2%, anxiety 75.6% vs -4.3%, and stress 64.2 vs 10.4% ( $P < 0.0001$ ). Similarly, significant improvements were seen in all subsets of the general health questionnaire: somatic stress, stress and anxiety, social dysfunction and severe depression ( $P < 0.0001$ ). Additionally, greater serum cortisol reductions were seen with active treatment compared to placebo: 27.9% vs 7.9% ( $P < 0.0006$ ) (Chandrasekhar et al 2012).

The herb's pharmacological effects, such as its GABA-mimetic activity (Mehta et al 1991) and ability to lower cortisol levels (Kurandikar et al 1986), provide a theoretical basis for its use in anxiety states. In vivo studies with withania root extract (WS 100, 200 or 500 mg/kg) confirm its anxiolytic effects and its ability to potentiate diazepam at subtherapeutic doses (WS 50 mg/kg) (Gupta & Rana 2007).

## IN COMBINATION

One study used a herbal combination treatment known as Geriforte, which contains primarily *W. somnifera*. The product was taken by 34 subjects with anxiety neurosis, and after 12 weeks significant reductions in the frequency, duration and intensity of symptoms were observed (Ghosal et al 1990).

An RCT of 81 people with moderate to severe anxiety received naturopathic care (dietary counselling, deep-breathing relaxation techniques, multivitamin and withania 300 mg BD) or psychotherapy, the same deep-breathing techniques and placebo. The Beck Anxiety

Inventory (BAI) was the primary outcome measure. In all, 93% of participants were followed for 8 or more weeks, with final BAI scores reducing 56.5% ( $P < 0.0001$ ) in naturopathic care group and 30.5% in the psychotherapy group ( $P < 0.0001$ ), with a significant difference favouring naturopathic care ( $P < 0.003$ ), where *W. somnifera* was a major treatment (Cooley et al 2009).

### Anabolic and weight gain promotion

Both animal and human studies have shown significant improvements in weight gain during the growth phase with the use of withania (Sharma et al 1986, Ziauddin et al 1996). It is suspected that an anabolic effect is responsible. This theory is supported by more recent research which shows that withania can increase testosterone levels (Ahmad et al 2010). Withania-fortified milk (2 g/day for 60 days) has been investigated in children and found to induce weight gain and increase total plasma proteins and haemoglobin levels (Venkatraghavan et al 1980).

### Anaemia

The herb is used in the treatment of iron-deficiency anaemia due to its effects on haematopoiesis and natural iron content (Aphale et al 1998, Ziauddin et al 1996). This use has been supported by studies showing increased haemoglobin levels in children, induced by withania.

### Attention-deficit hyperactivity disorder (ADHD)

#### IN COMBINATION

An RCT of 120 children aged 6–12 years tested the effect of a herbal combination including *Withania somnifera*, *Paeonia alba*, *Centella asiatica*, *Spirulina plantensis*, *Bacopa monniera* and *Melissa officinalis*. The participants met the *Diagnostic and Statistical Manual of Mental Disorders* (fourth edition) (DSM-IV) criteria for ADHD and took the test of variables of attention (TOVA) at baseline and after 4 months of treatment. The active treatment group had a significant improvement in all four subsets of TOVA, compared to placebo ( $P < 0.004$ ) (Katz et al 2011). The 2:1 randomisation of participants to the treatment and placebo groups, with a high drop-out rate in the placebo arm, has affected study quality. Additionally the dose of each herb used within the combination was not reported.

### Cancer therapy

The substantial preclinical research conducted to date with withania indicates a potential role in the treatment of cancer as a means of improving survival time and reducing treatment toxicity. Currently, only one clinical study has been conducted with oral withania extract which was used together with chemotherapy in women with breast cancer. The prospective non-randomised open study of 100 women (mean age 50 years) with breast cancer (77% having stage II or III disease) compared treatment with chemotherapy to treatment with chemotherapy and oral withania (2 g three times daily). Fatigue score

and quality-of-life scores were monitored before, during and on the final cycle of chemotherapy treatment. Fatigue scores were significantly less, as were seven out of 18 quality-of-life symptoms ( $P < 0.001$ ), and 24-month survival favoured the treatment group (72% versus 56%), but was no longer statistically significant at median follow-up (26 months:  $P < 0.176$ ) (Biswall et al 2012). Larger RCTs are needed to further explore the potential benefits and limitations of concomitant treatment.

Preclinical research has shown that *W. somnifera* reduces tumour cell proliferation while increasing overall survival time in animal trials. It enhances the effectiveness of radiation therapy while potentially attenuating the undesirable side effects of radio- and chemotherapeutic agents (including cyclophosphamide and paclitaxel) without interfering with the tumour-reducing actions of the drugs (Winters 2006).

Withania has been attributed with antitumour activity (Davis & Kuttan 2002, Jayaprakasam et al 2003), antiangiogenic effects (Mathur et al 2006, Mohan et al 2004) as well as antigenotoxic effects on bone marrow (Panjamurthy et al 2008). The antioxidant effects aid in the prevention of DNA damage by mutagens (Khanam & Devi 2005) and this, in combination with detoxifying properties, anti-inflammatory and immunomodulatory effects, determined in animal studies, is likely to contribute to its chemopreventive action (Prakash et al 2001, 2002).

Animal studies suggest a potential role for withania as an adjunctive treatment during chemotherapy for the prevention of drug-induced bone marrow depression (Davis & Kuttan 1999, Gupta et al 2001).

The ability to stimulate stem-cell proliferation has led to concerns that *W. somnifera* could reduce cyclophosphamide-induced toxicity and therefore reduce its usefulness in cancer therapy (Davis & Kuttan 1998). However, preliminary animal studies indicate that withania could prove to be a potent and relatively safe radiosensitiser and chemotherapeutic agent (Uma Devi 1996, Yang et al 2011). In one animal experiment, pretreatment with a standardised withania extract (300 mg/kg; 1.5% withanolides) attenuated the cardiotoxic side effects of doxorubicin (10 mg/kg) (Hamza et al 2008). In mice, the addition of *W. somnifera* (400 mg/kg orally once weekly for 4 weeks) to paclitaxel treatment (33 mg/kg intraperitoneally once weekly for 4 weeks) may extend its chemotherapeutic effect through modulating protein-bound carbohydrate levels and marker enzymes. The combination may effectively treat benzo(a)pyrene-induced lung cancer by offering protection against damage from ROS and also by suppressing cell proliferation (Senthilnathan et al 2006a).

### Diabetes

Preclinical research suggests a hypoglycaemic effect which has been tested for clinical significance in a small study of six people with mild non-insulin-dependent diabetes mellitus. Treatment with

withania root extract was used for 30 days and a decrease in blood glucose levels was detected and described as comparable to oral hypoglycaemic medicines (Andallu & Radhika 2000). No further published clinical studies have been located.

### Drug and alcohol withdrawal

Withania is used in herbal combination therapy during opiate and alcohol withdrawal. This is based on preclinical research which suggests a potential role; however no clinical studies have been conducted thus far. In animal studies, repeated administration of withania (100 mg/kg) inhibited morphine tolerance and dependence (Kulkarni & Ninan 1997) and reduced neuronal damage during co-administration with chronic morphine use, but not during the withdrawal phase in rats (Kasture et al 2009). An ethanol withdrawal mouse model concluded that withania reduced the number of seizures and anxiety associated with alcohol withdrawal (Ruby et al 2012). It may also be useful in the management of withdrawal-induced anxiety due to chronic ethanol consumption (Gupta & Rana 2008). Another in vivo study found that withania root extract significantly impaired motivation for drinking alcohol, a result probably mediated by GABAB receptors (Peana et al 2014).

### Hypercholesterolaemia

Treatment for 30 days with a withania root extract significantly decreased serum cholesterol, triglycerides, low-density lipoproteins and very-low-density lipoproteins in a small open study of six volunteers starting with mildly elevated lipids (Andallu & Radhika 2000). Further clinical research is warranted.

### Osteoarthritis

The documented anti-inflammatory, chondroprotective (Rasool & Varalakshmi 2007, Sumantran et al 2007) and antioxidant activities of withania provide some support for its traditional use in arthritis. Arthritis results from dysregulation of proinflammatory cytokines (e.g. TNF and IL-1 $\beta$ ) and enzymes that mediate the production of prostaglandins (e.g. COX-2) and leukotrienes (e.g. lipoxigenase), together with the expression of adhesion molecules and matrix metalloproteinases, and hyperproliferation of synovial fibroblasts. These factors are regulated by the activation of the transcription factor NK- $\kappa$ B, which is inhibited by withanolides (Khanna et al 2007).

Withania root powder (500 and 1000 mg/kg) exerts a potent analgesic effect in rats and appears to retard amplification and propagation of the inflammatory response without causing any gastric damage (Rasool & Varalakshmi 2006). The root powder (1000 mg/kg) has also been shown to rectify biochemical changes resulting from experimentally induced arthritis (Rasool & Varalakshmi 2007). It should be noted, however, that this dose is not likely to be reproducible in human trials.

### IN COMBINATION

While no RCT has been conducted with stand-alone withania treatment, several randomised clinical studies have been conducted using herbal combinations which contain withania as one of the ingredients, producing positive results. While promising, the contribution of withania to these results is difficult to determine.

One randomised, double-blind, placebo-controlled, crossover study of 42 patients with osteoarthritis found that a herbal combination treatment consisting of roots of *Withania somnifera*, the stem of *Boswellia serrata*, rhizomes of *Curcuma longa* and a zinc complex (Articulon-F) produced a significant decrease in the severity of pain ( $P < 0.001$ ) and disability score ( $P < 0.05$ ), although radiological assessment did not show any significant changes in either group (Kulkarni et al 1991). Similarly, a double-blind RCT of 90 patients with knee osteoarthritis found treatment with RA-11 (ARTREX, MENDAR), a standardised multiherb Ayurvedic treatment (*Withania somnifera*, *Boswellia serrata*, *Zingiber officinale* and *Curcuma longa*), produced a significant reduction in pain compared to placebo ( $P < 0.05$ ) and significant improvement in the WOMAC scores at week 16 and week 32 ( $P < 0.01$ ) and was well tolerated (Chopra et al 2004).

### Osteoporosis

An ethanolic extract of withania root markedly prevented bone loss and associated biochemical changes in ovariectomised rats, indicating possible prevention of osteoporosis (Nagareddy & Lakshmana 2006). Controlled trials in humans are currently lacking.

### Sleep

As its alkaloids are considered to be sedative and able to reduce blood pressure and heart rate (Chevallier 1996, Malhotra et al 1965a), withania is also used as a treatment for insomnia, although controlled trials are lacking in this area. Compared to diazepam (0.5 mg/kg) alone, the addition of withania root extract (100 mg/kg) to sleep-disturbed mice significantly attenuates the negative consequences of sleep deprivation. These include reduction in body weight, reduced locomotor activity, anxiety and altered antioxidant status (Kumar & Kalonia 2007).

### Male infertility

Several recent clinical trials suggest a possible role in male infertility, which needs to be explored further.

A prospective study of 75 infertile (25 normozoospermic, 25 oligozoospermic and 25 asthenozoospermic) but otherwise healthy men (with fertile partners) that had not conceived after 1 year were matched against 75 fertile men (who had at least one pregnancy and normal sperm count) and were given 5 g of withania root powder in milk a day. Sperm concentration and motility were increased in all groups but remained suboptimal in the asthenozoospermic subset. Sperm volume was increased in

all ( $P < 0.01$ ) but the asthenozoospermic group, but sperm count per ejaculate was increased in all ( $P < 0.01$ ). Additionally, oxidative biomarkers were all significantly improved ( $P < 0.01$ ), and vitamins A, C, E ( $P < 0.01$ ) and corrected seminal fructose ( $P < 0.05$ ) were all improved from baseline. There were also significant increases in testosterone and luteinising hormone and decreases in follicle-stimulating hormone and prolactin in all treatment groups (Ahmad et al 2010).

In a similar group of men, sperm apoptosis, intracellular ROS, sperm concentration and levels of essential metal ions in seminal plasma (copper, zinc, gold and iron) were measured before and after 3-month treatment with withania powder 5 g/day. Degree of apoptosis and intracellular ROS were significantly reduced from abnormal baselines ( $P < 0.05$ ), while deficient metal ions all increased after treatment ( $P < 0.01$ ) (Shukla et al 2011). A prospective parallel trial by the same authors matched 60 normozoospermic fertile men with 60 normozoospermic infertile men, further divided into 20 men with psychological stress (measured by State Anxiety Index), 20 men who were heavy smokers and 20 men with infertility of unknown origin. Each was administered 5 g/day of powdered withania root for 3 months. After treatment, semen concentration, liquefaction time and motility improved in all groups and pregnancy outcome was 14% overall, but only 10% in the smoking group. Additionally, biomarkers of oxidative stress, the hormones testosterone, luteinising hormone, follicle-stimulating hormone, prolactin and blood cortisol were all significantly improved in all groups (Mahdi et al 2011).

## OTHER USES

Traditionally used in convalescence for people who are stressed and both physically and emotionally exhausted, it is considered a non-stimulating tonic allowing for the restoration of vitality.

In rural parts of India, withania is applied topically as an antidote to snakebite. *W. somnifera* glycoprotein inhibits the hyaluronidase activity of cobra (*Naja naja*) and Russell's viper (*Daboia russelii*) venoms, providing some support for this use (Machiah et al 2006). Hyaluronidase activity is involved in rapid spreading of the toxins by destroying the integrity of the extracellular matrix.

Kalani et al (2012) report the case of a 57-year-old woman with non-classical adrenal hyperplasia with androgen excess who self-medicated with withania for 6 months, who showed significant reduction of biochemical markers and reduced hair loss.

## DOSAGE RANGE

- Fluid extract (1:1): 20–50 mL/week (Australian manufacturer recommendations).
- Dried root: 3–6 g/day in capsule, milk or tea form.

## According to clinical trials

- Anxiety and depression: 300–600 mg/day of withania extract standardised to 5% withanolides.

- Male infertility: 5 g/day in milk of powdered withania root.
- Breast cancer: 2 g oral withania 3 times a day.

## ADVERSE REACTIONS

Withania appears well tolerated according to clinical research. Large doses can cause gastrointestinal upset, diarrhoea and vomiting (Tierra 2005).

A case report exists of thyrotoxicosis in a 32-year-old woman after taking a herbal capsule containing withania (van der Hooff et al 2005). Central nervous system and respiratory depression (Malhotra et al 1965b), decreased body temperature (Malhotra et al 1965b), gastrointestinal upset (Lindner 1996), kidney and liver abnormalities (Arseculeratne et al 1985) and fixed drug eruptions (Sehgal et al 2012) have also been noted.

Acute toxicity studies in animals show a good margin of safety with a high therapeutic index (Aphale et al 1998, Prabu et al 2013, Rege et al 1999, Sharada et al 1993, Singh et al 2001, 2003).

In a safety and tolerability study, 18 adults aged 18–30, body mass index 19–30 were administered an aqueous 8:1 extract via capsule in variable increasing doses every 10 days for 30 days in two divided doses (750 mg, 1000 mg and 1250 mg). Only one subject experienced any adverse effects, leaving the study at the lowest dose with increased appetite and libido, hallucination and vertigo. All physical and biochemical parameters remained normal in the rest (Raut et al 2012).

## SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

### Antipsychotic/neuroleptic agents

In animal experiments, withania has been shown to be useful in the treatment of drug-induced dyskinesia (chewing movements, tongue protrusion and buccal tremors) due to reserpine and haloperidol (Bhattacharya et al 2002, Naidu et al 2003, 2006). Beneficial interaction theoretically possible.

### Barbiturates

Additive effects are theoretically possible, leading to increased sedation (NMCD 2005, Tierra 2005). Observe patients taking withania and barbiturates concurrently — beneficial interaction possible under medical supervision.

### Benzodiazepines

Based on evidence from in vivo models (Kumar & Kalonia 2007), an increased sedative effect is theoretically possible (Upton 2000). Observe patients taking withania and benzodiazepines concurrently. Beneficial interaction theoretically possible under professional supervision.

## Chemotherapy

Animal studies suggest a potential role for withania as an adjunctive treatment during chemotherapy. Observe — beneficial interaction theoretically possible — only to be used under professional supervision.

## Cyclophosphamide

While the ability to stimulate stem-cell proliferation has led to concerns that *W. somnifera* could reduce cyclophosphamide-induced toxicity and therefore reduce its usefulness in cancer therapy (Davis & Kuttan 1998), preliminary animal studies indicate that withania could prove to be a potent and relatively safe radiosensitiser and chemotherapeutic agent (Uma Devi 1996).

## Doxorubicin

In rats pretreatment with a standardised withania extract (300 mg/kg; 1.5% withanolides) attenuates the cardiotoxic side effects of doxorubicin (10 mg/kg) (Hamza et al 2008).

## Paclitaxel

In mice the addition of *W. somnifera* (400 mg/kg, orally once weekly for 4 weeks) to paclitaxel (33 mg/kg, intraperitoneally once weekly for 4 weeks) may extend its chemotherapeutic effect through modulating protein-bound carbohydrate levels and marker enzymes. The combination may effectively treat the benzo(a)pyrene-induced lung cancer by offering protection from oxidative damage and also by suppressing cell proliferation (Senthilnathan et al 2006a, 2006b).

## Digoxin assays

Withania may modestly interfere with serum digoxin measurements by the fluorescent polarisation immunoassay and other assays (Dasgupta et al 2007, 2008).

## Immunosuppressants

The ability to stimulate stem-cell proliferation has led to concerns that *W. somnifera* could reduce the effectiveness of immunosuppressant drugs (Davis & Kuttan 1998). Caution should be exercised with patients taking immunosuppressants concurrently; however, a beneficial interaction may be possible under professional supervision.

## Morphine

In animal studies, repeated administration of withania (100 mg/kg) inhibited morphine tolerance and dependence (Kulkarni & Ninan 1997). For this reason it is sometimes used in opiate withdrawal. Theoretically beneficial interaction possible under professional supervision.

## Thyroid medication (e.g. levothyroxine)

Additive effects are theoretically possible. An in vivo study reported that daily administration of withania

enhanced serum thyroxine concentrations (Upton 2000) and a case report exists of withania-induced thyrotoxicosis (van der Hooff et al 2005) — observe patients taking withania and thyroid medications concurrently.

### Practice points/patient counselling

- Withania is an Ayurvedic herbal medicine, also referred to as Indian ginseng or ashwaganda. Scientific human research has only recently begun; however, extensive laboratory investigation and evidence from traditional use provide a guide.
- It is traditionally used for improving stress adaptation responses in people who are both physically and emotionally stressed and exhausted, and during periods of convalescence.
- New clinical research suggests a possible role in treating stress, anxiety and depression.
- Preliminary evidence suggests it increases haematopoiesis, promotes weight gain, reduces anxiety symptoms, increases cognitive function, improves male fertility and exerts a neuroprotective effect. It has shown promise in early investigations in Parkinson's and Alzheimer's disease.
- It has also demonstrated antioxidant, immunomodulating, antineoplastic, antifungal and antibacterial, anti-inflammatory and glucose-lowering activity in animal or test tube studies.
- The herb should not be taken in pregnancy, and should be used with caution in people sensitive to the Solanaceae family of plants.

### CONTRAINDICATIONS AND PRECAUTIONS

Use with caution in peptic ulcer disease: withania may cause gastrointestinal irritation (Upton 2000). People who are sensitive to the Solanaceae family should use this herb with caution.

### PREGNANCY USE

Western texts urge caution in pregnancy (Lindner 1996) due to a reputed abortifacient activity and antifertility effects noted in early animal studies, despite there being no evidence of fetal damage (Mills & Bone 2005). More recently a 500 mg polyherbal supplement (*Withania somnifera*, *Tribulus terrestris*, *Mucuna pruriens* and *Argyrea speciosa*) containing withania 300 mg out of 500 mg total was tested in mice, resulting in an oral toxicity LD<sub>50</sub> of 5000 mg/kg with a significant improved birth rate, birth number and survival over two generations (Riaz et al 2010). Note that withania is used to support pregnancy and lactation in the Ayurvedic tradition (McGuffin et al 1997, Tirtha & Shiva 2002).

## Metformin

Withania may protect type 2 diabetics on metformin from drug-induced hypothyroidism (Jatwa & Kar 2009). A potentially beneficial interaction that should only be used under supervision due to theoretical risk of induced thyrotoxicosis (see above).

## ! PATIENTS' FAQs

### What will this herb do for me?

Preliminary scientific research shows beneficial effects in stress, anxiety and depression and possibly some types of male infertility. Most information comes from other research and traditional use which suggests possible roles in improving memory, increasing red blood cell production, increasing immune responses and in convalescence.

### When will it start to work?

Symptoms of anxiety and stress improve within 2 months' continual use and male fertility may improve after 4 months. It is not known when other effects start to develop.

### Are there any safety issues?

The herb should not be taken in pregnancy, and should be used with caution in people sensitive to the Solanaceae family of plants.

## Zinc

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Zinc was recognised as being essential for the growth of numerous plant and animal species by the 1960s. However, it was not until a fortuitous meeting in 1961, between the clinical scientist Prasad and a group of young Iranian men with severe growth retardation and hypogonadism, that zinc essentiality in humans was considered (Prasad 2013). A decade of controversy followed, ending with the discovery that zinc deficiency was central to the pathology of acrodermatitis enteropathica, a rare autosomal recessive trait that produces severe multisystem disease shortly after infants start weaning. In 1974 the National Research Council of the National Academy of Sciences finally declared zinc to be essential in human nutrition and established a recommended dietary allowance (RDA) (Prasad 2013). In human nutrition this is a relatively recent discovery and, as such, explains why zinc research is still in its infancy.

Zinc is an essential trace element known to play an important role in all human living cells. The human body contains approximately 2 g zinc in total, distributed across all body tissues and fluids, with 60% found in skeletal muscle and 30% in bone mass (Wahlqvist et al 2002). In spite of being a dietary trace element, it is one of the most abundant elements within cells and a complex homeostatic system maintains cellular zinc concentrations within a narrow range (King 2011). Its wide distribution and diverse roles have attracted the label of the ‘ubiquitous nutrient’ given by some authors (Hambridge 2000, King & Cousins 2006). Zinc belongs to the class of type II nutrients which are considered the cellular building blocks (Golden 1996, King & Cousins 2006) and therefore zinc, together with the other type II nutrients (essential amino acids,

magnesium, potassium, phosphorus, protein and sulfur), is required for the synthesis of any new tissue. They are not stored by the body and are under tight physiological control.

Dietary intake of zinc by healthy adults is 6–15 mg/day; however, less than half of this is absorbed (Beers & Berkow 2003). Zinc absorption is influenced by many factors and adequate dietary intake does not guarantee adequate zinc status. The International Zinc Nutrition Consultative Group (IZiNCG) concludes that the two key dietary influences on zinc bioavailability are phytates and calcium. Foods with high phytate content significantly reduce zinc absorption due to the formation of strong and insoluble complexes (Lonnerdal 2000) and a phytate:zinc molar ratio  $\geq 15$ , e.g. whole grains, seeds and nuts, is reported to render the zinc virtually unobtainable (IZiNCG 2004). In addition to this, calcium in large amounts constitutes the main antagonistic mineral interaction and therefore calcium-rich diets may also precipitate zinc deficiency. Soy protein has been shown to negatively impact zinc bioavailability, above and beyond its phytate content (Lim et al 2013). In contrast, the amount of animal protein in a meal positively correlates to zinc absorption and the amino acids histidine and methionine, and various organic acids present in foods, such as citric, malic and lactic acids, can also increase absorption. As such, zinc, similarly to iron, is best absorbed from animal food sources (King 2003). These combined factors may partly explain why vegetarians are at risk of low zinc status, a finding reported in a 2013 meta-analysis of 26 studies (Foster et al 2013).

Zinc absorption is a saturable process occurring in the small intestine principally via ZIP4, ZnT1 and, to a lesser extent, DMT1 (the shared divalent metal transporter) and CTR1 (primarily a copper

transporter) (Espinoza et al 2012, King 2010, 2011); however, there is evidence of unregulated paracellular uptake with very high doses. Regulated zinc uptake is influenced by current dietary intake of the mineral, i.e. as the total amount of zinc ingested increases, the fractional uptake decreases. This adjustment to high intakes is particularly apparent when single doses >20 mg are administered (Tran et al 2004). Several papers report that zinc bioavailability from supplements is significantly better than from food; however, longer-term studies have revealed that this diminishes over a few days of consecutive dosing, due to compensatory down-regulation of zinc transporters, and quickly becomes comparable with the fractional absorption seen with food (Hambidge et al 2010, King 2010, Tran et al 2004). Studies assessing bioavailability using disparate methods and sources have produced contrasting figures, from 46% to 74% (Tran et al 2004). A recent study evaluating average uptake from a standard Brazilian diet which controlled for phytate levels found that, while bioavailability varied from 11% to 47%, mean uptake was 30% (Ribeiro et al 2013).

Zinc homeostasis principally occurs in the gastrointestinal tract, whereby zinc uptake is balanced with endogenous zinc losses (Hambidge et al 2010, King 2010) which are estimated to total 0.5–3 mg/day. Other losses occur via urine and skin (0.5–0.7 mg) and semen (1 mg/ejaculate) (Lim et al 2013). When dietary zinc intake is insufficient, the body's homeostatic response is to minimise zinc losses and increase gastrointestinal absorption. As there is only a small zinc pool within the body, deficiency features develop quickly if dietary intake remains low. In growing children, deficiency signs and/or symptoms can develop within days, whereas for adults, this happens in a few weeks. Once zinc intake is increased, repletion can occur quickly, with rapid improvement of the clinical picture within days of supplementation (King 2011). Metallothionein (MT) is a cysteine-rich molecule found all over the body which can bind  $\leq 7$  zinc molecules, as well as other metals such as copper and cadmium. Gut and pancreatic MT concentrations respond readily to changes in dietary zinc; for example, high intakes induce MT synthesis and limit zinc absorption by binding zinc within the enterocyte and inhibiting basolateral transfer. Low dietary zinc produces a decline in pancreatic and renal MT, facilitating the decline in faecal and urinary zinc losses (King 2011).

Zinc is mainly an intracellular nutrient; little is found in the cytoplasm or found 'free' (loosely bound). This is likely due to its role in second-messenger systems, which means zinc levels need to be tightly regulated (primarily via MT) and largely sequestered inside organelles (Lazarczyk & Favre 2008).

Typically, only 5% of body zinc is found extracellularly (King 2011). Inflammatory processes and increased glucocorticoids can cause redistribution of

zinc, leading to sequestration by the liver and adipocytes (Ferro et al 2011). Two recent studies investigating altered zinc homeostasis in obesity (Feitosa et al 2013, Ferro et al 2011) found evidence of lower erythrocyte zinc, while Feitosa et al demonstrated an inverse relationship specifically with tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ), consistent with the hypothesis that chronic inflammation in obesity will negatively impact zinc homeostasis.

Lastly, zinc homeostasis is altered in the elderly due to both higher intracellular levels of MT and defective zinc influx transporters, ultimately producing less available free intracellular zinc (Mocchegiani et al 2011).

## CHEMICAL COMPONENTS

Zinc sulfate and gluconate are the most common forms of zinc found in commercially produced supplements. There is growing research on other forms, such as zinc picolinate and methionine and carnitine complexes, the latter specifically for gastrointestinal complaints. There is currently a lack of human research comparing the bioavailability of these forms; however, animal studies suggest that zinc sulfate is approximately twice as bioavailable as zinc oxide (in dogs, horses and rabbits), while zinc methionine and zinc propionate also produced significant increases in plasma zinc (Andermann & Dietz 1982, Wedekind & Lowry 1998, Wedekind et al 1992, 1994, Wichert et al 2002).

## FOOD SOURCES

Meat, liver, eggs and seafood (especially oysters and shellfish) are the best sources both quantitatively and qualitatively. While zinc is also found in nuts, legumes, whole grains and seeds, the high phytate content (stored phosphate) of these foods makes them an inferior source. Phytates can be reduced through fermentation or sprouting, which in turn would improve zinc bioavailability in these foods. Other dietary sources include miso, tofu, brewers' yeast, mushrooms and green beans. It has been reported that, while zinc is found as organic complexes in meats, it is presented as inorganic salts in plant foods (Lim et al 2013) and this may in part explain the superior bioavailability of zinc from animal products and seafood.

## DEFICIENCY SIGNS AND SYMPTOMS

Severe deficiency is rarely seen in industrialised countries, but marginal deficiency and inadequate intakes are not uncommon. According to a large national survey conducted in the United States of over 29,000 people, only 55.6% had adequate zinc intakes (based on total intakes of >77% of the 1989 US recommended daily intake (RDI) levels). Young children aged 1–3 years, female adolescents and older people aged  $\geq 71$  years had the lowest percentage of 'adequate' zinc intake, and were identified at greatest risk of deficiency (Briefel et al 2000).

Due to its important role in growth and development, zinc deficiency is characterised by impaired growth (linear growth velocity, weight or body composition) (Hambidge 2000). This will produce overt presentations in those life stages and tissues, necessitating rapid replication and turnover for health (Hambidge 2000), e.g. embryos, early childhood, adolescence, immune cells, epidermal and gastrointestinal tissue (Hambidge 2000, IZiNCG 2004, King 2000, King & Cousins 2006, Mahomed et al 1993), but often indiscernible pictures outside of these.

The clinical picture of mild zinc deficiency is subtle, ambiguous, idiosyncratic (Golden 1996, Hambidge 2000) and notoriously difficult to diagnose (Golden 1996, Wood 2000). King (2011) reminds us that, being a type II nutrient, zinc deficiency evokes sophisticated conservation mechanisms to limit endogenous losses and a metabolic adaptation to reduce the high-demand pathways for zinc such as growth and immunity. Altogether this can rapidly produce non-specific signs of metabolic or clinical dysfunction, such as malaise and apathy. Another prominent zinc researcher says, 'the ubiquity and versatility of zinc in subcellular metabolism suggest that zinc deficiency may well result in a generalised impairment of many metabolic functions' (Hambidge 2000, p 1345S).

### Signs and symptoms of deficiency

#### Most consistently reported

- Anorexia, impaired sense of taste and smell
- Slowed growth and development
- Delayed sexual maturation, hypogonadism, hypopermia and menstrual problems
- Dermatitis, particularly around the body's orifices, as seen in acrodermatitis enteropathica
- Alopecia
- Chronic and severe diarrhoea
- Immune system deficiencies and increased susceptibility to infection, including bacterial, viral and fungal
- Impaired wound healing due to decreased collagen synthesis
- Night blindness; swelling and clouding of the corneas
- Behavioural disturbances such as mental fatigue and depression (King 2003).

#### Less consistently reported

- Erectile dysfunction
- Anergy
- Glossitis
- Nail dystrophy
- Hypopigmented hair
- Photophobia
- Photic injury
- Swelling and clouding of the corneas
- Reduced serum testosterone in males
- Reduced alcohol clearance
- Hyperammonaemia
- Impaired protein synthesis.

Zinc deficiency in pregnancy is associated with the following (Bedwal & Bahuguna 1994, Prasad 1996):

- Increased maternal morbidity, pre-eclampsia and toxemia
- Prolonged gestation
- Inefficient labour
- Atonic bleeding
- Increased risk of abortion and stillbirths
- Teratogenicity
- Low-birth-weight infants
- Diminished attention in the newborn and poorer motor function at 6 months (Higdon 2003).

### PRIMARY DEFICIENCY (Table 1)

Primary deficiency occurs as a result of inadequate intake, with greatest risks seen in vegetarians and individuals consuming high-phytate diets. This is particularly the case in many developing countries, with the World Health Organization estimating that suboptimal zinc nutrition affected nearly half the world's population in 2002 (Mistry & Williams 2011).

In developed countries, phytate levels are greatest in 'healthy high-fibre diets' with greater intake of wholegrains and legumes and can provide in excess of 1000 mg phytic acid/day. Hambidge et al (2010) used a mathematical model to determine that the RDA would need to be doubled for such individuals. A study of 20 women with type 2 diabetes consuming a high-fibre diet ( $1194 \pm 824$  mg/day) found that this was a risk factor for zinc deficiency (Foster et al 2013). Recently a systematic review and meta-analysis of 26 studies examining the zinc status of vegetarians concluded that both dietary zinc intake and serum zinc were significantly lower in this group, with particular at-risk sub-groups being females, vegans and those living in developing countries (Foster et al 2013). As zinc is a type II nutrient (see Clinical note — Measuring zinc status is difficult), which is essential for cellular growth, the life stages that are most at risk of deficiency include childhood, adolescence and pregnancy.

### SECONDARY DEFICIENCY

Factors which interfere with zinc absorption (i.e. malabsorption), distribution (i.e. inflammation), retention (i.e. weight loss), excretion (e.g. antihypertensive drugs) or significantly increase requirements (i.e. specific infections or periods of growth) can all play a part in producing a secondary zinc deficiency, as per the following (Gehrig & Dinulos 2010):

- Acrodermatitis enteropathica, a rare autosomal recessive defect in zinc transporters that manifests rapidly as severe zinc deficiency in infants after weaning
- Anorexia nervosa
- Antihypertensive medication (in particular angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers and thiazide diuretics) (Braun & Rosenfeldt 2013)

TABLE 1 COMMON FEATURES OF MILD, MODERATE AND SEVERE ZINC DEFICIENCIES (PRASAD 2013)

Mild deficiency	Moderate deficiency	Severe deficiency
↓ Serum testosterone	Growth retardation	Growth retardation
Oligospermia	Male adolescent hypogonadism	Male adolescent hypogonadism
↓ Natural killer cell activity	Rough skin	Bullous pustular dermatitis, especially around orifices and extremities
↓ Interleukin-2 activity	↓ Appetite	Blepharitis, conjunctivitis
↓ T-helper cells	Mental lethargy	Photophobia
↓ Serum thymulin activity	Delayed wound healing	Alopecia
Hyperammonaemia	Cell-mediated immune dysfunction	Diarrhoea and changes to small intestinal villi
Hypogeusia (impaired taste)	Abnormal neurosensory changes	Weight loss
↓ Dark adaptation		Emotional disorders, e.g. irritability, emotional instability
↓ Lean body mass		↓ Healing of ulcers
		Death

- Breastfeeding
- Chronic alcoholism
- Malabsorption syndromes, e.g. Crohn's and coeliac disease (CD), ulcerative colitis, cystic fibrosis
- Renal impairments and dialysis
- Extensive cutaneous burns
- Hepatic or pancreatic insufficiency
- HIV infection
- Intestinal bypass procedures — percentage zinc absorption decreases significantly from 32.3% to 13.6% at 6 months after gastric bypass, with partial correction at 18 months (Ruz et al 2011)
- Prematurity with low zinc storage
- Penicillamine or chlorothiazide therapy
- *Yersinia enterocolitica* infection (Gehrig & Dinulos 2010)
- Obesity and cardiometabolic syndrome — redistribution due to chronic inflammation (Feitosa et al 2013, Ferro et al 2011, Foster & Samman 2012).

## MAIN ACTIONS

### Cofactor in many biochemical reactions

In humans, zinc metalloenzymes outnumber all the other trace mineral-dependent enzymes combined, with between 70 and 200 present in humans (Gropper et al 2009), found across all six different enzyme classes (Hambidge 2000). Consequently, zinc is involved in myriad chemical reactions that are important for normal body functioning, such as carbohydrate metabolism, protein and DNA synthesis, protein digestion, bone metabolism and endogenous antioxidant systems (Merck 2009, Wahlqvist et al 2002, Wardlaw et al 1997).

At the cellular level, zinc's functions can be divided into three categories: catalytic, structural and regulatory (King 2003, 2011). In its catalytic

capacity, zinc metalloenzymes are defined as those apometalloenzymes which are dependent upon the binding of zinc for their activity, such as alkaline phosphatase. Structural roles are evident in a range of proteins, enzymes, e.g. CuZn, superoxide dismutase (SOD) and biomembranes. Of particular note is the zinc finger motif, which allows zinc to be bound in a tetrahedral complex with two cysteines within the protein.

Zinc's contribution as an intra- and intercellular regulatory ion continues to emerge and includes its profound role in gene expression, whereby zinc binds to a metal-binding transcription factor and a metal response element in the promoter of the regulated gene to stimulate transcription (King 2011). Other regulatory roles include receptor-mediated signal transduction, neurotransmitter release from synaptic vesicles, packaging of insulin into pancreatic granules and subsequent release, antigen-dependent T-cell activation and insulin-like growth factor receptor binding (Hambidge 2000, King 2011, King & Cousins 2006).

### Growth and development

Zinc is essential for the formation of biomembranes and zinc finger motifs found in DNA transcription factors (Semrad 1999) and, belonging to the type II nutrient class, is required for the building of all new tissues (King 2011). Additionally, several studies of children with growth retardation and zinc deficiency have confirmed that repletion leads to increased levels and activity of growth hormone and insulin-like growth factor and insulin-like growth factor-binding proteins (Prasad 2013).

### Normal immune responses

Zinc is involved in many aspects of immunological function. It is essential for the normal development

**Clinical note — Measuring zinc status is difficult**

According to the scientific evidence, there is currently no means of assessing zinc status in humans (particularly with respect to the detection of marginal deficiency states) that has demonstrated absolute accuracy, and the identification of such a test has been flagged as an area requiring urgent research (Bales et al 1990, Hambidge 2000, IZiNCG 2004, Wood 2000). The assessment of zinc in orthodox medicine currently utilises serum or plasma assays (Gropper et al 2009, IZiNCG 2004, Wood 2000). Principally validated as a tool to assess zinc adequacy of populations (IZiNCG 2004, Wood 2000), serum/plasma zinc lacks the sensitivity to accurately ascertain the zinc status of the individual, with decreased values reflective of end-stage depletion only (Gordon et al 1982, Gropper et al 2009, Hambidge 2000, 2003, IZiNCG 2004, Wood 2000). Multiple established confounding variables include diurnal variation, concomitant infections and inflammation, acute stress and trauma, haemodilution of pregnancy, low serum albumin, high white blood cell counts and the concomitant use of hormones and steroids (King & Cousins 2006, Wood 2000). Each of these scenarios is susceptible to producing false negatives, underpinning concerns regarding the specificity of serum/plasma zinc assessment (Hambidge 2003, Hotz et al 2003). In addition to this, data from the National Health and Nutrition Examination Survey (NHANES II) revealed significant differences in the mean values of 'healthy individuals' dependent on age and sex alone (IZiNCG 2004). In spite of these documented limitations, this test remains the first-line assay in orthodox medicine.

A range of other biochemical indices have been used to assess zinc, including red (Kenney et al 1984, Prasad 1985) and white blood cells (Bunker et al 1987, Prasad 1985), platelets (Baer & King 1984), hair (Bunker et al 1987, Erten et al 1978, Hambidge 2003, McBean et al 1971, McKenzie 1979), nails (McKenzie 1979), saliva (Bales et al 1990, Freeland-Graves et al 1981, Greger &

Sickles 1979), sweat (Baer & King 1984, Eaton et al 2004) and urinary concentrations (Hambidge 2003, McKenzie 1979, Prasad 1985). All represent static measures and, as such, lack the sensitivity required to account for zinc's dynamic and complex homeostasis (Gropper et al 2009). Many researchers believe that an accurate indicator of zinc nutriture will therefore also need to be dynamic, similar to using ferritin as a marker for iron status (Hambidge 2000, 2003, Wood 2000) and measurement of both serum and erythrocyte metallothionein seems a likely candidate (King 2011).

One area of functional zinc assessment extensively researched since the 1970s is taste acuity testing (Gibson 1990, Gibson et al 1989, Henkin et al 1975b). Hypogeusia is recognised as an early indicator of zinc deficiency (Buzina et al 1980, Gibson 1990, Henkin et al 1975a, Kosman & Henkin 1981, Tanaka 2002, Wright et al 1981) and is believed to be the result of compromised gustin activity, a carbonic anhydrase zinc metalloenzyme which facilitates differentiation, growth and turnover of taste buds (Gibson et al 1989, Henkin et al 1975b, 1977, Law et al 1987, Thatcher et al 1998). The zinc taste response test (also known as the Bryce-Smith taste test) is a popular measure among naturopathic practitioners. It relies on patients detecting a taste after oral administration of 5–10 mL of a zinc sulfate heptahydrate solution. Delayed taste perception or lack of taste recognition is interpreted as a zinc deficiency state. This method is not particularly accurate and is hampered by variations in patients' subjective sense of taste and the fact that agents other than zinc influence taste perception. Clinical studies with zinc taste tests have confirmed the inconsistency of the results (Birmingham et al 2005, Eaton et al 2004, Garg et al 1993, Mahomed et al 1993) and a literature review of the zinc taste test, that remains popular in Australia and some other countries, reached the same conclusions (Gruner & Arthur 2012).

and function of cells, for mediating non-specific immunity such as neutrophils, monocytes and natural killer cells and for affecting the development of acquired immunity and T-lymphocyte function. Deficiency primarily impacts on T-lymphocyte function, reducing both peripheral numbers and thymic cells, compromising function of the T-helper and cytotoxic cells and reducing serum levels of thymulin and T-helper subset 1 cell cytokines, e.g. interleukin-2 and interferon-gamma. In addition, zinc depletion rapidly diminishes antibody and cell-mediated responses in both humans and animals, altogether leading to increased opportunistic infections and mortality rates (Fraker et al 2000, Prasad 2009, 2013).

Animal models have shown that suboptimal zinc intake over 30 days can lead to 30–80% loss in defence capacity and that this occurs significantly earlier than changes in serum or plasma values (Prasad 2013). Investigation using a human model has demonstrated that even mild deficiency in humans adversely affects T-cell functions (Prasad 1998). Conversely, high-dose zinc supplementation (20-fold RDI) can also produce immune dysfunction due to an induced copper deficiency.

A key area of research interest currently relates to zinc's influence on cytokine production. Zinc is regarded as a key anti-inflammatory nutrient due to its ability to both reduce the source of oxidative stress, reactive oxygen species (ROS), and control

the body's inflammatory response by reducing nuclear factor-kappaB (NF- $\kappa$ B), TNF-alpha and interleukin-beta (Feitosa et al 2013, Overbeck et al 2008, Prasad 2009, 2013). It is important to note, however, the new evidence of negative zinc redistribution that occurs in chronic inflammation that would hamper this anti-inflammatory role (Feitosa et al 2013).

### Gastrointestinal structure and function

Numerous animal studies demonstrate the deleterious effects of zinc deficiency on villi (atrophy, reduced height), crypt cells (reduced number and depth), mucosal cells (increased apoptosis), tissue integrity (increased ulceration, disruption of junctional complexes and cytoskeleton disorganisation in CaCo<sub>2</sub> cells) and immune response (increased inflammation) (Scrimgeour & Condlin 2009, Tran et al 2011). Secondary to this is clear evidence of impaired function, including reduced expression of the brush border disaccharidases. New animal research suggests that, in part, these actions require not just adequate zinc but healthy levels of MT. Importantly, zinc supplementation (in individuals with normal MT production) corrects these observed gastrointestinal tract anomalies (Tran et al 2011).

### Neurological function

Central nervous system zinc is found predominantly in the brain, specifically the hippocampus, amygdala and cortex, where it possesses both catalytic (cofactors) and regulatory roles (Szewczyk et al 2008). While 95% of brain zinc is bound to metalloproteins, the remainder is found in presynaptic vesicles. Neurons that contain these are known as zinc-enriched neurons (ZEN) (Frederickson & Danscher 1990, Frederickson & Moncrieff 1994, Frederickson et al 2000, Szewczyk et al 2008). Cerebellar ZEN are primarily associated with gamma-aminobutyric acid (GABA) neurotransmission, whereas in the other regions they are found in glutamate-producing neurons. Zinc therefore has the ability to inhibit both GABA and glutamergic receptors, making it a candidate for neuronal excitability modulation. It also potentially plays an important role in synaptic plasticity (Szewczyk et al 2008). Other general actions include the stabilisation of certain stored macromolecules in presynaptic vesicles, the inhibition of GSK3 phosphorylation, which leads to increased brain-derived neurotrophic factor (BDNF) levels, and its anti-inflammatory functions, which are all important for the health and function of the brain.

Specific neurotransmitter actions include potent dopamine transporter inhibition, which allows dopamine to stay and engage with receptors longer within the synapse. Zinc is now considered an important regulator of dopamine transporter function (Stockner et al 2013). There is also evidence of zinc modulating serotonin uptake in vitro (Szewczyk et al 2008).

### Prostate health

The prostate contains the highest zinc concentration of any soft tissue in humans. The concentration of zinc found in the prostate differs between the four lobes and is tightly regulated according to their different functions. The peripheral lobes hold the highest concentration and this relates to their central role in secretion of prostatic fluid, which contains  $\approx$ 500 mcg/mL of zinc compared with plasma, 1–2 mcg/mL. With ageing, the zinc content of both the prostate and its fluid declines, a factor which has been linked with declining fertility. Beyond acting as a reservoir for the high zinc needs of prostatic fluid, zinc also plays an important role in making citrate available, which is also found in large amounts in prostatic fluid and zinc is at unusually high levels within prostatic mitochondria (unknown reason). Lastly, zinc has an antimicrobial role within the fluid and the greater gland itself (Kelleher et al 2011).

Low prostatic zinc has been linked to prostate disease and, while there is evidence of some dysregulation of zinc within the gland in these individuals, dietary zinc deficiency alone has been associated with increased DNA damage in the prostate during oxidative stress. This becomes a vicious circle, in that the greater the oxidative stress, the greater the prostate's need for zinc (Kelleher et al 2011).

### Fertility

Zinc is important for both male and female fertility. In adult males, the testis and prostate have the highest concentration of zinc of any organ in the body (Bedwal & Bahuguna 1994). In moderate to severe zinc deficiency male hypogonadism has been well-documented (Prasad 2013). Zinc in humans is necessary for the formation and maturation of spermatozoa, for ovulation and for fertilisation (Favier 1992). Studies generally have shown a positive correlation between seminal zinc levels and sperm counts and motility. As an antioxidant, zinc protects vulnerable sperm from excess ROS, heavy metals, fluoride, cigarette smoke and heat (Sankako et al 2012, Talevi et al 2013, Yamaguchi et al 2009). An in vivo model of acute dietary zinc deficiency revealed that a zinc-deficient diet for 3–5 days pre-ovulation (preconception) dramatically disrupted oocyte chromatin methylation and preimplantation development (Tian & Diaz 2013). Zinc also has multiple actions on the metabolism of androgen hormones, oestrogen and progesterone, and these, together with the prostaglandins and nuclear receptors for steroids, are all zinc finger proteins.

### Pregnancy and lactation

Zinc is recognised as being a key nutrient during embryogenesis, fetal growth and development (Donangelo & King 2012, Mistry & Williams 2011). Severe deficiency results in a range of devastating outcomes, including multiple fetal

malformations, growth retardation or death, embryonic death and potentially life-threatening complications in both pregnancy and delivery (Chaffee & King 2012, Donangelo & King 2012). The consequences of mild to moderate deficiency are less clear, although most studies demonstrate reduced birth weights and some found increased prematurity, possibly secondary to maternal infection. There is also specific interest in zinc's antioxidant and anti-inflammatory roles in pregnancy and prevention of pre-eclampsia and fetal growth restriction, both of which have oxidative stress as an essential component (Chen et al 2012, Mistry & Williams 2011).

While it has been reported that zinc requirements in pregnancy would theoretically necessitate an 18–36% increase in dietary intake, most pregnant women do not increase zinc consumption (Donangelo & King 2012). This has led researchers to conclude that the primary means of meeting these higher zinc needs is via homeostatic adjustment; however, the exact mechanisms remain unclear and fail to completely compensate when zinc intake is significantly inadequate.

Similarly, zinc is essential for healthy mammary gland function, specifically the expansion and reduction of mammary tissue dependent upon stage of pregnancy and lactation, differentiation into secretory tissue, proliferation of the mammary epithelial cells which line the acini and transfer nutrients into milk, and milk secretion (Kelleher et al 2011). When milk zinc levels are compromised, this results in failure to thrive, diarrhoea, irritability and dermatitis in the infant (Kelleher et al 2011). Zinc losses in breast milk are significant, e.g. mean 1.35 mg/day, and if this was to be met by diet alone, a 50% increase in zinc intake would be required; however, limited evidence points to some adaptive mechanisms such as increased intestinal absorptive capacity, reduced faecal losses and increased renal conservation. The greatest contribution to maternal zinc during the postpartum period is speculated to be through resorption of trabecular bone. During 6 months of exclusive breastfeeding, 4–6% of maternal bone mass is lost, and this would contribute about 20% of the breast milk zinc during this period (Donangelo & King 2012).

### Antioxidant

Zinc limits oxidant-induced damage in a number of indirect ways. It protects against vitamin E depletion, controls vitamin A release, contributes to the structure of the antioxidant enzyme extracellular SOD, restricts endogenous free radical production, maintains tissue concentrations of MT, is a possible scavenger of free radicals, antagonising both iron and copper levels, and stabilises membrane structure (DiSilvestro 2000, Rai et al 2013). It was observed to decrease lipid peroxidation and protect mononuclear cells from TNF- $\alpha$ -induced NF- $\kappa$ B activation associated with oxidative stress (Prasad et al 2004).

### Supporting glycaemic control

Zinc pancreatic concentrations are very high, negatively impacted by deficiency and, not surprisingly, zinc possesses multiple related roles, including the processing, storage, secretion and action of insulin in  $\beta$  cells. In fact, as insulin and zinc are co-stored within the dense core vesicles (DCVs), when insulin is exocytosed (released), a substantial amount of ionic zinc is also released into local circulation, with important autocrine and paracrine effects on nearby cells (Li 2013, O'Halloran et al 2013), including 'switching off' glucagon release from the pancreatic  $\alpha$  cells (Kelleher et al 2011). The co-storage of zinc and insulin within  $\beta$  cells appears critical, such that polymorphisms that reduce expression of the zinc transporters expressed on these DCVs are associated with significantly reduced insulin secretion, increased HbA<sub>1c</sub> and an increased risk of type 2 diabetes (Chimienti 2013). Zinc is also an essential cofactor for insulin degradation, peripheral insulin signalling and several key zinc finger transcription factors are required for  $\beta$ -cell development and insulin gene expression (Kelleher et al 2011, O'Halloran et al 2013). Furthermore, zinc is necessary for activity of several gluconeogenic enzymes, including phosphoenolpyruvate carboxykinase, making zinc central in glucose metabolism regulation (Kelleher et al 2011).

Interestingly, another zinc-dependent enzyme, called insulin-responsive aminopeptidase (IRAP), is localised with GLUT4 transporters on cell membranes, with both upregulating in response to insulin (Kelleher et al 2011). Although the exact action of IRAP is yet to be elucidated, its membrane expression in muscle cells and adipocytes is reduced in type 2 diabetes, just like the GLUT4s, suggesting a strong link between zinc signalling and insulin activity.

Suboptimal zinc status decreases insulin secretion from the pancreas while during severe deficiency hyperglycaemia and hyperinsulinaemia can manifest (Kelleher et al 2011) and zinc supplementation has been shown to ameliorate some physiological aspects of diabetes.

### CLINICAL USE

Most of the clinical uses of zinc supplements are for conditions thought to arise from a marginal zinc deficiency, but some indications are based on the concept that high-dose zinc supplements act as a therapeutic agent above and beyond the point of repletion.

### Deficiency

Traditionally, zinc supplementation has been used to treat or prevent deficiency in conditions such as acrodermatitis enteropathica, anorexia nervosa, malabsorption syndromes, conditions associated with chronic, severe diarrhoea, alcoholism and liver cirrhosis, diabetes, HIV and AIDS, recurrent infections, severe burns, after major surgery, Wilson's disease and sickle cell anaemia. Zinc supplements are

also popular among athletes in order to counteract zinc losses that occur through perspiration. There are numerous supplementation and fortification schemes which include zinc in developing countries, where deficiency is most prevalent.

### Common cold

Oral zinc supplements, lozenges, nasal sprays and gels have been investigated in the prevention and treatment of the common cold. It has been demonstrated that a transient increase in zinc concentrations in and around the nasal cavity prevents rhinovirus binding to cells and disrupts infection (Novick et al 1996) and/or modulates inflammatory cytokines and histamine release, as well as astringes the trigeminal nerve, to reduce cold symptoms (Kurugöl et al 2007, Science et al 2012). There is also evidence to suggest that zinc inhibits viral replication and speculation regarding zinc's ability to change the activities of different transcription factors and thus the expression patterns of cellular and viral genes (Lazarczyk & Favre 2008).

Zinc's administration via a lozenge form appears particularly important regarding its efficacy in upper respiratory tract infections (URTIs). A prolific researcher in this area explains this via the 'mouth-nose biologically closed electric circuit' (BCEC) (Eby & Halcomb 2006). The BCEC moves electrons from the nose into the mouth and, in response to the electron flow, moves positively charged metal ions, such as ionic zinc, from the mouth into the nose, where it then exerts its key virucidal actions via competing with rhinoviruses for attachment to the intracellular adhesion molecule-1 receptor in nasal epithelium (Singh & Das 2013). If correct, this underscores the importance of using 'free' or ionic forms of zinc in the lozenge, rather than tightly bound ones (see Oral supplements, below).

### Acute treatment

#### Nasal preparations

At least three placebo-controlled studies indicate that intranasal preparations containing zinc have benefits in the treatment of the common cold; however safety issues regarding transient anosmia limit its use in practice.

Administration of a zinc sulfate (0.12%) nasal spray reduced the total symptom score significantly better than placebo, according to a double-blind randomised controlled trial involving 160 people. The same treatment had no effect on the duration of cold symptoms or mean time to resolution (Belongia et al 2001). Two other placebo-controlled trials showed that zinc in a nasal gel formulation significantly reduced cold duration compared with placebo when used within 24–48 hours of symptom onset (Hirt et al 2000, Mossad 2003). The active nasal gel spray contained 33 mmol/L zinc gluconate and was administered as one dose per nostril four times daily until symptoms resolved or for a maximum of 10 days. Symptoms that responded

included nasal drainage, hoarseness and sore throat (Mossad 2003).

Despite these promising results, concerns have been raised regarding temporary anosmia secondary to use of the zinc gluconate nasal preparations (Duncan-Lewis et al 2011). Based on consumer reports, in 2009 the US Food and Drug Administration issued a warning against the use of zinc nasal preparations, which were subsequently removed from the US market. The safety of these preparations has been the subject of debate between industry and government.

Anosmia has been reported in animal models following the application of nasal zinc chloride or sulfate preparations and a more recent study which nasally irrigated rats with zinc gluconate further confirmed temporary anosmia compared with placebo. While the sensory loss is only transient and the mechanism remains unclear, any sensory loss is worrying (Duncan-Lewis et al 2011, Hemila 2011).

#### Oral supplements

According to two meta-analyses, zinc lozenges ( $\geq 75$  mg/day) significantly reduce symptom duration compared to placebo in the acute treatment of URTIs but not symptom severity (Science et al 2012, Singh & Das 2013). Ideally, lozenges should be taken every 2 hours and started as soon as symptoms arise, thereby reducing symptom duration by about 1.65 days in adults (95% confidence interval  $-2.50$  to  $-0.81$ ) (Science et al 2012). They should not be taken with any food or beverage which may limit zinc absorption or ionisation (see Background and relevant pharmacokinetics, above).

While the body of evidence is positive, some adult studies do not demonstrate benefits, which may be due to differences in study methodology and whether zinc in the test preparation is accompanied by other ingredients which affect its release and/or absorption, such as citrate, tartrate, sorbitol or glycine, which decrease the level of free zinc ion (Hemila 2011). Since zinc ionisation is considered an important step in the clinical effectiveness of zinc, this is of particular concern. Ideally, future researchers should pay careful attention to exact lozenge composition in order to minimise this confounding factor (Hemila 2011, Silk & LeFante 2005). It has also been suggested that zinc lozenges be allowed to completely dissolve in the mouth without chewing and that citrus fruits or juices be avoided 30 minutes before or after dissolving each lozenge to avoid negating the therapeutic effects of zinc (Silk & LeFante 2005).

An updated Cochrane review of 16 double-blind randomised controlled trials ( $n = 1357$ ) investigating zinc administration  $\geq 75$  mg/day for acute treatment of URTIs concluded there was a significant mean reduction in symptom duration compared to placebo ( $P = 0.003$ ) and a smaller proportion of symptomatic individuals after 7 days in treatment groups; however, there was no significant difference in the severity of cold symptoms (Singh & Das 2013). Due

to the heterogeneity of the studies, the authors urge caution regarding their calculated average estimates. Another 2013 systematic review and meta-analysis tried to improve upon the Cochrane methodology, including 17 trials ( $n = 2121$ ) of oral zinc administration within 3 days of URTI symptom onset. They too concluded that, although no significant difference in symptom severity was evident, there was a mean reduction in duration (mean difference [MD]  $-1.65$  days, 95% confidence interval [CI]  $-2.50$  to  $-0.81$ ). A subgroup analysis revealed that the effect was only significant in adults (MD  $-2.63$ , 95% CI  $-3.69$  to  $-1.58$ ) and was restricted to studies using a zinc acetate form and when administered at higher doses, e.g.  $\geq 75$  mg/day. The authors speculate that the lack of significance in paediatric cohorts is due to lower doses, reduced frequency of administration and alternative forms used, e.g. syrups rather than lozenges. Their findings would suggest that the impact of zinc administration on reducing URTI duration has previously been underestimated in studies that fail to attend to these important details (Science et al 2012).

An earlier systematic review focused specifically on zinc lozenges in acute URTI treatment, with all but one study conducted in adults (Hemila 2011). This review demonstrates, and argues convincingly for the merit of, several differences in statistical analysis. Firstly, the authors make the point that URTI symptom duration is highly variable independent of any treatment, and, as such, is more logical to calculate via relative effect on duration, rather than an absolute, e.g. percentage rather than days. When calculated like this, the authors found the evidence strengthened for zinc lozenge efficacy. The review also presents an extended discussion of lozenge dose and form, most notably pointing out that there is a sevenfold difference in total daily zinc dose across the included studies. Subgroup analysis found no effect was evident in the five trials using  $< 75$  mg/day. In contrast, the majority of studies using  $> 75$  mg/day demonstrated positive effects. The review also found greater reductions in symptom duration with zinc acetate (mean  $-42\%$ , 95% CI 35–48) compared with other forms (mean effect  $-20\%$ , 95% CI 12–28). These findings were recently echoed by Science et al (2012).

### Prevention of colds

There is relatively little research dedicated to determining whether long-term zinc supplementation reduces URTI incidence. A 2013 Cochrane review included only two studies investigating zinc as a prophylactic treatment ( $n = 394$ ) and concluded there was very low-level evidence of efficacy; however, the studies differed in many key variables, e.g. dose, form, duration of administration and still collectively produced an incident rate ratio of 0.64 ( $P = 0.006$ ) (Singh & Das 2013). Critics of this review suggest that bias has insufficiently been accounted for and therefore the effect of zinc has possibly been overstated (Peters et al 2012).

### In children

A recent double-blind randomised controlled trial not included in the Cochrane review of 100 8–13-year-old children showed that administration of zinc *bis*-glycinate 15 mg once a day for 3 months was not sufficient to reduce the incidence of URTIs but did reduce symptom severity and duration associated with colds if an URTI developed, as compared to placebo (Rerksupphol & Rerksupphol 2013).

### In the elderly

Both zinc deficiency, due to poor dietary intake and altered homeostasis, and impaired cell-mediated immunity are commonly reported in the elderly ( $> 55$  years) and have been used to explain the increased infection rates observed in this population. A double-blind randomised controlled trial involving 50 healthy elderly subjects found that the majority had a marginal zinc deficiency and 35% were below the cut-off for frank deficiency, as measured via plasma zinc at baseline (Prasad et al 2007). Participants taking zinc gluconate supplements (45 mg/day) for 12 months experienced a significant reduction in infection incidence compared to placebo (88% vs 29%), with protective effects evident against URTIs (12% vs 24%), the common cold (10% vs 40%) and influenza (0% vs 12%). Also of note, while no individual in the treatment group experienced more than one infection in the 12-month period, six individuals taking placebo had two infections, and three subjects had three or more infections during the same period. Inflammatory cytokines and markers of oxidative stress were also investigated in this study, confirming zinc's role as both an anti-inflammatory and antioxidant in the elderly. Prior studies using much smaller zinc doses (15–20 mg/day) in multivitamin and mineral combinations failed to demonstrate efficacy in this cohort (Avenell et al 2005, Girodon et al 1999, Hemila 2011).

There is ongoing research interest in the relationship between zinc status and senescence, with preliminary *in vivo* studies pointing to zinc dysregulation being a key factor in the increasing inflammation and reduced immunocompetence seen with ageing (Mocchegiani et al 2011, Wong et al 2013).

### Pneumonia

Worldwide, pneumonia is the leading cause of paediatric morbidity and mortality and approximately 95% of the pneumonia-related deaths occur in developing countries where zinc deficiency is most prevalent (Shah et al 2012). Several studies have investigated both prevention and treatment of paediatric pneumonia using zinc supplementation, usually as an adjunct to standard treatment.

### Prevention

Supplemental zinc (70 mg/day) significantly reduced the incidence of pneumonia (relative risk [RR] 0.83) compared to placebo and significantly reduced

mortality ( $P = 0.013$ ) in a randomised controlled trial of 1665 poor, urban children aged < 12 months. In addition, active treatment resulted in a 49% decrease in the incidence of severe pneumonia and reduced URTI by 8% and reactive airways disease (bronchiolitis) by 12% (Brooks et al 2005).

Serum zinc concentrations have been shown to negatively correlate with pneumonia incidence in a study of nursing-home residents, prompting researchers to consider zinc as a potential prophylactic in this population also; however, there are currently no randomised controlled trials (Overbeck et al 2008).

### Active treatment

In terms of acute treatment, positive findings include the study by Brooks et al (2004) — a randomised controlled trial involving 270 children aged between 6 and 12 months, hospitalised with pneumonia, which found that those given 20 mg/day of zinc (as acetate) experienced significant reductions in recovery time from severe pneumonia. Overall hospital stay duration was also reduced when used with standard antimicrobial therapy (Brooks et al 2004). Results from a similarly designed study, however, failed to corroborate zinc as an effective treatment (Bose et al 2006).

It is possible that the lack of differentiation between bacterial and non-bacterial pneumonia in these studies is an important feature. Another study which investigated the efficacy of adjunctive zinc treatment (10 mg zinc sulfate administered twice daily) in paediatric patients (<2 years) hospitalised for severe pneumonia identified that zinc supplementation in bacterial pneumonia had detrimental effects which were not seen in non-bacterial cases (Coles et al 2007). Further research is not available to confirm these results.

A Cochrane review includes four trials of zinc given as an adjunct to standard antimicrobial therapy in children ( $n = 3267$ ) aged 2–35 months suffering with severe and non-severe pneumonia (Haider et al 2011). The studies by Brooks et al (2004) and Bose et al (2006) were included along with two other moderately-sized trials. All four studies tested 20 mg elemental zinc per day, except that by Valentiner-Branth et al (2010), who administered only 10 mg/day for <12 months. Duration of treatment varied from as little as 5 days to >14 days (discharge). The reviewers concluded that there was no significant reduction in clinical recovery in the groups receiving adjunctive zinc; however, none of the studies identified whether the aetiology was bacterial or viral, which, according to the findings of Coles et al (2007), limits the meaningfulness of these conclusions.

A 2012 meta-analysis of seven studies ( $n = 1066$ ), including many of the ones already discussed, concludes that zinc supplementation fails to produce significant reductions in recovery time from paediatric pneumonia. The authors acknowledge several limitations of the review, including lack of

distinction between bacterial and viral aetiologies (Das et al 2012). They also suggest that future studies should consider higher doses given the absence of adverse reactions and standardise definitions, recovery parameters, timing and doses of zinc before drawing definitive conclusions.

Since these two reviews were published, two other key studies have been conducted which provide additional insight. A Ugandan study of 352 children aged 6–59 months (Srinivasan et al 2012) provides us with a well-thought-out methodology, clearly taking into account the findings of recent research in this area, such as that by Coles et al (2007). Zinc gluconate was administered (<12 months received 10 mg/day, >12 months 20 mg/day) to the treatment group for 7 days. Both placebo and treatment groups also received vitamin A, in line with World Health Organization recommendations. Baseline plasma zinc levels were lower than seen in other studies (e.g. 4.4 micromol/L [1.3–8.0]) and the researchers confirmed that 17.7% of the sample were HIV-positive (highly active antiretroviral treatment-naïve). Interestingly, while zinc failed to reduce recovery time, it significantly reduced mortality (18.8% in placebo versus 6.7%; RR 0.3). This protective effect seen across the treatment group on further analysis was found to be greatest amongst the HIV-positive children (11% in placebo vs 0%; RR 0.2). Additionally, children with either bacterial or viral pneumonia when treated with zinc demonstrated reduced mortality; the majority of cases (75.5%) had a viral cause. The number needed to treat in order to save one life was 13 and, poignantly, the authors comment that this comes at a meagre cost of US\$4.

Another study of adjunctive zinc (20 mg/day sulfate; administered for a maximum of 14 days) in paediatric (2–24 months) pneumonia ( $n = 550$ ) where baseline plasma zinc averaged  $\approx 9$  micromol/L found that, in spite of significant increases in plasma zinc levels in the treatment group ( $4.3 \pm 5.6$  micromol), there was no significant reduction in time to recovery overall (Wadhwa et al 2013). Further analysis revealed that children diagnosed with very severe pneumonia at baseline did exhibit increased recovery time with zinc supplementation and there was a non-significant trend of reduced treatment failure in this subgroup.

### Age-related macular degeneration (ARMD)

Both dietary and supplemental zinc have been investigated in the prevention and/or delayed progression of ARMD. This is not surprising as evidence that lifetime oxidative stress plays an important role in the development of ARMD is now compelling (Hogg & Chakravarthy 2004). ARMD is thought to be the result of free radical damage to photoreceptors within the macula, and therefore it is suspected that inefficient macular antioxidant systems play a role in disease development. After ageing, smoking is the next significant risk factor and a direct association between risk and the number

of cigarettes smoked has been reported (Coleman et al 2008, Wills et al 2008a). Smokers have four times greater retinal cadmium concentrations than non-smokers and the associated morphological changes are reasonably consistent with ARMD pathology (Wills et al 2008a).

A 2005 study found that high dietary intake of zinc, beta-carotene and vitamins C and E was associated with a 35% reduced risk in elderly persons (van Leeuwen et al 2005). Similarly, the Blue Mountains Eye Study, an Australian prospective population-based cohort study conducted over 10 years, demonstrated protective effects of lutein and zeaxanthin, but also found that those individuals consuming the highest zinc had an RR of 0.56 for any ARMD and 0.54 for early ARMD compared with all other participants (Tan et al 2008). An interesting study has revealed that increased lifetime exposure to blue light appears to amplify the risk of low dietary antioxidants and zinc (Fletcher et al 2008). Originally it was believed that zinc simply acts as an antioxidant in this condition, yet ongoing discussions of zinc's possible actions in the prevention of this aetiology has produced new hypotheses.

A comparison of zinc and copper concentrations within the retinal pigment epithelium and choroid complex of eye donor subjects previously suffering from ARMD and those without the condition has revealed a 23–24% reduction in these metals in afflicted subjects (Erie et al 2009). Furthermore, *in vitro* studies confirm that zinc and copper, as well as manganese (the latter being most potent), effectively prevent the intracellular concentration of cadmium in retinal tissues and hence modulate its toxicity (Satarug et al 2008, Wills et al 2008b). Taken together, the knowledge that zinc and copper supplementation, in combination with antioxidants, has delayed progression of ARMD points towards a critical role for metal homeostasis in retinal health.

A 2006 Cochrane review assessed the effects of antioxidant vitamin and/or mineral supplementation on the progression of ARMD and found that evidence of effectiveness is currently dominated by one large trial that showed modest benefit in people with moderate to severe signs of the disease (Evans 2002). The study the authors refer to is the Age-Related Eye Disease Study (AREDS 2001), which showed that high-dose vitamins C and E, beta-carotene and zinc supplementation delayed the progression from intermediate to advanced disease by 25% over 5 years. The 11-centre, double-blind, prospective study involved 3640 volunteers aged between 55 and 80 years who were randomly divided into four treatment groups, receiving either antioxidant supplements (500 mg vitamin C, 400 IU vitamin E, and 15 mg beta-carotene daily), zinc oxide and cupric oxide (80 mg elemental zinc, 2 mg elemental copper daily), antioxidants plus zinc, or placebo. This treatment effect appeared to persist following 5 additional years of follow-up after the clinical trial was stopped. The AREDS

formulation became the standard of care for persons who are at high risk for ARMD (Chew 2013); however, the actual contribution of zinc to this result is unknown (see Lutein monograph for more information about ARMD).

A more recent randomised controlled trial tested supplementation with zinc monocrystalline (25 mg elemental zinc twice daily) as a stand-alone treatment to 80 ARMD patients over 6 months (Newsome 2008). Those in the treatment group experienced improved visual acuity, contrast sensitivity and reduced macular light flash recovery time when compared with the placebo group, with some benefits evident 3 months into the treatment.

Overall, current evidence suggests that zinc supplementation, either alone or in combination with other antioxidants, may help to prevent ARMD in those at least at moderate risk and delay progression of this condition in those suffering the early stages. Additional evidence suggests that genetic factors may be important when determining who will best respond to this treatment. Retrospective analyses of the AREDS study demonstrated a strong interaction between those individuals whose progression of the condition was delayed by zinc supplementation and the presence of the complement factor H genotype (Klein et al 2008, Lee & Brantley 2008). Substantiation of these findings could assist in the improved targeting of ARMD nutritional therapies.

### Herpes simplex virus (HSV) infection

Various topical zinc applications have been studied, producing encouraging results in reducing the incidence, severity and duration of symptoms in HSV infection.

In a study of 90 volunteers with diagnosed genital herpes, three different concentrations of liquid zinc sulfate (1%, 2% and 4%) were compared. The strongest concentration (4%) gave the lowest risk of recurrence over a 6-month test period compared to the others or a control group using only distilled water (Mahajan et al 2013). The treatments were applied with a cotton bud to genital herpetic lesions every 5 days for a month, then every 10 days for 2 months and finally every 15 days for 3 months. This protective effect has also been demonstrated *in vivo* for topical zinc acetate (0.5–1%) in a carrageenan-based gel applied locally for 7 days prior to vaginal or rectal exposure to the virus (Kenney et al 2013).

A double-blind randomised controlled trial of 46 people with facial and circumoral herpes infection showed that prompt application of a zinc oxide and glycine cream every 2 hours reduced recovery time from 6.5 to 5 days. The people using active treatment also experienced a reduction in the overall severity of signs and symptoms, particularly blistering, soreness, itching and tingling, compared to controls. The only side effects reported were a burning and itching sensation (Godfrey et al 2001). Previously, another double-blind randomised controlled trial showed that a zinc sulfate (1%) gel

applied every few hours resulted in 50% of patients with HSV-1 becoming symptom-free by day 5 compared to only 35% in the placebo group (Kneist et al 1995). Another study of 200 volunteers with herpes simplex found that a lower dose of only 0.25% zinc sulfate solution, started within 24 hours of lesion appearance and applied 8–10 times daily, cleared lesions within 3–6 days (Finnerty 1986). Not surprisingly, a randomised controlled trial using a far lower dose of 0.05% or 0.025% zinc sulfate found no effects on frequency, duration or severity of herpes attacks, suggesting that stronger concentrations are required for effectiveness (Graham et al 1985).

According to an experimental study using zinc oxide, the attachment of HSV-2 to target cells is inhibited by the presence of zinc (Antoine et al 2012). In vitro studies also confirm that zinc can inhibit the replication of HSV; however, the concentration required is much higher than possible in a physiological context (Overbeck et al 2008).

Interestingly, new research suggests that people with recurrent HSV-1 have significantly lower salivary zinc levels compared to healthy controls and that levels are lowest in the acute phase compared to the convalescent phase (Khozeimeh et al 2012).

### Diabetes mellitus (type 1 and 2)

Zinc is abundant in the pancreas due to extensive roles in both its endocrine and exocrine functions. During deficiency, this is one of the few tissues that demonstrates reduced concentrations (Islam & Loots 2007). Limited data derived from both epidemiological studies and animal models suggest that increased dietary zinc intake may be protective against the development of both types of diabetes (Bolkent et al 2009, Islam & Loots 2007, Sun et al 2009). It is suspected that zinc may have a protective role due to its antioxidant activity, both directly and indirectly, via MT induction (Islam & Loots 2007). Decreasing oxidative stress may protect beta cells from damage and therefore assist in maintaining normal insulin secretion.

Zinc supplementation is sometimes used to avoid deficiency, a state synonymous with both type 1 and type 2 diabetes due to a combination of increased losses and reduced uptake (Chimienti 2013, Cunningham et al 1994). While animal studies have demonstrated improved glucose management with zinc, the results from human studies are less consistent (Chimienti 2013). It remains unclear whether simply addressing zinc deficiency or using high-dose zinc to induce other effects will be beneficial in the clinical management of diabetes, its complications or its prevention, as evidence from both animal and human studies has produced varying results (Baydas et al 2002, Cunningham et al 1994, Farvid et al 2004, Gupta et al 1998, Niewoehner et al 1986, Roussel et al 2003, Tobia et al 1998).

Several intervention studies utilising oral zinc have produced positive results in populations with type 1 diabetes, with evidence of reduced HbA<sub>1c</sub>

amongst individuals in the treatment group (30 mg/day elemental zinc for 3 months) when compared to controls (Al-Marouf & Al-Sharbati 2006), improved blood lipid profiles following 12 weeks of zinc treatment (100 mg/day zinc sulfate) in another study (Partida-Hernández et al 2006) and improved glycaemic control and diabetic neuropathy in 20 patients administered 660 mg/day zinc sulfate over 6 weeks (Hayee et al 2005). Interestingly, new research has identified a fourth autoantibody common to type 1 diabetes which is made against the zinc transporter unique to islet cells (ZnT8) and therefore impairs zinc accumulation within the DCVs, making altered zinc regulation a potential cause (Chimienti 2013, O'Halloran et al 2013). Incredibly, since the 1930s it was known that the pancreas of diabetics contained only half of the zinc found in healthy individuals (Chimienti 2013).

Zinc supplementation to address the secondary multisystem effects of type 1 diabetes has been investigated with regard to vascular changes in mice. In control genetic type 1 diabetes mice, significant increases in aortic oxidative damage, inflammation, fibrosis and thickness were observed; however, in mice receiving ZnSO<sub>4</sub> 5 mg/kg over 3 months these changes were completely prevented, reportedly due to upregulation of both MT and Nrf2 (Miao et al 2013). In vitro studies of human endothelial cells have produced similar findings.

With respect to type 2 diabetes, a prospective, double-blind, clinical interventional study of 56 obese women with normal glucose tolerance randomised subjects to treatment with zinc, 30 mg/day, or placebo for 4 weeks (Marreiro et al 2002). Zinc treatment decreased insulin resistance from 5.8 to 4.3 and insulin decreased from 28.8 to 21.2 mU/mL, but was unchanged in the placebo group. These results are particularly noteworthy because the women were not zinc-deficient, suggesting a therapeutic role for zinc. Another small study of metformin-resistant patients with type 2 diabetes administered zinc (zinc acetate 50 mg/day) in combination with melatonin (10 mg/day) ± metformin to two treatment groups and placebo to a third (Hussain et al 2006). This combined treatment proved effective in improving fasting and postprandial glucose levels and augmented the action of the hypoglycaemic drug.

Zinc deficiency has been established as an independent risk factor for fatal coronary heart disease events in a large cohort of patients with type 2 diabetes, with serum zinc values < 14.1 micromol/L associated with 20.8% patients with fatal events versus 12.8% ( $P < 0.001$ ) (Sarmiento et al 2013, Soinio et al 2007). Studies investigating zinc's potential for reducing these secondary deleterious effects are still emerging. One randomised double-blind crossover study of 50 patients with type 2 diabetes with microalbuminuria, administered 30 mg/day elemental zinc over 3 months, revealed a significant reduction in homocysteine levels (from  $13.71 \pm 3.84$  micromol/L to  $11.79 \pm 3.06$  micromol/L;

$P < 0.05$ ), a cardiovascular inflammatory mediator, while improving folate and B<sub>12</sub> status. Other proposed protective effects are via both general anti-inflammatory and antioxidant actions as well as via MT induction (Miao et al 2013).

Regarding diabetic retinopathy, hypothesised protective mechanisms include zinc's inhibition of vascular endothelial growth factor, involved in the initiation and progression of neovascularisation and vascular leakage in diabetic retinopathy; however, clinical studies are lacking to date (Miao et al 2013).

Further studies with larger sample sizes are required to validate zinc as an effective treatment in type 1 and 2 diabetes and elucidate the optimal dosing and administration regimen. There is currently a study under way in Sri Lanka investigating zinc supplementation in prediabetics which may also further our knowledge in this area (Ranasinghe et al 2013).

#### **Clinical note — Zinc deficiency and diabetes**

Diabetes affects zinc homeostasis in many ways and is associated with increased urinary loss, decreased absorption and decreased total body zinc (Chausmer 1998, Cunningham et al 1994). The role of zinc and zinc deficiency in diabetes and its complications or prevention is currently unclear. It has been suggested that deficiency may exacerbate destruction of islet cells in type 1 diabetes and may adversely affect the synthesis, storage and secretion of insulin, a process that requires zinc. Furthermore, evidence indicates that patients with type 1 diabetes have a higher concentration of free radicals than healthy controls; this is due to increased oxidant production and/or decreased efficiency of endogenous antioxidant systems (Davison et al 2002). It is suspected that deficiency of key micronutrients (i.e. zinc, copper, manganese and selenium), which are integral components of important antioxidant systems, may be partly responsible.

#### **Wound healing**

Zinc is an essential cofactor in both wound healing and immune function. Therefore, zinc deficiency retards both fibroplasia and epithelialisation, and results in delayed wound healing in spite of maintained skin stores of zinc, except in instances of severe concomitant protein restriction (Lansdown et al 2007). Zinc supplements are used to restore zinc status in cases of wound healing associated with malnutrition and deficiency. Additionally, zinc administered orally or topically to wounds can promote healing and reduce infection, according to one major review (Lansdown 1996).

#### **Oral application**

In 2001, a randomised study demonstrated that oral zinc sulfate significantly improved healing of cutaneous leishmaniasis (Sharquie et al 2001). Results showed that the cure rate for a dose of 2.5 mg/kg

was 83.9%, for 5 mg/kg it was 93.1% and for 10 mg/kg it was 96.9%, whereas no lesions showed any sign of healing in the control group. The results of several studies suggest a specific role for oral zinc in surgical wound repair (Lansdown et al 2007). Zinc redistribution and sequestration in the liver occur following both surgical trauma and infection. The corresponding reduction in serum zinc may then impair the individual's healing capacity, as demonstrated in a study of 80 total hip replacement patients (mean age 66 years), in whom serum zinc levels were significantly related to rates of infection and dehiscence (Lansdown et al 2007). Similarly, an interventional study of pre- and postoperative zinc infusion (30 mg/day) in patients undergoing major vascular reconstructive surgery attenuated the anticipated decline in serum zinc and produced significantly fewer wound-healing complications than placebo.

#### **Topical application**

Theoretically, topical zinc treatment is most suited to human wound healing that necessitates epithelialisation, e.g. suction blister wound, superficial small incision and split-thickness skin graft donor sites. While clinical trials have demonstrated its efficacy in relation to treatment of leg ulcers, pressure ulcers, diabetic foot ulcers and burn wounds (Lansdown et al 2007), one study also demonstrated that *Staphylococcus aureus* was cultured significantly less frequently in zinc oxide-treated wounds, which points to the additional antiseptic action. Topical zinc oxide promotes cleansing and re-epithelialisation of ulcers and reduces the risk of infection and deterioration of ulcers compared with placebo, according to one double-blind trial of leg ulcer patients with low serum zinc levels (Agren 1990). Evidence from animal and in vitro research suggests that topically applied zinc solution is more effective when combined with iron than when used alone, and can effectively enhance healing in acute partial-thickness and second-degree burn wounds (Feiner et al 2003). The form of zinc used topically may be of marked importance, with some studies investigating high concentrations of zinc sulfate delaying healing and increasing dermal inflammatory cell infiltration (Lansdown et al 2007). Preparations such as zinc oxide may be more suitable than readily water-soluble forms, providing a sustained release of bio-available zinc at non-cytotoxic levels. Interestingly, pharmacopoeias attribute various zinc forms with different qualities/actions, e.g. zinc sulfate is regarded as a local astringent and antiseptic, insoluble zinc oxide as a mild antiseptic, astringent and protective agent, particularly indicated in inflamed skin and wounds.

#### **Arterial and venous leg ulcers**

Chronic leg ulcer patients often exhibit abnormal zinc metabolism and depressed serum concentrations (Lansdown et al 2007). A 2000 Cochrane review assessed six placebo-controlled trials of zinc sulfate

supplementation ( $\approx 220$  mg administered three times daily) in arterial and venous leg ulcers and concluded that, overall, there is no evidence of a beneficial effect on the number of ulcers healed. However, there is some evidence that oral zinc might improve healing of venous ulcers in people with low serum zinc levels (Wilkinson & Hawke 2000).

Double-blind studies producing encouraging results have used oral zinc (600 mg/day) combined with topical treatment and compression bandages (Haeger & Lanner 1974, Hallbook & Lanner 1972).

### Acne and other skin conditions

Over the past two to three decades, tetracyclines and macrolide antibiotics have been widely prescribed for the treatment of acne; however, resistance has been reported, especially to erythromycin and clindamycin, with cross-resistance being widespread among strains of *Propionibacterium acnes* and increasing (Iinuma et al 2011). As a result, non-antibiotic treatments such as topical/oral zinc preparations have been investigated as both alternatives and adjunctive therapy.

Overall, there is increasingly consistent clinical evidence of the efficacy of zinc (both oral and topical) for the treatment of acne, showing it can improve skin condition. However, definitive conclusions are hampered by some poor-quality studies. Some studies utilise zinc supplementation in combination with other nutrients, making it difficult to ascertain the role of zinc but providing clinical guidance nonetheless.

Surprisingly, it is only recently that epidemiological research has demonstrated lower plasma zinc in acne patients ( $P < 0.001$ ) and that blood zinc (and vitamin E) correlates with acne severity (Ozuguz et al 2014). Dietary analysis was not performed in this study, which still leaves the question of whether the low zinc is the cause or consequence of acne.

### Oral supplementation

Numerous studies have been conducted investigating the effects of zinc supplementation in acne vulgaris (Dreno et al 1989, 1992, 2001, Goransson et al 1978, Hillstrom et al 1977, Orris et al 1978, Verma et al 1980, Weimar et al 1978, Weismann et al 1977). Doses between 90 mg and 200 mg (30 mg elemental zinc) daily taken over 6–12 weeks have been associated with generally positive results, whereas larger doses tend to be poorly tolerated.

Two double-blind studies have compared the effects of oral zinc supplementation with two antibiotic medicines, minocycline or oxytetracycline, over 3 months (Cunliffe et al 1979, Dreno et al 1989). Zinc sulfate (135 mg) was as effective as oxytetracycline after 12 weeks' use, decreasing acne scores by 65% in one study, whereas the same dose was not as effective as minocycline (500 mg) in the second study. An open study involving 30 subjects with inflammatory acne found that a lower dose of oral zinc gluconate (30 mg) taken daily reduced the

number of inflammatory lesions after 2 months, regardless of whether *P. acnes* was present (Dreno et al 2005).

Both oral and topical zinc have also been investigated as an adjunct to antibiotic therapy under laboratory conditions. When administered in combination with erythromycin, it inhibits erythromycin-resistant propionibacteria according to two in vitro studies (Dreno et al 2005, Oprica et al 2002).

### IN COMBINATION

A more recent open-label observational study involving 48 subjects with moderate acne vulgaris, treated with a zinc antioxidant combination (equivalent to 15 mg elemental zinc, 60 mg vitamin C, 15 IU vitamin E and 0.13 mg chromium) administered over 12 weeks produced a 79% response rate. Although a large clinical improvement (80–100%) was reported, particularly with respect to reduced inflammatory features, the absence of a control group and blinding of the intervention detract from the positive findings (Sardana & Garg 2010). Similarly, another open-label trial with positive findings in acne patients adds little to our evidence base for zinc, given the intervention was a multivitamin mineral containing forms of zinc and other minerals with poor bio-availability, i.e. oxides (Shalita et al 2012).

### Topical application

A number of studies have investigated the effects of a topical erythromycin–zinc acetate ( $\approx 1.2\%$ ) formulation (Bojar et al 1994, Feucht et al 1980, Habbema et al 1989, Morgan et al 1993, Pierard & Pierard-Franchimont 1993, Pierard-Franchimont et al 1995, Schachner et al 1990).

Statistically significant effects have been observed within the first 12 weeks of treatment for acne severity grades, and for papule, pustule and comedo counts, with the effect of the combination superior to preparations containing erythromycin alone (Habbema et al 1989, Schachner et al 1990). A systematic review of acne treatments also concluded that topical erythromycin–zinc appears to be more effective than the antibiotic alone for the treatment of both inflammatory and non-inflammatory lesions (Purdy & de Berker 2011).

A 2013 review of 29 studies investigating zinc and acne concluded that there is inconsistent or limited quality patient-centred evidence for either oral or topical treatment with zinc; however, the review was funded and partly written by Galderma, a manufacturer of non-zinc-based acne treatments, thereby requiring confirmation by other researchers (Brandt 2013).

Human studies have identified antibacterial activity against *Propionibacterium* spp. in short-term treatment, which is mostly attributed to zinc (Fluhr et al 1999) and sebosuppressive effects (Pierard & Pierard-Franchimont 1993). New in vitro research, building on prior successful studies using topical ascorbic acid derivatives, has found superior antimicrobial activity in zinc ascorbate compared with other ascorbates, e.g. 0.064% concentration compared with 5%

(Iinuma et al 2011). The study also confirms an additive effect when combined with some topical antibiotics (i.e. erythromycin and clindamycin) and, perhaps more impressively, demonstrated that zinc ascorbate was effective as a stand-alone treatment in inhibiting the proliferation of antibiotic-resistant strains of *P. acnes* (minimum inhibitory concentration 640 mcg/mL). The same researchers have shown topical zinc ascorbate similarly possesses potent antimicrobial activity against *Staphylococcus aureus* and, to a lesser extent, *Escherichia coli*, Gram-negative bacteria that typically act in concert with *P. acnes* in acne vulgaris. Again this is seen at significantly lower concentrations than with other ascorbate derivatives and ascorbic acid alone (Iinuma & Tsuboi 2012). Both zinc and ascorbic acid's capacity to inhibit ROS production (SOD-like activity) is speculated as an important attribute in acne treatment, with previous research demonstrating that elevated ROS and impaired SOD are characteristic features in acne patients, leading to an excess inflammatory response.

### Reduced male fertility

Zinc deficiency leads to several clinical signs, such as decreased spermatogenesis, altered sperm morphology and impaired male fertility and, given zinc's pivotal role in DNA transcription, this is not surprising. Furthermore, zinc finger proteins are critical to the genetic expression of steroid hormone receptors. Together with zinc's additional antiapoptotic and antioxidant actions, these effects make zinc a promising contributor to healthy sperm (Ebisch et al 2007). The relationship between zinc concentrations in seminal fluid and semen fertility, however, remains somewhat unclear.

When zinc deficiency is not present, a 2002 survey found no statistically significant relationship between zinc in seminal plasma or serum and semen quality or local antisperm antibody of the immunoglobulin G (IgG) or IgA class (Eggert-Kruse et al 2002). Furthermore, zinc levels did not influence sperm capacity to penetrate cervical mucus in vitro or in vivo, nor affect subsequent fertility. However, a study of Chinese men (aged 20–59 years) revealed that, when serum zinc concentration was low, the risk of asthenozoospermia increased and the Cu/Zn ratio was higher in those with progressive motility abnormalities (Yuyan et al 2008).

In contrast to this, a small number of both animal (Kumar et al 2006) and human supplementation studies (Ebisch et al 2006) have produced positive results. The latter study, involving 40 subfertile and 47 fertile men treated for 26 weeks with 66 mg/day zinc sulfate and 5 mg/day folic acid or placebo, produced a 74% increase in normal sperm count in the subfertile subjects; however, more studies with larger sample sizes and measurement of pregnancy outcomes are required to substantiate these preliminary findings. In spite of this relative paucity of randomised controlled trial evidence, a trend of treatment has begun. A recent review of antioxidant

supplementation in the treatment of idiopathic oligoasthenoteratospermia observes that, while elevated ROS is undoubtedly damaging to spermatids and mature spermatozoa and is implicated in male infertility, antioxidant treatment including zinc, which has become widely accepted, is yet to be established as efficacious (Agarwal & Sekhon 2010).

### Impotence

In men, zinc deficiency may lead to impaired testosterone synthesis, resulting in hypogonadism and impotency. One placebo-controlled study has investigated whether oral zinc supplementation improves erectile dysfunction. The study involved 20 uraemic haemodialysis patients and showed that 6 months' treatment with oral zinc acetate (25 mg elemental zinc) taken twice daily 1–2 hours before meals resulted in greater libido, improved potency and more frequent intercourse compared to placebo (Mahajan et al 1982). Active treatment also resulted in significant increases in plasma zinc, serum testosterone and sperm count and decreases in serum levels of luteinising hormone and follicle-stimulating hormone.

### Attention-deficit hyperactivity disorder (ADHD)

Zinc deficiency has been implicated in the pathogenesis of ADHD from numerous perspectives. With a critical role in neurological development and evidence of impaired learning and depressed psychomotor retardation in deficiency states, zinc may constitute a direct aetiological cause (Black 2003, Fanjiang & Kleinman 2007). An interesting longitudinal paediatric study found that children with malnutrition (protein, zinc and iron deficiencies) at 3 years of age demonstrated higher externalisation behaviour problems at 8, 11 and 17 years, when compared to replete children (Liu & Raine 2006), with this trifecta of deficiencies, a particularly common combination in young children.

Hypotheses of indirect actions of zinc deficiency include negative behavioural effects mediated via impaired fatty acid metabolism, blockage of the dopamine transporter to increase synaptic concentrations and through the exacerbation of heavy-metal effects.

In 1990, Arnold et al observed that boys aged 6–12 years with ADHD and a higher baseline hair zinc level had better responses to amphetamine therapy than children with hair concentrations indicative of mild zinc deficiency. At the time, it was suggested that poor/non-responders to drug therapy and those presenting with suboptimal zinc status would require zinc supplementation instead of amphetamine treatment to address the condition. Since then, numerous controlled studies have identified that children with ADHD have lower zinc tissue levels (serum, red cells, hair, urine, nails) than normal children (Arnold & DiSilvestro 2005). It is not certain why this occurs, but it may result from not sitting for long enough to consume a balanced diet, picky eating, stimulant-related appetite suppression, malabsorption or biochemical changes.

Recently it has been suggested that zinc may be a proxy of poor diet quality in this group (Ghanizadeh & Berk 2013). Zinc status has also been shown to correlate with the amplitude and latency of select brain waves, suggesting that zinc may particularly influence information processing in ADHD children (Yorbik et al 2008).

Three early double-blind studies, all conducted in Middle Eastern populations, investigated whether oral zinc supplementation has a beneficial effect in ADHD, producing promising results. One randomised study involving 400 Turkish children with a mean age of 9.6 years found that treatment with 150 mg zinc sulfate (equivalent to 40 mg of elemental zinc) daily for 12 weeks resulted in significant reductions in hyperactive, impulsive and impaired socialisation features, but not in reducing attention deficiency symptoms, as assessed by the ADHD scale (Bilici et al 2004). A significant difference between zinc and placebo was evident by week 4 ( $P = 0.01$ ). Older children with low zinc and free fatty acid levels and high body mass index responded best to treatment.

A second placebo-controlled trial used a combination of 55 mg zinc sulfate (equivalent to 15 mg elemental zinc) and methylphenidate (1 mg/kg) daily for 6 weeks in Iranian children aged 5–11 years and reported significant benefits with the combination (Akhondzadeh et al 2004). Zinc (15 mg/day elemental) or placebo was administered to 218 grade three students in a low-income district of Turkey over 10 weeks, resulting in a reduced prevalence of clinically significant ratings of attention deficit and hyperactivity in the treatment group (Uçkardeş et al 2009). As all of these early studies were conducted in Middle Eastern countries where zinc deficiency is particularly prevalent, researchers were keen to see results of studies conducted in other regions and the chance arose with an American three-phased pilot study published in 2011 (Arnold et al 2011).

Being a pilot study, the numbers are small ( $n = 52$ , with only 28 assigned to zinc); however, the methodology is regarded as substantially superior to prior studies, including more comprehensive zinc assessment both pre- and posttreatment. The first phase was essentially a single-blind 8-week trial of zinc (15 mg/day as glycinate) compared with placebo, while the second phase added in open-label amphetamine (dosage according to body weight), maintained over 2 weeks. The third phase, which lasted 3 weeks, allowed clinicians to closely monitor and accordingly titrate the dose of amphetamine with no change to the zinc or placebo from the first phase. The findings were that zinc supplementation was not effective either alone or as an adjunct to amphetamines in the management of ADHD; however, it did reduce the effective dose necessary of the stimulant medication. What is particularly interesting about this study, the negative findings of which are given a lot of weight in a recent review by Ghanizadeh & Berk (2013), is the low zinc dose

used and the subsequent failure to raise serum zinc in the supplemented group. In fact, in the third phase the researchers doubled this dose in 8 subjects, which produced greater improvements both on serum levels and behaviour ratings, begging the question of whether the dose administered to the majority was inadequate.

Somewhat similarly, two longer-term studies (6 months) conducted in Mexico and Guatemala failed to find a positive effect from zinc supplementation. However, in both instances, zinc oxide (a poorly absorbed form) was used to provide only 10 mg elemental zinc per day and there were numerous other confounding variables, e.g. lead intoxication (Kordas et al 2005) and lack of diagnostic criteria and selection for ADHD children only (DiGirolamo et al 2010).

The aforementioned systematic review includes the American study by Arnold and two of the mid-Eastern trials, ultimately concluding that there is insufficient evidence of efficacy for zinc in the management of ADHD and recommending that future studies correct for methodological flaws of the past (Ghanizadeh & Berk 2013). Until there is research of a higher standard with consistent outcomes, the case for zinc in ADHD is promising but requires further investigation to determine optimal dosage, treatment regimens and what symptoms are most likely to respond.

## Depression

Zinc deficiency has been investigated as a contributing factor to the development of depression. Zinc supplementation has also been investigated as a treatment in depression, most commonly as an adjunctive therapy taken with standard pharmaceutical agents, for which there is positive evidence.

Epidemiological evidence has revealed an inverse relationship between serum zinc and depression-rating scores in depressed patients (Nowak et al 2005, Siwek et al 2010), the elderly (Marcellini et al 2006) and postpartum women (Wojcik et al 2006). Inadequate dietary intake has also been correlated with increased depression rates, particularly amongst women, in an American food frequency study (Maserejian et al 2012). A meta-analysis of 17 epidemiological studies ( $n = 1643$  depressed individuals and 804 controls) investigating zinc levels and depression adds further weight to this association (Swardfager et al 2013), with 16 studies demonstrating a relationship. While meta-analysis found the actual difference in plasma/serum zinc to be small — approximately  $-1.85$  micromol/L lower in depressed compared with control individuals ( $P < 0.00001$ ) — the effect size increased in individuals with more severe depression, inpatients and studies with more robust methodology. It is important to note that these lower levels were typically still within the established reference range. While associations do not prove causality, there is also an increasing body of evidence piecing together how zinc might convey such antidepressant effects.

Zinc supplementation produces antidepressant-like effects in animal tests and models such as the forced-swim test and can augment the action of orthodox antidepressants in these scenarios (Nowak et al 2005). Theories regarding zinc's aetiological role in depression traditionally centred on its inhibition of *N*-methyl-D-aspartate receptor function and regulation of both hippocampal and cortical glutamergic circuits and, interestingly, suicide victims demonstrate a statistically significant 26% decrease in zinc's antagonistic potency in hippocampal tissue, suggestive of an aberrant interaction between this mineral and the receptor underlying the psychopathology (Nowak et al 2003). There is current interest in the increased inflammatory markers evident in depressed individuals, which would, through redistribution of zinc, potentially create a pseudodeficiency (Marcellini et al 2006, Nowak et al 2005) and, via zinc's roles in both immunity generally and antioxidant defence specifically, improve with supplementation (Swardfager et al 2013, Szewczyk et al 2011). Other theories regarding mechanisms include zinc's capacity to increase synaptic dopamine levels (Stockner et al 2013), its critical role in fatty acid metabolism (Swardfager et al 2013), increased neural plasticity, increased hippocampal BDNF RNA and inhibition of the GSK-3 enzyme (Szewczyk et al 2008).

In spite of growing interest in zinc's antidepressant potential, there have been limited published interventional studies to date. Twenty patients with unipolar depression had an improved response to antidepressant medication when it was taken with zinc aspartate supplements (equivalent to 25 mg elemental daily), according to a small, double-blind pilot study (Nowak et al 2003). Significantly greater reductions in Hamilton Depression Rating Scale scores were achieved with zinc treatment compared to placebo by the 6th week and maintained until the end of the 12-week study. The same research group published the results of a study very similar in design, using  $\approx$ 140 mg imipramine and 25 mg supplemental zinc ( $n = 30$ ), compared with imipramine and placebo in the control group ( $n = 30$ ) over 12 weeks, also with positive findings (Siwek et al 2009), and in a follow-up publication were able to show that treatment-resistant subjects had lower serum zinc ( $-14\%$ ) when compared with those subjects responsive to treatment, as did those who had had depression for a longer duration. They also found that serum zinc increased in all responders whether supplemented or not, concurrent with remission and a negative correlation between serum zinc and ratings on the Montgomery-Asberg Depression Rating Scale at the study's conclusion in all subjects (Siwek et al 2010). Based on their findings, Siwek et al go as far as to say that changes in serum zinc can be viewed as a state marker of depression and remission. A 2012 review paper which includes the Nowak et al and Siwek et al studies, as well as two others, concludes that there is consistent evidence of zinc's efficacy as an adjunct

to antidepressants but less certainty as a stand-alone treatment (Lai et al 2012).

### Diarrhoea

An updated 2013 Cochrane review of oral zinc treatment for paediatric diarrhoea which analysed results from 18 randomised controlled trials ( $n = 6165$ ) concluded that zinc supplementation consistently reduced the duration and volume of both acute and persistent diarrhoea within a few days (for example, by day 3 of the intervention: RR 0.69, 95% CI 0.59–0.81; 1073 children, two trials) (Lazzerini & Ronfani 2013). While zinc-treated children were significantly more likely to experience vomiting as an adverse reaction to the supplement, it was concluded that the benefits of the treatment outweighed this side effect.

Typically, the intervention consisted of 10 mg/day of zinc, as a sulfate, acetate or gluconate salt, administered in a single or divided dose over 2 weeks to children aged 1 month to 5 years presenting with acute or persistent diarrhoea or dysentery. It is important to note that all except three of these trials were conducted in countries considered to be at high risk of widespread zinc deficiency and in such instances, due to the high rates of malnourishment, the RDA for zinc for <5-year-olds jumps to 2–4 mg/kg compared with only 3–5 mg/day in developed countries. Interestingly, however, there was no effect from geographical location, background zinc deficiency, supplemental form or general nutritional status. This review found no benefit in children less than 6 months old and it remains unclear at this time whether morbidity rates were impacted in children of any age.

### Coeliac disease

Untreated coeliac patients demonstrate increased turnover and losses of intestinal zinc, although the mechanisms behind this appear to be greater than malabsorption alone (Tran et al 2011). In fact, researchers claim that zinc deficiency is the earliest and most pronounced nutritional issue in untreated CD adults (Scrimgeour & Condlin 2009), and researchers investigating zinc status in children undergoing investigation for CD concluded that a low serum zinc should be a prompt in this cohort for small-bowel biopsy (Hogberg et al 2009). A study of zinc homeostasis in children with CD found a correlation between impaired disaccharide digestion, reduced fractional zinc absorption and reduced zinc status and suggested that treated CD patients with ongoing gastrointestinal derangement are key candidates for zinc deficiency (Tran et al 2011). Interestingly, zinc is a potent inhibitor of the tissue transglutaminase (tTG) type 2 enzyme, therefore in zinc deficiency this will lead to greater activation of tTG, ultimately increasing the inflammation and villi atrophy at the core of CD pathology (Scrimgeour & Condlin 2009, Stenberg et al 2008). Recent research adds to concerns of zinc deficiency in the CD population, in finding that a gluten-free

diet provides inadequate zinc levels for most individuals, therefore making supplementation a necessity (Shepherd & Gibson 2013). To date there are no published studies investigating the benefits of zinc supplementation in CD.

### Crohn's disease

Zinc is important in the maintenance of gastrointestinal barrier function. Research has revealed that patients with inflammatory bowel disease with low mucosal zinc levels typically accumulate neutrophils in epithelial crypts and the intestinal lumen, resulting in the formation of crypt abscesses, which constitute a serious complication of the disease (Scrimgeour & Condlin 2009). Although reduced zinc status has long been associated with chronic diarrhoea and Crohn's disease (Sturmiolo et al 1980), the results from a small open study demonstrated that oral zinc sulfate (110 mg three times daily) resolved intestinal permeability problems in people with increased permeability and decreased relapse rates (Sturmiolo et al 2001). Given animal and human evidence suggesting that the supplemental form, zinc carnosine, has particular injury/ulcer-preventing actions (Mahmood et al 2007, Watari et al 2013), some researchers speculate whether this may be especially indicated in patients with inflammatory bowel disease (Scrimgeour & Condlin 2009).

### Anorexia nervosa

Evidence suggests zinc deficiency may be intimately involved with anorexia nervosa, if not as an initiating cause, then as an accelerating or 'sustaining' factor for abnormal eating behaviours that may deepen the pathology of the anorexia in relation to neurological, immunological and metabolic aberrations (McClain et al 1992, Saito et al 2007, Shay & Mangian 2000). Zinc status is compromised due to an inadequate zinc intake, with supplementation (50 mg elemental zinc/day) shown to decrease depression and anxiety, stop body weight loss and improve weight gain (Katz et al 1987, Safai-Kutti 1990). According to one randomised, double-blind, placebo-controlled trial, 100 mg of zinc gluconate (14 mg/day elemental) doubled the rate of subjects with anorexia nervosa increasing their body mass index compared to placebo (Birmingham et al 1994); however, two other studies in a similar cohort administered 50 mg zinc/day failed to show any improvement over placebo in weight gain (Flament et al 2012). Results from a series of animal studies suggest that zinc may stimulate food intake in short-term zinc-deficient rats through the afferent vagus nerve, with subsequent effects on hypothalamic peptides, such as increased expression of neuropeptide Y and orexin (Suzuki et al 2011). Accordingly, some key researchers advocate for routine prescribing of zinc for a minimum of 2 months in all anorexia nervosa patients (Birmingham & Gritzner 2006), in spite of reviewers concluding there is inadequate evidence to support this practice (Flament et al 2012).

Recent research has highlighted significantly greater serum zinc in recovered individuals when compared with those who remain ill; however, this is speculated to be largely due to altered dietary intake (Zepf et al 2012a) and, although leptin levels also increase during remission, a small epidemiological study failed to find a correlation between these two phenomena (Zepf et al 2012b).

### Improves taste perception

Dysfunctional taste perception, or dysgeusia, is a condition that can at the least affect quality of life and occasionally can become life-threatening. Research into the aetiology of taste impairment has revealed a long list of possible causes and contributing factors, including various pathologies and drugs (Brown & Toma 1986, Deems et al 1991, Ikeda et al 2005, Kettaneh et al 2005, Osaki et al 1996, Rareshide & Amedee 1989, Zverev 2004). The pioneer of research in zinc-related taste acuity, Henkin, concluded in 1976 that zinc could not explain all cases of taste impairment (Henkin et al 1976). A subsequent review concurred: 'depletion of zinc can lead to decreased taste acuity but decreased taste acuity is not necessarily associated with depletion of zinc' (Catalanotto 1978).

Impaired gustatory function in the elderly is also well established (Bales et al 1986, Bartoshuk 1989, Deems et al 1991, Greger 1977, Greger & Geissler 1978, Ikeda et al 2005, Kettaneh et al 2005, Sandstead et al 1982, Schiffman 1983), particularly in relation to salt perception (Bales et al 1986, Greger & Sickles 1979, Sandstead et al 1982). Although zinc status also characteristically declines with age (Bales et al 1986, Greger 1977, Greger & Geissler 1978, Sandstead et al 1982), many studies have failed to demonstrate a consistent correlation between the two phenomena. While this has been challenged by the findings of a study (Stewart-Knox et al 2005), previous large-scale studies of elderly patients presenting with hypogeusia or ageusia have indicated that zinc deficiency represents the sole cause in <40% of elderly patients (Deems et al 1991, Ikeda et al 2005). Other major causes of taste impairment in this age group include the effect of medications and systemic diseases (Deems et al 1991, Ikeda et al 2005, Schiffman 1983). Consequently, confirmation of zinc deficiency in patients with taste impairment is necessary in order to determine the suitability of zinc as a treatment.

Several interventional studies investigating zinc as a treatment for taste impairment have produced generally positive findings. Zinc supplementation of 140 mg of zinc gluconate (20 mg/day elemental) in 50 patients with idiopathic dysgeusia improved gustatory function when compared with placebo (Heckmann et al 2005). In another study of 109 patients with idiopathic taste impairment, including some with low serum zinc, subjects were randomly assigned to either placebo or one of three zinc treatment groups: 17 mg/day, 34 mg/day or 68 mg/day zinc carnosine for 12 weeks (Sakagami et al 2008).

Only those patients receiving 68 mg/day demonstrated significantly improved gustatory sensitivity over placebo. Two studies focusing specifically on improving taste perception in the elderly (Ikeda et al 2008, Stewart-Knox et al 2008) have been successful, particularly in relation to increased salt sensitivity and in the former study achieved a 74% response rate for improved gustatory function generally. However, benefit was only evident at doses  $\geq 30$  mg/day elemental zinc presented either as a gluconate or as a carnosine complex (Aliani et al 2013).

In contrast, treatment with zinc sulfate (45 mg three times daily) concomitant with and 1 month following radiotherapy treatment in patients suffering from head and neck cancers did not prevent taste alterations typically associated with this treatment and previously speculatively linked with poor zinc status (Halyard et al 2007). A more recent double-blind randomised controlled trial investigating zinc supplementation (50 mg elemental per day as a sulfate) over 3 months in taste disorders of patients receiving chemotherapy ( $n = 58$ ) also failed to demonstrate any beneficial effect over placebo (Lyckholm et al 2012). Limitations of this study include the informal assessment of taste and lack of baseline zinc assessment, with the researchers concluding that more studies are necessary. New areas of research are investigating relationships between zinc status and specific genetic polymorphisms that impact taste (Noh et al 2013).

### Tinnitus

In addition to its many diverse neurological roles, zinc has specifically been shown to modulate synaptic function in the cochlear nucleus through its involvement with glutamate receptors (Coehlo et al 2007). Also required for production of Cu/Zn SOD, the most abundant antioxidant enzyme in this tissue, zinc has a critical role in its healthy function through control of oxidation and the large amounts of generated ROS. There is also evidence that a deficiency of Cu/Zn SOD potentiates ear hair cell degeneration secondary to excessive oxidative damage. Other recent theories regarding zinc's role include its role in the structure of carbonic anhydrase, which removes free radicals in the vascular stria of the cochlea, and its ability to alter the endocochlear potential, altering cochlear electrophysiology (Ferreira et al 2009). In 1987, a report was published suggesting a link between reduced zinc status and intermittent head noises in people suffering with tinnitus (Gersdorff et al 1987). This has been further investigated in several studies; however, the poorly defined patient groups and use of serum zinc as the means of measuring zinc status make interpretation of results difficult to assess (Coehlo et al 2007). Results from these studies, however, suggest a non-significant trend of lower serum zinc values for patients suffering this condition compared to healthy controls.

In 1991 Paaske et al reported the results of a double-blind randomised controlled trial of 48

patients with tinnitus that failed to find a significant effect on symptoms with sustained-release zinc sulfate tablets. Of note, only one subject had low serum zinc levels. A study of 111 subjects aged 20–59 years found that individuals with tinnitus who had normal hearing had significantly lower serum zinc levels than controls, whereas zinc levels were normal for those with accompanying hearing loss (Ochi et al 2003). In addition, a significant correlation between average hearing sensitivity and serum zinc level was observed. Yetiser et al (2002) investigated serum zinc levels and response to supplementation in 40 patients with severe tinnitus of various origins. Some relief in tinnitus symptoms was reported by 57.5% of all subjects who received 220 mg of zinc daily for 2 months; however, the effect was considered minor. When results were divided by age, a different finding emerged, as 82% of people over 50 years of age experienced an improvement on the tinnitus scale compared to only 48% of younger subjects. There was no correlation between severity of tinnitus and serum zinc levels. Zinc supplementation (50 mg/day) was further studied in a randomised, placebo-controlled trial involving 41 Turkish patients with tinnitus of no known cause. Active treatment for 2 months produced clinically favourable progress in 46.4% of subjects; however, this result was not statistically significant (Arda et al 2003).

A review of these studies concluded that, although hampered by methodological weaknesses, zinc treatment may be beneficial in some tinnitus sufferers and, while an optimal dose for zinc has yet to be elucidated, most successful designs have employed 50–66 mg/day of elemental zinc in divided doses (Coehlo et al 2007). A randomised double-blind placebo-controlled cross-over trial designed by Coehlo et al tried to address the limitations of previous studies (Coehlo et al 2013). In a total sample size of 94, individuals were administered zinc 50 mg/day or placebo for a duration of 4 months followed by a 1-month wash-out and then treatment with the other for the same period. Final analysis revealed that 5% of individuals found their tinnitus improved with zinc and 2% with placebo, the difference being not statistically significant. Subsequently these authors concluded that zinc is not an effective treatment in tinnitus.

### Warts

Oral zinc sulfate (10 mg/kg) supplements administered in three divided doses per day (up to 600 mg/day) for 2 months completely cleared recalcitrant viral warts in 87% of patients, according to a single-blind, placebo-controlled trial of 80 volunteers with at least 15 viral warts that were resistant to other treatments (Al Gurairi et al 2002). Warts were completely cleared in 61% of patients after 1 month of treatment, whereas none of the patients receiving placebo reported a successful response and some developed new warts. In both placebo and treatment groups, the drop-out rates were high: 50% and

45%, respectively. Interestingly, patients in the treatment group with low serum zinc baseline levels (mean 62.4 mcg/100 mL) reportedly exhibited no signs or symptoms of deficiency and zinc serum levels failed to rise in the patients who remained resistant to zinc therapy. Treatment with high-dose zinc supplements was accompanied by nausea and in some cases vomiting and mild epigastric pain, although these symptoms were described as mild and transient. A similar intervention was employed in a 2011 open-label study of 31 individuals with non-genital recurring warts with the same dose of zinc sulfate administered over 2 months. While 58% of subjects had deficient serum zinc at baseline, 50% were classed as responders, with full resolution of the warts and no recurrences within a 6-month follow-up (Mun et al 2011).

### Wilson's disease

Due to the fact that zinc blocks copper absorption and increases its elimination in people with Wilson's disease, zinc supplementation is a common treatment in this condition. Patients with diagnosed Wilson's disease have increased hepatic glutathione and reduced oxidation when supplemented with zinc sulfate (220 mg three times daily) for 3 months, compared with those using penicillamine (Farinati et al 2003).

## OTHER USES

### Reducing the risk of cancer

Epidemiological studies suggest that zinc deficiency may be associated with increased risk of cancer (Prasad & Kucuk 2002). Research into mechanisms behind zinc and cancer prevention are being actively pursued via both in vitro (Hong et al 2012) and in vivo research and a key topic of discussion centres around evidence of zinc dysregulation in both prostate and breast cancer (Alam & Kelleher 2012, Ho et al 2011). As yet, however, there are no clinical trials or clear clinical directives from this research.

### HIV and AIDS

Given zinc deficiency most profoundly compromises T-cell function, interest in zinc treatment for HIV and AIDS has been ongoing. Low plasma zinc concentration occurs in HIV infection, especially with advancing illness (Wellinghausen et al 2000). The balance of evidence favours the view that a low plasma zinc level is a marker for disease progression (Siberry et al 2002). A series of small interventional studies have produced mixed results, some demonstrating improved immune markers and reduced opportunistic infections (Mocchegiani et al 1995, Zazzo et al 1989), while others suggesting either no therapeutic effect or increased risk of progression from HIV to AIDS (Tang et al 1996). These contrasting findings have been speculatively attributed to differences in baseline zinc status amongst subjects. One author points out that antiretroviral

treatment has been shown to counteract zinc deficiency and therefore administering zinc to individuals taking this medication may enhance the risk of zinc toxicity and its associated immune impairment (Overbeck et al 2008). A small pilot study ( $n = 31$ ) looked specifically at zinc supplementation in the treatment of immune discordance (defined as complete viral suppression without a rise in CD4<sup>+</sup> counts, which is associated with increased morbidity and mortality) amongst HIV-positive patients (Asdamongkol et al 2013). While the results found that 39% of these individuals had deficient plasma zinc, this is not strikingly dissimilar from the incidence in the general HIV population. They also reported that zinc supplementation (15 mg/day as a chelate for 6 months) resulted in increases in CD4<sup>+</sup> counts; however, due to the small numbers and lack of control group, their findings are weakened.

In a well-designed larger randomised placebo-controlled study of 231 HIV-positive adults, the treatment group received 12 mg (females) or 15 mg (males) zinc daily for 18 months. In comparison to placebo, zinc treatment was found to reduce the rate of immunological failure, defined as any CD4<sup>+</sup> count <200 cells/mm<sup>3</sup> fourfold (RR = 0.24;  $P < 0.002$ ) and also significantly reduced the occurrence of diarrhoea (OR = 0.4;  $P = 0.019$ ) (Baum et al 2010).

A 2010 Cochrane review, which does not include the studies cited here, included just two trials in adults ( $n = 559$ ) and two in children ( $n = 128$ ) and concluded that zinc supplementation is yet to be established as a beneficial adjunct in HIV management, except in the instance of prevention of diarrhoea in children, where there is a significant decrease in those treated with zinc ( $P = 0.001$ ) (Irlam et al 2013). One of the limitations, however, of this review is the disparate nature of the HIV populations (from pregnant women to those suffering protracted diarrhoea), as well as heterogeneous design.

### Malaria

Duggan et al (2005) identified low plasma zinc levels in children with acute malaria, including a significant correlation between evidence of illness severity, C-reactive protein levels and zinc status; however, this may be an artifact of the acute-phase effects on zinc homeostasis, rather than indicative of genuine depletion (Overbeck et al 2008). Similarly, a recent cross-sectional survey of children in Laos revealed a surprising inverse relationship between serum zinc and anti-*Plasmodium falciparum* IgG antibodies (e.g. an increase of 1 mcg/dL in serum zinc equated with  $-0.453$  in antibody titre,  $P = 0.003$ ) in individuals with active malaria; however, low zinc secondary to inflammation is flagged as a possible confounding variable by the researchers (Akiyama et al 2013).

Zinc supplementation (10 mg elemental) randomly allocated to preschool children residing in a malaria-endemic region of Papua New Guinea for

6 days a week over 46 weeks reduced morbidity due to *P. falciparum* (Shankar et al 2000). Further studies have produced contradictory findings in relation to zinc's capacity to prevent malaria, while studies of treatment regimens that include zinc as an adjuvant to standard chemotherapy have found no benefit (Overbeck et al 2008). A 2011 review into zinc treatment and the prevention of both morbidity and mortality in <5 years old in developing countries included four studies wherein zinc supplementation was assessed for effect on malaria incidence and found the pooled data failed to reach statistical significance (RR = 0.92;  $P = 1.04$ ) (Yakoob et al 2011). Similarly, with regard to malaria-related mortality, there was a 10% non-significant reduction in association with zinc supplementation (RR = 0.90;  $P = 1.06$ ).

#### IN COMBINATION

Subsequent to this review a study designed to investigate whether zinc adds to the preventive effects of vitamin A supplementation in malaria morbidity in Ghana infants administered either a one-off dose of 100,000 IU (<12 months old)/200,000 IU (>12 months old) vitamin A alone ( $n = 88$ ) or additional elemental zinc of 10 mg/day for 6 months ( $n = 87$ ) (Owusu-Agyei et al 2013). Follow-up was also performed 6 months after the conclusion of the supplementation phase. Results show a further 27% reduction in uncomplicated malaria incidence in those infants administered zinc ( $P = 0.03$ ), which equates to reducing incidence from 62.5% in the vitamin A group to 46% in the combined treatment group. The combined intervention, however, failed to have any statistically significant impact on the incidence of other key morbidities such as diarrhoea, pneumonia and severe malaria over vitamin A alone: the reason for this is unknown. It is perhaps noteworthy that the change in plasma zinc from baseline to end point did not reach statistical significance in the supplemented group.

#### Alzheimer's dementia

There is significant ongoing discussion about the role of zinc deficiency in Alzheimer's disease in the scientific literature. Epidemiological studies have produced some mixed results (da Silva et al 2013, Kyumcu et al 2013, Szwedczyk 2013), which may well be the result of disparate methodologies for assessment.

Cognitive performance was temporarily improved after 3 months of zinc supplementation (zinc chelate 15 mg) taken twice daily by six subjects with Alzheimer's disease (Potocnik et al 1997). Although the initial improvement was not maintained in this small open study, a modest cognitive improvement on psychometric testing was observed at 12 months for the four patients evaluated. A double-blind study tested 150 mg of a new zinc formulation per day (unknown elemental zinc content) or placebo for 6 months given to 58 subjects, 29 with Alzheimer's disease and 29 age- and sex-matched controls

(Brewer & Kaur 2013). Zinc supplementation was found to raise serum zinc and reduce free copper as anticipated, but cognitive effects were limited to a non-significant trend towards improvement. Post hoc analysis, however, of those subjects >70 years in the treatment group ( $n = 14$ ) revealed a significant cognitive benefit on all three tests ( $P = 0.067$ ). While the researchers report these to be 'exciting' results, they also concede that the small sample size and need for post hoc analysis mean that much larger and better-designed studies are necessary to confirm their findings.

#### DOSAGE RANGE

##### Australian RDI

###### Children

- 1–3 years: 3 mg/day
- 4–8 years: 4 mg/day
- 9–13 years: 6 mg/day
- Males 14–18 years: 13 mg/day
- Females 14–18 years: 7 mg/day.

###### Adults

- Males >18 years: 14 mg/day
- Females >18 years: 8 mg/day.

###### Pregnancy

- <19 years: 10 mg/day
- ≥19 years: 11 mg/day.

###### Deficiency

- 25–50 mg elemental zinc daily.

#### According to clinical studies

- Common cold — zinc acetate lozenges are the most effective (free of sorbitol, mannitol or citric acid).
- Adults: 9–24 mg elemental zinc dissolved in the mouth, without chewing, every 2 hours for acute treatment. Total daily dose should provide ≥75 mg of elemental zinc.
- School-aged children: zinc acetate lozenges four times daily for acute treatment.
- It is recommended that citrus fruits or juices be avoided 30 minutes before or after dissolving each lozenge to avoid negating the effects of zinc.
- Improved immune function in elderly — 45 mg/day elemental zinc as zinc gluconate.
- Common cold — nasal gel sprays are no longer recommended due to the high incidence of temporary anosmia associated with their use.
- Pneumonia — 70 mg/day prophylactically or 20 mg/day in children suffering acute infection — especially in non-bacterial cases.
- Malaria — 10 mg/day elemental zinc.
- ARMD — zinc oxide (equivalent to 80 mg elemental zinc), together with 500 mg vitamin C, 400 IU vitamin E, taken daily, or 50 mg/day of zinc as zinc monocyteine as stand-alone treatment.
- ADHD — 30–40 mg elemental zinc daily.

- Depression — 25 mg elemental zinc per day.
- Type 1 diabetes — 30 mg/day (type of zinc unknown).
- Type 2 diabetes — 50 mg/day zinc acetate.
- Wound healing — 2.5 mg/kg zinc sulfate daily: zinc oxide form preferable topically.
- Leg ulcers — 600 mg zinc sulfate daily.
- Male fertility — 60 mg/day of zinc sulfate and 5 mg/day as folic acid.
- Acne vulgaris — 90–200 mg (50 mg elemental) daily.
- Crohn's disease — 110 mg zinc sulfate taken three times daily. However, a zinc carnosine preparation may be more appropriate.
- Diarrhoea — 10–20 mg/day elemental zinc in children between 6 months and 5 years for 2 weeks. Note: this dose was used in populations with a high prevalence of zinc deficiency.
- Herpes infection — 4% zinc sulfate solution applied via a cotton bud every 5 days for a month, then every 10 days for 2 months and finally every 15 days for 3 months.
- Anorexia nervosa — 14–50 mg elemental zinc daily.
- Dysgeusia — 20 mg/day elemental zinc as zinc gluconate and 68 mg/day as zinc carnosine.
- Tinnitus — 50–200 mg daily of zinc (salt unknown). Unclear benefit.
- Warts — 10 mg/kg zinc sulfate taken orally in three divided doses (up to 600 mg/day) for 1–2 months.

## TOXICITY

Signs of toxicity are nausea, vomiting, diarrhoea, fever and lethargy and have been observed after ingestion of 4–8 g zinc according to a 2002 World Health Organization report. Single doses of 225–450 mg of zinc usually induce vomiting (King 2003).

Doses of zinc ranging from 100 to 150 mg/day interfere with copper metabolism and cause hypocuprinaemia, red blood cell microcytosis and neutropenia if used long-term.

## ADVERSE REACTIONS

Mild gastrointestinal distress has been reported at doses of 50–150 mg/day of supplemental zinc (King 2003). According to a randomised, double-blind study, zinc gluconate glycine lozenge (104 mg, equivalent to 13.3 mg ionic zinc) taken every 3–4 hours is well tolerated (Silk & Lefante 2005). Of the side effects that were reported, dry mouth and a burning sensation on the tongue were probably related to use, whereas symptoms of nausea, dizziness, lightheadedness and upset stomach were considered as possibly related.

## SIGNIFICANT INTERACTIONS

### Calcium

High levels of dietary calcium impair zinc absorption in animals, but it is uncertain whether this occurs in humans — separate doses by 2 hours.

### Angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers and thiazide diuretics

These drugs reduce zinc status, most likely due to increased urinary excretion of zinc (Braun and Rosenfeldt 2013). Increased zinc intake may be required with long-term drug treatment.

### Coffee

Coffee reduces zinc absorption — separate intakes by 2 hours (Pecoud et al 1975).

### Copper

High zinc intakes (100–150 mg/day) interfere with copper metabolism and can cause hypocuprinaemia with long-term use. Avoid using high-dose zinc supplements long-term, or increase intake of copper.

### Folate

Folate intake may reduce zinc levels — observe patient for signs and symptoms of zinc deficiency with long-term folate supplementation.

### Iron

Supplemental (38–65 mg/day elemental) iron decreases zinc absorption (King 2003) — separate doses by 2 hours.

### Non-steroidal anti-inflammatory drugs

Zinc interacts with non-steroidal anti-inflammatory drugs by forming complexes with these drugs (Dendrinou-Samara et al 1998) — separate dose by 2 hours.

### Tetracyclines and quinolones

Complex formation between zinc and tetracycline results in reduced absorption of both substances with potential reduction in efficacy — separate dose by 2 hours.

### Thiazide and loop diuretics

These diuretics increase urinary zinc loss — monitor for signs and symptoms of zinc deficiency with long-term drug use. Increased zinc intake may be required with long-term therapy.

### Methylphenidate

The efficacy of this drug is improved by supplementation with zinc sulfate (15 mg elemental zinc) for 6 weeks in children with ADHD. There is no change to side effects reported (Akhondzadeh et al 2004).

### Vaccinations

Zinc acetate improved seroconversion of vibriocidal antibodies in children given a cholera vaccination (Albert et al 2003) in both faecal and serum titres (Karlsen et al 2003).

### Radiotherapy

Radiotherapy reduces plasma zinc levels (Ertekin et al 2004). Supplementation may be required with intensive radiotherapy treatment.

### Interferon-alpha/ribavirin

Interferon-alpha and ribavirin treatment for hepatitis C patients is not affected by zinc supplementation (Ko et al 2005).

### Orlistat

Orlistat has no significant effect on zinc levels (Zhi et al 2003).

### Tricyclic antidepressants and selective serotonin reuptake inhibitors (SSRIs)

Zinc supplementation (25 mg elemental zinc daily) improves the efficacy of antidepressants such as tricyclic antidepressants and SSRIs after 2 weeks of intervention (Nowak et al 2003) — beneficial interaction possible.

#### **?** CONTRAINDICATIONS AND PRECAUTIONS

Amiloride reduces zinc excretion and can lead to zinc accumulation (Reyes et al 1983). Therefore, supplementation should be used with caution.

#### **S** PREGNANCY USE

Zinc is safe in pregnancy and may improve fetal heart rate in zinc-deficient mothers (in conjunction with iron and folic acid) (Merialdi et al 2004).

#### Practice points/Patient counselling

- Zinc is involved in many chemical reactions that are important for normal body functioning and it is essential for health and wellbeing.
- Although zinc supplements are traditionally used to treat deficiency, they are also used to prevent deficiency in conditions associated with low zinc status or deficiency, such as acrodermatitis enteropathica, anorexia nervosa, malabsorption syndromes, conditions associated with chronic diarrhoea, alcoholism, liver cirrhosis, diabetes, HIV and AIDS, recurrent infections, severe burns, postsurgery and sickle cell anaemia.
- Zinc supplements are also popular among athletes in order to counteract zinc loss that occurs through perspiration.
- Zinc lozenges have been used to prevent and treat the symptoms of the common cold and oral supplements have been used to treat acne vulgaris, improve wound healing and chronic leg ulcers, resolve intestinal permeability problems and reduce recurrences in Crohn's disease, treat recalcitrant warts, reduce symptoms of tinnitus and improve ADHD.
- Topical applications of zinc have been used to treat acne vulgaris (in combination with erythromycin) and herpes simplex and to promote wound healing.
- Numerous interactions exist between other minerals, foods and medicines and zinc.

### **!** PATIENTS' FAQs

#### *What will this supplement do for me?*

Zinc is found in every cell of the body and is essential for health and wellbeing. Some studies have found that supplements are not only useful to treat and prevent deficiency, but may also be useful in conditions such as the common cold, poor wound healing and leg ulcers, diabetes, Crohn's disease, acne vulgaris, warts, ADHD and tinnitus. Topical preparations may be useful in acne vulgaris (with erythromycin), herpes infection and chronic wounds.

#### *When will it start to work?*

This depends on the indication (refer to monograph for more details).

#### *Are there any safety issues?*

Used in high doses, zinc can cause nausea, vomiting, gastrointestinal discomfort and, if used long-term, reduce copper levels. Zinc also interacts with a number of other minerals, foods and medicines.

# APPENDIX 1

## GLOSSARY AND ABBREVIATIONS

**Abortifacient**—Substance used to terminate a pregnancy.

**ACE**—angiotensin-converting enzyme.

**ACM**—all-cause mortality.

**ACTH**—adrenocorticotrophic hormone.

**Active constituents**—Chemical components that exhibit pharmacological activity and contribute to the agent's overall therapeutic effects.

**Acute**—Beginning abruptly; sharp and intense; subsiding after a short period.

**Adaptogen**—Innocuous agent, non-specifically increasing resistance to physical, chemical, environmental, emotional or biological factors ('stressors') and having a normalising effect independent of the nature of the pathological state.

**ADHD**—attention deficit hyperactivity disorder.

**ADI**—acceptable daily intake.

**Adjuvant**—Substance added to a mixture to enhance the effect of the main ingredient.

**ADR**—adverse drug reaction.

**ADRAC**—Adverse Drug Reactions Advisory Committee (Australia).

**Adverse reaction**—Unintended harmful, undesirable or seriously unpleasant response to a medicine at doses intended for prophylaxis, diagnosis or therapeutic effect.

**Aerial parts**—All parts of a plant that are above the ground. Very often, plants that have useful aerial parts are harvested when flowering (e.g. St John's wort — *Hypericum perforatum* of the Hypericaceae family).

**Agonist**—Substance that binds to and activates a receptor, thereby causing a response.

**Alkaloid**—Naturally occurring cyclic organic compound containing nitrogen in a negative oxidation state, which has limited distribution in living organisms. Based on their structures, alkaloids are divided into several subgroups: non-heterocyclic alkaloids and heterocyclic alkaloids, which are again divided into 12 major groups according to their basic ring structure. They tend to have marked physiological effects in vivo (e.g. morphine, codeine, nicotine).

**Allostatic responses**—Changes that occur in the body in order to adapt and respond to physical or psychological change (e.g. standing, sitting, stress). They are critical to survival, have broad boundaries and involve the sympathetic nervous system and the hypothalamus–pituitary–adrenal axis.

**ALT**—alanine aminotransferase.

**Amino acid**—Organic compound composed of one or more basic amino groups and one or more acidic carboxyl groups; form the basic structural units of protein.

**AMP**—adenosine monophosphate.

**Analgesic**—Substance that relieves the symptoms of pain.

**ANF**—atrial natriuretic factor.

**Antagonist**—Substance that binds to a receptor (blocking others from doing so), but does not activate it, causing a diminished response.

**Anthelmintic**—Substance that destroys or assists in the expulsion of intestinal worms.

**Anthocyanins**—Compounds responsible for the bright colours of most flowers and fruits; water-soluble pigments that occur as glycosides and their aglycones (anthocyanidins) and have significant antioxidant activity.

**Anti-allergic**—Substance that reduces the allergic response (e.g. antihistamine activity or mast-cell stabilisation).

**Anti-asthmatic**—Substance that prevents asthma attacks and/or reduces their severity.

**Anti-emetic**—Substance or procedure that prevents or alleviates nausea and vomiting.

**Anticholinergic**—Agent that blocks cholinergic receptors (e.g. atropine), which results in inhibition of transmission of parasympathetic nerve impulses.

**Anticoagulant**—Substance that prevents or delays blood coagulation (e.g. warfarin).

**Antidiabetic**—Substance that aids in blood glucose management or improves management of diabetes via other mechanisms.

**Antigen**—Substance that the body recognises as foreign and to which it can evoke an immune response; often it is a protein.

**Antimicrobial**—Substance that kills microorganisms or inhibits their growth or replication.

**Antioxidant**—Substance that inhibits or delays the oxidation of a second substance; also described as scavenging free-radical molecules.

**Antiplatelet**—Substance that inhibits platelet aggregation and thereby prolongs bleeding time (e.g. aspirin).

**Antipruritic**—Substance or procedure that relieves or prevents itching.

**Antipyretic**—Substance or procedure that reduces fever.

**Antispasmodic**—Substance that reduces smooth muscle spasms.

**Antitussive**—Substance that suppresses the cough reflex.

**Anxiolytic**—Substance used to treat and relieve anxiety states.

**Apolipoprotein**—Protein on the surface of lipoproteins that may bind to receptors, activate enzymes involved in lipoprotein metabolism and provide structure.

**Apoptosis**—Programmed cell death.

**ARMD**—age-related macular degeneration.

**AST**—aspartate aminotransferase.

**Astringent**—Substance that precipitates proteins, causes vasoconstriction and constriction of mucous membranes, and reduces cell permeability when applied topically.

**ATP**—adenosine triphosphate.

**Bark**—Outermost protective layer of a tree trunk, formed by layers of living cells just above the wood itself. There are usually high concentrations of the active ingredients in the bark (e.g. cinnamon from *Cinnamomum camphora* of the Lauraceae family).

**Bioavailability**—Proportion of an administered dose that reaches the systemic circulation intact.

**Bitter tonic**—Herbs with a bitter taste, which are used to stimulate the upper gastrointestinal tract (i.e. stomach, liver, pancreas). They stimulate appetite and digestive function.

**BMD**—bone mineral density.

**BMI**—body mass index.

**BPH**—benign prostatic hypertrophy.

**Bulb**—Fleshy structure made up of numerous layers of bulb scales, which are leaf bases. Bulbs that are popular for medicinal use include onion and garlic (*Allium cepa* and *A. sativum*, respectively, both of the Liliaceae family).

**BZM**—bortezomib.

**CAM**—complementary and alternative medicine.

**Cardioprotective**—Substance that protects the heart from damage by toxins or ischaemia (oxygen deficiency).

**Carminative**—Substance that relieves flatulence, abdominal distension, spasm and discomfort by relaxing the intestinal muscles and sphincters.

**Carotenoid**—Group of red, yellow or orange highly unsaturated pigments found naturally in foods. Some

are converted to vitamin A in the body and most exhibit antioxidant properties.

**CFS**—chronic fatigue syndrome.

**Chelation**—Chemical interaction of a metal ion with another substance, which results in the formation of a molecular complex with the metal firmly bound and isolated.

**Chemoprevention**—Substance or intervention that reduces the incidence of cancer.

**Cholagogue**—Substance that stimulates the release of stored bile from the gall bladder.

**Choleretic**—Substance that stimulates both the production and the flow of bile.

**Chronic**—Persisting for a long period of time.

**Chylomicrons**—Large particles that transport dietary cholesterol and fatty acids from the gastrointestinal tract to the liver.

**CMEC**—Complementary Medicines Evaluation Committee.

**CMs**—complementary medicines.

**CNS**—central nervous system.

**Cognitive activator**—Substance or procedure that stimulates the mental processes such as memory, judgment, reasoning and comprehension.

**Cohort study**—Study concerning a specific population that shares a common characteristic (e.g. same age, same gender).

**Cold extraction**—Process in which plant material is extracted in a solvent of differing polarity at room temperature, enabling maximum extraction of most components.

**Contraindication**—Any factor that makes it undesirable or dangerous to administer a medicine or perform a procedure on a specific patient.

**Corticosteroids**—Steroidal hormones that are synthesised and released from the adrenal cortex; includes both glucocorticoids and mineralocorticoids.

**COX**—cyclo-oxygenase.

**CPI**—consumer product information.

**CRP**—C-reactive protein.

**Crude herb**—Raw plant before it is processed or dried.

**CVD**—cardiovascular disease.

**Cytochrome P450 (CYP)**—Proteins involved in extra-mitochondrial electron transfer, chiefly in the liver and during detoxification. There are many CYPs; they are named by the root symbol CYP, followed by a number for family, a letter for subfamily, and another number for the specific gene.

**DBP**—diastolic blood pressure.

**Debridement**—Removal of foreign objects, damaged tissue, cellular debris and dirt from a wound or burn to prevent infection and promote healing.

**Decoction**—Aqueous medicine made from an extract of water-soluble substances, usually with the aid of boiling water.

**Decongestant**—Substance or procedure that reduces or eliminates congestion and swelling, usually of mucous membranes.

**Demulcent**—Substance that soothes and reduces irritation of tissues such as skin or mucous membranes.

**DHA**—docosahexaenoic acid.

**DHEA**—dehydroepiandrosterone.

**Diuretic**—Substance that modifies kidney function to increase the rate of urine flow.

**DMBA**—7,12-dimethylbenz[a]anthracene.

**Double-blind study**—Study in which neither the test subject nor the clinician knows whether a placebo or active medicine is being administered. The substances are often identifiable by a code that is revealed after results are obtained. This method is widely used in clinical studies to confer greater objectivity.

**DSM-IV**—*Diagnostic and Statistical Manual [of Mental Health Disorders]*, 4th edn.

**EAR**—estimated average requirement.

**EBM**—evidence-based medicine.

**ECG**—electrocardiogram.

**EEG**—electroencephalogram.

**EGCG**—epigallocatechin-3-gallate.

**Emmenagogue**—Substance that increases the strength and frequency of uterine contractions, and initiates and promotes menstrual flow (some are also abortifacients).

**Emollient**—Substance that softens tissue and reduces irritation, usually of the skin and mucous membranes.

**Endogenous**—Originating from within the body; synthesised by the body.

**Epidemiological study**—Study of occurrence and distribution of disease in large human populations.

**Ergogenic aid**—Substance that improves energy utilisation with the expectation that it will enhance physical performance.

**Erythropoiesis**—Process of erythrocyte production in the bone marrow.

**ESADDI**—estimated safe and adequate daily dietary intake.

**ESCP**—European Scientific Cooperative on Phytotherapy.

**ESR**—erythrocyte sedimentation rate.

**Essential amino acids**—Eight amino acids that are required for health and must be obtained from the diet: isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine.

**Essential fatty acids (EFA)**—Polyunsaturated acids that are required for growth and general health and must be obtained from the diet (e.g. omega-3 EFAs found in fish oils).

**Essential oil**—Volatile oils usually extracted from plants through a process of either steam distillation or microwave extraction. They consist of terpenes (mono- and sesquiterpenoids and coumarins) and are of considerable importance as active ingredients (e.g. peppermint oil from *Mentha × piperita* from the Lamiaceae family).

**Expectorant**—Substance that promotes the expulsion of mucus, fluids or sputum from the respiratory tract.

**Extract**—Substance prepared by the use of solvents or evaporation to separate it from the original material.

**Fatty oils**—Non-volatile, insoluble oils pressed from either the seeds or the fruits of a plant (e.g. olive oil).

**FDA**—Food and Drug Administration (USA).

**FEV<sub>1</sub>**—forced expiratory volume in 1 second.

**Flavonoids**—Compounds responsible for the colour of flowers, fruits and sometimes leaves. The name derives from the Latin *flavus*, meaning yellow. Some may contribute to the colour as co-pigment.

Flavonoids protect the plant from UV damage and play a role in reproduction by attracting pollinators.

**Flowers**—Commonly used in medicine (e.g. cloves (*Syzygium aromaticum*, Myrtaceae family), chamomile (*Chamomilla recutita*, Asteraceae family) and marigold (*Calendula officinalis*, Asteraceae family)).

**Fluid extract**—Hydro-ethanolic extract of crude herbal material with a drug solvent ratio of 1:1 or 1:2 (e.g. 1 part herb to 1 or 2 parts solvent).

**Free radical**—Unstable organic compound with at least one unpaired electron.

**Fresh plant tincture**—Herbal extract made from fresh plant instead of dried material.

**Fruit**—Most commonly used seeds are anis (*Pimpinella anisum*) and fennel (*Foeniculum vulgare*), both of the Apiaceae family. In some instances, the fruit peel is used specifically (e.g. citrus spp, from the Rutaceae family).

**FSH**—follicle stimulating hormone.

**FVC**—forced vital capacity.

**GABA**—gamma-aminobutyric acid.

**GAD**—generalised anxiety disorder.

**Galactagogue**—Substance that promotes the production and flow of breast milk.

**GI**—glycaemic index.

**GLUT**—glucose transporters.

**Glycoside**—Sugar-containing compound with a glycone (sugar) and aglycone (non-sugar) components that can be cleaved on hydrolysis.

**GSH**—glutathione.

**Gum**—Solids consisting of mixtures of polysaccharides that are water-soluble and are partially digested by humans. Gums sometimes flow from a damaged plant stem as a defence mechanism or sometimes as a protective system against the invasion of bacteria and fungi. Well-known examples are gum arabic (*Acacia senegal*, Leguminosae), and aloe gel (*Aloe vera*, Liliaceae family: gum mixed with water).

**Gy**—gray (unit of radiation).

**Haemostasis**—Physiological process that stops bleeding (i.e. vessel constriction, platelet plug formation and blood coagulation).

**HbA<sub>1C</sub>**—haemoglobin A<sub>1C</sub>.

**HBeAg**—hepatitis B early antigen.

**HDL**—high-density lipoprotein.

**Hepatoprotective**—Substance that reduces or prevents liver damage; protects against the destructive effect of hepatotoxins.

- High-performance liquid chromatography**—Very popular and widely used method for the analysis and isolation of bioactive natural products.
- HIV**—human immunodeficiency virus.
- HMG-CoA**—3-hydroxy-3-methylglutaryl coenzyme A.
- HPA**—hypothalamus–pituitary–adrenal [axis].
- HRT**—hormone replacement therapy.
- HSV**—herpes simplex virus.
- Hypnotic**—Substance that induces sleep or the feeling of dreamy sleepiness.
- Hypoglycaemic**—Substance that reduces blood glucose levels.
- Hypolipidaemic**—Substance that reduces blood levels of lipids (e.g. cholesterol, triglycerides).
- Iatrogenic**—Condition caused by medical or surgical treatment or diagnostic procedures.
- IBS**—irritable bowel syndrome.
- IFN**—interferon.
- Ig**—immunoglobulin.
- IL**—interleukin.
- IM**—integrative medicine.
- Immunomodulation**—Substance that alters the immune response; also described as having a balancing effect on immune responses.
- Immunostimulant**—Substance that augments the immune response.
- Immunosuppressant**—Substance that inhibits the immune response.
- Infused oil**—Herbal extract using a fixed oil as the solvent.
- Infusion (herbal)**—Herbal tea prepared by pouring boiling water over plant parts and steeping for a short time.
- iNOS**—inducible nitric oxide synthase.
- Inotrope**—Substance that has an effect on the force of myocardial contractility. A positive inotrope increases the force of contraction whereas a negative inotrope decreases the force of contraction.
- INR**—international normalised ratio.
- Interaction**—Pharmacological interaction is said to occur when the response to one medicine varies from what is usually predicted because another substance has altered the response. An interaction may lead to drug toxicity or a loss of drug effect; however, it can also be manipulated to benefit the patient by improving outcomes, reducing side effects or reducing drug dose and costs.
- IO**—integrative oncology.
- IP**—intraperitoneal.
- IQ**—intelligence quotient.
- Ischaemia**—Oxygen deficiency.
- IV**—intravenous.
- IVF**—in vitro fertilisation.
- Laxative**—Substance that causes bowel evacuation.
- LD<sub>50</sub>**—median lethal dose.
- LDL**—low-density lipoprotein.
- LH**—luteinising hormone.
- LOHAS**—lifestyles of health and sustainability.
- Maceration**—Method of herbal extraction in which cut herb is soaked in solvent (such as cold water) for a period of time before draining, straining and pressing.
- Meta-analysis**—Quantitative statistical procedure for combining the results of independent studies to better analyse the efficacy of a specific treatment.
- Mineral**—Compound containing a non-metal, metal, radical or phosphate required for proper body functioning and health maintenance.
- Mineral oil**—Faecal softener and laxative.
- MND**—motor neuron disease.
- MOA**—monoamine oxidase.
- MRL**—maximum residue level.
- MRSA**—methicillin-resistant *Staphylococcus aureus*.
- MSSA**—methicillin-sensitive *Staphylococcus aureus*.
- MTHFR**—methylenetetrahydrofolate reductase.
- Mucilage**—Sticky mixture of carbohydrates produced by plant cell activity. Herbs with a high mucilaginous content are often used as demulcents (e.g. *Ulmus fulvus* (slippery elm), *Althea officinalis* (marshmallow)).
- Mucolytic**—Substance that dissolves or destroys mucus.
- Myocardial infarction (MI)**—Necrosis (death) of a portion of the heart muscle; also called a heart attack.
- NAD**—nicotinamide adenine dinucleotide.
- NADPH**—nicotinamide adenine dinucleotide phosphate.
- Narrow therapeutic index (NTI)**—The dose required to produce a toxic effect in 50% of test animals (TD<sub>50</sub>) is close to the dose required to produce an effective therapeutic response in 50% of test animals (ED<sub>50</sub>); NTI drugs are particularly susceptible to adverse interactions (e.g. digoxin).
- Nervine**—Substance that exerts a relaxant effect; described as nourishing and strengthening the nervous system.
- Neurotransmitter**—Chemical that acts as a messenger, enabling transmission of nerve impulses across synapses and neuromuscular junctions. The most important are acetylcholine, catecholamines (noradrenaline, adrenaline and dopamine), serotonin, some amino acids and neuro-active peptides.
- NK**—natural killer [cell].
- NO**—nitric oxide.
- NSAID**—non-steroidal anti-inflammatory drug.
- Nutritive**—Substance that contains numerous nutrients such as vitamins, minerals, carbohydrates and fats.
- NYHA**—New York Heart Association [classification].
- OA**—osteoarthritis.
- OCP**—oral contraceptive pill.
- OS**—oxygen species.
- OTC**—over-the-counter.
- Oxytotic**—Substance that exerts similar effects to oxytocin (i.e. stimulates smooth muscle, usually of the uterus, to contract).

**P-glycoprotein (P-gp)**—P-gp is a transport protein found on the surface of hepatocytes, renal tubular epithelial cells, epithelial cells in the intestine, and placenta and capillary epithelial cells in the brain. It has a counter-transport activity (i.e. can transport medicines from the blood back into the gastrointestinal tract, thereby reducing bioavailability).  
**PCOS**—polycystic ovaries syndrome.

**PEF**—peak expiratory flow.

**Peri-operative**—Pertaining to the time of surgery.

**PG**—prostaglandin.

**Pharmacodynamics**—Study of the effects of drugs on living organisms.

**Pharmacokinetics**—Study of the actions of drugs within the body (i.e. absorption, distribution, metabolism and excretion, onset of action and duration of effect).

**Phytochemical**—Naturally occurring chemical found in a plant.

**Phytotherapy**—Study and application of plant medicine; a modern term used to describe scientifically investigated and validated herbal medicine.

**Placebo**—Harmless inactive substance that does not contain an active medicine; used in clinical studies for comparison with medicines suspected of exerting a clinical effect to determine whether in fact a significant response does occur.

**PMS**—premenstrual syndrome.

**PO**—per os (oral).

**Polypharmacy**—Use of many medicines by a patient with one or more health conditions.

**Polysaccharide**—Carbohydrate polymer formed from three or more sugar molecules.

**Postprandial**—After a meal.

**Poultice**—Paste made from crushed fresh plant, either mixed with oil or alcohol or simply made in water and applied to the parts of the body.

**PPI**—proton-pump inhibitors.

**ppm**—parts per million.

**Prospective study**—Study designed to determine the relationship between a condition and a characteristic shared by some members of a group. Usually the population selected is healthy at the beginning of the study and is observed over a period of time for the development of certain conditions in the different subgroups (e.g. smokers and non-smokers).

**PTH**—parathyroid hormone.

**PUFA**—polyunsaturated fatty acid.

**PUVA**—psoralen ultraviolet A.

**QOL**—quality of life.

**RA**—rheumatoid arthritis.

**RAST**—radioallergosorbent test.

**RCT**—randomised controlled trial.

**RDA**—recommended daily allowance.

**RDI**—recommended daily intake.

**Resin**—Excreted from specialised cells or ducts in plants, this consists of a mixture of essential oils and polymerised terpenes; usually insoluble in water.

Well-known examples include frankincense (*Boswellia sacra*) and myrrh (*Commiphora molmol*), both of the Burseraceae family.

**Restorative**—Restores or renews a person's state of health or consciousness to normal.

**Rhizome**—Root; underground fleshy stem that grows horizontally and acts as food storage for the plant.

**Risk factor**—Factor that increases a person's susceptibility to an unwanted, unpleasant or unhealthy event or disease.

**Root**—Fleshy or woody, usually underground, part of a plant; may be fibrous (e.g. *Urtica dioica* or *U. radix* of the Urticaceae family, stinging nettle), solid (e.g. *Glycyrrhiza glabra* of the Leguminosae family, licorice) or fleshy (e.g. *Harpagophytum procumbens* of the Pedaliaceae family, devil's claw).

**ROS**—reactive oxygen species.

**Salicylate**—Substance that contains or is derived from salicylic acid.

**Saponin**—Vast group of glycosides that occur in many plants; dissolve in water and form a soapy solution when shaken; used in demulcents.

**SBP**—systolic blood pressure.

**SC**—subcutaneous.

**Seeds**—Contained in the fruit and used medicinally (e.g. fennel seed, *Foeniculum vulgare*: Apiaceae).

**SLE**—systemic lupus erythematosus.

**SSRI**—selective serotonin reuptake inhibitor.

**SVCT**—sodium vitamin C co-transporters.

**Synergistic**—Several components acting or working together in a coordinated manner to produce an effect greater than that of the sum of the individual effects.

**Tannin**—Substance that forms a precipitate with proteins, nitrogenous bases, polysaccharides and some alkaloids and glycosides (e.g. *Camellia sinensis*, the herb commonly used to make 'tea', is a rich source of tannins).

**TCM**—traditional Chinese medicine.

**TGA**—Therapeutic Goods Administration (Australia).

**Th**—T helper cell.

**Therapeutic index**—Measure of the safety of a medicine based upon the dose required to produce a toxic effect in 50% of test animals (TD<sub>50</sub>) divided by the dose required to produce an effective therapeutic response in 50% of test animals (ED<sub>50</sub>); i.e. TI = TD<sub>50</sub>/ED<sub>50</sub>.

**Thin layer chromatography**—Analytical method using glass or aluminium plates precoated with the sorbent (e.g. silica gel) to separate a compound mixture according to the polarity of its components.

**Tincture**—Hydro-ethanolic extraction of crude herbal material; usually extracted in the ratio of 1:5 (1 part herb to 5 parts solvent). Glyceride tinctures may be prepared by using glycerol rather than alcohol.

**TNF**—tumour necrosis factor.

**TPN**—total parenteral nutrition.

**TSH**—thyroid stimulating hormone.

**URTI**—upper respiratory tract infection.

**UTI**—urinary tract infection.

**UV**—ultraviolet.

**VAS**—visual analogue scale.

**VDR**—vitamin D receptors.

**Vitamin**—Organic compound essential to life. With few exceptions, vitamins cannot be synthesised in the body and must be obtained from the diet.

**VLDL**—very low-density lipoprotein.

**WOMAC**—Western Ontario and McMaster University Osteoarthritis Index.

**WSR**—whole systems research.

# APPENDIX 2

## HERB/NUTRIENT-DRUG INTERACTIONS

### ASSUMPTIONS MADE WHEN COLLATING AND ASSESSING INFORMATION FOR THIS TABLE

- Information is compiled from the 132 monographs included in this book.
- The clinical significance of many interactions is still unknown because controlled trials are lacking in most cases. In these instances, interactions are based on evidence of pharmacological activity and case reports, and have a sound theoretical basis, although remain to be tested.
- All information refers to oral dose forms unless otherwise specified.
- Information is correct at the time of writing; however, because of the ever-expanding knowledge base developing in this area, new research is constantly being published.
- The interaction table is provided as a guide only and should not replace the use of professional judgement. It has been developed to assist clinicians when advising patients.

### USING THIS GUIDE IN PRACTICE

- Refer to Chapter 8: Interactions with Herbal and Natural Medicines for background information.
- Commonly used prescription and over-the-counter medications are organised by therapeutic class and subclass and are listed alphabetically.
- Common names have been used when referring to herbs.
- Refer to the original monograph for more information about a particular substance.

### RECOMMENDATIONS

**Avoid** — there may be insufficient information available to be able to advise using the two substances safely together, so avoid until more is known. The drug may have a narrow therapeutic index and there is sufficient evidence to suggest that the interaction may be clinically significant. Consider an alternative treatment that is unlikely to produce an undesirable interaction.

**Avoid use unless under medical supervision** — harmful effects of the potential interaction can be avoided if doses are altered appropriately under professional supervision or the patient is closely monitored. Some of these interactions can be manipulated to the advantage of the patient. Changes to the dosage regimen may be required for safe combined use.

**Caution** — the possibility exists of an interaction that may change effects clinically; be aware and monitor. It is prudent to tell patients to be aware and seek advice if they are concerned.

**Observe** — interaction may not be clinically significant at the usual recommended doses and theoretical; however, the clinician should be alert to the possibility of an interaction.

**Beneficial interaction possible** — prescribing the interacting substance may improve clinical outcomes; for example, reducing drug requirements, complementing drug effects, reducing drug side-effects, counteracting nutritional deficiencies caused by drugs, alleviating drug withdrawal symptoms and enhancing patient wellbeing.

**KEY TO THE TABLE BY HERB/SUPPLEMENT**

Adhatoda	
Anti-tussives	
Codeine.....	1241
Theophylline.....	1298
Albizia	
Antidepressants including SSRIs, SNRIs, tricyclics and MAOIs.....	1262
Antihistamines and mast-cell-stabilising drugs..	1241
Barbiturates.....	1267
Tricyclic antidepressants.....	1263
Aloe vera	
CYP3A4 and CYP2D6 inhibition.....	1238
Digoxin (e.g. Lanoxin).....	1254
Doxorubicin.....	1288
<i>Helicobacter pylori</i> triple-therapy.....	1277
Hypoglycaemic (e.g. metformin).....	1272
Laxatives.....	1277
Topical corticosteroids (e.g. hydrocortisone)....	1288
Vitamins A and E, increased absorption.....	1299
Alpha Lipoic Acid	
Antiplatelet drugs (e.g. aspirin).....	1248
Coenzyme Q10.....	1294
Copper.....	1294
Hypoglycaemic agents.....	1272
Levothyroxin.....	1275
Manganese.....	1294
Vitamin C.....	1294
Vitamin E.....	1294
Warfarin.....	1244
Zinc.....	1294
Andrographis	
Alcohol.....	1298
Anticoagulants (e.g. warfarin).....	1242
Antiplatelet drugs.....	1248
Barbiturates.....	1267
Hepatotoxic drugs.....	1301
Hypoglycaemic (e.g. metformin).....	1273
Immunosuppressant drugs.....	1291
Paracetamol.....	1242
Tricyclic antidepressants.....	1263
Arginine	
Antihypertensive medicines.....	1250
Lysine.....	1294
Astragalus	
Digoxin (e.g. Lanoxin).....	1254
Aciclovir.....	1283
Cyclophosphamide.....	1287
Nitroglycerin/glyceryl trinitrate (e.g. anginine).....	1243
Positive inotropic drugs (e.g. Lanoxin).....	1254
Baical skullcap	
Antihistamines and mast-cell-stabilising drugs..	1241
Cyclosporin.....	1278
Immunosuppressant drugs.....	1291
Interferon.....	1279
Warfarin/anticoagulants.....	1244
Bergamot	
Organic anion-transporting polypeptide 1A2 (OATP1A2).....	1240
Beta-carotene	
Anti-convulsants.....	1259
Cholestyramine (e.g. Questran lite, colestipol [e.g. Colestid]).....	1257
Fibric acid derivatives.....	1258
Bilberry	
Anticoagulants (e.g. warfarin).....	1244
Antiplatelet drugs.....	1248
Chemotherapy.....	1286
Hypoglycaemic (e.g. metformin).....	1273
Bitter melon	
Hypoglycaemic (e.g. metformin).....	1273
Black cohosh	
Cisplatin.....	1291
Doxorubicin.....	1288
Docetaxel.....	1288
Brahmi	
Cholinergic drugs (e.g. Tacrine).....	1265
Selective serotonin re-uptake inhibitors.....	1262
Calcium	
Alendronate.....	1271
Antacids, including H <sub>2</sub> antagonists and proton pump inhibitors.....	1276
Caffeine.....	1255
Calcium-channel blockers (e.g. verapamil).....	1253
Cardiac glycosides (e.g. digoxin).....	1254
Corticosteroids.....	1270
Digoxin (e.g. Lanoxin).....	1254
Etidronate (e.g. Didronel).....	1271
Excess fibre, including guar gum.....	1300
Iron.....	1294
L-Dopa (levodopa).....	1265
Levothyroxine (e.g. Oroxine).....	1275
Lysine.....	1294
Magnesium.....	1294
Oestrogen and progesterone.....	1272
Penicillamine (e.g. D-penammine).....	1297
Phosphorus/Phosphoric acid.....	1295
Quinolone antibiotics (e.g. norfloxacin [e.g. Noroxin]).....	1281
Sucralfate (e.g. Carafate, Ulcyte).....	1277
Tetracycline antibiotics (e.g. minocycline [e.g. Minomycin], doxycycline).....	1281
Thiazide diuretics.....	1256
Zinc.....	1256, 1294, 1296
Carnitine	
Anticoagulants (e.g. warfarin).....	1243
Anticonvulsants.....	1259
Betamethasone.....	1270
Carboplatin.....	1287
Cisplatin.....	1291
Doxorubicin (e.g. Adriamycin).....	1289
HIV drugs (e.g. zidovudine [AZT, e.g. Retrovir]).....	1283
HMG CoA-reductase inhibitors (statins).....	1258
Interferon-alpha.....	1279
Interleukin-2-immunotherapy.....	1292
Celery	
Anticoagulants (e.g. warfarin).....	1243
Barbiturates.....	1267
Levothyroxine (e.g. Oroxine).....	1275
NSAIDs.....	1283
Phenobarbitone.....	1260

- PUVA therapy ..... 1303  
Sodium valproate ..... 1261
- Chamomile  
Benzodiazepines ..... 1268  
NSAIDs ..... 1283
- Chaste tree  
Dopamine antagonists ..... 1300  
Oral contraceptive pill ..... 1269
- Chitosan  
B-group vitamins (B<sub>2</sub>, B<sub>12</sub>) ..... 1300  
Fat-soluble nutrients ..... 1300  
Lipophilic drugs ..... 1302  
Vitamin C ..... 1300  
Warfarin ..... 1244
- Chondroitin  
Anticoagulants (e.g. warfarin) ..... 1244  
NSAID ..... 1244
- Chromium70  
Corticosteroids ..... 1270  
Hypoglycaemic medications (e.g. metformin) .. 1273  
Hypolipidaemic medications ..... 1257
- Cinnamon  
Hypoglycaemic (e.g. metformin) ..... 1238
- Citrus aurantium  
CYP3A ..... 1240  
P-glycoprotein dependent medications ..... 1240
- Cocoa  
Iron ..... 1300  
Colostrum ..... 1238  
NSAIDs ..... 1284
- Coenzyme Q10  
Alpha Lipoic acid ..... 1294  
Anticoagulants (e.g. warfarin) ..... 1244  
Antimigraine preparations ..... 1253  
Beta-adrenergic-blocking agents ..... 1252  
Clonidine (e.g. Catapres) ..... 1253  
Doxorubicin (e.g. Adriamycin) ..... 1289  
Fibric-acid derivatives (e.g. gemfibrozil) ..... 1258  
HMG-CoA reductase inhibitors (statins) ..... 1258  
Hydralazine (e.g. Apresoline, Alphapress) ..... 1252  
Hydro-chlorothiazide (e.g. Diclotride) ..... 1256  
Methyldopa (e.g. Aldomet) ..... 1252  
Phenothiazines ..... 1264  
Sulfonylureas ..... 1275  
Theophylline ..... 1297  
Timolol eye drops ..... 1276  
Tricyclic antidepressants ..... 1263  
Vitamin E ..... 1295
- Copper  
Alpha Lipoic acid ..... 1294
- Coriolus versicolor  
Cyclosporin ..... 1278
- Cranberry  
Antacids ..... 1276  
Anticoagulants (e.g. warfarin) ..... 1244  
CYP3 A substrates ..... 1238
- Damiana  
Hypoglycaemic (e.g. metformin) ..... 1273
- Dandelion  
Quinolone antibiotics (e.g. norfloxacin [e.g. Noroxin]) ..... 1281
- Dandelion leaf  
Diuretics ..... 1255
- Devil's claw  
Anti-arrhythmic agents ..... 1243  
Anticoagulants (e.g. warfarin) ..... 1244
- Echinacea  
Cyclophosphamide ..... 1287  
Cyclosporin ..... 1278  
Essential fatty acids – omega 3 & omega 6 ..... 1250  
Etoposide ..... 1290  
Myelosuppressive chemotherapeutic agents ..... 1292
- Elderflower  
Diuretic drugs ..... 1255  
Hypoglycaemic drugs ..... 1273  
Immunosuppressant drugs ..... 1291
- Eucalyptus  
CNS sedatives ..... 1266  
Hypoglycaemic agents ..... 1273
- Evening primrose oil  
Anticoagulants (e.g. warfarin) ..... 1245  
Antihypertensive drugs ..... 1251  
Antiplatelet drugs ..... 1248  
Phenothiazines (e.g. chlorpromazine, trifluoperazine) ..... 1264
- Fenugreek  
Anticoagulants (e.g. warfarin) ..... 1245  
Hypoglycaemic (e.g. metformin) ..... 1273  
Iron ..... 1300
- Feverfew  
Anticoagulants (e.g. warfarin) ..... 1245  
Antimigraine preparations ..... 1253  
Antiplatelet drugs ..... 1248
- Fish oils  
Anticoagulants (e.g. warfarin) ..... 1245  
Antiplatelet drugs ..... 1248  
NSAIDs ..... 1283  
Pravastatin (e.g. Pravachol) ..... 1259
- Folate  
Antacids ..... 1276  
Anticonvulsants ..... 1259  
Barbiturates ..... 1266  
Cholestyramine (e.g. Questran lite, colestipol [e.g. Colestid]) ..... 1258  
Gastric-acid inhibitors (proton-pump inhibitors [e.g. omeprazole], H<sub>2</sub>-receptor antagonists [e.g. ranitidine]) ..... 1277  
Methotrexate ..... 1290  
Oral contraceptive pill ..... 1269  
Pancreatin ..... 1276  
Pyrimethamine (e.g. Daraprim) ..... 1282  
Sulfasalazine (e.g. Salazopyrin) ..... 1286  
Trimethoprim (e.g. Triprim) ..... 1282  
Zinc ..... 1295
- Garlic  
Anticoagulants (e.g. warfarin) ..... 1245  
Antihypertensive drugs ..... 1251  
Antiplatelet drugs ..... 1248  
*Helicobacter pylori* triple-therapy ..... 1277  
Hepatotoxic drugs ..... 1301  
Hydrochlorothiazide ..... 1256  
Hypolipidaemic agents ..... 1257  
Immunosuppressant drugs ..... 1291

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>DRUGS METABOLISED/UTILISED BY</b>				
<b>Cytochrome P450 (e.g. CYP2E1, CYP2D6, CYP2C8, CYP2C9, CYP2C19, CYP3A, CYP3A4)</b>				
Aloe vera	CYP3A4 and CYP2D6	Inhibition	Caution	Aloe vera juice was found to inhibit both CYP3A4 and CYP2D6 by both CYP and non-CYP mechanisms. The estimated IC <sub>50</sub> inhibition values was suggestive of no major interference in humans, however some degree of caution and acknowledgement should be exercised.
Citrus aurantium	CYP3A	Reduced drug effects	Caution	Theoretically, an interaction exists for CYP 3A and P-glycoprotein substrates, as human studies indicate that the juice made from <i>Citrus aurantium</i> (Seville orange) inhibits CYP3A and possibly P-glycoprotein. * More research is required to investigate the effect of <i>Citrus aurantium</i> on individual medications.
Cranberry	CYP3A	Reduced drug effects	Caution. Monitor patients taking high-strength cranberry preparations and medicines chiefly metabolised by CYP3A. Special care should be taken if the medicines have a narrow therapeutic index.	Cranberry juice has the potential to inhibit the metabolism of drugs chiefly metabolised by CYP3A isoenzymes. It appears to be dependent on the concentration of three triterpenes (maslinic acid, corosolic acid and ursolic acid) in the juice. These have been identified as the important constituents responsible for inhibiting intestinal CYP3A and most likely explain the inter-brand differences seen in various clinical and preclinical trials.
Golden seal	CYP3A4 and CYP2D6	Inhibition	Caution	Studies in healthy volunteers demonstrated that CYP3A4 and CYP2D6 were significantly down-regulated following goldenseal treatment.
Green tea	CYP3A4	Potential inhibition	Observe. Separate doses by at least 2 hours	In vitro and animal research has shown green tea to inhibit CYP3A4 metabolism and a probable inhibition of intestinal CYP3A4, but clinical relevance is unknown.
Honey	CYP3A4	Altered drug metabolism.	Observe. Separate doses by at least 2 hours.	Oral intake of honey may induce CYP3A4 enzyme activity.
Hops	CYP2C8, CYP2C9, CYP2C19	Altered drug metabolism.	Observe the patient for signs of altered drug effectiveness.	Altered drug effect — cytochrome (CYP) inhibition has been demonstrated in vitro. However, it is unknown whether these effects are clinically significant.
Kava	CYP2E1	Reduced drug absorption	Caution	Inhibition of CYP2E1 has been demonstrated in vivo — serum levels of CYP2E1 substrates may become elevated.
Korean Ginseng	CYP1A, CYP2D6 and CYP3A4	Reduced drug absorption	Caution. Observe for increased drug bioavailability and clinical effects.	Mixed reports exist as to whether ginseng may act as an inhibitor of cytochrome CYP1A. Whether these effects are likely to be clinically significant has not been established.

Licorice	CYP3A4	Reduced drug absorption	Caution. Observe for increased drug bioavailability and clinical effects.	Licorice has been shown to cause a moderate, clinically relevant, induction of CYP3A4. Other constituents have been found to affect various CYP P450 isoforms in vitro. Until studies in humans come to light, the clinical significance of this remains unclear.
Nigella	CYP2B, CYP3A2, CYP2C11, and CYP1A2	Reduced drug absorption	Separate doses by at least 2 hours	Preliminary animal study data suggests that Nigella may be protective against carbon tetrachloride-induced downregulation of Cytochrome P450 enzymes CYP2B, CYP3A2, CYP2C11, and CYP1A2. A potential interaction with drugs with Cytochrome P450 metabolising activity is theoretical and speculative. Further research is required to determine clinical significance.
Peppermint	CYP3A4	Increased oral bioavailability	Observe	Peppermint may increase the oral bioavailability of certain drugs by inhibition of CYP3A4-mediated drug metabolism, which has been demonstrated in vitro but not in test animals. Although these studies seem to suggest that peppermint may modulate drug-metabolising enzymes, the clinical significance of this is unknown and requires further investigation.
Quercetin	CYP1A1, CYP1A2, CYP3A4	Altered metabolism	Carefully monitor the concurrent use of all drugs chiefly metabolised by CYP1A1, CYP1A2, CYP3A4	Possible inhibition of CYP1A1, CYP1A2 activity should be considered when prescribing. According to a recent crossover RCT, 500 mg of oral quercetin significantly induces CYP3A4.
Rhodiola	CYP3A4	Raised drug serum levels	Caution. Monitor the concurrent use of all drugs chiefly metabolised by CYP3A4	In vitro tests reveal that Rhodiola extract inhibits CYP3A4; this has also been suggested in vivo — clinical significance is unknown. Until further tests have been conducted, caution is advised when concurrently using medicines chiefly metabolised by CYP3A4 as the interaction could result in raised drug serum levels.
Schisandra	CYP3A4 substrates	Increased serum levels of drugs chiefly metabolised by CYP 3A4	Avoid, unless already under medical care	Increased serum levels of drugs chiefly metabolised by CYP 3A4 are possible, based on current evidence. Practitioners are advised to carefully monitor patients that are already taking drugs that are CYP3A4 substrates to avoid inducing drug side effects caused by increased serum levels. Schisandra should not be prescribed together with CYP3A4 substrates that have a narrow therapeutic index in order to avoid inducing drug toxicity.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>P-glycoprotein</b>				
Citrus aurantium	P-glycoprotein	Reduced drug effects	Caution	Theoretically, an interaction exists for CYP 3A and P-glycoprotein substrates, as human studies indicate that the juice made from <i>Citrus aurantium</i> (Seville orange) inhibits CYP3A and possibly P-glycoprotein. *More research is required to investigate the effect of <i>Citrus aurantium</i> on individual medications.
Quercetin	P-glycoprotein	Altered metabolism	Carefully monitor the concurrent use of all drugs chiefly metabolised by P-glycoprotein	Possible modulation of P-glycoprotein activity should be considered when prescribing. According to a recent crossover RCT, 500 mg of oral quercetin significantly induces CYP3A4.
Rhodiola	Drugs metabolised by P-glycoprotein substrates	Potential altered metabolism	Observe	In vitro tests reveal that Rhodiola extract inhibits P-glycoprotein — clinical significance is unknown.
Rosemary	Drugs dependent on P-glycoprotein transport	Potential altered metabolism	Observe	Theoretically, increased drug uptake can occur with those drugs dependent on P-glycoprotein transport. The clinical significance of this finding remains to be tested, although it has been suggested that this activity may be used to enhance the effects of chemotherapeutic agents.
Schisandra	P-glycoprotein substrates	Serum levels of P-gp substrates could be increased	Avoid, unless already under medical care	Based on current evidence, it appears that P-gp inhibition is possible. As a result, serum levels of P-gp substrates could be increased. Practitioners are advised to carefully monitor patients who are already taking drugs that are P-gp substrates to avoid inducing drug side effects caused by increased serum levels. Schisandra should not be prescribed together with P-gp substrates that have a narrow therapeutic index in order to avoid inducing drug toxicity.
Soy	P-glycoprotein substrates	Altered metabolism	Caution	It has been suggested that isoflavones can inhibit the oxidative and conjugative metabolism of drugs in vitro and interact with transporters such as P-glycoprotein; however, their ability to interact with drugs remains uncertain until clinical studies can confirm these findings.
<b>Other (e.g. OATP1A2, UGT1A3)</b>				
Bergamot	Organic anion-transporting polypeptide 1A2 (OATP1A2)	Possible reduced drug effects	Observe	Theoretical concern about possible interactions due to the presence of naringin in bergamot. This constituent is also found in grapefruit juice and while it does not have any appreciable effect on cytochromes, it may inhibit OATP1A2.

Schisandra	Drugs metabolised by UGT1A3	Altered metabolism	Avoid, unless already under medical care	Deoxychizandrin and schisantherin A have demonstrated an inhibitory effect on UDP-glucuronosyltransferase 1A3 (UGT1A3) <i>in vitro</i> . This suggests a potential for herb-drug interactions between Schisandra and drugs that mainly undergo UGT1A3-mediated 12 metabolism, however, the effect has not been confirmed clinically.
<b>ALLERGIC DISORDERS</b>				
<b>Antihistamines</b>				
Antihistamines and mast-cell-stabilising drugs	Albizia	Additive effects	Beneficial interaction possible	Both <i>in vitro</i> and <i>in vivo</i> tests have reported significant mast-cell-stabilisation effects similar to those of cromoglycate.
	Baical skullcap	Additive effects	Beneficial interaction possible	Luteolin and baicalin have been shown to inhibit IgE antibody-mediated immediate- and late-phase allergic reactions in mice.
	Perilla	Additive effects	Observe	Perilla seed extract has been shown to inhibit histamine release from mast cells in a dose-dependent manner — drug dosage may need modification.
	St John's wort	Increased elimination of drug	Observe. Monitor drug requirements	In rats, SJW enhanced the elimination of fexofenadine, an antihistamine and P-glycoprotein substrate, into the bile when given once daily for 14 days.
<b>ANALGESIA</b>				
<b>Narcotic analgesics</b>				
Codeine	Adhatoda	Additive effects	Beneficial interaction possible	Theoretically will increase antitussive effects of drug.
	Kava	Additive effects	Caution	Increased CNS depression theoretically possible.
Morphine	Kava	Additive effects	Caution	Increased CNS depression theoretically possible.
	Tyrosine	Additive effects	Observe patients taking tyrosine and morphine sulfate concurrently — potential beneficial interaction.	Tyrosine potentiates morphine-induced analgesia by 154% in mice. Suggestive of a clinically relevant effect but not confirmed
	Withania	Reduced morphine tolerance/dependence	Beneficial interaction possible with professional supervision	In animal studies, repeated administration of withania (100 mg/kg) inhibited morphine tolerance and dependence, so it is sometimes used in opiate withdrawal.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Oxycodone	St John's wort	Reduced plasma concentrations of oxycodone	Avoid	St John's wort greatly reduced the plasma concentrations of oral oxycodone.
<b>Simple analgesics and antipyretics</b>				
Simple analgesics and antipyretics	Meadowsweet	Additive effects	Observe Beneficial interaction possible	Additive anti-inflammatory and analgesic effects theoretically possible.
	Nigella	Additive effects	Beneficial interaction possible	Potentiation effects are possible when using black seed at high doses based on animal models. Clinical significance unknown.
Aspirin	Vitamin E	Additive effects	Beneficial interaction possible Drug dosage may require modification	Vitamin E may enhance the pain-modifying effects of drug in RA.
	Willowbark	Additive effects	Observe Beneficial interaction possible	Additive anti-inflammatory and analgesic effects theoretically possible.
	Grapeseed extract	Increased bruising and bleeding	Observe Beneficial interaction possible	Theoretically may enhance antiplatelet and anti-inflammatory activity of aspirin.
	Licorice	Reduce gastro-irritant effects of drug therapy	Observe Beneficial interaction possible	Co-administration with licorice may reduce gastro-irritant effects induced by drug therapy — potentially beneficial interaction. Whether the effect is clinically significant for licorice remains to be determined — use high doses with caution.
	Meadowsweet	Increased bruising and bleeding	Observe Beneficial interaction possible	Theoretically may enhance anti-inflammatory and antiplatelet effects.
Paracetamol	Policosanol	Increased bruising and bleeding	Observe	Doses > 10 mg/day may inhibit platelet aggregation.
	Vitamin C	Decreased vitamin C effects	Beneficial interaction	Aspirin may interfere with both absorption and cellular uptake mechanisms for vitamin C, thereby increasing vitamin C requirements, as observed in animal and human studies. Increased vitamin C intake may be required with long-term therapy.
	Willowbark	Increased bruising and bleeding	Observe Beneficial interaction possible Caution with high-dose (> 240 mg salicin daily)	Theoretically may enhance anti-inflammatory and antiplatelet effects. Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect.
Paracetamol	Andrographis	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by paracetamol.

	Garlic	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by paracetamol.
	Quercetin	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by paracetamol.
	St Mary's thistle	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by paracetamol.
	SAME	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by paracetamol.
	Schisandra	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by paracetamol.
Salicylate drugs	Willowbark	Additive effects	Observe Beneficial interaction possible	Additive anti-inflammatory and analgesic effects theoretically possible.
<b>CARDIOVASCULAR SYSTEM</b>				
<b>Anti-angina agents</b>				
Nitroglycerin/ glyceryl trinitrate (e.g. anginine)	Vitamin E	Prevention of drug tolerance	Beneficial interaction possible	Oral vitamin E prevented nitrate tolerance when given concurrently with transdermal nitroglycerin (10 mg/24 h) according to one randomised placebo-controlled study.
<b>Anti-arrhythmic agents</b>				
	Astragalus	Additive effects	Observe	Additive effects are theoretically possible with IV administration of astragalus, based on positive inotropic activity identified in clinical studies; the clinical significance of these findings for oral dose forms is unknown.
	Devil's claw	Additive effects	Observe	Devil's claw has demonstrated anti-arrhythmic activity, but interaction is theoretical and clinical significance is unclear.
	Hawthorn	Additive effects	Observe	Hawthorn has demonstrated anti-arrhythmic activity in vitro and in vivo, but interaction is theoretical and clinical significance is unclear.
	Magnesium	Additive effects	Observe	High-dose oral magnesium has demonstrated anti-arrhythmic activity according to one clinical trial.
Amiodarone	Vitamin B <sub>6</sub>	Increased side effects	Caution	Pyridoxine may increase the risk of drug-induced photosensitivity. Exercise caution with patients taking pyridoxine and amiodarone concurrently.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>Anticoagulants, antiplatelets</b>				
Monitor bleeding time and signs and symptoms of excessive bleeding				
Anticoagulants (e.g. warfarin)	Alpha Lipoic Acid	Potential bruising and bleeding	Observe — monitor bleeding time	ALA reduces platelet reactivity in vitro. It is uncertain whether the effect is clinically significant — observe patients taking these agents together.
	Andrographis	Increased bruising and bleeding	Caution — monitor bleeding time	Andrographolide clinically confirmed to inhibit platelet-activating-factor-induced platelet aggregation. However, andrographis used together with warfarin did not produce any significant effects on the pharmacokinetics of warfarin, and had even less effect on its pharmacodynamics in vivo.
	Baical Skullcap	Increased risk of bleeding	Caution	Increased risk of bleeding is theoretically possible.
	Bilberry	Increased bruising and bleeding	Caution with high-dose (>170 mg) anthocyanadins unless under medical supervision	Dose is particularly high and not relevant to clinical practice.
	Carnitine	Increased bruising and bleeding	Caution — monitor bleeding time and signs and symptoms of excessive bleeding	According to one case report, L-carnitine 1 g/day may potentiate the anticoagulant effects of acenocoumarol.
	Celery	Increased bruising and bleeding	Observe with concentrated extracts	Although it contains naturally occurring coumarins, interaction is unlikely.
	Chitosan	Increased bruising and bleeding	Avoid	Chitosan may potentiate warfarin by inhibiting absorption of fat-soluble vitamin K.
	Chondroitin	Increased bruising and bleeding	Observe with high-dose supplements	Theoretical risk; not observed in clinical trials.
	Coenzyme Q10	Reduced drug effects theoretically possible with high doses	Caution	A double-blind crossover study found that oral CoQ10 100 mg/day had no significant effect on INR or warfarin levels; however, in vivo tests using 10 mg/kg/day CoQ10 decreased serum concentrations of warfarin by increasing drug metabolism.
	Cranberry	Increased bruising and bleeding	Caution	Based on case reports. Until the interaction can be better understood, patients taking warfarin with cranberry juice should continue to monitor their INR changes and signs and symptoms of bleeding.
	Devil's claw	Increased bruising and bleeding	Caution	Case reports suggest possible anticoagulant activity.

	Evening primrose oil	Increased bruising and bleeding	Caution with high-dose supplements	Gamma-linoleic acid in evening primrose oil affects prostaglandin synthesis, leading to inhibition of platelet aggregation — clinical significance is unknown.
	Fenugreek	Increased bruising and bleeding	Observe	Contains naturally occurring coumarins, but a placebo-controlled study found no effect on platelet aggregation, fibrinogen or fibrinolytic activity.
	Feverfew	Increased bruising and bleeding	Observe	Although feverfew inhibits platelet aggregation in vitro and in vivo, no effects were seen in a clinical study.
	Fish oils	Increased bruising and bleeding	Caution with doses <12 g Avoid with very high doses (>12 g) unless under medical supervision	Bleeding time is increased at doses of 12 g/day, according to a clinical study.
	Garlic	Increased bruising and bleeding	Avoid at high dose (>4 g) unless under medical supervision	Large doses may increase INR.
	Ginger	Increased bruising and bleeding	Avoid at high dose (>10 g) unless under medical supervision	Inhibits platelet aggregation at high doses.
	Ginkgo biloba	Increased bruising and bleeding	Caution	Although case reports suggest possible anticoagulant effect, two recent clinical studies indicate no effect on pharmacokinetics, pharmacodynamics or clinical effects of warfarin.
	Glucosamine	Possible increased risk of bruising and bleeding	Caution	Case reports exist of glucosamine and glucosamine/chondroitin combinations increasing bruising, bleeding and INR among people taking warfarin.
	Ginseng — Korean	Increased bruising and bleeding	Avoid unless under medical supervision	Inhibits platelet aggregation both in vitro and in vivo; clinical significance unknown.
	Ginseng — Siberian	Increased bruising and bleeding	Observe	In vivo study demonstrated that an isolated constituent in Siberian ginseng has anticoagulant activity and a clinical trial found a reduction in blood coagulation induced by intensive training in athletes — whether these effects also occur in non-athletes is unknown.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Goji	Increased bruising and bleeding	Caution	Case reports exist in the literature, suggesting an interaction between warfarin and goji is possible; however, causality remains unclear as it is unknown whether the suspected products were tested for authenticity and presence of contaminants.
	Grapeseed extract	Increased bruising and bleeding	Caution	Inhibits platelet aggregation in vitro — clinical significance unknown.
	Green tea	Reduced drug effects	Caution with high doses	A case report of excessive intake (2.25–4.5 L green tea daily) was reported to inhibit warfarin activity and decrease INR.
	Guarana	Increased bruising and bleeding	Caution	In vitro and in vivo research has identified antiplatelet activity.
	Horse chestnut	Possible increased risk of bruising and bleeding	Observe	Properly prepared HCSE should not contain aesculin and should not carry the risk of antithrombin activity. The clinical significance is unclear.
	Horseradish	Increased bruising and bleeding risk	Observe with high-dose supplements	Although it contains coumarins, interaction unlikely, but this has not been established clinically.
	Licorice	Increased bruising and bleeding	Caution with high doses	Isoliquiritigenin inhibits platelet aggregation, and glycyrrhizin inhibits prothrombin, according to in vitro and in vivo tests — clinical significance unknown.
	Maca	Theoretical interactions	Observe. Separate doses by 2 hours	Theoretical interactions have been suggested to be plausible in people taking anticoagulants. However, there are no reported drug interactions.
	Meadowsweet	Increased bruising and bleeding	Observe	In vitro tests have indicated anticoagulant activity — clinical significance unknown.
	Myrrh	Increased bruising and bleeding	Observe with myrrh preparations Caution with guggul preparations	Guggul inhibited platelet aggregation in vitro and in a clinical study, so concurrent use may theoretically increase the risk of bleeding — implications for <i>Commiphora molmol</i> use unclear.
	Nigella	Theoretical interactions	Caution	Theoretical interaction predicted based on antiplatelet, anticoagulant and conversely coagulant effects observed in vitro and in vivo. Clinical significance unknown.
	Noni	Decreased drug effects	Caution	There is one case report of noni juice consumption causing resistance to warfarin. Further investigation is required to determine the certainty of this causal association.
	Policosanol	Increased bruising and bleeding	Caution with doses > 10 mg daily	Current evidence is contradictory, as one study failed to detect an interaction between policosanol and warfarin, but others have found that doses > 10 mg/day may inhibit platelet aggregation.

	Psyllium	Decreased drug absorption	Separate doses by at least 1 hour	Soluble fibre may decrease the bioavailability of coumarin derivatives.
	Red clover	Increased bruising and bleeding	Observe	Red clover contains coumarin, which could theoretically exert anticoagulant activity and therefore increase the clinical effects of warfarin. Observe patients taking red clover and anticoagulants concurrently.
	Rosemary	Increased bruising and bleeding	Caution	Rosemary demonstrates antithrombotic activity in vitro and in vivo.
	Slippery elm	Altered rate and/or extent of absorption	Caution. Separate doses by 2 hours	Controlled studies are unavailable, but interactions are theoretically possible with some medicines. Slippery elm forms an inert barrier over the gastrointestinal lining and may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. warfarin). The clinical significance of this is unclear.
	St John's wort	Decreased drug effects	Avoid unless under medical supervision to monitor for signs of reduced drug effectiveness and adjust dose if necessary Prothrombin time or INR should be closely monitored with addition or withdrawal of St John's wort	Metabolism of warfarin is chiefly by CYP2C9, and a minor metabolic pathway is CYP3A4. St John's wort increases metabolism of drug.
	St Mary's thistle	Increased drug effects	Caution — monitor for signs of increased drug effectiveness	Possible CYP (liver cytochrome) inhibition effects; but conflicting evidence makes evaluation difficult.
	Tribulus	Increased INR values	Observe for changes in INR.	A herbal combination of <i>Tribulus terrestris</i> , <i>Panax ginseng</i> and <i>Avena sativa</i> was reported to significantly increase INR values in two patients prescribed warfarin. It is unknown if the tribulus contributed to this effect.
	Tulsi	Potential interactions based on actions	Observe for interactions	There are no reports of significant interactions with tulsi. As tulsi has anti-platelet actions there is a theoretically possibility of interactions with anti-coagulant medications but such interactions have not been reported.
	Turmeric	Increased bruising and bleeding	Caution with concentrated extracts	Curcumin inhibits platelet aggregation in vitro and in vivo. Theoretically, high-dose turmeric preparations may increase the risk of bleeding when used together with anticoagulant drugs. Clinical significance unknown.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Vitamin E	Increased bruising and bleeding	Caution with high-dose supplements (> 1000 IU daily) until clinical significance can be established prothrombin time or INR should be closely monitored with addition or withdrawal of high-dose vitamin E supplements	Clinical studies have produced conflicting results: several found no effects of platelet aggregation or coagulation, although others found an increased bleeding risk People with reduced levels of vitamin K may be more susceptible to the effects of vitamin E potentiating warfarin activity.
	Willowbark	Potential bruising and bleeding	Exercise caution with high doses > 240 mg salicin/day.	Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect. The use of willow bark was associated with an increased risk of self-reported bleeding in patients using warfarin. Controlled studies are now warranted to confirm whether oral willowbark preparations induce clinically significant changes to bleeding.
Antiplatelet drugs (e.g. aspirin)	Alpha Lipoic Acid	Potential bruising and bleeding	Observe — monitor bleeding time	ALA reduces platelet reactivity in vitro. It is uncertain whether the effect is clinically significant — observe patients taking these agents together.
	Andrographis	Increased bruising and bleeding	Observe	Andrographis inhibits platelet aggregation, observed in animal and clinical studies.
	Bilberry	Increased bruising and bleeding	Caution with high-dose (>170 mg) anthocyanadins unless under medical supervision	Dose is particularly high and not relevant to clinical practice.
	Evening primrose oil	Increased bruising and bleeding	Observe, although beneficial interaction possible	Theoretically may enhance anti-inflammatory and antiplatelet effects.
	Feverfew	Increased bruising and bleeding	Observe	Although feverfew inhibits platelet aggregation in vitro and in vivo, no effects were seen in a clinical study.
	Fish oils	Additive effects	Observe — beneficial interaction possible under professional supervision	No haemorrhagic effects were seen in a clinical study — theoretical concern.
	Garlic	Increased bruising and bleeding	Caution at doses >4 g/day	
	Ginger	Increased bruising and bleeding	Caution at high dose (>10 g) unless under professional supervision	Inhibits platelet aggregation at very high doses.

Ginkgo biloba	Increased bruising and bleeding	Observe	Theoretically possible because of platelet-activating-factor inhibitor activity, but three trials cast doubt on the clinical significance of this effect.
Grapeseed extract	Increased bruising and bleeding	Observe	Theoretically may enhance antiplatelet activity.
Guarana	Increased bruising and bleeding	Observe	Decreases platelet aggregation.
Hawthorn	Potential additive effects	Observe	Although <i>Crataegus laevigata</i> does not display antiplatelet effects as a stand-alone treatment, this has not been tested in patients with atherothrombotic vascular disease in conjunction with antiplatelet drugs.
Horse chestnut	Possible increased risk of bruising and bleeding	Observe	Properly prepared HCSE should not contain aesculin and should not carry the risk of antithrombin activity. The clinical significance is unclear.
Myrrh	Increased bruising and bleeding	Observe	Guggul inhibited platelet aggregation in vitro and in a clinical study, so concurrent use may theoretically increase the risk of bleeding. It is uncertain what implications this observation has for use of <i>Commiphora molmol</i> .
Nigella	Theoretical interactions	Caution	Theoretical interaction predicted based on antiplatelet, anticoagulant and conversely coagulant effects observed in vitro and in vivo. Clinical significance unknown.
Policosanol	Increased bruising and bleeding	Observe	Increased antiplatelet effects may develop in patients taking aspirin and policosanol concurrently.
St John's wort	Additive effects	Observe. Monitor drug requirements (interaction may be beneficial)	SJW might represent a valid option to increase the antiplatelet effect of clopidogrel in non- and/or hypo-responders. For example, SJW increased platelet inhibition by enhancement of CYP3A4 metabolic activity for clopidogrel in hypo-responsive volunteers, and a recent study showed that residual platelet reactivity improved with SJW during the first month post percutaneous coronary intervention.
Tulsi	Potential interactions based on actions	Observe for interactions	There are no reports of significant interactions with tulsi. As tulsi has anti-platelet actions there is a theoretical possibility of interactions with anti-coagulant medications but such interactions have not been reported.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Turmeric	Increased bruising and bleeding	Observe with concentrated extracts	Curcumin inhibits platelet aggregation <i>in vitro</i> and <i>in vivo</i> . Turmeric has a theoretical interaction with antiplatelet drugs, therefore it may produce an additive effect — clinical significance unknown.
Aspirin	Grapeseed extract	Additive effects	Beneficial interaction possible	Theoretically may enhance antiplatelet and anti-inflammatory activity of aspirin.
	Meadowsweet	Increased bruising and bleeding	Observe — beneficial interaction possible	Theoretically may enhance anti-inflammatory and antiplatelet effects.
	Policosanol	Increased bruising and bleeding	Observe	Doses >10 mg/day may inhibit platelet aggregation.
	Vitamin C	Decreased vitamin C effects	Observe	Aspirin may interfere with both absorption and cellular uptake mechanisms for vitamin C, thereby increasing vitamin C requirements, as observed in animal and human studies. Increased vitamin C intake may be required with long-term therapy.
	Willowbark	Increased bruising and bleeding	Caution with high dose (>240 mg/day)	Theoretically may enhance anti-inflammatory and antiplatelet effects. Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect.
Cilostazol	Ginkgo biloba	Additive effects	Observe. Beneficial interaction possible	Used for intermittent claudication with peripheral arterial disease, adjunctive use with Ginkgo biloba may produce additional benefits based on <i>in vivo</i> .
Clopidogrel	St John's Wort	Additive effects	Observe. Monitor drug requirements (interaction may be beneficial)	SJW might represent a valid option to increase the antiplatelet effect of clopidogrel in non- and/or hypo-responders. For example, SJW increased platelet inhibition by enhancement of CYP3A4 metabolic activity for clopidogrel in hypo-responsive volunteers, and a recent study showed that residual platelet reactivity improved with SJW during the first month post percutaneous coronary intervention.
<b>Antihypertensive agents</b>				
Antihypertensive drugs	Arginine	Additive effects	Caution	Theoretically, additive hypotensive effects may occur — use with caution. Potential benefits under professional supervision.
	Essential fatty acids — omega-3 and omega-6	Increased drug effects	Observe — beneficial interaction possible	Both omega-3 and omega-6 fatty acids exhibit antihypertensive activity.

Evening primrose oil	Additive effects	Observe — monitor drug requirements (interaction may be beneficial)	Evening primrose oil has been shown to enhance the effects of several antihypertensive drugs, including dihydralazine, clonidine and captopril in rats under experimental conditions.
Guarana	Antagonistic effects	Caution	Theoretical concern
Garlic	Additive effects	Caution — monitor drug requirements (interaction may be beneficial)	Clinical trials have shown garlic to reduce blood pressure.
Hawthorn	Additive effects	Caution — monitor drug requirements (interaction may be beneficial)	Mild antihypertensive activity has been reported with long-term use of hawthorn.
Licorice	Reduced drug effect	Caution — monitor blood pressure when high-dose licorice preparations are taken for more than 2 weeks	High-dose glycyrrhizin taken long-term can lead to increased blood pressure.
Maca	Theoretical interactions	Observe. Separate doses by 2 hours	Theoretical interactions have been suggested to be plausible in people taking antihypertensives. However, there are no reported drug interactions.
Nigella	Additive effects	Observe. Beneficial interaction possible.	A clinical study reported that Nigella reduced blood pressure in patients with mild hypertension.
Oats (oat-based cereals)	Additive effects	Observe — monitor drug requirements (interaction may be beneficial)	A clinical trial has shown that ingestion of oat-based cereals decreased blood pressure in 73% of hypertensive patients and reduced drug requirements.
Olive leaf and olive oil	Additive effects	Beneficial interaction possible	
St John's wort	Altered drug effects	Caution. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.	SJW was shown to induce nifedipine metabolism <i>in vivo</i> .
Stinging nettle	Additive effects	Observe patients taking antihypertensives concurrently	Additive effects are theoretically possible.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Hydralazine (e.g. Apresoline, Alphapress)	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible	Increased CoQ10 intake may be required with long-term therapy.
	Vitamin B <sub>6</sub> (pyridoxine)	Reduced vitamin B <sub>6</sub> absorption	Separate doses by at least 2 hours	A clinical trial has shown that the drug may induce B <sub>6</sub> deficiency, so increased intake may be required with long-term therapy.
Methyldopa (e.g. Aldomet)	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible	Increased CoQ10 intake may be required with long-term therapy.
ACE inhibitors (e.g. captopril, enalapril)	Iron	Reduced drug effect	Separate doses by at least 2 hours	A small clinical trial found that concomitant iron administration reduced area-under-the-curve plasma levels of unconjugated captopril by 37%.
	Zinc	Reduced zinc levels	Monitor for zinc efficacy and zinc status	These drugs reduce zinc status, most likely due to increased urinary excretion of zinc. Increased zinc intake may be required with long-term therapy.
ACE inhibitors (e.g. Losartan)	Rhodiola	Potential for increased drug serum levels	Avoid	Rhodiola significantly alters the pharmacokinetic properties of losartan after concurrent oral administration to rabbits. The results indicate that rhodiola is likely to inhibit CYP3A4 resulting in increased drug serum levels. Avoid — until further research is available to determine the level of the interaction.
Angiotensin 2 receptor blockers	Zinc	Reduced zinc levels and increased excretion	Monitor for zinc efficacy and zinc status	These drugs reduce zinc status, most likely due to increased urinary excretion of zinc.
Verapamil	St John's wort	Reduces drug levels via increased metabolism	Monitor and adjust dose as necessary under medical supervision	Decreases serum levels of verapamil via CYP induction.
Beta-adrenergic-blocking agents	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible	Increased CoQ10 intake may be required with long-term therapy.
Propranolol	Myrrh	Reduced drug effect	Observe	A clinical trial has shown that guggulipid reduces bioavailability of propranolol. It is uncertain what implications this has for use of <i>Commiphora molmol</i> .
	Vitamin E	Reduced drug effect	Observe	According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts — clinical significance unknown.

Calcium-channel blockers (e.g. verapamil)	Calcium	Reduced drug effect/Antagonist effect	Avoid high-dose supplements unless under medical supervision	Calcium may reduce antihypertensive effect of drug. Can have an antagonistic effect on the desired action of calcium channel blockers.
	Magnesium	Additive effects	Observe — monitor drug requirements (interaction may be beneficial)	A meta-analysis of 20 randomised trials showed that magnesium has a modest antihypertensive activity.
	Vitamin D	Reduced drug effect	Caution unless under medical supervision	
Felodipine	Peppermint oil	Increased drug effects	Caution	Peppermint oil has been shown to increase the oral bioavailability of felodipine in animal studies.
Nifedipine	Ginseng — Korean	Increased drug effects	Caution	Ginseng was found to increase the mean plasma concentration of the calcium channel blocker nifedipine by 53% at 30 minutes in an open trial. Exercise caution.
	St John's wort	Altered drug effects	Caution. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.	SJW was shown to induce nifedipine metabolism in vivo.
Diltiazem	Myrrh	Reduced drug effect	Prudent to avoid guggulipid preparations	A clinical trial has shown that guggulipid reduces bioavailability of diltiazem. It is uncertain what implications this has for use of <i>Commiphora molmol</i> .
	Quercetin	Increased drug effects	Caution. Use under professional supervision	Increased drug bioavailability observed in vivo.
<b>Antimigraine preparations</b>				
Antimigraine preparations	Coenzyme Q10	Additive effects	Beneficial interaction possible	CoQ10 demonstrated migraine prevention activity in a clinical study.
	Feverfew	Additive effects	Beneficial interaction possible	Feverfew demonstrated migraine prevention activity in several clinical studies, so migraine medication requirements may reduce.
	Vitamin B <sub>2</sub> (riboflavin)	Additive effects	Beneficial interaction possible	Vitamin B <sub>2</sub> has demonstrated migraine prevention activity in several clinical studies.
Clonidine (e.g. Catapres)	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible	In vivo study indicates that clonidine reduces serum CoQ10 levels. Increased CoQ10 intake may be required with long-term therapy.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>Cardiac inotropic agents</b>				
Cardiac glycosides	Calcium	May potentiate digoxin toxicity	Caution, unless under medical supervision	Administered concurrently, high-dose calcium may potentiate digoxin toxicity — use this combination with caution unless under medical supervision.
	Hawthorn	Additive effects	Caution — monitor drug requirements (interaction may be beneficial)	Theoretical interaction, as in vitro and in vivo studies indicate that hawthorn has positive inotropic activity. Small clinical study found interaction not clinically significant when digoxin 0.25 mg taken with Hawthorn (WS1442) 450 mg twice daily.
	Psyllium	Decreased drug absorption	Caution. Separate doses by 2 hours	Soluble fibre may decrease the bioavailability of cardiac glycosides.
Digoxin (e.g. Lanoxin) Adverse effects of high-dose digoxin include: nausea, vomiting, diarrhoea, confusion, fainting, palpitations, irregular heart beat, visual disturbances	Aloe vera	Increased drug toxicity	Avoid long-term use of high-dose preparations	Long-term oral use of aloe can deplete potassium levels and reduced potassium status lowers the threshold for drug toxicity.
	Astragalus	Additive effects	Observe patients using high-dose astragalus preparations	Additive effects are theoretically possible with intravenous administration of Astragalus, based on positive inotropic activity identified in clinical studies. The clinical significance of these findings for oral dose forms is unknown.
	Calcium	May potentiate digoxin toxicity	Caution, unless under medical supervision	Administered concurrently, high-dose calcium may potentiate digoxin toxicity — use this combination with caution unless under medical supervision.
	Ginseng — Korean	Interferes with therapeutic drug monitoring for digoxin	Caution — drug assay may produce false-positive results	Ginseng contains glycosides with structural similarities to digoxin, which may interfere with digoxin results.
	Ginseng — Siberian	Interferes with therapeutic drug monitoring for digoxin	Caution — drug assay may produce false-positive results	Refer to Chapter 8 on interactions for further information.
	Guarana	Increased drug toxicity	Avoid long-term use of high-dose preparations	Long-term guarana use can deplete potassium levels and reduced potassium status lowers the threshold for drug toxicity.

	Licorice	Increased drug toxicity	Avoid long-term use of high-dose preparations (>100 mg glycyrrhizin daily >2 weeks) unless under medical supervision	Reduced potassium status lowers the threshold for drug toxicity.
	Quercetin	Increased drug toxicity	Avoid concurrent use	Increased drug bioavailability possible.
	Slippery elm	Altered rate and/or extent of absorption	Caution. Separate doses by 2 hours	Controlled studies are unavailable, but interactions are theoretically possible with some medicines. Slippery elm forms an inert barrier over the gastrointestinal lining and may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. digoxin). The clinical significance of this is unclear.
	St John's wort	Reduced drug effects	Avoid unless under medical supervision Monitor for signs of reduced drug effectiveness and adjust dose if necessary When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required	St John's wort induces CYP enzymes and P-glycoprotein. A clinical trial shows that St John's wort significantly decreases serum levels of drug within 10 days of concomitant use.
Digoxin assays	Withania	Altered test results	Caution. Use under medical care. Monitor test results.	Withania may modestly interfere with serum digoxin measurements by the fluorescent polarisation immunoassay (FPIA) and other assays.
<b>Diuretics</b>				
Caffeine	Calcium	Increases urinary excretion of calcium	Separate doses by 2-3 hours	Caffeine increases urinary excretion of calcium and may affect calcium absorption — ensure adequate calcium intake and monitor for signs and symptoms of deficiency in those with high caffeine intake.
Diuretics	Dandelion leaf	Additive effects	Observe	Theoretically increased diuresis is possible — clinical significance is unknown.
	Elder	Additive effects	Observe	Elderflower has diuretic activity. Increased diuresis is possible with concomitant use.
	Green tea	Additive effects	Observe	Based on the caffeine content of green tea, high intakes of green tea can theoretically increase the diuretic effects of drugs such as frusemide; however, the clinical significance of this is unknown.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Guarana	Additive diuretic effects but decreased hypotensive effects of drug	Caution Monitor potassium status	Theoretically increased diuresis and decreased hypotensive effects are possible — clinical significance is unknown.
	Licorice	Increased potassium excretion	Avoid long-term use unless under medical supervision Monitor potassium status	Potassium loss may become significant when licorice is used in high dose (>100 mg glycyrrhizin daily) for longer than 2 weeks.
	Stinging nettle	Additive effects	Observe patients taking this combination	Theoretically increased diuresis is possible — clinical significance is unknown.
Loop diuretics	Magnesium	Increased magnesium excretion	Monitor magnesium efficacy and status — beneficial interaction possible	Increased magnesium intake may be required with long-term therapy.
	Stinging nettle	Additive effects	Observe	Theoretically increased diuresis is possible — clinical significance is unknown.
	Vitamin B <sub>1</sub> (thiamin)	Reduced B <sub>1</sub> levels	Monitor B <sub>1</sub> efficacy and status — beneficial interaction possible	Increased B <sub>1</sub> dietary intake may be required with long-term therapy. Consider long-term supplementation.
	Zinc	Increased urinary zinc excretion	Monitor zinc efficacy and status — beneficial interaction possible	Increased zinc intake may be required with long-term therapy.
Potassium-sparing diuretics	Magnesium	Increased magnesium effects	Observe	
Thiazide diuretics	Calcium	Decreased urinary calcium excretion	Observe Monitor serum calcium and look for signs of hypercalcaemia	Thiazide diuretics decrease urinary excretion of calcium. Monitor serum calcium and look for signs of hypercalcaemia, such as anorexia, polyipsia, polyuria, constipation and muscle hypertonía when using high-dose calcium supplements.
	Magnesium	Increased magnesium excretion	Monitor magnesium efficacy and status — beneficial interaction possible	Increased magnesium intake may be required with long-term therapy.
	Zinc	Increased urinary zinc excretion	Monitor zinc efficacy and status — beneficial interaction possible	Increased zinc intake may be required with long-term therapy.
Hydrochlorothiazide (e.g. Diclortide)	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible	Increased CoQ10 intake may be required with long-term therapy.
	Garlic	Raises drug serum levels	Cautious use under medical supervision	Co-administration may require a reduction in the dose of hydrochlorothiazide due to a pharmacokinetic interaction raising drug serum levels.

	Vitamin B <sub>12</sub>	Reduces hyper-homocysteinaemia	Beneficial interaction possible in conjunction with folate	Hydrochlorothiazide may increase homocysteine levels.
<b>Hypolipidaemic agents</b>				
Hypolipidaemic agents	Chromium	Additive effects	Observe — monitor drug requirements (interaction may be beneficial)	Clinical trials indicate that chromium reduces total cholesterol levels.
	Garlic	Additive effects	Observe — monitor drug requirements (interaction may be beneficial)	A meta-analysis of 13 clinical trials concluded that garlic significantly reduces total cholesterol levels — effects are described as modest.
	Myrrh	Additive effects	Observe — monitor drug requirements (interaction may be beneficial for guggul preparations)	Guggul has demonstrated cholesterol-lowering activity in several clinical studies.
	Nigella	Additive effects	Observe. Beneficial interaction possible — monitor drug requirements	Black seed has been shown to modulate lipid levels according to clinical trials.
	Oats (oat-based cereals)	Additive effects	Beneficial interaction possible — monitor drug requirements	Clinical trials indicate that oat-based cereals reduce total cholesterol levels.
	Policosanol	Additive effects	Caution, although beneficial interaction possible under medical supervision	Policosanol may theoretically increase cholesterol-lowering effects of statins, but a theoretical concern exists as to whether concurrent use will also increase incidence of adverse effects.
	Vitamin B <sub>3</sub> (niacin)	Additive effects	Beneficial interaction possible — caution with sustained-release form	Several clinical trials confirm the cholesterol-lowering activity of niacin and the safety of niacin with statins, but the sustained-release form may be unsafe.
	Vitamin D	Reduced absorption of vitamin D	Observe. Administer the vitamin D at least 1 hour prior to or 4–6 hours after ingestion of the drug.	Hypolipidaemic agents may compromise the absorption of all fat-soluble vitamins. To avoid the interaction, administer the supplement at least 1 hour prior to or 4–6 hours after ingestion of the drug. Conversely, long-term use of statins is associated with increased 25(OH)D levels via an unknown mechanism.
Cholestyramine (e.g. Questran lite, colestipol [e.g. Colestid])	Beta-carotene	Reduced absorption of beta-carotene	Separate doses by 2 hours	Drugs that reduce fat absorption, such as cholestyramine, colestipol and orlistat, may also reduce absorption of beta-carotene.
	Fat-soluble vitamins (A, D, E, K, beta-carotene)	Reduced vitamin absorption	Separate doses by at least 4 hours and monitor vitamin status	Increased vitamin intake may be required with long-term therapy.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Folate	Reduced folate absorption	Separate doses by at least 4 hours and monitor iron status	Increased vitamin intake may be required with long-term therapy.
	Iron	Reduced iron absorption	Separate doses by at least 4 hours and monitor iron status	Increased iron intake may be required with long-term therapy.
	Vitamin A	Reduced vitamin A absorption	Separate doses by at least 4 hours and monitor vitamin A status	Reduces vitamin A absorption — increase dietary intake of vitamin A-rich foods or consider supplementation with long-term use.
	Vitamin D	Reduced absorption of vitamin D	Observe. Administer the vitamin D at least 1 hour prior to or 4–6 hours after ingestion of the drug.	Hypolipidaemic agents may compromise the absorption of all fat-soluble vitamins. To avoid the interaction, administer the supplement at least 1 hour prior to or 4–6 hours after ingestion of the drug. Conversely, long-term use of statins is associated with increased 25(OH)D levels via an unknown mechanism.
	Vitamin E	Reduced vitamin absorption	Separate doses by at least 4 hours and monitor vitamin status	Increased vitamin intake may be required with long-term therapy.
Chitosan	Vitamin C	May increase cholesterol-lowering effect	Beneficial interaction possible	
Fibric-acid derivatives (e.g. gemfibrozil)	Beta-carotene		Beneficial interaction possible	There may be a positive interaction between fibrate and natural beta-carotene, which has been found to significantly increase HDL cholesterol levels.
	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible — separate doses by 4 hours	Increased CoQ10 intake may be required with long-term therapy.
HMG-CoA reductase inhibitors (statins)	Carnitine	Additive effects	Beneficial interaction possible	the addition of L-carnitine (2 g/day) to simvastatin therapy (20 mg/day) appears to lower lipoprotein-a serum levels in patients with type 2 diabetes.
	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible	Clinical study indicates several statin drugs reduce CoQ10 levels — increased CoQ10 intake may be required with long-term therapy.
	Red rice yeast	Additive effects	Observe	Red rice yeast products contain low doses of natural statins and, as such, a pharmacodynamic interaction is possible with other statin medications with increased lipid lowering effects.
	St John's wort	Reduced drug effects	Monitor for signs of reduced drug effectiveness and adjust the dose if necessary When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required	SJW reduces the efficacy of atorvastatin, so lipid-lowering effects are compromised.

	Vitamin A	Increased vitamin A activity	Observe	A clinical trial has reported increased serum levels of vitamin A — clinical significance unclear.
	Vitamin B <sub>3</sub> (niacin)	Additive effects	Beneficial interaction possible — caution with sustained-release form	Several clinical trials confirm the cholesterol-lowering activity of niacin and the safety of niacin with statins, but the sustained release form may be less safe.
	Vitamin E	Reduced vitamin E levels	Observe. Monitor for vitamin E deficiency	The effect of statins on lowering blood lipid levels of vitamin E have been suggested as a risk factor in the development of statin-associated myopathy. Further studies are warranted.
Pravastatin (e.g. Pravachol)	Fish oils	Additive effects	Beneficial interaction possible	A clinical trial suggests improved lipid-lowering effects when used concurrently.
Simvastatin (e.g. Lipex, Zocor)	Peppermint oil	Additive effects	Observe — monitor drug requirements (interaction may be beneficial)	Peppermint oil has been shown to increase the oral bioavailability of simvastatin in animal studies.
	St John's wort	Reduced drug effects and serum levels	Monitor for signs of reduced drug effectiveness and adjust the dose if necessary When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required	St John's wort increases metabolism of simvastatin. Decreases serum levels of simvastatin via CYP induction.
	St Mary's thistle	Increased drug effect	Observe — monitor drug requirements	May reduce metabolism of drug resulting in increased serum levels and adverse effects (difficult to evaluate evidence).
<b>CENTRAL NERVOUS SYSTEM</b>				
<b>Anticonvulsants</b>				
Anticonvulsants	Beta-carotene	Reduced plasma beta-carotene	Observe	Epileptic patients who gain weight with valproate therapy have been found to have reduced plasma concentrations of beta-carotene and other fat-soluble antioxidant vitamins.
	Carnitine	Reduced side-effects	Beneficial interaction possible	L-Carnitine deficiency may cause or potentiate valproic acid toxicity, and supplementation is known to reduce the toxicity of valproate as well as symptoms of fatigue — concurrent use is recommended, as a beneficial interaction is possible.
	Folate	Reduced side-effects	Monitor for drug effectiveness Beneficial interaction possible	Requires close supervision to ensure that drug efficacy is not substantially reduced.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Ginkgo biloba	Reduced drug effects	Caution — monitor for reduced drug effectiveness	Based on case reports. One report was of a patient taking Dilantin and Depakote and ginkgo, together with other herbal medicines, who suffered a fatal breakthrough seizure, with no evidence of non-compliance with anticonvulsant medications. The autopsy report revealed subtherapeutic serum levels for both anticonvulsants.
	Nigella	Interaction may be beneficial	Observe — monitor drug requirements	Small clinical study shows anticonvulsant effects in epileptic children refractory to their antiepileptic medication. The constituent thymoquinone was reported to reduce sodium valproate-induced hepatotoxicity in one animal study.
	St John's wort	Reduced drug effects	Avoid unless under medical supervision to alter doses appropriately When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required	St John's wort may increase drug metabolism, resulting in reduced drug efficacy.
	Vitamin B <sub>12</sub>	Additive effect	Observe. Possible beneficial effect	Administration of sodium valproate has been shown to increase plasma vitamin B <sub>12</sub> concentrations, with one study citing increases of over 50% of baseline.
Carbamazepine (e.g. Tegretol) NTI: signs of overdose include CNS and respiratory depression, hypotension, vomiting, fluid retention	St Mary's thistle	Increased drug effects	Caution — monitor drug requirements	May reduce metabolism of drug resulting in increased serum levels and adverse effects (difficult to evaluate evidence).
	Vitamin B <sub>12</sub>	Decreased B <sub>12</sub> levels	Observe for signs and symptoms of B <sub>12</sub> deficiency Beneficial interaction possible	In studies with children, long-term carbamazepine use led to a decrease in vitamin B <sub>12</sub> levels. Increased intake may be required with long-term therapy.
Phenobarbitone	Celery	Prolonged action	Caution	Celery juice has been found to prolong the action of phenobarbitone in rats — clinical significance unknown.
	Kava	Increased sedation	Caution	

	Vitamin B <sub>6</sub> (pyridoxine)	Reduced drug effects	Caution — monitor for reduced drug effectiveness	B <sub>6</sub> in high doses may lower plasma levels and efficacy of drug and decrease seizure control. Monitor for drug effectiveness, and exercise caution when these drugs are being taken concurrently.
	Withania	Increased sedation	Observe although beneficial interaction possible	
Phenobarbitone and phenytoin	Kava	Increased sedation	Caution	
	Slippery elm	Altered rate and/or extent of absorption	Caution. Separate doses by 2 hours	Controlled studies are unavailable, but interactions are theoretically possible with some medicines. Slippery elm forms an inert barrier over the gastrointestinal lining and may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. phenytoin). The clinical significance of this is unclear.
	St John's wort	Decreased drug effects (increased drug metabolism)	Avoid — monitor drug requirements. When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required	
	Vitamin B <sub>6</sub> (pyridoxine)	Reduced drug effects	Caution — monitor for reduced drug effectiveness	B <sub>6</sub> in high doses may lower plasma levels and efficacy of drug and decrease seizure control. Monitor for drug effectiveness, and exercise caution when these drugs are being taken concurrently.
	Vitamin B <sub>12</sub>	Increased serum B <sub>12</sub> levels	Observe	One clinical study reported that combined long-term use of phenobarbitone and phenytoin resulted in significantly increased serum B <sub>12</sub> levels — clinical significance unknown.
Phenytoin	Vitamin B <sub>6</sub> (pyridoxine)	Reduced drug effects	Caution — monitor for reduced drug effectiveness	B <sub>6</sub> in high doses may lower plasma levels and efficacy of drug and decrease seizure control. Monitor for drug effectiveness, and exercise caution when these drugs are being taken concurrently.
Phenytoin and valproate	Vitamin D	Reduced side-effects	Beneficial interaction possible	Anticonvulsants induce catabolism of vitamin D through liver induction — prolonged use is associated with increased risk of developing rickets and osteomalacia, therefore increased intake may be useful with long-term therapy.
Sodium valproate	Celery	Reduced side-effects	Observe — beneficial interaction possible	In animal studies, celery was found to have a protective effect against sodium valproate's well-established toxicity to the testes and sperm production.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>Antidepressants</b>				
Antidepressants including SSRIs, SNRIs, tricyclics and MAOIs	Albizia	Additive effects	Observe	Increased risk of serotonergic syndrome is theoretically possible, as the herb increases serotonin levels, according to in vivo studies — clinical significance unknown
	Brahmi	Additive effects	Caution until further investigation can confirm.	Serotonergic activity has been identified for Bacopa extracts therefore there is a theoretical increased risk of serotonin syndrome when bacopa is used together with SSRI and SNRI medicines — the clinical significance of the interaction is unclear.
	Ginkgo biloba	Reduced side-effects	Beneficial interaction possible	Reduced sexual dysfunction side-effects reported in a clinical study and may also improve sleep continuity.
	Green tea	Reduced drug effects	Caution	Caution is advised when using highly concentrated supplements with monoamine oxidase inhibitors or dopaminergic drugs because catechins are metabolised by catechol-O-methyltransferase.
	Maca	Theoretical interactions	Observe. Separate doses by 2 hours	Theoretical interactions have been suggested to be plausible in people taking antidepressants. However, there are no reported drug interactions.
	Rhodiola	Reduced drug effects	Observe	In vitro tests suggest an inhibition of MAO A by Rhodiola extracts, a theoretical interaction exists with MAOI antidepressants. The clinical significance of this and whether other antidepressants may be affected is as yet unclear.
	Saffron	Additive effects	Caution. Use under medical supervision.	Saffron exhibits significant antidepressant activity; concomitant use should be carefully supervised. It is theoretically possible that pharmaceutical antidepressant dosage requirements will decrease with the addition of saffron in therapeutic doses.
	St John's wort	Additive effects	Avoid unless under medical supervision	SJW decreases serum levels of some antidepressants via CYP induction in vivo. Risk of serotonergic syndrome if combined use is not carefully monitored. Avoid concurrent use unless under medical supervision, so that doses may be altered appropriately.
	SAME	Additive effects	Caution	Theoretically may increase risk of serotonergic syndrome, and a case report exists; however, an experimental study found that brain SAME levels were significantly reduced after chronic treatment with imipramine.
	Tyrosine	Additive effects	Avoid unless under medical supervision	Tyrosine is a precursor for several neurotransmitters, which theoretically increases risk of serotonin syndrome.

	Vitamin B <sub>2</sub> (riboflavin)	Decreased B <sub>2</sub> levels	Monitor for signs and symptoms of B <sub>2</sub> deficiency Beneficial interaction possible	Tricyclic antidepressants may reduce the absorption of riboflavin. Increased B <sub>2</sub> intake may be required with long-term therapy.
SSRI (Bupropion/ Zyban)	St. John's Wort	Decreased plasma concentration. Reduced drug effects	Avoid	SJW statistically significantly decreased plasma concentrations of bupropion, probably by increasing the clearance of bupropion.
MAOIs	Green tea	Reduced drug effects	Caution	Caution is advised when using highly concentrated supplements with monoamine oxidase inhibitors or dopaminergic drugs because catechins are metabolised by catechol-O-methyltransferase.
	Rhodiola	Reduced drug effects	Observe	In vitro tests suggest an inhibition of MAO A by Rhodiola extracts, a theoretical interaction exists with MAOI antidepressants. The clinical significance of this and whether other antidepressants may be affected is as yet unclear.
	Tyrosine	Increased side-effects	Avoid	Some tyrosine may be metabolised to tyramine Concurrent use with MAOIs may lead to hypertensive crisis.
Tricyclic antidepressants	Albizia	Additive effects	Observe	Increased risk of serotonin syndrome is theoretically possible as Albizia increases serotonin levels, according to in vivo studies — clinical significance unknown.
	Andrographis	Reduced side-effects	Beneficial interaction possible	Andrographis may exert hepatoprotective activity against liver damage induced by tricyclic antidepressants.
	Coenzyme Q10	Reduced CoQ10 serum levels	Beneficial interaction possible	Increased CoQ10 intake may be required with long-term therapy.
	SAME	Additive effects	Caution. Use under medical supervision	Co-administration of SAME with SSRIs has shown benefits in partial responders and may be a useful combination under professional supervision.
	St. John's wort	Additive effects	Avoid unless under medical supervision	Although St. John's wort decreases drug plasma levels of tricyclic antidepressants, it may increase available serotonin.
	St. Mary's thistle	Reduced side-effects	Beneficial interaction possible	St. Mary's thistle may exert hepatoprotective activity against liver damage induced by tricyclic antidepressants.
	Tyrosine	Additive effects	Avoid unless under medical supervision	Tyrosine is a precursor for several neurotransmitters, which theoretically increases risk of serotonin syndrome.
	Vitamin B <sub>2</sub> (riboflavin)	Decreased B <sub>2</sub> levels	Monitor for signs and symptoms of B <sub>2</sub> deficiency Beneficial interaction possible	Tricyclic antidepressants may reduce the absorption of riboflavin. Increased B <sub>2</sub> intake may be required with long-term therapy.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Imipramine	Vitamin B <sub>3</sub> (niacin)	Additive effects	Beneficial interaction possible	A combination of imipramine with L-tryptophan 6 g/day and niacinamide 1500 mg/day has been shown to be more effective for people with bipolar disorder than imipramine alone.
<b>Antipsychotic agents</b>				
	Withania	Reduced side-effects	Observe — beneficial interaction possible under professional supervision	In animal experiments, withania has been shown to be useful in the treatment of drug-induced dyskinesia (chewing movements, tongue protrusion and buccal tremors) due to reserpine and haloperidol.
Clozapine	Ginkgo biloba	Increased drug effects	Observe — beneficial interaction possible under professional supervision	Ginkgo may enhance the effects of clozapine on negative affect in refractory schizophrenic patients.
Haloperidol (e.g. Sereance)	Ginkgo biloba	Increased drug effects and reduced side-effects	Observe — beneficial interaction possible under professional supervision	Three clinical trials demonstrate that ginkgo increases drug effectiveness.
	Iron	Reduced iron effect	Monitor iron status	May cause decreased blood levels of iron — clinical significance unclear. Increased iron intake may be required with long-term therapy.
	Quercetin	Reduced drug side-effects	Beneficial interaction possible	According to in vivo studies, reduced chewing movements and tongue protrusions (tardive dyskinesia) possible with concurrent use.
	Valerian	Increased side effects and oxidative stress	Observe patient for side effects. Use under medical supervision	In a rat study, oxidative stress parameters in the liver were increased when haloperidol was taken in combination with valerian via a significant increase in lipid peroxidation levels (enhanced oxidation of thiobarbituric acid reactive species and dichlorofluorescein reactive species as well as an inhibition of hepatic d-ALA-D activity). The significance in humans is unknown.
Phenothiazines (e.g. chlorpromazine, trifluoperazine)	Coenzyme Q10	Reduced drug effects	Beneficial interaction possible	CoQ10 reduces adverse effect this drug class has on CoQ10-related enzymes, NADH oxidase and succinoxidase — beneficial interaction with co-administration.
	Evening primrose oil	Reduced drug effects	Avoid concomitant use until safety can be established	Several case reports suggest that evening primrose oil may reduce seizure threshold and reduce drug effectiveness in patients with schizophrenia treated with phenothiazines.
Chlorpromazine (e.g. Largactil)	Vitamin E	Reduced drug effects	Observe	According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts — clinical significance unknown.

<b>CNS agents</b>				
Acetylcholinesterase inhibitor drugs	Vitamin B <sub>5</sub>	Additive effects	Observe. Use under medical supervision.	A theoretical concern exists that pantothenic acid, since it is involved in the biosynthesis of acetylcholine, might increase the effects of acetylcholinesterase inhibitor drugs.
Cholinergic drugs Tacrine (e.g. Cognex)	Brahmi	Additive effects	Observe Beneficial interaction possible	Cholinergic activity has been identified for brahmi, so increased drug activity is theoretically possible.
	Ginkgo biloba	Additive effects	Observe Beneficial interaction possible	Cholinergic activity has been identified for ginkgo, so increased drug activity is theoretically possible.
	Lemon balm	Additive effects	Observe Beneficial interaction possible	Cholinergic activity has been identified for lemon balm, so increased drug activity is theoretically possible.
	St Mary's thistle	Reduced side-effects	Beneficial interaction possible	St Mary's thistle may exert hepatoprotective activity against liver damage induced by tacrine.
CNS stimulants	Green tea	Additive effects	Observe	Based on the caffeine content of Green tea, high intakes of green tea can theoretically increase the CNS stimulation effects of drugs such as nicotine and beta-adrenergic agonists (e.g. salbutamol); however, the clinical significance of this is unknown.
	Guarana	Additive effects	Caution	Herb has demonstrated CNS stimulant activity.
	Tyrosine	Additive effects	Caution	Tyrosine is a precursor for several neurotransmitters (theoretical concern).
Methylphenidate (e.g. Ritalin)	Zinc	Additive effects	Observe under medical care	The efficacy of this drug may be improved by supplementation with zinc sulfate (15 mg elemental zinc) for 6 weeks in children with ADHD. There is no change to side effects reported.
<b>Movement disorders</b>				
L-Dopa (levodopa)	Calcium	Reduced drug absorption	Separate doses by 2 hours	L-dopa can form an insoluble complex with calcium.
	Iron	Reduced drug absorption	Separate doses by 2 hours	L-dopa can form an insoluble complex with iron.
	Kava	Reduced drug effects	Avoid unless under medical supervision	Theoretical interaction, as dopamine antagonist effects have been reported for kava.
	Magnesium	Reduced drug absorption	Separate doses by 2 hours	L-dopa can form an insoluble complex with magnesium.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Psyllium	Potential increased drug absorption	Observe. Monitor drug effectiveness.	Animal research suggests that concomitant administration of psyllium husks with levodopa results in an improvement in the levodopa kinetic profile with higher final concentrations and a longer plasma half-life.
	SAME	Reduced drug effects	Observe	SAME methylates levodopa, which could theoretically reduce the effectiveness of levodopa given for Parkinson's disease; however, the effect has not been observed clinically.
	Tyrosine	Decreased drug and tyrosine effect	Avoid unless under medical supervision	L-dopa competes with tyrosine for uptake, so concurrent use may decrease uptake of both substances, thereby reducing efficacy.
	Vitamin B <sub>6</sub> (pyridoxine)	Reduced drug effects	Observe Monitor for reduced drug effectiveness	Interaction does not occur with combination L-dopa products. In people with Parkinson's disease, L-dopa can cause hyperhomocysteinaemia, the extent of which is influenced by B-vitamin status. To maintain normal plasma homocysteine concentrations, the B-vitamin requirements are higher in L-dopa-treated patients than in those not on L-dopa therapy. B-vitamin supplements may be warranted for PD patients on L-dopa therapy.
	Vitamin C	Reduced side-effects	Beneficial interaction possible	A case report of co-administration with vitamin C suggests this may reduce drug side-effects.
	Zinc	Reduced drug absorption	Separate doses by 2 hours	L-Dopa can form an insoluble complex with zinc.
L-Dopa with carbidopa	Iron	Reduced drug effects	Separate doses by at least 2 hours	May reduce bioavailability of carbidopa and L-dopa.
<b>Sedatives, hypnotics</b>				
CNS sedatives	Eucalyptus	Addictive effects	Caution	Oral ingestion of eucalyptus has been associated with CNS depression, therefore additive effects are theoretically possible.
	Green tea	Reduced drug effects	Observe	Based on the caffeine content of green tea, high intakes of green tea can theoretically decrease the CNS depressant effects of drugs such as benzodiazepines; however, the clinical significance of this is unknown.
	Guarana	Reduced drug effects	Observe	Theoretically guarana may reduce the sedative effects of drug via its CNS stimulation effects; however, an in vivo study found no interaction with pentobarbitone.
	Hops	Additive effects	Caution	

	Kava	Additive effects	Caution Beneficial interaction possible under medical supervision	May be useful in benzodiazepine withdrawal.
	Lavender oil	Additive effects	Observe	
	Passionflower	Additive effects	Caution Beneficial interaction possible under medical supervision	May be useful in benzodiazepine withdrawal.
	St John's wort	Decreased the plasma concentration of zolpidem	Avoid	Repeated administration of SJW decreases the plasma concentration of zolpidem, probably by enhancing CYP3A4 activity.
	Valerian	Additive effects	Caution Beneficial interaction possible under medical supervision	Theoretically, potentiation effects may occur at high doses. May be useful in benzodiazepine withdrawal.
Midazolam (e.g. Hypnovel)	St John's wort	Reduced drug effects	Caution Monitor for signs of reduced drug effectiveness and adjust the dose if necessary	St John's wort may increase drug metabolism and so reduce serum levels of drug.
Barbiturates	Albizia	Additive effects	Caution Beneficial interaction possible under medical supervision	Potentiation of phenobarbitone-induced sleeping was observed in vivo — clinical significance unknown.
	Andrographis	Additive effects	Observe Beneficial interaction possible under medical supervision	Potentiation effects observed in vivo — clinical significance unknown.
	Celery	Additive effects	Caution. Use under medical supervision	Celery juice has been found to prolong the action of pentobarbitone in rats. Use with caution.
	Folate	Reduced drug effects	Caution Monitor for signs of reduced drug effectiveness	Concomitant folic acid use can reduce seizure control.
	Kava	Additive effects	Caution Beneficial interaction possible under medical supervision — monitor drug dosage	Increased sedation.
	Lemon balm	Additive effects	Observe Beneficial interaction possible under medical supervision	Increased sedation.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Passionflower	Additive effects	Caution Beneficial interaction possible under medical supervision — monitor drug dosage	Increased sedation.
	Slippery elm	Altered rate and/or extent of absorption	Caution. Separate doses by 2 hours	Controlled studies are unavailable, but interactions are theoretically possible with some medicines. Slippery elm forms an inert barrier over the gastrointestinal lining and may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. barbiturates). The clinical significance of this is unclear.
	St John's wort	Reduced drug effects	Avoid — monitor drug requirements. When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required	St John's wort induces CYP enzymes and P-glycoprotein, so can reduce drug serum levels.
	Valerian	Additive effects	Caution Beneficial interaction possible under medical supervision	Increased sedation.
	Vitamin B <sub>6</sub> (pyridoxine)	Reduced plasma levels and drug effects	Caution Monitor for drug effectiveness	Concomitant B <sub>6</sub> use can reduce seizure control.
	Withania	Additive effects	Observe Beneficial interaction possible under medical supervision	Theoretically may increase sedation.
Benzodiazepines	Chamomile	Additive effects	Observe Beneficial interaction possible under medical supervision	Theoretically an additive effect can occur with concurrent use.
	Kava	Additive effects	Caution Beneficial interaction possible under medical supervision — monitor drug dosage	Combination has been used to ease symptoms of benzodiazepine withdrawal under medical supervision.
	Passionflower	Additive effects	Caution Beneficial interaction possible under medical supervision — monitor drug dosage	Increased sedation. Passionflower may be a useful support during benzodiazepine withdrawal; use under medical supervision.

	St John's wort	Reduced serum levels and drug effects	Observe and caution. Use under medical supervision and monitor for signs of reduced drug effectiveness.	Decreases serum levels of alprazolam via CYP induction. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.
		Reduced serum levels and drug effects	Observe and caution. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.	Decreases serum levels of midazolam via CYP induction.
	Valerian	Additive effects	Observe Beneficial interaction possible under medical supervision	Combination has been used to ease symptoms of benzodiazepine withdrawal under medical supervision.
	Withania	Additive effects	Observe Beneficial interaction possible under medical supervision	
<b>CONTRACEPTIVE AGENTS</b>				
<b>Combined oral contraceptive agents</b>				
Oral contraceptive pill	Chaste tree	Reduced herb effects	Observe	There has been speculation as to whether chaste tree is effective when OCPs are being taken. Several clinical studies conducted in women taking the OCP have confirmed that chaste tree still reduces symptoms of premenstrual syndrome.
	Folate	Reduced folate levels	Beneficial interaction possible	Folate levels are reduced with long-term use. Increased intake may be required with long-term therapy.
	Licorice	Increased side-effects	Observe Caution with high-dose licorice (>100 mg/day glycyrrhizin) or long-term use (> 2 weeks)	Increased risk of side-effects such as hypokalaemia, fluid retention and elevated blood pressure have been noted in case reports.
	St John's wort	Reduced drug effects	Caution — avoid use with low-dose OCP	Breakthrough bleeding has been reported in 12 cases, which may indicate decreased effectiveness. Caution related to hyperforin.
	Vitamin A	Increased vitamin A levels	Observe. Monitor Vitamin A status	OCP increases serum vitamin A levels.
	Vitamin B <sub>2</sub> (riboflavin)	Reduced vitamin B <sub>2</sub> levels	Observe for signs and symptoms of B <sub>2</sub> deficiency	OCP may increase demand for vitamin B <sub>2</sub> . Increased intake may be required with long-term therapy. Supplementation may be required.
	Vitamin B <sub>3</sub> (niacin)	Reduced vitamin B <sub>3</sub> levels	Observe for signs and symptoms of B <sub>3</sub> deficiency	Increased intake may be required with long-term therapy.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Vitamin B <sub>5</sub> (pantothenic acid)	Reduced vitamin B <sub>5</sub> levels	Observe for signs and symptoms of B <sub>5</sub> deficiency	Increased intake may be required with long-term therapy. Supplementation may be required.
	Vitamin B <sub>6</sub> (pyridoxine)	Reduced vitamin B <sub>6</sub> levels	Observe for signs and symptoms of B <sub>6</sub> deficiency	OCP may induce pyridoxine deficiency. Increased intake may be required with long-term therapy.
	Vitamin B <sub>12</sub>	Reduced vitamin B <sub>12</sub> levels	Observe for signs and symptoms of B <sub>12</sub> deficiency	OCP users showed significantly lower concentrations of cobalamin than controls in a clinical study. Increased intake may be required with long-term therapy. Observe for signs and symptoms of B <sub>12</sub> deficiency and conduct testing if deficiency is suspected.
	Vitamin E	Reduced vitamin E levels	Observe for signs and symptoms of vitamin E deficiency	Very small cross sectional study suggests the OCP significantly lowered coenzyme Q10 and alpha tocopherol levels. Further studies are needed.
<b>ENDOCRINE AND METABOLIC DISORDERS</b>				
<b>Adrenal steroid hormones</b>				
Corticosteroids	Calcium	Reduced side-effects. Reduced calcium absorption	Beneficial interaction possible. Ensure adequate calcium intake.	Through inhibiting vitamin D-mediated calcium absorption and increased excretion, overall levels of calcium may be decreased. Increased calcium intake may be required with long-term therapy.
	Chromium	Reduced side-effects	Beneficial interaction possible	Corticosteroids increase urinary losses of chromium, and chromium supplementation has been shown to aid in recovery from steroid-induced diabetes mellitus.
	Licorice	Additive effects	Beneficial interaction possible but patients should be monitored closely for corticosteroid excess	Concurrent use of licorice preparations potentiates the effects of topical and oral corticosteroids (e.g. prednisolone) as glycyrrhizin inhibits the metabolism of prednisolone. Some practitioners use licorice to minimise requirements for, or to aid in withdrawal of, corticosteroid medications.
	Vitamin B <sub>12</sub>	Decreased vitamin B <sub>12</sub> levels	Observe for signs and symptoms of B <sub>12</sub> deficiency. Separate doses by at least 2 hours	Decreased vitamin B <sub>12</sub> levels have been reported in the cerebrospinal fluid and serum of multiple sclerosis patients following high-dose (1000 mg) intravenous methylprednisolone daily for 10 days.
	Vitamin C	Reduced vitamin C effects	Beneficial interaction possible	May increase requirement for vitamin C. Increased intake may be required with long-term therapy.
	Vitamin D	Reduced vitamin D absorption	Beneficial interaction possible	Increased vitamin D intake may be required with long-term therapy.

Betamethasone	Carnitine	Additive effects	Beneficial interaction possible	RCT has shown that a combination of low-dose betamethasone (2 mg/day) and L-carnitine (4 g/5 days) was more effective in preventing respiratory distress syndrome (7.3% vs 14.5%) and death (1.8% vs 7.3%) in preterm infants than high-dose betamethasone given alone (8 mg/2 days).
<b>Agents affecting calcium and bone metabolism</b>				
Alendronate (e.g. Fosamax) and Etidronate (e.g. Didronel)	Calcium	Reduced drug absorption	Separate doses by at least 2 hours	Calcium may reduce drug absorption; however, adequate calcium is required for optimal drug effects.
	Iron	Reduced drug absorption	Separate doses by at least 2 hours	
	Magnesium	Reduced drug absorption	Separate doses by at least 2 hours	Magnesium may reduce drug absorption; however, adequate magnesium is required for optimal drug effects.
	Zinc	Reduced drug absorption	Separate doses by at least 2 hours	
<b>Glucocorticoids</b>				
	Vitamin D	Reduced vitamin D absorption	Separate doses by at least 2 hours	In high doses, these drugs directly inhibit vitamin-D-mediated calcium uptake in the gastrointestinal tract and through unknown mechanisms may deplete levels of active vitamin D. During long-term therapy with either oral or inhaled corticosteroids, calcium and vitamin D supplementation should be considered.
<b>Gonadal hormones</b>				
Oestrogen	Hops	Additive effects	Observe	Theoretical interaction, based on mild oestrogenic effect of hops.
	Red clover	Reduced drug effects	Observe	Theoretically, if taken in large quantities phyto-oestrogens may compete with synthetic oestrogens for receptor binding — clinical significance unknown.
	Vitamin D	Additive effects	Observe	Vitamin D works synergistically with oestrogens to prevent bone loss.
Oestrogen receptor blockers (Tamoxifen)	Soy	Additive effects	Possible beneficial effect under professional supervision	Animal studies have shown that soy enhances the therapeutic effects of tamoxifen as both have SERM actions. Additionally, in vivo studies suggest that the isoflavone daidzein may enhance the effect of tamoxifen against breast cancer burden and incidence.
	Vitamin C	Additive effects	Observe under medical care. Beneficial interaction possible	Vitamin C enhanced the antitumour activity in vitro.

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Oestrogen and progesterone	Calcium	Additive effects	Beneficial interaction possible	Possible beneficial interaction on bone mineralisation.
	Licorice	Increased side-effects	Observe Caution with high-dose licorice or long-term use (> 2 weeks)	OCP can increase sensitivity to glycyrrhizin side-effects such as hypertension, fluid retention and hypokalaemia.
Oestrogens and anti-androgen therapy	Tyrosine	Decreased plasma levels of tyrosine	Observe. Supplementation under medical supervision.	Oestrogens and anti-androgen therapies have been shown to decrease plasma levels of tyrosine by up to 18.3% after 4 and 12 months in transsexual patients; therefore supplementation may be suggested.
Testosterone	Licorice	Altered testosterone effect	Observe Monitor testosterone levels	Contradictory evidence suggests possible effects on testosterone levels.
<b>Haemopoietic agents</b>				
Erythropoietin	Ginseng — Korean	Enhanced drug effects	Beneficial interaction possible	The total saponin fraction has been shown to promote haematopoiesis — clinical significance for total herb unknown.
	Iron	Enhanced drug effects	Beneficial interaction possible	
	Withania	Enhanced drug effects	Beneficial interaction possible	Animal studies indicate herb increases haematopoiesis — clinical significance unknown.
<b>Human growth hormone</b>				
Human growth hormone	Glutamine	Enhanced nutrient absorption	Beneficial interaction possible	In patients with severe short bowel syndrome, concomitant use of glutamine and human growth hormone may enhance nutrient absorption.
<b>Hypoglycaemic agents</b>				
Hypoglycaemic (e.g. metformin) agents Adverse effects associated with increased hypoglycaemic effects include sweating, hunger, depression, tremor and headaches	Aloe vera	Additive effects	Observe	Oral aloe vera may have hypoglycaemic activity, so additive effects are theoretically possible.
	Alpha Lipoic Acid	Additive effects	Observe	Theoretically, concomitant use may affect glucose control and require medication dosage changes — observe.

Andrographis	Additive effects	Caution — blood glucose levels should be checked regularly Beneficial interaction possible under professional supervision	Andrographis has hypoglycaemic activity comparable to that of metformin <i>in vivo</i> , so additive effects are theoretically possible.
Bilberry	Additive effects	Observe	Animal study identified the constituent myricitrin as exerting hypoglycaemic actions — relevance for bilberry unclear.
Bitter melon	Additive effects	Caution Monitor drug requirements Possible beneficial effect under professional supervision	Theoretically an additive effect is possible, resulting in increased hypoglycaemic effects — caution.
Chromium	Additive effects	Caution Monitor drug requirements Beneficial interaction possible under professional supervision	Clinical studies have shown that chromium has hypoglycaemic activity in some individuals. Chromium may reduce requirements for hypoglycaemic agents. While a beneficial interaction is possible, this combination should be used with caution and drug requirements monitored and adjusted if necessary by a healthcare professional.
Cinnamon	Additive effects	Observe — potentially beneficial interaction	Oral ingestion of cinnamon capsules may reduce blood glucose levels; therefore theoretically, an additive effect is possible with concurrent use.
Damiana	Additive effects	Observe	Additive effects are theoretically possible, with unknown clinical significance.
Elderflower	Additive effects	Observe	Elderflower has demonstrated hypoglycaemic effects <i>in vitro</i> ; the clinical significance of this observation remains unknown, and further research is required.
Eucalyptus	Additive effects	Caution	If used in combination with oral glucose-lowering conventional or complementary medicines oral by people with diabetes, doses of eucalyptus might contribute to hypoglycaemia. Blood glucose levels should be monitored to detect hypoglycaemia.
Fenugreek	Additive effects	Caution — blood glucose levels should be checked regularly Beneficial interaction possible under professional supervision	Additive effects are theoretically possible in diabetes and drug dose reductions may be required in some patients.
Ginseng — Siberian	Additive effects	Observe	Speculation is based on IV use in animal studies and has not been observed in humans with oral dose forms.
Green tea	Additive effects	Observe	Clinical significance unknown.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Gymnema	Additive effects	Caution — blood glucose levels should be checked regularly Beneficial interaction possible	Gymnema may enhance the blood glucose-lowering effects of insulin and hypoglycaemic agents.
	Horse chestnut	Possible additive effects	Observe	Due to possible hypoglycaemic activity, blood glucose levels should be monitored when horse chestnut or HCSE and hypoglycaemic agents are used concurrently. The clinical significance is unclear.
	Myrrh	Additive effects	Caution — blood glucose levels should be checked regularly Beneficial interaction possible	Myrrh has been shown to increase glucose tolerance in both normal and diabetic rats — clinical significance unknown.
	Nigella	Additive effects	Caution — however interaction may be beneficial	Preliminary clinical studies suggest Nigella reduces blood glucose levels and improves glucose tolerance in patients with type 2 diabetes, including those with the co-morbidity in dyslipidaemic patients.
	Oats	Additive effects	Observe. Beneficial interaction possible under supervision.	An uncontrolled pilot study found that oatmeal reduced insulin requirements in hospitalised patients with metabolic syndrome; the effect persisted after a 4-week outpatient period. Insulin requirements should be monitored in patients taking oat beta-glucans as a change to medication dose could be required.
	Olive leaf extract	Additive effects	Beneficial interaction possible — drug dose may need modification	
	Psyllium	Additive effects	Separate doses by 2 hours. Drug dose may need modification	Additive hypoglycaemic effects are theoretically possible.
	Tulsi	Potential interactions based on actions	Observe for interactions	There are no reports of significant interactions with tulsi. As tulsi has anti-diabetic actions there is a theoretically possibility of interactions with anti-diabetic medications but such interactions have not been reported.
	Vitamin B <sub>3</sub> (niacin)	Increased drug requirement	Caution Monitor drug effectiveness	Niacin may affect glycaemic control and increase fasting blood glucose levels, so medication doses may need to be reviewed.
	Vitamin B <sub>12</sub>	Decreased vitamin B <sub>12</sub> levels	Observe	In patients with type 2 diabetes, metformin has been shown to reduce levels of vitamin B <sub>12</sub> (and folate) and increase homocysteine. Increased B <sub>12</sub> intake may be required with long-term drug use.

	Withania	Reduced side effects	A potentially beneficial interaction that should only be used under supervision due to theoretical risk of induced thyrotoxicosis	Withania may protect type 2 diabetics on metformin from drug-induced hypothyroidism. A potentially beneficial interaction that should only be used under supervision due to theoretical risk of induced thyrotoxicosis.
Gliclazide	St John's wort	Increased clearance of drug	Observe and caution. Closely monitor to evaluate possible signs of reduced efficacy	Treatment with SJW significantly increases the apparent clearance of gliclazide, which is independent of CYP2C9 genotype, according to a crossover clinical study. People with diabetes receiving this combination should be closely monitored to evaluate possible signs of reduced efficacy.
Pioglitazone	Quercetin	Increases the bioavailability of drug	Caution	Quercetin may increase the bioavailability of pioglitazone (Actos). Due to the potential for toxicity, careful monitoring of hepatic and cardiac function is required.
Sulfonylureas	Coenzyme Q10	Reduced adverse effects of sulfonylureas	Observe. Beneficial interaction with co-administration	CoQ10 reduces adverse effects this drug class has on CoQ10-related enzymes. NADH oxidase and low CoQ10 levels have been observed in people with diabetes — beneficial interaction with co-administration.
<b>Thyroid hormones and antithyroid agents</b>				
Levothyroxine (e.g. Oroxine)	Alpha Lipoic Acid	Suppress T4 to T3 conversion	Observe. Separate doses by 2-4 hours	Uncertain interaction exists. When co-administered, ALA may suppress T4 to T3 conversion, decrease total cholesterol, triglycerides, albumin and total protein.
	Calcium	Reduced drug absorption	Separate doses by 2-4 hours	Calcium and thyroxine form an insoluble complex. Calcium administered concurrently may reduce drug absorption, while levothyroxine may block absorption of calcium, e.g. calcium carbonate.
	Celery	Decreased drug effect	Observe	One case report suggests that celery extract may reduce drug effects. Clinical significance unknown.
	Horseradish	Increased drug requirement	Observe Monitor thyroid function. Dose may need to be adjusted	Isothiocyanates may inhibit thyroxine formation and be goitrogenic, although this has not been demonstrated clinically.
	Iron	Decreased drug absorption	Separate doses by 2-4 hours	Iron supplements may decrease absorption of thyroid medication; however, iron deficiency may impair the body's ability to make thyroid hormones.
	Magnesium	Reduced drug absorption	Separate doses by 2-4 hours	Magnesium and thyroxine form an insoluble complex together.
	SAME	Unknown	Caution	Caution and monitoring may be warranted.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Tyrosine	Additive effects	Observe	Additive effects theoretically possible, as tyrosine is a precursor to thyroid hormones.
	Withania	Additive effects	Observe	An in vivo study reported that daily administration of <i>Withania somnifera</i> root extract enhanced serum T4 concentration.
	Zinc	Reduced drug absorption	Separate doses by 2–4 hours	Zinc and thyroxine form an insoluble complex together.
<b>EYE</b>				
<b>Glaucoma preparations</b>				
Timolol eye drops	Coenzyme Q10	Reduced side-effects	Beneficial interaction possible	A clinical trial of people with glaucoma found that oral CoQ10 reduced cardiovascular side-effects of timolol eye drops without affecting intraocular pressure.
<b>GASTROINTESTINAL SYSTEM</b>				
<b>Digestive supplements</b>				
Pancreatin	Folate	Reduced folate absorption	Monitor for folate efficacy and folate status	Reduced folate absorption.
<b>Hyperacidity, reflux and ulcers</b>				
Aluminium-based antacids	Calcium	Increased urinary excretion of calcium	Separate doses by 2–3 hours	Aluminium-containing antacids may increase urinary excretion of calcium.
	Vitamin C	Increased aluminium absorption	Separate doses by at least 2 hours	Vitamin C increases the amount of aluminium absorbed.
Antacids	Calcium	Reduced calcium absorption	Separate doses by 2–3 hours	Antacids that raise gastric pH may reduce calcium absorption, especially that of calcium carbonate or calcium phosphate as these salts require an acidic environment for solubilisation before calcium can be absorbed. Aluminium- and magnesium-containing antacids may increase urinary excretion of calcium.
	Cranberry	Increased B <sub>12</sub> absorption	Beneficial interaction possible	Cranberry juice increases the absorption of vitamin B <sub>12</sub> when used concurrently with PPI medicines.
	Folate	Reduced folate absorption	Separate doses by 2–3 hours	
	Iron	Reduced iron absorption	Separate doses by at least 2 hours	

	Licorice	May enhance ulcer-healing drug effects	Observe. Beneficial interaction possible	Adjunctive licorice treatment may enhance ulcer-healing drug effects — potentially beneficial interaction.
<b>Anticancer drugs</b>				
Sucralfate (e.g. Carafate, Ulcyte)	Vitamin E	Reduced vitamin absorption	Separate doses by at least 4 hours Monitor vitamin status	Increased vitamin intake may be required with long-term therapy.
	Calcium	Reduced calcium absorption	Monitor calcium status	Calcium supplementation may be required.
Gastric-acid inhibitors (proton-pump inhibitors [e.g. omeprazole], H <sub>2</sub> -receptor antagonists [e.g. ranitidine])	Folate	Reduced folate absorption	Separate doses by 2–3 hours	
	Iron	Reduced drug and iron effect	Monitor for iron efficacy and iron status	Drug reduces gastric acidity and therefore iron absorption.
	Licorice	May enhance ulcer-healing drug effects	Observe. Beneficial interaction possible	Adjunctive licorice treatment may enhance ulcer-healing drug effects — potentially beneficial interaction.
	St. John's wort	Decreases serum levels of the drug	Avoid	Decreases serum levels of omeprazole via CYP induction in vivo.
	Vitamin B <sub>12</sub>	Reduced B <sub>12</sub> absorption	Beneficial interaction possible Monitor B <sub>12</sub> status	B <sub>12</sub> supplementation may be required with long-term therapy.
<i>Helicobacter pylori</i> triple-therapy	Garlic	Additive effects	Interaction may be beneficial	Garlic inhibits growth of <i>H. pylori</i> in vitro and in vivo and two studies have shown a synergistic effect with omeprazole.
<b>Laxatives</b>				
	Aloe vera	Additive effects	Caution	Anthraquinones have significant laxative activity and may increase adverse effects of griping.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>GENITOURINARY SYSTEM</b>				
<b>Bladder function disorders</b>				
5-alpha-reductase inhibitors (e.g. finasteride [e.g. Proscar])	Pygeum	Additive effects	Beneficial interaction possible	
	Saw palmetto	Additive effects	Beneficial interaction possible	Meta-analyses show that herb is beneficial for BPH and in vitro tests show it may also inhibit 5-alpha-reductase activity.
	St John's wort	Reduced plasma concentration of drug	Caution. Monitor drug requirements under professional care.	SJW treatment for 2 weeks induced the metabolism of finasteride and caused a reduced plasma exposure of the drug. A case report reports on an increased PSA value for a man who had started SJW 900 mg/day, 10 weeks prior to the test and who was previously well controlled on finasteride.
	Stinging nettle root	Additive effects	Beneficial interaction possible	Clinical studies show nettle root to improve symptoms of BPH.
<b>IMMUNOLOGY</b>				
<b>Immune modifiers</b>				
Cyclosporin	Baical skullcap	Decreased drug effects	Avoid	A decoction of baical skullcap has been reported to significantly decrease plasma levels of cyclosporin in rats. The co-administration of these two substances should be avoided until further research is available.
	Coriolus versicolor	Decreased drug effects	Avoid	The use of Coriolus versicolor polysaccharopeptides are contraindicated when immune suppression is desired. Polysaccharopeptides reduce the potency of immunosuppressants such as cyclosporin.
	Echinacea	Decreased drug effects	Caution	Theoretically, the immunostimulant activity of the herb may reduce drug effects — clinical significance unknown.
	Goldenseal	Increased drug effects	Caution	RCT conducted with berberine constituent — clinical relevance for goldenseal difficult to assess.
	Licorice	Reduced oral bioavailability	Observe. Monitor cyclosporin levels closely	An in vivo study found that GA induced P-glycoprotein and CYP3A4, resulting in reduced oral bioavailability of cyclosporin — monitor cyclosporin levels closely.

Nigella	Possible additive and antagonistic effects	Caution. Use under medical supervision.	Based on laboratory and animal studies, black seed displays immunomodulatory activity and may theoretically interact with either immunostimulant or immunosuppressant drugs. Human studies are not available, therefore interactions are currently speculative and based on evidence of pharmacological activity. Clinical significance unknown.
Peppermint	Additive effects	Avoid unless under medical supervision	Peppermint oil has been shown to increase the oral bioavailability of cyclosporin in animal studies — clinical significance unknown.
Quercetin	Reduced oral bioavailability	Avoid.	Animal studies demonstrate that co-administration of quercetin significantly decreases the oral bioavailability of cyclosporin.
Red rice yeast	Potential increased side-effects	Observe	Monacolins are metabolised by the cytochrome P450 system and therefore cyclosporin and other P450 inhibitors have the potential to increase the risk of rhabdomyolysis. This is a theoretical concern only — clinical significance unclear.
St John's wort	Reduced drug effects	Avoid	Decreases plasma levels significantly within 3 days of concomitant use.
St Mary's thistle	Reduced drug side-effects but may increase drug effects	Caution	Decreases hepatotoxicity; however, herb may reduce drug metabolism leading to increased effects — clinical significance unknown.
Baical skullcap	Increased side-effects	Caution	There have been reports of acute pneumonitis due to a possible interaction between Sho-saiko-to preparation (containing baical skullcap) and interferon, which appears to be due to an allergic-immunological mechanism rather than direct toxicity.
Interferon	Reduced side-effects	Beneficial interaction possible	Clinical trials with patients being treated with interferon-alpha for hepatitis C found a reduction in fatigue associated with treatment when carnitine 2 g/day was co-administered.
Interferon-alpha	Increased side-effects	Avoid	The combination of peginterferon $\alpha$ and SJW (taken for 6 weeks during 8-week drug treatment) resulted in a severe acute hepatitis in a 61-year-old woman.
Pegylated Interferon alpha (peginterferon $\alpha$ )	Reduced drug effects	Avoid unless under medical supervision	Decreased drug serum levels via CYP induction.
Tacrolimus (e.g. Prograf)	Reduced drug effects	Beneficial interaction possible	May reduce the risk of post-vaccine reactions.
<b>Vaccines</b>			
Influenza virus vaccine	Reduced side-effects	Beneficial interaction possible	May reduce the risk of post-vaccine reactions.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Shatavari	Diphtheria, tetanus, pertussis (DTP) vaccine	Additive effect	Observe. Beneficial effects possible	Experimental studies have suggested a possible immunoadjuvant effect in animals immunised with diphtheria, tetanus, pertussis (DTP) vaccine, increasing antibody titres to <i>Bordetella pertussis</i> and providing improved immunoprotection on challenge.
<b>INFECTIONS AND INFESTATIONS</b>				
Antibiotics	Ginger	Possible enhanced absorption of antibiotics	Observe	Ginger may enhance the absorption of antibiotics such as azithromycin, erythromycin, cephalixin when used in doses of between 10 and 30 mg/kg due to the herb's modulating effect on the gastric mucosa; however, the clinical significance of this effect is untested.
	Ginkgo biloba	Increased drug tolerance	Observe	Animal model studies indicate that ginkgo extract EGB 761 reduces oxidative stress induced by bleomycin. This may improve drug tolerance; however, clinical studies have not yet been conducted to test this further.
	Ginseng — Korean	Possible additive effects	Beneficial interaction possible.	In animal studies, the combination of ginseng polysaccharides with vancomycin resulted in a 100% survival rate for animals treated for <i>Staphylococcus aureus</i> compared to only 67 or 50% survival in animals treated with ginseng polysaccharides or vancomycin alone. Clinical use in humans has not yet been established.
	Probiotics	Reduced side-effects	Beneficial interaction possible	Reduces gastrointestinal and genitourinary side-effects. A meta-analysis of nine studies found that <i>Lactobacilli</i> and <i>Saccharomyces boulardii</i> successfully prevent antibiotic-induced diarrhoea. Increase intake with antibiotic therapy.
	Soy	Reduced phyto-oestrogen effect	Observe. Separate doses by 2–3 hours.	Inhibits metabolism of isoflavones to equal through inhibition of intestinal microflora.
	Vitamin B <sub>1</sub> (thiamin)	Reduces endogenous vitamin production	Observe. Separate doses by 2–3 hours.	Antibiotics can reduce the endogenous production of B-group vitamins by gastrointestinal flora. Increase dietary intake or consider supplementation with long-term therapy.
	Vitamin B <sub>2</sub> (Riboflavin)	Reduces endogenous vitamin production	Observe. Separate doses by 2–3 hours.	Antibiotic can reduce endogenous production of B-group vitamins — increase intake of vitamin B <sub>2</sub> .
	Vitamin B <sub>5</sub> (pantothenic acid)	Reduces endogenous vitamin production	Observe. Separate doses by 2–3 hours.	Increase dietary intake or consider supplementation with long-term therapy.

Aminoglycosides (e.g. gentamicin)	Magnesium	Decreased magnesium absorption	Caution Monitor for signs and symptoms of magnesium deficiency	Aminoglycosides may deplete magnesium levels and result in neuromuscular weakness. Increased magnesium may be required with long-term therapy.
	Nigella	Reduced side effects	Observe. Beneficial interaction possible	Theoretically protective against gentamicin-induced nephrotoxicity, based on findings in animal studies but the clinical significance is unknown.
Quinolone antibiotics (e.g. norfloxacin [e.g. Noroxin])	Calcium	Reduced drug absorption	Separate antibiotic dose by at least 2 hours before or 4 hours after oral calcium	Drug bioavailability may be reduced by concurrent administration with calcium supplements, reducing drug efficacy and increasing risk of developing bacterial resistance.
	Dandelion	Reduced drug absorption	Separate doses by at least 2 hours	Reduced drug absorption and bioavailability observed in an experimental study.
	Iron	Reduced drug absorption	Separate antibiotic dose by at least 2 hours before or 4-6 hours after oral iron	
	Magnesium	Reduced drug absorption	Separate antibiotic dose by at least 2 hours before or 4 hours after oral magnesium	Magnesium may decrease absorption of fluoroquinolone antibiotics.
	Quercetin	Reduced drug effect	Caution	Theoretical concern based on test tube studies.
	Zinc	Reduced drug and zinc absorption	Separate doses by at least 2 hours	Complex formation between zinc and quinolones results in reduced absorption of both substances, with potential reduction in efficacy.
Tetracycline antibiotics (e.g. minocycline [e.g. Minomycin], doxycycline)	Calcium	Reduced drug and calcium absorption	Separate doses by at least 2 hours	Tetracyclines form insoluble complexes with calcium, thereby reducing its absorption.
	Iron	Reduced drug and iron absorption	Separate doses by at least 4 hours	Tetracyclines form insoluble complexes with iron, thereby reducing its absorption.
	Magnesium	Reduced drug and magnesium absorption	Separate doses by at least 2 hours	Tetracyclines form insoluble complexes with iron, thereby reducing its absorption.
	Vitamin A	Increased side effects	Avoid	Adjunctive use may increase side effects such as headaches, pseudotumour cerebri.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Vitamin B <sub>12</sub>	Reduced drug absorption	Separate doses by at least 2 hours	B complexes containing B <sub>12</sub> may significantly reduce the bioavailability of tetracycline hydrochloride.
	Zinc	Reduced drug and zinc absorption	Separate doses by at least 2 hours	Complex formation between zinc and tetracycline results in reduced absorption of both substances, with potential reduction in efficacy.
Other antibiotics and anti-infectives (Trimethoprim [e.g. Triprim])	Folate	Reduced folate levels	Caution Monitor folate status with long-term or high-dose therapy Beneficial interaction possible	Trimethoprim is a folate antagonist drug. Increased folate intake may be required with long-term or high-dose therapy.
Anthemimetics (e.g. Albendazole)	Ginseng — Korean	Accelerated drug clearance	Caution. Avoid, unless under medical supervision	Panax ginseng significantly accelerated the intestinal clearance of the anthelmintic albendazole sulfoxide, when co-administered to rats.
Other: Stibionate	Quercetin	Improved efficacy and reduced drug side effects	Observe. Beneficial interaction possible.	Concurrent use of quercetin with the antileishmanial drug stibionate appears to improve the efficacy of the drug and reduce anaemia and parasitaemia associated with the condition.
<b>Antimalarials</b>				
Pyrimethamine (e.g. Daraprim)	Folate	Reduced folate effects	Beneficial interaction possible with folic acid	Impaired folate utilisation occurs with drug use — supplementation may be required.
Chloroquine (e.g. Chlorquin)	Vitamin E	Reduced drug effects	Observe	According to <i>in vitro</i> research, vitamin E inhibits drug uptake in human cultured fibroblasts — clinical significance unknown.
<b>Antituberculotics and Antileprotics</b>				
Cycloserine and isoniazid	Vitamin B <sub>6</sub> (pyridoxine)	Reduced B <sub>6</sub> levels	Beneficial interaction possible	Drug may induce pyridoxine deficiency. Increased intake may be required with long-term therapy.
Isoniazid	Vitamin B <sub>3</sub> (niacin)	Reduced B <sub>3</sub> levels	Beneficial interaction possible	Prolonged isoniazid therapy (the drug replaces niacinamide in NAD) may induce pellagra. Increased intake may be required with long-term therapy.
	Vitamin B <sub>6</sub>	Increase B <sub>6</sub> requirements	Observe. Use under medical care	Isoniazid increases vitamin B <sub>6</sub> requirements. Increase intake of vitamin B <sub>6</sub> -rich foods or consider supplementation with long-term drug treatment.
	Vitamin D	Induced catabolism of vitamin D	Observe. Use under medical care	Drugs such as rifampicin and isoniazid have been reported to induce catabolism of vitamin D and in some cases manifest as reduced levels of metabolites. This may represent a concern in those patients already at risk of poor vitamin D status.

	Vitamin E	Reduced vitamin absorption	Separate doses by at least 4 hours and monitor vitamin status	Increased vitamin intake may be required with long-term therapy.
Rifampicin	Vitamin D	Reduced vitamin D levels	Beneficial interaction possible	Increase vitamin D intake with long-term therapy.
<b>Antiviral agents</b>				
Aciclovir	Astragalus	Possible additive effects	Beneficial interaction possible	Possibly enhances antiviral activity against herpes simplex type 1. Adjuvante use may be beneficial.
HIV drugs (e.g. zidovudine [AZT, e.g. Retrovir])	Carnitine	Reduced carnitine levels	Beneficial interaction possible	In vitro studies indicate prevention of muscle damage due to carnitine depletion. Increased intake may be required with long-term therapy.
	Ginseng — Korean	Delay in the development of resistance	Observe. Monitor use under medical supervision.	Long-term intake (60 ± 15 months) of Korean red ginseng in HIV-1-infected patients has been shown to delay the development of resistance mutation to zidovudine.
HIV non-nucleoside transcriptase inhibitors	St John's wort	Reduced drug effects	Avoid	St John's wort increases drug metabolism, thereby reducing drug serum levels.
HIV protease inhibitors (e.g. Indinavir)	St John's wort	Reduced drug effects	Avoid	St John's wort increases drug metabolism, thereby reducing drug serum levels.
Saquinavir	Garlic	Reduced drug effects	Avoid	A clinical study found that garlic reduces serum levels of saquinavir and therefore drug efficacy.
	Quercetin	Potential reduced absorption of drug	Caution under the care of medical supervision	Despite the inhibition of P-glycoprotein by quercetin, co-administration does not appear to alter plasma saquinavir concentrations. There appears to be a substantial inter- and intrasubject variability in saquinavir intracellular concentrations, caution should be exerted until more is known.
<b>MUSCULOSKELETAL SYSTEM</b>				
<b>Non-steroidal anti-inflammatory drugs</b>				
	Celery seed extract	Reduced side-effects	Beneficial	Gastroprotective activity seen in animal model.
	Chamomile	Reduced side-effects	Beneficial interaction	Gastroprotective activity seen in animal model.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Chondroitin	Additive effects	Beneficial interaction possible Drug dosage may require modification	May enhance the anti-inflammatory effects of the NSAID.
	Colostrum	Reduced side-effects	Beneficial interaction	Gastroprotective activity.
	Devil's claw	Additive effects	Beneficial interaction possible Drug dosage may require modification	May enhance the anti-inflammatory effects of the NSAID.
	Fish oils	Additive effects	Beneficial interaction possible Drug dosage may require modification	May enhance the anti-inflammatory effects of the NSAID and improve symptom relief.
	Ginger	Additive effects	Beneficial interaction possible Drug dosage may require modification	May enhance the anti-inflammatory effects of NSAIDs at high doses.
	Glucosamine	Additive effects	Beneficial interaction possible Drug dosage may require modification	May enhance the anti-inflammatory effects of the NSAID.
	Glutamine	Reduced side-effects	Beneficial interaction	May ameliorate the increased intestinal permeability caused by indomethacin.
	New Zealand (NZ) green-lipped mussel	Additive effects	Beneficial interaction possible. Drug dosage may require modification	Anti-inflammatory activity reported in a clinical study — may enhance the anti-inflammatory effects of the NSAID.
	Nigella	Additive effects	Beneficial interaction possible. Drug dosage may require modification	Based on laboratory and animal studies, black seed displays anti-inflammatory activity and may therefore theoretically interact with nonsteroidal anti-inflammatory agents and COX 2 inhibitors. Human studies are not available, therefore interactions are currently speculative and based on evidence of pharmacological activity, but may theoretically be beneficial.
	SAME	Additive effects	Beneficial interaction possible Drug dosage may require modification	Anti-inflammatory activity reported in a clinical study — may enhance the anti-inflammatory effects of the NSAID.
	St John's wort	Decreased serum levels of drug	Avoid	Decreases serum levels via CYP induction in vivo.
	Stinging nettle	Additive effects	Beneficial interaction possible Drug dosage may require modification	Anti-inflammatory activity reported in a clinical study — may enhance the anti-inflammatory effects of the NSAID.

	Vitamin E	Additive effects	Beneficial interaction possible Drug dosage may require modification	May enhance the pain-modifying effects of the NSAID when used in high doses for RA.
	Willowbark	Additive effects	Beneficial interaction possible Drug dosage may require modification	May enhance the anti-inflammatory effects of the NSAID.
	Zinc	Reduced absorption	Separate doses by at least 2 hours	Zinc interacts with NSAIDs by forming complexes with these drugs.
NSAIDs (etoricoxib)	St John's wort	Decreased serum levels of drug	Avoid	Decreases serum levels of etoricoxib via CYP induction in vivo.
Aspirin	Grapeseed extract	Additive effects	Observe Beneficial interaction possible	Theoretically may enhance antiplatelet and anti-inflammatory activity of aspirin and may increase risk of bleeding.
	Licorice	Reduce gastro-irritant effects of drug therapy	Observe Beneficial interaction possible	Co-administration with licorice may reduce gastro-irritant effects induced by drug therapy — potentially beneficial interaction. Whether the effect is clinically significant for licorice remains to be determined — use high doses with caution.
	Meadowsweet	Increased bruising and bleeding	Observe Beneficial interaction possible	Theoretically may enhance anti-inflammatory and antiplatelet effects.
	Policosanol	Increased bruising and bleeding	Observe	Doses >10 mg/day may inhibit platelet aggregation.
	Vitamin C	Decreased vitamin C effects	Beneficial interaction	Aspirin may interfere with both absorption and cellular uptake mechanisms for vitamin C, thereby increasing vitamin C requirements, as observed in animal and human studies. Increased vitamin C intake may be required with long-term therapy.
	Willowbark	Increased bruising and bleeding	Observe Beneficial interaction possible Caution with high dose (>240 mg salicin daily)	Theoretically may enhance anti-inflammatory and antiplatelet effects. Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect.
Diclofenac sodium (topical)	Licorice	Additive effects	Beneficial interaction possible	In vitro studies have shown that the addition of glycyrrhizin enhanced the topical absorption of diclofenac sodium — significance for licorice unknown.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>Other</b>				
Colchicine	Vitamin A	Altered Vitamin A absorption	Observe	Colchicine may interfere with vitamin A absorption and homeostasis.
	Vitamin B <sub>12</sub>	Reduced absorption of B <sub>12</sub>	Observe and monitor B <sub>12</sub> levels	The use of colchicine may reduce the absorption of orally administered vitamin B <sub>12</sub> — monitoring of serum B <sub>12</sub> concentration is recommended, particularly if history of deficiency.
Neuromuscular blockers	Magnesium	Additive effects	Observe	May potentiate effects of neuroblockers.
Sulfasalazine (e.g. Salazopyrin)	Folate	Reduced drug absorption	Separate doses by 2–3 hours	Folic acid can reduce drug absorption.
	Iron	Reduced drug and iron effects	Separate doses by at least 2 hours	May bind together, decreasing the absorption of both.
<b>NEOPLASTIC DISORDERS</b>				
	St John's wort	Reduction of plasma concentrations of various antineoplastic agents	Avoid	By inducing both the CYP3A4 and the P-glycoprotein (P-gp), Hypericum can reduce the plasma concentrations of different antineoplastic agents such as imatinib, irinotecan and docetaxel, thus reducing the clinical efficacy of these drugs. Although these interactions are often predictable, the concomitant use of Hypericum extract should be avoided in cancer patients taking interacting medications.
Chemotherapy	Bilberry	Possible reduction of chemotherapy effectiveness	Observe	An in vitro study using human colon cancer cells showed anthocyanin-rich berry extracts may be protective of DNA damage caused by topoisomerase drugs and therefore may reduce chemotherapy effectiveness. As the concentration required (>50 mcg/mL) to cause this effect is likely greater than could be achieved through oral ingestion, it remains theoretical.
	Ginseng — Korean	Improved treatment tolerance	Caution — possible beneficial interaction under medical supervision	Panax ginseng saponins may reduce nausea and vomiting associated with chemotherapy, radiotherapy and general anaesthetics by antagonising serotonin (5-hydroxytryptamine) type 3A receptors. Ginseng may also help to sensitise cancer cells to chemotherapeutic agents.
	Ginseng — Siberian	Improved treatment tolerance	Caution — possible beneficial interaction under medical supervision	Co-administration may increase drug tolerance and improve immune function. An increased tolerance for chemotherapy and improved immune function has been demonstrated in women with breast and ovarian cancer undergoing chemotherapy treatment. Caution, as co-administration may theoretically reduce drug effects. However, beneficial interaction may be possible under medical supervision.

	Nigella	Possibly enhance anti-tumour activity	Caution — possible beneficial interaction under medical supervision	A theoretical and speculative interaction exists between nigella when used in combination with antineoplastic agents. Cytotoxic, apoptotic and necrotic effects have been observed in laboratory studies with the constituents thymoquinone and alpha-hederin. Theoretically beneficial interactions exist, but further research required to determine significance in humans.
	Pelargonium	Reduced drug effects	Avoid	Theoretically, use of this herb may reduce the effectiveness of immunosuppressant medication — avoid until safety can be established.
	Rosemary	Increased drug effects of P-gp substrates	Caution	Inhibits P-glycoprotein so may affect the bio-availability of P-gp substrates.
	Vitamin A	Reduced vitamin A absorption	Observe and monitor vitamin A status	Reduces vitamin A absorption — increase dietary intake of vitamin A-rich foods or consider supplementation with long-term use.
	Vitamin C	May enhance anti-tumour activity	Beneficial interaction possible	Controversial
	Withania	Reduced side-effects	Observe Beneficial interaction possible under medical supervision	Animal studies suggest a potential role for withania as an adjunctive treatment during chemotherapy for the prevention of drug-induced bone marrow suppression — clinical significance unknown.
Radiotherapy	Zinc	Reduced plasma zinc levels	Monitor zinc levels and use under medical care	Radiotherapy reduces plasma zinc levels. Supplementation may be required with intensive radiotherapy treatment.
<b>Alkylating agents</b>				
Carboplatin	Carnitine	Increased urinary loss	Use combination under professional supervision	Treatment with carboplatin appears to result in marked urinary losses of L-carnitine and acetyl-L-carnitine, most likely due to inhibition of carnitine reabsorption in the kidney.
Cyclophosphamide	Astragalus	Possible reduction of adverse effects	Only use combination under professional supervision	Adjunctive treatment with astragalus may have beneficial effects in regards to improving patient wellbeing and reducing adverse effects associated with treatment such as nausea and vomiting.
	Echinacea	Reduced drug effects	Avoid	Echinacea appears to increase the immunostimulatory effect of low-dose cyclophosphamide, which may be detrimental in autoimmune disease where low doses are used.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Rhodiola	Additive effect. Possible reduction of adverse effects	Observe. Use under medical care	Rhodiola rosea root extract synergises the antitumour activity of cyclophosphamide and decreases its hepatotoxicity in an experimental rodent model. Whether the effects are clinically relevant remains to be tested.
	Turmeric	Reduced drug effects	Avoid	Animal studies suggest that curcumin may reduce drug efficacy.
	Vitamin C	Additive effect.	Observe. Use under medical care	Vitamin C enhanced the therapeutic drug effect in vivo.
Immuno-suppressants (e.g. cyclophosphamide)	Withania	Reduced drug effects Reduced side-effects/toxicity	Caution — possible beneficial interaction	The ability to stimulate stem cell proliferation has led to concerns that withania could reduce cyclophosphamide-induced toxicity, although preliminary animal studies indicate a potential role as a potent and relatively safe radiosensitiser and chemotherapeutic agent. Theoretically it may also decrease the effectiveness of other immunosuppressant drugs.
	Herbs with immunostimulant properties (e.g. echinacea, andrographis, astragalus, baical skullcap, garlic, Ginseng — Korean Ginseng — Siberian)	Reduced drug effects	Observe	Theoretically, immunostimulating agents may reduce drug effectiveness; however, clinical significance is unknown.
<b>Antibiotic cytotoxics</b>				
Docetaxel	Black cohosh	Increased the cytotoxicity of Docetaxel	Avoid	Black cohosh extracts increased the cytotoxicity of Docetaxel. It is advisable that patients undergoing cancer therapy should be made aware that use of black cohosh could alter their response to the agents commonly used to treat breast cancer.
Doxorubicin (e.g. Adriamycin)	Aloe vera	Reduced drug effects	Caution	In vitro evidence suggests that aloe emodin antagonises the cytotoxic effects on both paclitaxel and doxorubicin. While the clinical relevance of this remains unknown, caution should be observed in patients concurrently taking aloe with either of these chemotherapeutic agents.
	Black cohosh	Increased the cytotoxicity of doxorubicin	Avoid	Increased cytotoxicity of doxorubicin in an experimental breast cancer model — while the clinical significance of this finding is unknown, it is recommended patients taking doxorubicin avoid black cohosh until safety can be confirmed.

Carnitine	Reduced side-effects	Beneficial interaction possible	Animal and human studies suggest that long-term carnitine administration may reduce the cardiotoxic side-effects of Adriamycin. Potentially beneficial interaction; use only under professional supervision.
Coenzyme Q10	Reduced side-effects	Beneficial interaction possible	Animal and human studies suggest that the cardiotoxic side-effects of Adriamycin are reduced with CoQ10 supplementation.
Ginkgo biloba	Reduced side-effects	Beneficial interaction possible	In vivo research suggests that ginkgo can prevent doxorubicin-induced cardiotoxicity, although no human studies are available to confirm this.
Nigella	Reduced side-effects	Observe — beneficial interaction possible	The constituent thymoquinone is theoretically protective against doxorubicin-induced cardiotoxicity and renal toxicity based on findings in animal studies. Clinical significance unknown.
Quercetin	Reduced side-effects and potentiated antitumour effects	Observe — beneficial interaction possible	When combined with doxorubicin, quercetin potentiated antitumour effects, specifically in the highly invasive breast cancer. Moreover, in non-tumour cells, quercetin reduced doxorubicin cytotoxic side effects. Therefore, it theoretically may have benefits in reducing doxorubicin-mediated toxicity. Further investigation is required to confirm.
Rhodiola	Reduced side-effects	Observe. Beneficial interaction is possible under clinical supervision	Rhodiola extract has been shown to reduce the liver dysfunction (suggested by a sharp increase in blood transaminase levels) associated with Adriamycin in vivo without affecting the drug's antitumour effects. Theoretically, a beneficial interaction is possible under clinical supervision.
St Mary's thistle	Reduced side-effects	Observe. Use may be beneficial when used under professional supervision	Silymarin reduces cardiotoxicity and possibly chemosensitises resistant cells to anthracyclines.
Vitamin C	Reduces side-effects and enhances therapeutic action	Beneficial interaction possible	Vitamin C enhanced the therapeutic drug effect and reduced drug toxicity in vivo. Encouraging — further evidence required.
Vitamin E	Reduced side-effects	Beneficial interaction possible	One study found that oral DL-alpha tocopheryl acetate (1600 IU/day) prevented doxorubicin-induced alopecia; however, the same dosage failed to prevent alopecia after doxorubicin treatment after mastectomy for breast cancer.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Etoposide	Withania Echinacea Vitamin C	Reduced side-effects Increased drug effects Increased drug effects	Observe. Beneficial interaction possible Avoid Observe. Use may be beneficial when used under professional supervision	In rats pretreatment with a standardised withania extract (300 mg/kg; 1.5% withanolides) attenuates the cardiotoxic side-effects of doxorubicin (10 mg/kg). A recent case study reported a probable interaction of cisplatin and etoposide with echinacea resulting in profound thrombocytopenia requiring platelet transfusion. The authors postulated an interaction via the CYP3A4 enzyme with Echinacea being an inhibitor of CYP3A4 in vitro and etoposide being a substrate of CYP3A4. Vitamin C enhanced the antitumour activity of etoposide in vitro.
<b>Antimetabolites</b>				
Methotrexate	Folate Nigella Licorice	Reduced side-effects but may reduce drug response Reduced side-effects Additive effects	Caution in cancer treatment Observe in other conditions Observe. Beneficial interaction possible Caution. Monitor for signs of methotrexate toxicity.	Methotrexate is a folate antagonist drug; supplementation may reduce toxicity. This action may be problematic in cancer treatment and reduce drug response, but beneficial in other uses. Theoretically, the antioxidant properties of black seed may ameliorate the gastrointestinal adverse effects associated with methotrexate, according to preliminary animal studies. Clinical studies are not yet available. Concurrent administration of methotrexate and either GL or licorice decoction can significantly increase MRT and AUC. Until clarification of this interaction occurs, use combination with caution and monitor for signs of methotrexate toxicity.
Paclitaxel	St John's wort Licorice Quercetin	Additive effects and increased toxicity Additive effects Increased drug effects	Caution. Monitor for signs of methotrexate toxicity. Observe Caution	Co-administration of 300 and 150 mg/kg of SJW significantly increased the systemic exposure and toxicity of methotrexate. A constituent of licorice has been demonstrated to significantly potentiate the effects of paclitaxel in vitro — clinical significance for licorice unknown. Increased drug bio-availability seen in animal study.

	Withania	Increased/extended drug effects	Caution	In mice, the addition of Withania (400 mg/kg, orally once weekly for 4 weeks) to paclitaxel (33 mg/kg, intraperitoneally once weekly for 4 weeks) may extend its chemotherapeutic effect through modulating protein-bound carbohydrate levels and marker enzymes. The combination may effectively treat the benzo(a)pyrene-induced lung cancer by offering protection from oxidative damage and also by suppressing cell proliferation.
<b>Immunosuppressant drugs</b>				
	Andrographis	Reduced drug effects	Caution	Immunostimulant activity has been demonstrated in vivo.
	Astragalus	Reduced drug effects	Caution	Due to known immunostimulant effects observed clinically.
	Baical skullcap	Reduced drug effects	Caution	Due to known immunostimulant effects observed clinically.
	Echinacea	Reduced drug effects	Caution	Due to known immunostimulant effects observed clinically.
	Garlic	Reduced drug effects	Caution	Due to known immunostimulant effects observed clinically.
	Ginseng — Korean and Ginseng — Siberian	Reduced drug effects	Caution	Due to known immunostimulant effects observed clinically.
Cisplatin	Black cohosh	Decreased cytotoxicity of cisplatin	Avoid	Decreased cytotoxicity of cisplatin in an experimental breast cancer model — while the clinical significance of this finding is unknown, it is recommended that patients taking cisplatin should avoid black cohosh until safety can be confirmed.
	Camitine	Reduced side-effects	Beneficial interaction possible under professional supervision	Research into the use of L-carnitine 4 g/day for 7 days showed reduced fatigue from treatment with cisplatin.
	Ginger		Observe. Beneficial interaction possible under professional supervision	Pretreatment has restored testicular antioxidant parameters and sperm motility in cisplatin-induced damage in an animal model. Clinical implications are uncertain; however, potential benefits may be found upon further testing.
	Ginkgo biloba	Reduced side-effects	Beneficial interaction possible under professional supervision	As an antioxidant, Ginkgo may reduce the nephrotoxic effects of cisplatin. Animal model studies have indicated that ginkgo may protect against cisplatin-induced ototoxicity.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
	Nigella	Reduced side-effects	Observe — interaction theoretically beneficial.	Thymoquinone is theoretically protective against cisplatin-induced nephrotoxicity and deleterious drug effects on haemoglobin levels and leucocyte count, based on animal study findings. Synergistic effects were observed when thymoquinone was used in combination with cisplatin in lung cancer cells and in animal models. Clinical significance unknown.
	Quercetin	Increased drug effects	Beneficial interaction theoretically possible under professional supervision	Pre-treatment may sensitise human cervix carcinoma cells to drug according to preliminary research.
	St John's wort	Reduced side-effects	Caution. Pretreatment with SJW under professional supervision may have a beneficial interaction	Cisplatin-induced histological abnormality of the kidney was blocked by pretreatment with SJW in vivo. Total and free cisplatin concentration in serum was not influenced by SJW treatment suggesting that this may be a beneficial interaction under professional supervision.
	St Mary's thistle	Increased drug effects Reduced side-effects	Beneficial interaction possible under professional supervision	Preliminary research has shown that this combination may reduce toxicity effects yet enhance antitumour activity.
	Selenium	Reduced side-effects	Beneficial interaction possible under professional supervision	In vitro and in vivo studies indicate that selenium may reduce drug-associated nephrotoxicity, myeloid suppression and weight loss.
	Vitamin C	Increased drug effects Reduced side-effects	Beneficial interaction possible under professional supervision	Vitamin C enhanced the antitumour activity of cisplatin in several in vitro tests and reduced drug toxicity in experimental models.
	Vitamin E	Reduced side-effects	Beneficial interaction possible under professional supervision	Oral vitamin E (300 mg/day) taken before cisplatin treatment and continued for 3 months significantly reduced the incidence and severity of neurotoxicity, according to a randomised study.
Dasatinib	Magnesium	Potentially beneficial interaction	Observe. Beneficial interaction possible under professional supervision	May increase magnesium blood levels.
Interleukin-2-immunotherapy	Carnitine	Reduced side-effects	Beneficial interaction possible under professional supervision	Clinical trials using L-carnitine (1000 mg/day orally) found that it may successfully prevent cardiac complications during IL-2-immunotherapy in cancer patients with clinically relevant cardiac disorders.
Myelosuppressive chemotherapeutic agents	Echinacea	Potentially beneficial interaction	Potentially beneficial interaction under professional supervision	Use of echinacea between treatment cycles may theoretically improve white cell counts, reduce dose-limiting toxicities on myelopoiesis and improve patient's quality of life.

<b>Proteasome inhibitors</b>			
PS-341 (Bortezomib, Velcade)	Vitamin C	Reduced drug effects	Avoid until safety can be established.
<b>Pyrimidine analogues</b>			
Fluorouracil	Vitamin C	Additive effects	Observe under professional supervision
<b>Vinca alkaloids</b>			
Vinblastine	Licorice	Additive effects	Observe Beneficial interaction possible under medical supervision
Vincristine	Vitamin C	Additive effects	Observe under professional supervision
<b>NUTRITION</b>			
<b>Anorectics and weight-reducing agents</b>			
Olestra	Lutein and zeaxanthin	Reduced lutein and zeaxanthin absorption	Separate doses by at least 4 hours Monitor lutein and zeaxanthin status
Orlistat (e.g. Xenical)	Lutein	Reduced lutein absorption	Separate doses by at least 4 hours Monitor lutein status
	Vitamin A	Reduced vitamin absorption	Separate doses by at least 4 hours Monitor vitamin status
	Vitamin D	Reduced vitamin absorption	Separate doses by at least 4 hours Monitor vitamin status
	Vitamin E	Reduced vitamin absorption	Separate doses by at least 4 hours Monitor vitamin status
			Lutein and zeaxanthin levels have been found to decrease with long-term use of olestra. Increased dietary intake of lutein should be considered.
			Long-term use of orlistat leads to reduced plasma levels of lutein due to reduced gastric absorption. Increased dietary intake of lutein should be considered.
			Reduces vitamin A levels. Increased dietary vitamin intake may be required with long-term therapy. Supplementation may be considered with long-term use.
			Increased vitamin intake may be required with long-term therapy.
			Increased vitamin intake may be required with long-term therapy.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>Nutrient–Nutrient interactions</b>				
Alpha Lipoic Acid	Coenzyme Q10	Positive additive effects	Monitor vitamin status	ALA reconstitutes coenzyme Q10 from the oxidised form to an un-oxidised form as part of the antioxidant cycle in humans — beneficial interaction.
	Copper	Reduced absorption/ Chelation	If not using for chelation, separate dose by 3 hours	ALA is a metal chelator and binds to copper in vivo — separate dose by 3 hours, unless this is the desired effect.
	Glutathione	Positive additive effects	Monitor glutathione status	ALA reconstitutes glutathione from the oxidised form to an un-oxidised form as part of the antioxidant cycle in humans — beneficial interaction.
	Manganese	Reduced absorption/ Chelation	Separate dose by 3 hours	ALA is a metal chelator and binds to manganese in vivo.
	Vitamin C	Positive additive effects	Monitor vitamin status	ALA reconstitutes vitamin C from the oxidised form to an un-oxidised form as part of the antioxidant cycle in humans — beneficial interaction.
	Vitamin E	Positive additive effects	Monitor vitamin status	ALA reconstitutes vitamin E from the oxidised form to an un-oxidised form as part of the antioxidant cycle in humans — beneficial interaction.
	Zinc	Reduced absorption/ Chelation	Separate dose by 3 hours	ALA is a metal chelator and binds to zinc in vivo.
Arginine	Lysine	Reduced/ competitive absorption	Caution. Separate dose by 3 hours	Arginine may compete with lysine uptake by tissues. Caution is needed if considering the administration of both amino acids.
Calcium	Iron	Reduced absorption	Separate dose by 2 hours	Concurrent administration of calcium with iron may reduce absorption of both minerals.
	Lysine	Additive effect	Observe. Beneficial interaction	Additive effects may occur as lysine enhances intestinal absorption and reduces renal excretion of calcium.
	Magnesium	Reduced absorption	Separate dose by 2 hours	Magnesium decreases calcium absorption as they compete for the same absorption pathway, however it is unclear if this mineral interaction is clinically significant.
	Zinc	Reduced absorption	Separate dose by 2 hours	Concurrent administration of calcium and zinc may reduce absorption of both minerals, however it is unclear if this is clinically significant. Calcium supplementation has been shown in some studies to increase faecal losses of zinc. Ensure adequate zinc intake and monitor for signs and symptoms of deficiency.

Citric acid	Vitamin B <sub>1</sub>	Additive	Beneficial interaction	Citric acid may enhance oral bioavailability of thiamin.
Coenzyme Q10	Vitamin E	Additive	Beneficial interaction	Reconstitutes oxidised vitamin E to its unoxidised form — beneficial interaction with co-administration.
Copper	Zinc	Reduced copper levels	Avoid using high-dose zinc supplements long term, or increase intake of copper.	High zinc intakes (100–150 mg/day) interfere with copper metabolism and can cause hypocuprinaemia with long-term use.
Folate	Zinc	Reduced zinc levels	Observe patients for signs and symptoms of zinc deficiency	At high doses of folate (>15 mg/day), minor zinc depletion may develop.
Iron	Vitamin C	Additive	Beneficial interaction	Vitamin C increases the absorption of iron.
	Zinc	Decreases zinc absorption	Separate dose by 2 hours	Supplemental (38–65 mg/day elemental) iron decreases zinc absorption.
Lysine	Calcium	Additive effect	Observe. Beneficial interaction	Lysine enhances intestinal absorption and decreases renal excretion of calcium.
Magnesium	Calcium	Increased renal excretion	Monitor for signs and symptoms of calcium deficiency	If magnesium intake is excessive, calcium levels decline due to inhibition of PTH release and increased renal excretion. There is additional redistribution with impaired calcium influx and release from intracellular stores. Magnesium can also bind calcium-binding sites and mimic its actions.
	Potassium	Magnesium deficiency leads to increased renal excretion	Monitor for signs and symptoms of potassium deficiency	Hypomagnesaemia results in hypokalaemia due to increased potassium efflux from cells and renal excretion. Magnesium supplementation may be required.
	Vitamin D	Altered metabolism of vitamin D	Monitor for signs and symptoms of both magnesium and vitamin D deficiency	Either an excess or inadequate level of magnesium can impact on vitamin D status. The final hydroxylation step to 1,25(OH) <sub>2</sub> D <sub>3</sub> is dependent upon magnesium and a deficiency would compromise this. However, high levels of magnesium, mimicking calcium, can suppress PTH secretion, also suppressing the activation phase. Therefore magnesium levels within the normal range will enhance activation of vitamin D to its active form.
Phosphorus	Calcium	Increased excretion	Monitor for signs and symptoms of deficiency	Excess intake (soft drinks, meat consumption) can increase urinary excretion of calcium — ensure adequate calcium intake and monitor for signs and symptoms of deficiency.
Quercetin	Iron	Reduced absorption and increased chelation	Separate dose by 2 hours	Quercetin is a powerful iron chelator so should not be ingested at the same time as iron supplements or iron rich foods to avoid reducing absorption.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Selenium	Iodine	Additive effects	Beneficial interaction	Selenium facilitates the conversion of T4 to T3 and is also responsible for the only iodine recycling pathway of the body through the action of the deiodinases on excess or unnecessary thyroid hormones to release the iodine.
Vitamin B <sub>1</sub>	Vitamins B <sub>2</sub> and B <sub>6</sub>	Concurrent deficiencies	Observe and correct deficiencies	Thiamin deficiency commonly occurs in conjunction with poor B <sub>2</sub> and B <sub>6</sub> status.
	Iron	Reduces B <sub>1</sub> absorption	Separate dose by 2 hours	Iron precipitates thiamin, thereby reducing its absorption.
Vitamin C	Vitamin B <sub>1</sub>	Additive	Beneficial interaction	Vitamin C may enhance oral bioavailability of thiamin.
	Iron	Additive	Beneficial interaction	Vitamin C increases the absorption of iron.
Vitamin D	Magnesium	Altered metabolism of vitamin D	Monitor for signs and symptoms of both magnesium and vitamin D deficiency	Either an excess or inadequate level of magnesium can impact on vitamin D status. The final hydroxylation step to 1,25(OH) <sub>2</sub> D <sub>3</sub> is dependent upon magnesium and a deficiency would compromise this. However, high levels of magnesium, mimicking calcium, can suppress PTH secretion, also suppressing the activation phase. Therefore magnesium levels within the normal range will enhance activation of vitamin D to its active form.
Zinc	Calcium	Impaired zinc absorption	Separate dose by 2 hours	High levels of dietary calcium impair zinc absorption in animals, but it is uncertain whether this occurs in humans.
	Copper	Reduced copper levels	Avoid using high-dose zinc supplements long term, or increase intake of copper.	High zinc intakes (100–150 mg/day) interfere with copper metabolism and can cause hypocuprinaemia with long-term use.
	Folate	Reduced zinc levels	Observe patient for signs and symptoms of zinc deficiency with long-term folate supplementation.	Folate intake may reduce zinc levels.
	Iron	Decreases zinc absorption	Separate dose by 2 hours	Supplemental (38–65 mg/day elemental) iron decreases zinc absorption.
<b>POISONING, TOXICITY AND DRUG DEPENDENCE</b>				
<b>Agents used in drug dependence</b>				
Methadone	Kava	Additive effects	Caution	Increased sedation theoretically possible.
	St John's wort	Reduced drug effects	Avoid	Decreases serum levels via CYP induction.

Detoxifying agents, antidotes			
Penicillamine (e.g. D-penicillamine)	Calcium	Reduced drug effects	Separate doses by 2 hours Combination forms insoluble complex.
	Iron	Reduced drug and iron effects	Separate doses by at least 2 hours. Do not suddenly withdraw iron Sudden withdrawal of iron during penicillamine use has been associated with penicillamine toxicity and kidney damage.
	Magnesium	Reduced drug effects	Separate doses by 2 hours Combination forms insoluble complex.
	Vitamin B <sub>6</sub> (pyridoxine)	Reduced B <sub>6</sub> effect	Beneficial interaction possible Drug may induce pyridoxine deficiency — increase intake with long-term therapy. Consider supplementation in long-term use under medical supervision.
	Zinc	Reduced drug effects	Separate doses by 2 hours Combination forms insoluble complex.
RESPIRATORY SYSTEM			
Broncospasm relaxants			
Ephedrine	Tyrosine	Increased side-effects	Observe Tyrosine (200 and 400 mg/kg) has been shown to increase side effects of anorexia caused by ephedrine and amphetamine in a dose-dependent manner in rats — clinical significance unknown.
	Nigella	Additive effects	Observe. Beneficial interaction possible Black seed has been shown to have anti-asthmatic effects according to preliminary human study. Adjunctive use may be beneficial.
Theophylline	Coenzyme Q10	Potential interactions	Observe. Monitor for signs of reduced drug effectiveness An animal study suggests significant changes to the pharmacokinetics of theophylline such as time to peak concentration, half-life and distribution following treatment with CoQ10. While there is very limited research, there may be possible interactions.
	St John's wort	Reduced drug effects	Monitor for signs of reduced drug effectiveness and adjust the dose if necessary Decreased drug serum levels.
	Vitamin B <sub>6</sub> (pyridoxine)	Reduced B <sub>6</sub> levels	Beneficial interaction possible Drug may induce pyridoxine deficiency. Increased intake may be required with long-term therapy.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
<b>Expectorants, antitussives, mucolytics and decongestants</b>				
	Adhatoda	Increased drug effects	Observe	Results from animal studies show that <i>Adhatoda vasica</i> extract exerts considerable antitussive activity when administered orally and is comparable to codeine when cough is due to irritant stimuli.
Phenylpropranolamine (found in Neo-Diophen)	Tyrosine	Increased side-effects	Observe	Tyrosine (200 and 400 mg/kg) has been shown to increase side-effects of anorexia caused by phenylpropranolamine in a dose-dependent manner in rats — clinical significance unknown.
<b>SKIN</b>				
<b>Acne, keratolytics and cleansers</b>				
Isotretinoin (e.g. Roaccutane)	Vitamin A	Additive effects	Avoid	Isotretinoin is a vitamin A derivative, so adverse effects and toxicity may be increased.
	Vitamin B <sub>5</sub>	Reduced adverse reaction	Observe	A single study reports that a 5% dexpanthenol cream can help treat mucocutaneous adverse reactions caused by using isotretinoin for acne.
<b>Psoriasis, seborrhoea and ichthyosis</b>				
Ketoconazole (e.g. Nizoral)	Vitamin D	Reduced vitamin D effects	Beneficial interaction possible	Ketoconazole reduces the conversion of vitamin D to its active forms. Increased intake may be required with long-term therapy.
<b>Topical corticosteroids</b>				
Topical corticosteroids (e.g. hydrocortisone)	Aloe vera (topical)	Additive effects	Beneficial interaction possible	In addition to its own anti-inflammatory effects, animal studies have shown that aloe vera increases the absorption of hydrocortisone by hydrating the stratum corneum, inhibits hydrocortisone's antiwound-healing activity and increases wound tensile strength.
<b>OTHER</b>				
Alcohol	Andrographis	Reduced side-effects	Beneficial interaction possible	May reduce hepatic injury.
	Ginseng — Korean	Reduced side-effects	Beneficial interaction possible	May reduce hepatic injury.
	Kava	Additive effects	Observe	Potentiation of CNS sedative effects have been reported in an animal study; however, one double-blind, placebo-controlled study found no additive effects on CNS depression or safety-related performance.

	Magnesium	Increased urinary excretion of magnesium	Separate by at least 2 hours	Alcohol consumption results in increased urinary losses of magnesium. Additional magnesium may be necessary with higher chronic ingestion of alcohol.
	St Mary's thistle	Reduced side-effects	Beneficial interaction possible	May reduce hepatic injury.
	SAME	Reduced side-effects	Beneficial interaction possible	May reduce hepatic injury caused by such agents as paracetamol, alcohol and oestrogens.
	Schisandra	Reduced side-effects	Beneficial interaction possible	May reduce hepatic injury.
	Vitamins C and E	Additive effects	Beneficial interaction possible	Concurrent prescription of oral Aloe vera (both gel and latex) with vitamins C and E shows improved absorption and increased plasma life of vitamin concentration for both vitamins when taken together.
Aloe vera	Tyrosine	Increased side effects	Observe patients using this combination.	L-Tyrosine (200 and 400 mg/kg) has been shown to increase the side-effect of anorexia caused by phenylpropanolamine, ephedrine and amphetamine in a dose-dependent manner in rats.
Anaesthetics	Ginseng — Korean	Improved treatment tolerance	Caution — possible beneficial interaction under medical supervision	Panax ginseng saponins may reduce nausea and vomiting associated with chemotherapy, radiotherapy and general anaesthetics by antagonising serotonin (5-hydroxytryptamine) type 3A receptors. Ginseng may also help to sensitise cancer cells to chemotherapeutic agents.
Anaesthetics (e.g. Ketamine)	St John's wort	Reduced drug effects	Caution. Use under medical supervision	SJW greatly decreased the exposure to oral S-ketamine in healthy volunteers. Although this decrease was not associated with significant changes in the analgesic or behavioural effects of ketamine in the present study, usual doses of S-ketamine may become ineffective if used concomitantly with SJW.
Blueberries	Vitamin B <sub>1</sub>	Reduced absorption	Separate doses by at least 2 hours	Reduce the absorption of oral thiamin.
Brussel sprouts	Vitamin B <sub>1</sub>	Reduced absorption	Separate doses by at least 2 hours	Reduce the absorption of oral thiamin.

*Continued*

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Chitosan	B-group vitamins	Reduced absorption	Observe. Separate doses by at least 2 hours	In vitro studies using fluorescence and ultraviolet-visible absorption measurements have shown vitamin B <sub>2</sub> and B <sub>12</sub> interact with chitosan in an acid-aqueous environment replicate of the stomach. These studies suggest chitosan may inhibit the absorption of these nutrients; however, the degree of clinical significance is unknown.
	Fat-soluble nutrients	Reduced absorption	Observe. Separate doses by at least 2 hours	Given chitosan's capacity to bind dietary fats and reduce their absorption, chitosan can also affect the absorption of fat-soluble vitamins.
	Vitamin C	Additive	Beneficial interaction possible	According to a preliminary study in rats, taking vitamin C together with chitosan might provide additional benefit in lowering cholesterol.
Cocoa	Iron	Reduced absorption	Separate doses by at least 2 hours	Polyphenols may reduce iron absorption, with a cocoa beverage containing 100–400 mg total polyphenols per serving having been shown to reduce iron absorption by approximately 70%.
Coffee	Vitamin B <sub>1</sub>	Reduced absorption	Separate doses by at least 2 hours	Reduce the absorption of oral thiamin.
Dopamine antagonists	Chaste tree	Reduced drug effects	Observe	Reduced drug effects theoretically possible.
Ecstasy	Tyrosine	Increased concentration of tyrosine in the brain causing long-term depletion of 5-HT.	Avoid	Ecstasy users should be aware that MDMA increases the concentration of tyrosine in the brain causing long-term depletion of 5-HT.
Ephedrine	Tyrosine	Increased side effects	Observe patients using this combination.	L-Tyrosine (200 and 400 mg/kg) has been shown to increase the side-effect of anorexia caused by phenylpropanolamine, ephedrine and amphetamine in a dose-dependent manner in rats.
Fenugreek	Iron	Reduced absorption	Separate doses by at least 2 hours	Frequent use of fenugreek can inhibit iron absorption.
Fibre, including guar gum	*All medications	Reduced absorption	Separate doses by at least 2 hours	May delay or decrease absorption of medications. *More research is required to investigate the effect of fibre on individual medications.
	Calcium	Reduced absorption	Separate doses by at least 2 hours	May delay or decrease absorption of calcium.

Goitrogens	Iodine	Inhibition	Separate intake of iodine and goitrogens where possible	Interferes with iodine utilisation, uptake into the thyroid or thyroid hormone production.
Grapeseed extract	Iron and iron-containing preparations	Decreased iron absorption.	Separate doses by at least 2 hours	Decreased iron absorption. Tannins can bind to iron, forming insoluble complexes.
Green tea	Iron and iron-containing preparations	Decreased iron absorption.	Observe. Separate doses by at least 2 hours.	Tannins found in <i>Camellia sinensis</i> can bind to iron and reduce its absorption. Protein and iron have also been found to interact with tea polyphenols and decrease their antioxidant effects in vitro.
Hepatotoxic drugs	Andrographis	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol and tricyclic antidepressants.
	Garlic	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol.
	Nigella	Reduced side-effects	Beneficial interaction possible	Based on animal studies, black seed appears to confer hepatoprotective effects against a number of agents. A theoretically beneficial interaction exists, but further research required to determine significance in humans and with other hepatotoxic drugs.
	Quercetin	Reduced side-effects	Beneficial interaction	Hepatoprotective activity.
	St Mary's thistle	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol.
	SAME	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol, alcohol.
	Schisandra	Reduced side-effects	Beneficial interaction possible	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol.
Horsetail ( <i>Equisetum arvense</i> )	Vitamin B <sub>1</sub>	Reduced absorption	Observe. Avoid if pre-existing thiamin deficiency.	Theoretically, horsetail may destroy thiamin in the stomach due to the presence of a thiaminase-like compound found in the herb. Those that have a pre-existing thiamin deficiency or are at risk of thiamin deficiency may be advised to avoid concurrent use of horsetail.
Lutein	Vitamin C	Additive effects	Beneficial interaction	Lutein showed increased antioxidant efficacy with vitamin C in an animal study. A small in vivo study showed 2000 mg of vitamin C enhanced the absorption of lutein.
	Vitamin E	Additive effects	Beneficial interaction	Vitamin E showed increased antioxidant efficacy with lutein according to an animal study.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Licorice	Potassium	Reduced effect of potassium supplementation	Separate doses by at least 2 hours Observe the patient for signs of potassium deficiency.	Licorice may reduce the effect of potassium supplementation. In many cases potassium supplementation may be beneficial in reducing the hypokalaemic side effects of licorice.
Lipophilic drugs	Chitosan	Reduced drug absorption	Separate doses by at least 2 hours	Binds to dietary fats and reduces their absorption and so can also affect the absorption of lipophilic drugs.
Lithium	Fibre	Decreased bioavailability and absorption	Separate doses by at least 1–2 hours	Soluble fibre may decrease the bioavailability of lithium.
	Psyllium	Decreased bioavailability and absorption	Separate doses by at least 1–2 hours	Soluble fibre may decrease the bioavailability of lithium.
	Slippery elm	Potential decreased bioavailability and absorption	Separate doses by at least 2 hours	Since slippery elm forms an inert barrier over the gastrointestinal lining, it may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. barbiturates, digoxin, lithium, phenytoin, warfarin). The clinical significance of this is unclear.
	Vitamin B <sub>12</sub>	Decreased B <sub>12</sub> concentration	Observe. Separate doses by at least 2 hours	Lithium administration may result in a decrease in serum B <sub>12</sub> concentration; however, the clinical significance of these findings is not yet clear.
Meadowsweet	Iron	Reduced iron absorption	Separate doses by at least 2 hours	The tannin content of meadowsweet potentially forms an insoluble complex with iron reducing its absorption.
Mineral oil	Vitamin D	Reduced vitamin D absorption	Separate doses by at least 2 hours	Mineral oil impairs absorption of all fat-soluble nutrients and may therefore deplete oral intake of vitamin D sources.
Nigella	Iron	Increased iron status	Beneficial interaction	Increased iron status possible with consumption of black seed, based on limited animal study. Clinical significance is unknown, but theoretically beneficial in iron deficiency.
Phenylpropanolamine (norephedrine and norpseudoephedrine)	Tyrosine	Increased side effects	Observe patients using this combination.	L-Tyrosine (200 and 400 mg/kg) has been shown to increase the side-effect of anorexia caused by phenylpropanolamine, ephedrine and amphetamine in a dose-dependent manner in rats.
Phytosterols	Lutein	Reduced lutein absorption	Separate doses by at least 2 hours	High dietary intake of phytosterol esters (6.6 g/day) reduced plasma levels of lutein by 14% in a small clinical trial; however, this was reversed by increasing fruit and vegetable intake.

Psyllium	Calcium	Decreased bioavailability and absorption	Separate doses by at least 1–2 hours	Animal studies suggest that soluble fibre from sources of purified psyllium negatively impact calcium balance by decreasing the bioavailability of calcium from the diet. Psyllium and other soluble fibre supplements should be taken at least 1 hour before or after calcium.
	Lithium	Decreased bioavailability and absorption	Separate doses by at least 1–2 hours	Soluble fibre may decrease the bioavailability of lithium.
	Minerals	Decreased bioavailability and absorption	Separate doses by at least 1–2 hours	Given the known capacity of psyllium husks to decrease the absorption of calcium, it would be prudent to avoid co-administration of psyllium husks with any vitamin or mineral supplement.
	Vitamin B <sub>12</sub>	Decreased bioavailability and absorption	Separate doses by at least 1–2 hours	Soluble fibre may decrease the bioavailability of vitamin B <sub>12</sub> .
	Vitamins	Decreased bioavailability and absorption	Separate doses by at least 1–2 hours	Given the known capacity of psyllium husks to decrease the absorption of calcium, it would be prudent to avoid co-administration of psyllium husks with any vitamin or mineral supplement.
PUVA therapy	Celery	Additive effects	Caution	While celery has been found to contain psoralens, celery extract does not seem to be photosensitising, even after ingestion in large amounts; however, it may increase the risk of phototoxicity with concurrent PUVA therapy.
	St. John's wort	Additive effects	Caution	Hypericin may increase sensitivity to UV radiation.
Raspberry leaf	Calcium	Decreased absorption	Separate doses by at least 2 hours	Due to its high tannin content, raspberry leaf may decrease absorption of calcium, as well as some drugs.
	Iron	Decreased absorption	Separate doses by at least 2 hours	Due to its high tannin content, raspberry leaf may decrease absorption of iron, as well as some drugs.
	Magnesium	Decreased absorption	Separate doses by at least 2 hours	Due to its high tannin content, raspberry leaf may decrease absorption of magnesium, as well as some drugs.
Red cabbage	Vitamin B <sub>1</sub>	Reduced absorption	Separate doses by at least 2 hours	Reduce the absorption of oral thiamin.
Red rice yeast	Coenzyme Q10	May reduce endogenous production of Coenzyme Q10	Observe. When supplementing coenzyme Q10, separate doses by at least 2 hours	Similar to statin medications, Red rice yeast may reduce endogenous production of CoQ10 — a 3-month trial of CoQ10 supplementation may be worth considering with long-term use of red rice yeast in people complaining of fatigue.

Continued

Herb/Supplement	Pathway	Potential outcome	Recommendation	Evidence/Comments
Rosemary	Iron	Inhibition of absorption	Observe. Separate doses by 2 hours.	Rosemary extracts are widely used as an antioxidant to preserve foods; however, the phenolic-rich extracts may reduce the uptake of dietary iron.
Sage	Calcium	Reduced absorption	Observe. Separate doses by 2 hours.	Due to the tannin content, sage may reduce the absorption of calcium.
	Iron	Reduced absorption	Observe. Separate doses by 2 hours.	Due to the tannin content, sage may reduce the absorption of iron.
	Magnesium	Reduced absorption	Observe. Separate doses by 2 hours.	Due to the tannin content, sage may reduce the absorption of magnesium.
SAME	Betaine	Additive effects	Observe.	In studies supplementing mice with betaine, significant increases in SAME were observed with a three-fold elevation of the activity of methionine adenosyltransferase.
Selenium	Heavy metals (e.g. mercury, lead, arsenic, silver and cadmium)	Reduces toxicity of heavy metals	Observe. Beneficial interaction	Selenium reduces toxicity of heavy metals such as mercury, lead, arsenic, silver and cadmium by forming inert complexes.
Shatavari	Metoclopramide	Additive effect	Observe. Beneficial interaction	Shatavari root was found in animal studies to have similar effects on gastric emptying time to the antiemetic drug metoclopramide (a synthetic dopamine antagonist); an additive effect is possible.
Slippery elm	Lithium	Altered rate and/or extent of absorption	Caution. Separate doses by 2 hours	Controlled studies are unavailable, but interactions are theoretically possible with some medicines. Slippery elm forms an inert barrier over the gastrointestinal lining and may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. lithium). The clinical significance of this is unclear.
Soy	Calcium	Reduced absorption	Caution. Separate doses by 2–3 hours	Soy contains phytic acid, which may bind with calcium reducing availability.
	Copper	Reduced absorption	Caution. Separate doses by 2–3 hours	Soy contains phytic acid, which may bind with copper reducing availability.
	Iodine	Inhibition of absorption	Separate intake of iodine and goitrogens where possible	Ingestion of soy appears to inhibit iodine absorption to some extent (particularly when presented in its thyroxine form in the gut) and also high levels of the isoflavones, genistein and daidzein, can inhibit T3 and T4 production.
	Iron	Reduced absorption	Caution. Separate doses by 2–3 hours	Soy contains phytic acid, which may bind with iron reducing availability.

	Magnesium	Reduced absorption	Caution. Separate doses by 2-3 hours	Soy contains phytic acid, which may bind with magnesium reducing availability.
	Manganese	Reduced absorption	Caution. Separate doses by 2-3 hours	Soy contains phytic acid, which may bind with manganese reducing availability.
	Tamoxifen	Additive effects	Possible beneficial effect under professional supervision	Animal studies have shown that soy enhances the therapeutic effects of tamoxifen as both have SERM actions. Additionally, in vivo studies suggest that the isoflavone daidzein may enhance the effect of tamoxifen against breast cancer burden and incidence.
	Zinc	Reduced absorption	Caution. Separate doses by 2-3 hours	Soy contains phytic acid, which may bind with zinc reducing availability.
	Thyme	Clinical significance unknown	Observe	Thyme may induce enzymes in phase one and two detoxification in the liver. The clinical significance of this is unknown.
Tannins	Vitamin B <sub>1</sub>	Reduced absorption and increased precipitation	Observe. Separate doses by 2-3 hours	Tannins precipitate thiamin, thereby reducing its absorption.
Vaccinations	Zinc	Improved seroconversion of vibriocidal antibodies	Possible beneficial effect under professional supervision	Zinc acetate improved seroconversion of vibriocidal antibodies in children given a cholera vaccination in both faecal and serum titres.

# APPENDIX 3

## GUIDE TO THE SAFE USE OF COMPLEMENTARY MEDICINES DURING THE PREOPERATIVE PERIOD

This table is intended to provide clinicians with some guidance when advising patients due for surgery about the safe use of complementary medicines (CMs). It is limited to the CMs reviewed in this book, especially those that are known or suspected to increase bleeding or interact with drugs commonly used in the perioperative period. The recommendations are conservative and not likely to be relevant to many low-risk or minor surgical procedures, but it is imperative that each patient be individually assessed before surgery.

CMs are listed alphabetically by common name. The comments section includes a brief description of the type of evidence available to support the recommendation; more detailed information is given in the individual monographs. Several different recommendations are possible. Sometimes there is a recommendation to suspend use 1–2 weeks before surgery, which should provide ample time for bleeding rates to return to normal or potential interactions to be avoided. This is most likely an overestimation of the actual time required. Please

note that coumarin-containing and salicylate-containing herbs have not been included in the table unless they have demonstrated antiplatelet or anticoagulant effects in animal or human studies. Sometimes the recommendations are dose dependent; in other cases CM use appears safe but there is a theoretical concern.

It is acknowledged that, in practice, not all surgical patients will be able to follow these recommendations. In situations where bleeding would be a serious complication and a 1-week minimum deferment is not possible, tests of haemostasis prior to surgery should be considered.

It must be reiterated that the clinical relevance of some interactions and adverse effects is unknown and controlled studies in surgical patients are not available. However, it would seem prudent for healthcare providers to become familiar with these medicines, in order to advise patients appropriately and to anticipate, manage or avoid adverse events during the perioperative period.

Common name	Botanical name (where applicable)	Comments	Recommendation
Andrographis	<i>Andrographis paniculata</i>	Andrographolide inhibits platelet-activating-factor-induced platelet aggregation in a dose-dependent manner (confirmed clinically) (Amroyan et al 1999, Zhang et al 1994).	Suspend use 1 week before surgery.
Baical skullcap	<i>Scutellaria baicalensis</i>	There is a theoretical risk of anticoagulant activity; not observed in clinical trials.	Use under observation, but likely to be safe.
Evening primrose oil (EPO)	Omega-6 essential fatty acids or omega-6 fatty acids	Gamma linolenic acid in EPO affects PG synthesis, leading to inhibition of platelet aggregation — clinical significance unknown.	Suspend use of high-dose concentrated products 1 week before surgery; however, safety is difficult to assess.

Common name	Botanical name (where applicable)	Comments	Recommendation
Feverfew	<i>Tanacetum parthenium</i>	Evidence is contradictory as to whether feverfew inhibits platelet aggregation. Inhibition of platelet aggregation has been observed in several in vitro studies (Groenewegen & Heptinstall 1990, Marles et al 1992, Voyno-Yasenetskaya et al 1988); however, a small human study found no effects on platelet aggregation (Biggs et al 1982).	Use under observation but likely to be safe.
Fish oils	Omega-3 essential fatty acids or omega-3 fatty acids	Multiple clinical studies conducted in surgical patients with no significant increase in bleeding observed (Harris 2007). Some benefits reported (see monograph). Bleeding times increased at very high doses of 12 g/day of omega-3 fatty acids (Harris et al 1990).	Usual therapeutic doses are safe according to systematic review of use in surgical patients. Suspend use of high-dose products (12 g/day and higher) 1 week before surgery.
Garlic	<i>Allium sativum</i>	Inhibition of platelet aggregation is clinically significant — two cases of postoperative bleeding after excessive dietary intake have been reported (Burnham 1995, German et al 1995). One clinical study found reduced haematocrit values and plasma viscosity (Jung et al 1991).	Usual dietary intakes are likely to be safe. Suspend use of concentrated extracts (> 7 g) 1 week before surgery.
Ginger	<i>Zingiber officinale</i>	Standard intake likely to be safe. Oral doses of 4 g/day did not alter platelet aggregation or fibrinogen levels in one clinical study, whereas a high dose of 10 g/day significantly reduced platelet aggregation in another clinical study (Bordia et al 1997).	Usual dietary and therapeutic intakes are likely to be safe. Suspend use of high-dose (10 g/day) concentrated extracts 1 week before surgery.
Ginkgo	<i>Ginkgo biloba</i>	At least 10 clinical studies have found no significant effect on bleeding or platelets; however, rare cases of bleeding have been reported. One escalating dose study found that doses of 120 mg, 240 mg or 480 mg given daily for 14 days did not alter platelet function or coagulation (Bal Dit et al 2003).	Use under observation but likely to be safe.
Ginseng — Korean	<i>Panax ginseng</i>	Herb inhibits platelet aggregation according to both in vitro and animal studies, but clinical significance unknown. In contrast, the total saponin fraction has been shown to promote haemopoiesis by stimulating proliferation of human granulocyte-macrophage progenitors (Niu et al 2001).	Suspend use 1 week before surgery; however, safety is difficult to assess.
Ginseng — Siberian	<i>Eleutherococcus senticosus</i>	Siberian ginseng constituent 3,4-dihydroxybenzoic acid has demonstrated antiplatelet activity in vivo.	Suspend use 1 week before surgery; however, safety is difficult to assess.
Goji	<i>Lycium barbarum</i>	Inhibition of platelet aggregation in vitro — clinical significance unknown. Not demonstrated in human studies	Use under observation but likely to be safe.
Green tea	<i>Camellia sinensis</i>	Shown to exert antiplatelet aggregation and antithrombogenic activities. A case report of excessive daily intake 2.5–4.5 L/day decreased INR.	Usual dietary intake likely to be safe.

Continued

Common name	Botanical name (where applicable)	Comments	Recommendation
Guarana	<i>Paullinia cupana</i>	In vitro and in vivo research have identified antiplatelet activity (Bydlowski et al 1991).	Suspend use of concentrated extracts 1 week before surgery.
Kava Kava	<i>Piper methysticum</i>	Increased sedation due to significant CNS-depressant effects possible. Inhibition of CYP2E1 has been demonstrated in vivo therefore serum levels of CYP2E1 substrates may become elevated (e.g. the anaesthetic drugs). halothane isoflurane methoxyflurane	Suspend use of concentrated extract 1 week before surgery in cases when drug interactions possible.
Licorice root	<i>Glycyrrhiza glabra</i>	Isoliquiritigenin inhibits platelet aggregation (Tawata et al 1992) and glycyrrhizin inhibits prothrombin (Francischetti et al 1997) according to in vitro tests — clinical significance unknown.	Usual dietary intakes likely to be safe. Concentrated extracts should be used with caution.
Meadowsweet	<i>Filipendula ulmaria</i>	In vitro and in vivo tests have identified anticoagulant activity (Liapina & Koval'chuk 1993) — clinical significance of these findings is unknown.	Suspend use of concentrated extracts 1 week before surgery.
Myrrh	<i>Commiphora molmol</i>	Guggul inhibits platelet aggregation in vitro and in a clinical study (Bordia & Chuttani 1979).	Suspend use of guggul preparations 1 week before surgery.
Policosanol		Doses of 10 mg/day and greater reduce platelet aggregation, according to clinical studies (Arruzazabala et al 2002, Castano et al 1999). Effect of 20 mg/day is similar to aspirin 100 mg stat.	Suspend use of doses 10 mg/day or greater 1 week before surgery.
Rosemary	<i>Rosmarinus officinalis</i>	Rosemary demonstrates antithrombotic activity in vitro and in vivo, possibly through inhibition of platelets. Clinical significance unknown.	Suspend use of concentrated extracts 1 week before surgery; however, clinical significance difficult to assess.
Shark cartilage		Substance displays anti-angiogenic properties, which could theoretically hinder healing.	Suspend use of supplement 1 week before surgery and until postoperative healing is complete (approx 6 weeks).
St John's wort	<i>Hypericum perforatum</i>	Use of herb for more than 2 weeks can induce pharmacokinetic interactions with CYP3A4 and P-gp substrates. This will result in reduced therapeutic responses to these drugs e.g. alprazolam cyclosporin digoxin midazolam morphine nortriptyline warfarin	Do not cease use unless under supervision to avoid inducing drug interaction — consider patient benefits vs potential risks.  <b>Caution:</b> Withdrawal effects possible as SSRI-like activity is reduced and CYP and P-gp induction is removed — therapeutic failure of herb and possible drug toxicity.

Common name	Botanical name (where applicable)	Comments	Recommendation
Turmeric root	<i>Curcuma longa</i>	Curcumin inhibits platelet aggregation in vivo (Srivastava et al 1985, 1986, Chen et al 2007) and in vitro (Srivastava 1989, Srivastava et al 1995, Jantan et al 2008). The anticoagulant effect of curcumin is weaker than that of aspirin — clinical significance unknown.	Usual dietary intakes likely to be safe.
Vitamin E	Alpha-tocopherol	Contradictory results have been obtained in clinical studies that have investigated whether vitamin E affects platelet aggregation or coagulation. A dose of 1200 IU/day (800 mg of D-alpha-tocopherol) taken for 28 days had no effects on platelet aggregation or coagulation, according to one clinical study (Morinobu et al 2002). Similarly, a second clinical study found the lower dose of 600 mg (900 IU) of RRR-alpha-tocopherol taken daily for 12 weeks did not alter coagulation activity (Kitagawa et al 1989). Alternatively, increased risk of gingival bleeding at doses of 50 mg/day was found by another study (Liede et al 1998).	Usual therapeutic doses are likely to be safe. Suspend use of high-dose supplements (> 1000 IU/day) 1 week before surgery; however, safety is difficult to assess.
Willow bark	<i>Salix spp</i>	Although it has been assumed that willow bark affects platelet aggregation owing to its salicylate content, one clinical study found that consumption of <i>Salicis cortex</i> (240 mg salicin daily) produced minimal effects on platelet aggregation (Krivoy et al 2001).	Use under observation but likely to be safe.

# **APPENDIX 4**

## **CLINICAL USE AND SAFETY OF VITAMINS AND MINERALS**

Clinical use and safety of vitamins						
Vitamin	Australian and New Zealand RDI for adults (>18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity
A	Women: 700 mcg Men: 900 mcg	10,000–50,000 IU/day orally in divided doses Not recommended for more than 2 weeks without medical supervision	Treating deficiency Prevention of secondary deficiency (e.g. coeliac disease, cystic fibrosis, pancreatic disease) Reducing severity of infectious diseases in children Dermatology — many uses Adjunct to chemotherapy Slowing progression of retinitis pigmentosa Osteoporosis Anaemia	Hypersensitivity Pregnancy Hypervitaminosis A Retinoid analogue use Lactation Chronic renal failure or liver disease	<b>Early signs</b> Dry rough skin and mucous membranes, desquamation Coarse sparse hair, alopecia of eyebrows Diplopia Bone and joint pain <b>Later signs</b> Irritability Increased intracranial pressure and headache Dizziness Hepatotoxicity	Cumulative toxicity if > 100,000 IU long term. Acute toxicity possible if > 2,000,000 IU. The recommended adult daily amount of vitamin A from all sources is 2500 IU. Taking more than 8000 IU a day during pregnancy may cause birth defects.
B <sub>1</sub> (thiamin)	Women: 1.1 mg Men: 1.2 mg	5–3000 mg	Treating deficiency Prevention of secondary deficiency (e.g. hyperemesis and malabsorption states) Acute alcohol withdrawal Alzheimer's dementia Dysmenorrhoea Congestive heart failure Diabetes	Hypersensitivity	Well tolerated	Non-toxic
B <sub>2</sub> (riboflavin)	Women: 1.1 mg (<70 yrs: 1.3 mg) Men: 1.3 mg (>70 yrs: 1.6 mg)	10–400 mg/day	Treating deficiency Prevention of secondary deficiency (e.g. chronic diarrhoea, liver disease, chronic alcoholism) Prevention of migraine headaches Reducing incidence of both nuclear and cortical cataract Wound healing Pyridoxine metabolism Breast cancer adjunct to tamoxifen	Hypersensitivity	Generally well tolerated, but rare side effects include diarrhoea and polyuria.	Non-toxic

Continued

Clinical use and safety of vitamins continued							
Vitamin	Australian and New Zealand RDI for adults (> 18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity	
B <sub>3</sub> (niacin)	Women: 11 mg Men: 12 mg	1500–2000 mg crystalline niacin or sustained-release forms daily	Treating deficiency Pellagra Prevention of secondary deficiency (e.g. anorexia nervosa) Hypercholesterolaemia and hypertriglyceridaemia Syndrome X Tryptophan deficiency Diabetes	Hypersensitivity Diabetes Peptic ulcer disease Gout Hepatitis Liver function should be monitored and patients observed for symptoms of myopathy.	Flushing is a common side effect (not with nicotinamide). Night-time administration, extended-release (ER) niacin or concurrent administration of aspirin can reduce these effects. Palpitations, chills, pruritus, GIT upset and cutaneous tingling.	Tachycardia, chills, sweating, shortness of breath, nausea, vomiting, myalgias, hepatotoxicity. ER niacin is considered the safest form.	
B <sub>5</sub> (pantothenic acid)	Women: 4 mg/day Men: 6 mg/day	200–300 mg/day	Deficiency rare Prevention of secondary deficiency (e.g. malabsorption syndrome, alcoholism, diabetes, OCP and IBD) Enhanced wound healing Hypercholesterolaemia Prevention of NTD Female alopecia		Well tolerated Contact dermatitis from topical application	No toxicity level known	

<p><b>B<sub>6</sub></b> (pyridoxine)</p>	<p>Women: 1.3 mg (&gt; 50 yrs: 1.5 mg) Men: 1.3 mg (&gt; 50 yrs: 1.7 mg)</p>	<p>5–1200 mg/day</p>	<p>Treating deficiency Prevention of secondary deficiency (e.g. malabsorption syndromes, cancer, liver cirrhosis and alcoholism, hyperthyroidism) Relieving symptoms of PMS and morning sickness Leg cramps of pregnancy Hyperhomocysteinaemia (often with folic acid and vitamin B<sub>12</sub>) Reducing thromboembolism Improved outcomes after heart transplant Reducing repeated febrile convulsions in children Autism (with magnesium) Stress Cognitive performance/ Alzheimer's disease Schizophrenia Tardive dyskinesia Parkinson's disease</p>	<p>Hypersensitivity Long-term use of high-dose pyridoxine supplements (&gt;100 mg, although this level varies between individuals) should be used with caution.</p>	<p>Nausea, vomiting, headache, paraesthesias, sleepiness and low serum folic acid levels have been reported. If taken at night, may induce vivid dreams.</p>	<p>Paraesthesia, hyperaesthesia, bone pain, muscle weakness, numbness and fasciculation most marked at the extremities Unsteady gait: numbness of hands and feet, impaired tendon reflexes. Excess doses of B<sub>6</sub> can cause degeneration of the dorsal root ganglia in the spinal cord, loss of myelination and degeneration of sensory fibres in the peripheral nerves. Dose and time frame at which toxicity occurs varies significantly between individuals. Studies involving large populations found minimal or no toxicity with 100–150 mg/day over 5–10 years, whereas women self-medicating for PMS taking 117 ± 92 mg for 2.9 ± 1.9 years have reported increased incidence of peripheral neuropathy.</p>
--	--	----------------------	--	---	--	--

*Continued*

Clinical use and safety of vitamins <i>continued</i>						
Vitamin	Australian and New Zealand RDI for adults (> 18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity
B <sub>12</sub> (cobalamin)	Adult > 13 years: 2.4 mcg/day	0.5–2000 mg/day	Treating deficiency: primary deficiency (vegans and vegetarians, breast-fed infants of vegetarian mothers, elderly patients and alcoholics) Prevention of secondary deficiency (e.g. atrophic gastritis, achlorhydria, pancreatic insufficiency, Crohn's disease, bacterial or parasitic infestations) Pernicious anaemia Hyperhomocysteinaemia (with B <sub>6</sub> and folate) Cardiovascular protection Prevention of NTD Recurrent abortion Depression HIV infection Cognitive impairment Diabetic retinopathy Sleep disorders Tinnitus Multiple sclerosis Motor neuron disease (MND) (amyotrophic lateral sclerosis)	Hypersensitivity Avoid in cases of altered cobalamin metabolism or deficiency associated with chronic cyanide intoxication.	None known	Well-tolerated
Folate	Adults: 400 mcg/day Up to 1 mg/day in deficiency states	1–30 mg/day	Treating deficiency Prevention of secondary deficiency (e.g. malabsorption syndromes such as coeliac and Crohn's disease, HIV infection), MTHFR gene polymorphism Preconception care and pregnancy (prevention of neural tube defects) Hyperhomocysteinaemia Cardiovascular disease protection	Hypersensitivity Use may mask B <sub>12</sub> deficiency by correcting the apparent microcytic anaemia without altering the potential for or progression of neurological damage.	Doses > 5 mg/day: generalised urticaria, nausea, flatulence and bitter taste in the mouth, and some CNS activation in the form of irritability and excitability, altered sleep pattern.	Non-toxic

			<p>Cognitive impairment Anticonvulsant-induced folate deficiency Depression Schizophrenia Reducing incidence of cancer Periodontal disease Vitiligo Topical: periodontal disease</p>	<p>250–12,000 mg/day orally in divided doses More used when administered IV</p>	<p>45 mg</p>	<p>C</p>	<p>Considered non-toxic</p>	<p>None expected if &lt;3000–4000 mg/day, but this varies between individuals Gastrointestinal upset: nausea, diarrhoea, flatulence, distension Hyperoxaluria and renal stones now considered doubtful</p>	<p>Hypersensitivity Increases iron, and decreases copper, absorption Glucose-6-phosphate dehydrogenase deficiency Haemochromatosis Thalassaemia major Sideroblastic anaemia Renal impairment Interacts with numerous laboratory tests (e.g. serum cholesterol and triglycerides and urinary oxalate; refer to monograph)</p>	<p>Treating deficiency Prevention of secondary deficiency (e.g. heavy smokers, achlorhydria, chronic diarrhoea, major surgery) Treating iron deficiency anaemia (with iron) Prevention and treatment of common URTI such as colds and influenza and mild allergic responses Prevention and adjunctive treatment of cardiovascular disease and cancer Management of diabetes and asthma Atopy Prevention of cataracts Male infertility Adjunct for haemodialysis patients Oral and topical forms used for various dermatological conditions (e.g. wound healing, photo-aged skin, prevention of sunburn (with vitamin E)</p>
--	--	--	--	---	--------------	----------	-----------------------------	--	--	---

Clinical use and safety of vitamins <i>continued</i>						
Vitamin	Australian and New Zealand RDI for adults (>18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity
D	Children & adults <50 yrs: 200 IU/day Adults 51–70 yrs: 400 IU/day Adults >70 yrs: 600 IU/day	400–300,000 IU/day	Treating deficiency Inadequate sun exposure or poor dietary intake Prevention of secondary deficiency (e.g. malabsorption states) Hypoparathyroidism (with calcium) Hypophosphataemia (with phosphorus) Prevention of bone fracture and osteoporosis (with calcium) Hepatic and renal osteodystrophy Scleroderma Cancer Diabetes Prevention and treatment of infections Depression Multiple sclerosis Lupus	Hypersensitivity Hypercalcaemia Sarcoidosis Hyperparathyroidism SLE Vitamin D toxicity Pregnancy Lactation Renal failure Use of cardiac glycosides, thiazide diuretics, calcium-channel blockers	Not seen with doses <2400 IU/day Doses >3800 IU: hypercalcaemia, soft tissue calcification Fatigue, headache, nausea, vomiting, metallic taste, abdominal cramps, myalgia, tinnitus, arthralgia, constipation, polyuria, polydipsia	Caution when using high doses regularly. Between 50,000 and 100,000 IU/day: signs of hypercalcaemia 50,000–200,000 IU/day: nausea, vomiting, anorexia, polyuria, muscle pain Calcification of soft tissue and organs, cardiac arrhythmias Toxic levels cannot be obtained from sun exposure.

E	<p>Women: 7 mg alpha-tocopherol Men: 10 mg alpha-tocopherol</p>	<p>50–3200 IU/day</p>	<p>Treating deficiency Prevention of secondary deficiency (e.g. malabsorption syndromes, cystic fibrosis) Prevention of cardiovascular disease, certain cancers, ischaemic stroke in high-risk hypertensive patients, nitrate tolerance Enhancing immune function in the elderly Reducing incidence of common cold Slowing progression of Alzheimer's dementia Improving symptoms in PMS, dysmenorrhoea, menopause, intermittent claudication Reducing pain in OA and RA Cancer Age-related macular degeneration Huntington's disease Treating some forms of male infertility Oral and topical use for many dermatological states Scar tissue Prevention or treatment of many other conditions, such as exercise-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia</p>	<p>Hypersensitivity People with impaired coagulation, inherited bleeding disorders, history of haemorrhagic stroke, vitamin K deficiency or at risk of pulmonary embolism or thrombophlebitis Suspend use of supplements 1–2 weeks before major surgery.</p>	<p>Adverse effects are dose-related and tend to occur only at very high doses (&gt; 1200 IU/day) Side effects include diarrhoea, flatulence, nausea and heart palpitations Increased risk of bleeding if vitamin K deficiency present</p>	<p>Vitamin E is relatively non-toxic. Doses as high as 3200 mg/day have been used for 12 years without signs of toxicity.</p>
---	---	-----------------------	---	--	---	---

Clinical use and safety of minerals <i>continued</i>						
Mineral	Australian and New Zealand RDI for adults (> 18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity
Calcium	Adults: < 70 yrs: 1000 mg/day > 70 yrs: 1300 mg/day	100– 2000 mg/ day	Treating deficiency Prevention of secondary deficiency (e.g. achlorhydria and malabsorption syndromes), more common in elderly Prevention of osteoporosis, pre-eclampsia, maintenance of bone density, colorectal cancer Symptoms of PMS Hypertension and hyperlipidaemia Dyspepsia Weight loss Nephrolithiasis Dry eye	Hypersensitivity Hyperparathyroidism Hypercalcaemia Renal impairment or kidney disease Sarcoidosis or other granulomatous diseases only under medical supervision	Gastrointestinal discomfort, nausea, loss of appetite, constipation, flatulence, metallic taste, muscle weakness	Increased serum calcium level may be associated with hypotonia, depression, lethargy and coma. Prolonged hypercalcaemic state, especially if normal or elevated serum phosphate, can precipitate ectopic calcification of blood vessels, joints, gastric mucosa, cornea and renal tissue.
Chromium	Women: 25 mcg Men: 35 mcg	50– 1000 mcg	Treating deficiency Diabetes Hypoglycaemia Hyperlipidaemia Obesity Atypical depression Polycystic ovary syndrome Syndrome X Exercise aid Prevention of myocardial infarction	Hypersensitivity	Irritability and insomnia have been reported with chromium yeast supplementation. Chromium picolinate is well tolerated.	Chromium IV is used in industry and is highly toxic, whereas Cr III, which is used in supplements, is well tolerated.

Iodine	Adults: 150 mcg/day	0.5–6 mg	Treating deficiency Secondary deficiency (high consumption of goitrogens combined with low iodine intake) Preventing deficiency in high-risk groups including in utero, pregnancy, infancy Prevention of ADHA Fibrocystic breast disease Breast cancer Mastalgia	Hypersensitivity Thyroid conditions	Symptoms of iodine hypersensitivity are fever, painful joints, lymph node enlargement, eosinophilia, urticaria, angio-oedema, cutaneous and mucosal haemorrhage and fatal peri-arteritis.	Chronic iodine toxicity when intake is > 2 mg/day. Symptoms: brassy taste in mouth, burning sensation in mouth and throat, increased salivation, gastric irritation, abdominal pain, nausea, vomiting and diarrhoea Acneiform skin lesions, pulmonary oedema, depression Chronic ingestion > 500 mcg/day by children → increased thyroid size
Iron	Women: 19 to menopause: 18 mg Post-menopause: 8 mg Men: 8 mg	10–100 mg/day	Treating deficiency Prevention of secondary deficiency (e.g. menorrhagia, cystic fibrosis) Unexplained fatigue without anaemia Improving athletic performance Pregnancy Postpartum anaemia Cognitive function ADHD	Hypersensitivity Haemochromatosis Haemosiderosis Iron-loading anaemias (thalassaemia, sideroblastic anaemia) Liquid iron preparations can discolour teeth (brush teeth after use)	Gastrointestinal disturbances such as nausea, diarrhoea, constipation, heartburn, upper gastric discomfort Preliminary evidence indicates iron may be implicated in the pathogenesis of various disease states. Therefore, supplementation is indicated only with demonstrated biological need.	Haemochromatosis can develop from long-term excessive intake Iron toxicity causes severe organ damage and death The most pronounced effects are haemorrhagic necrosis of the gastrointestinal tract and liver damage.

Continued

Clinical use and safety of minerals <i>continued</i>						
Mineral	Australian and New Zealand RDI for adults (> 18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity
Magnesium	Women: 310 mg > 30 yrs: 320 mg Men: 400 mg > 30 yrs 420 mg	200– 1200 mg/ day	Treating deficiency Prevention of secondary deficiency (e.g. inflammatory bowel diseases, diabetes, hyperthyroidism, elevated cortisol) Alleviating symptoms of coronary heart disease, reducing hypertension, reducing plasma lipid levels, reducing incidence of arrhythmias in congestive heart failure Prevention of migraine headache, premenstrual headache, PMS, dysmenorrhoea, osteoporosis ADHD, autism spectrum disorders Kidney stone prevention Asthma Diabetes Dyspepsia Constipation Chronic leg cramps Leg cramps in pregnancy	Hypersensitivity Renal failure and heart block (unless pacemaker present)	<b>Most common</b> Diarrhoea and gastric irritation; usually not seen at doses <350 mg/day (elemental) Doses of inorganic magnesium >350 mg/day may be associated with adverse effects. Dividing doses will maximise bioavailability and reduce side effects. Overuse of magnesium hydroxide or magnesium sulfate may cause deficiencies of other minerals or lead to toxicity. <b>Other side effects</b> Decreased heart rate, hypotension, muscle weakness	Most commonly seen in patients with renal insufficiency. Symptoms: muscle weakness, sedation, ECG changes, confusion, hypotension
Selenium	Women: 60 mcg Men: 70 mcg	80– 200 mcg/day	Treating deficiency Prevention of secondary deficiency (e.g. cirrhosis, malabsorption syndromes, cystic fibrosis, coeliac disease, HIV infection) Reducing total cancer incidence and mortality (especially lung, colorectal and prostate cancers), adjunctive treatment HIV infection Cardiovascular disease Autoimmune thyroiditis Diabetes	Hypersensitivity NHMRC upper level of intake is 400 mcg/day	Nausea, vomiting, nail changes, irritability, fatigue Organic form of selenium found in high-selenium yeast is less toxic and safer than other forms.	Long-term use of excessive doses (> 1000 mcg/day) can produce fatigue, depression, arthritis, hair or fingernail loss, garlicky breath or body odour, gastrointestinal disorders and irritability.

Zinc	Women: 8 mg/day Men: 14 mg/day	25–200 mg/day	Symptoms of RA, asthma Male infertility Immune enhancement Anxiety and depression Reducing morbidity in preterm infants	Hypersensitivity	Mild gastrointestinal upset at doses of 50–150 mg/day	Single doses of 225–450 mg usually induce vomiting Nausea, vomiting, diarrhoea, fever and lethargy have been observed after ingestion of 4–8 g. Doses ranging from 100 to 150 mg/day interfere with copper metabolism and cause hypocupraemia, red blood cell microcytosis and neutropenia if used long term.
------	-----------------------------------	---------------	---	------------------	---	---

**NOTE**

*Multivitamins.* Overall, acute toxicity is unlikely with combination vitamin supplements unless huge amounts have been ingested. In the case of toxicity or side-effects, signs and symptoms will relate to the individual nutrient ingested. In general, gastrointestinal symptoms such as discomfort, nausea and diarrhoea are the most frequent adverse effects.

*Special care.* Of all the nutrients listed, extra special care must be taken when supplementing with vitamins A and D and the mineral iron. The forms of selenium and niacin used in practice also have a major influence on their safety profile and should be taken into consideration.

*RDI.* For more details regarding RDI for specific age groups: [www.nhmrc.gov.au/publications/synopses/n35syn.htm](http://www.nhmrc.gov.au/publications/synopses/n35syn.htm)  
For further information, refer to individual monographs.
