Macrophage-mediated oxidation of LDL cholesterol plays a major role in early atherogenesis. In animal models, glabridin accumulates in macrophages and inhibits macrophage-mediated oxidation of LDL by up to 80% (Aviram 2004). DGL (100 mg/day for 2 weeks) was found to reduce lipid peroxidation of LDL cholesterol after 1 week's use, according to a placebo-controlled trial (Fuhrman et al 1997).

### Lipid-lowering

Dietary licorice flavonoid oil (2% in feed over 21 days) significantly decreased hepatic total cholesterol levels, as well as plasma VLDL and LDL cholesterol compared to control in rats fed a high-fat diet (Honda et al 2013). Through mRNA analysis, it was found that this effect was likely to be mediated in part through significant up-regulation of the LDL receptor and LXRα, decreased HMG-CoA synthase and increased cholesterol metabolism via up-regulated CYP7A1.

Administration of licorice root powder (5 and 10 g in diet) to hypercholesterolaemic male albino rats for 4 weeks resulted in a 'significant reduction in plasma, hepatic total lipids, cholesterol, triglycerides and plasma low-density lipoprotein and VLDL cholesterol accompanied by significant increases in HDL cholesterol levels' (Visavadiya & Narasimhacharya 2006). These effects may have been due

in part to increases in faecal cholesterol, neutral sterols and bile acid excretion and an increase in hepatic 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase activity and bile acid production. Additionally, decreased hepatic lipid peroxidation with a concomitant increase in superoxide dismutase (SOD) and catalase activities and total ascorbic acid content were noted. In normocholesterolaemic rats, the higher dose also led to a significant reduction in plasma lipid profiles and an increase in HDL cholesterol content (Visavadiya & Narasimhacharya 2006).

### Anticancer effects

Licorice has demonstrated potent anti-angiogenic and antitumour activity in animal studies (Sheela et al 2006). Animal and in vitro studies have shown licorice components to be effective in reducing the occurrence and number of tumour cells in several cancer models (Shibata 1994, Wang & Mukhtar 1994, Wang & Nixon 2001, Wang K et al 2013, Wang et al 2014). The induction of apoptosis is frequently cited as a mechanism of cytotoxicity, although induction of caspase-dependent autophagy has also been implicated (Yo et al 2009). Licorice components have also been found to potentiate the effect of paclitaxel and vinblastine chemotherapy (Rafi et al 2000).

In vitro research reveals that chalcone and isoliquiritigenin significantly inhibit the proliferation of prostate cancer cell lines in a dose- and time-dependent manner and that beta-hydroxy-DHP inhibits breast and prostate tumour cells (Kanazawa et al 2003, Maggolini et al 2002, Rafi et al 2002). Isoangustone A inhibited the growth of prostate cancer cells (5–20 microM) and xenograft tumour growth in mice (1–5 mg/kg), which was associated with G1 arrest, and inhibition of CDK2 and mTOR activity (Lee et al 2013).

In human epithelial carcinoma cell lines, 18 $\beta$ GA was found to potentiate trichostatin A-induced apoptosis and cell death, whereas GL had no effect on cell death or apoptotic activity (Lee et al 2010). Isoliquiritigenin has also been shown to significantly inhibit the proliferation of lung and colon cancer cells, restrain cell cycle progression and induce apoptosis (Chin et al 2007, Li et al 2004, Takahashi et al 2004). Isoliquiritigenin reduced expression and secretion of vascular endothelial growth factor and inhibited migratory activity of metastatic breast cancer cells in vitro (Wang K et al 2013). Conversely, in a rat model of mammary tumorigenesis, isoliquiritigenin had no effect on the incidence of mammary tumours (Cuendet et al 2010).

Although the exact mechanism of action is still being determined, a 2001 review indicates that licorice and its derivatives may protect against carcinogen-induced DNA damage and that GA is an inhibitor of lipo-oxygenase and cyclo-oxygenase, inhibits protein kinase C and down-regulates the epidermal growth factor receptor (Wang & Nixon 2001).

### Anti-diabetic

In an animal model of streptozotocin-induced diabetes, glabridin (10, 20 and 40 mg/kg) daily for 28 days significantly reduced fasting blood glucose levels and glucose tolerance compared to diabetic control mice. Glabridin treatment was also associated with significant increases in SOD activity and reduced MDA contents in the liver, kidneys and pancreas (Wu et al 2013).

### Cognitive function

*Glycyrrhiza glabra* has shown promise as a memory-enhancing agent in both exteroceptive and interoceptive behavioural models of memory in mice. The effect is possibly due to facilitation of cholinergic transmission in the mouse brain (Dhingra et al 2004, Parle et al 2004).

In animal models, glabridin appears to reduce brain cholinesterase activity in mice (Cui et al 2008). Glabridin administration (25 mg/kg and 50 mg/kg) also improved memory and learning in control rats, and reversed induced memory and learning deficits in diabetic rats (Hasanein 2011). In rats, significant spatial memory retention enhancement has also been observed after 4 weeks of licorice administration (aqueous extract equivalent to 5 mg/mL of GL) in drinking water (Sharifzadeh et al 2008).

### Neuroprotective

In a model of experimentally-induced ischaemic brain damage, oral GL (30 mg/kg) was shown to improve neurological scores and motor activity as well as attenuate ischaemia-induced learning and memory deficits compared to control ischaemic mice (Barakat et al 2014). GL has also been shown to reduce the development of inflammation and tissue injury associated with spinal cord trauma in mice, resulting in improved recovery of limb function (Genovese et al 2008). Neuroprotective effects in post-ischaemic rat brain following middle cerebral artery occlusion (MCAO) have also been found with GL, with improvements in motor function and neurological deficit, and reduced microglial activation (Kim et al 2012).

Several other constituents have also demonstrated possible neuroprotective effects. Glabridin (25 mg/kg by intraperitoneal injection) was able to modulate the cerebral injuries induced by MCAO in rats. The neuroprotective effect appeared to be at least in part associated with the modulation of multiple pathways associated with apoptosis (Yu et al 2008). In addition, pretreatment with isoliquiritigenin (5, 10 and 20 mg/kg, IG) significantly reduced cerebral infarct volume and oedema, and produced a significant reduction in neurological deficits due to MCAO-induced focal cerebral ischaemia-reperfusion injury in rats (Zhan & Yang 2006).

In vitro, isoliquiritigenin was shown to protect dopaminergic neurons from 6-hydroxydopamine-induced toxicity, which corresponded with suppression

of reactive oxygen species, nitric oxide production and mediators of intrinsic apoptosis (Hwang et al 2012).

### Antidepressant (serotonin reuptake inhibition)

Several flavonoid constituents in licorice (glabridin 60%, 4'-O-methylglabridin 53% and glabrene 47%) inhibit serotonin reuptake in a dose-dependent manner, according to in vitro research (Ofir et al 2003). However, animal models suggest that the effect may be on noradrenaline and dopamine. In rats, licorice extract (150 mg/kg) administered orally for 7 days exerted an antidepressant effect comparable to that of imipramine (15 mg/kg IP) and fluoxetine (20 mg/kg IP); the effect, however, appeared to be mediated by an increase of brain noradrenaline and dopamine, not serotonin. It is likely that licorice exerts a monoamine oxidase inhibiting effect (Dhingra & Sharma 2006).

### Sedative

Licorice extract and glabrol have been shown to dose-dependently potentiate pentobarbitone-induced sleep in mice through positive allosteric modulation of GABA<sub>A</sub>-benzodiazepine receptors (Cho et al 2012). In particular, the flavonoid glabrol was found to increase sleep duration and decrease sleep latency in a dose-dependent manner.

### Hepatoprotective effects

RCTs have confirmed that GL and its derivatives reduce hepatocellular damage in chronic hepatitis B and C and reduce cirrhosis and hepatocellular carcinoma risk in hepatitis C (Fiore et al 2008). Animal studies demonstrate that licorice protects hepatocytes by inhibiting experimentally-induced lipid peroxidation (Rajesh & Latha 2004). Licorice water extract reduced enzymatic and histopathological changes associated with cadmium-induced hepatotoxicity in rats (Lee et al 2009). GL appears to alleviate carbon tetrachloride-induced liver injury by inducing haem oxygenase-1 and down-regulating pro-inflammatory mediators (tissue necrosis factor (TNF)-alpha, inducible nitric oxide synthase and cyclo-oxygenase-2 mRNA expression) (Lee et al 2007). Similarly, glycyrrhetic acid attenuated TNF- $\alpha$ -induced NF- $\kappa$ B activity, and reduced expression of iNOS and production of nitric oxide in rat primary hepatocytes (Chen et al 2014). In vitro studies have shown hepatoprotective effects of GL against aflatoxin B<sub>1</sub>-induced cytotoxicity in human hepatoma cells (Chan et al 2003), and animal studies have shown GA exerts hepatoprotective effects against carbon tetrachloride-induced liver injury (Jeong et al 2002).

Several mechanisms appear to be responsible for the hepatoprotective effect. Glycyrrhizic acid enhances the detoxifying activity of the liver enzyme CYP1A1 and glutathione S-transferase and protects against oxidative stress, when induced by aflatoxin (Chan et al 2003). GA has also been found to prevent intracellular GSH depletion and inhibit

mitochondrial membrane depolarisation in t-BHP-induced model of hepatocyte damage in vitro (Tripathi et al 2009).

Animal studies have found that GA inhibits expression of the liver enzyme CYP2E1. Once again, antioxidant mechanisms appear to be involved, as GA prevented glutathione depletion, an increase in ALT, AST activity, and hepatic lipid peroxidation in a dose-dependent manner when carbon tetrachloride exposure occurred (Jeong et al 2002). In addition, isoliquiritigenin may stimulate the proliferation of human hepatocytes according to in vitro studies (De Bartolo et al 2005).

### Cardioprotective

An in vitro study has shown that both glycyrrhizin and glycyrrhetic acid directly affect cardiac performance, although in opposing manners (Parisella et al 2012). Glycyrrhizin was found to induce significant positive inotropic and lusitropic effects, while glycyrrhetic acid negatively affected both parameters. Both GL and GA increased heart rate.

Dehydroglyasperin C has been shown to have significant preventive effects against markers of cardiovascular disease in vitro, including reduction in platelet-derived growth factor-induced cell number, inhibition of cell migration, and inhibition of actin filament dissociation (Kim HJ et al 2013) and significantly decreased PDGF-induced cell number and DNA synthesis in a dose-dependent manner without any cytotoxicity.

In vivo, *Glycyrrhiza glabra* extract was found to significantly prevent the depletion of myocyte antioxidant enzymes, prevented glutathione depletion and inhibited lipid peroxidation within the rat heart following ischaemia-reperfusion injury (Ojha et al 2013). Significant restoration of mean arterial pressure, heart rate and left ventricular end diastolic pressure were also observed.

In mice treated with doxorubicin (20 mg/kg IP), *Glycyrrhiza uralensis* extract was found to protect against doxorubicin-induced cardiotoxicity, as indicated through improved tissue morphology, increased glutathione and glutathione peroxidase levels and reduced lactate dehydrogenase and creatine kinase (Zhang et al 2011). While this is promising, the authors did not acknowledge possible additive toxicity with respect to adverse cardiac effects associated with licorice, including hypertension and hypokalaemia-related events, or that doxorubicin is a CYP3A4 substrate, thus its metabolism may be affected by licorice intake.

### Bone health

In vitro studies suggest the potential for glabridin to enhance osteoblast function (Choi 2005). As a result, glabridin has been proposed as a possible therapeutic aid in the prevention of osteoporosis and inflammatory bone diseases (Choi 2005), as well as cardiovascular diseases and bone disorders in postmenopausal women (Somjen et al 2004a, 2004b). Isoliquiritigenin was found to dose-dependently

inhibit RANKL-induced osteoclast formation in vitro and prevent inflammatory bone loss in mice through attenuation of osteoclast activity (Zhu et al 2012). Similarly, formononetin has been shown to enhance bone mechanical properties and bone mineral content in vivo, suggesting it too may be of benefit in osteoporosis (Kaczmarczyk-Sedlak et al 2013).

### Antiplatelet effect

Isoliquiritigenin purified from licorice has been shown to inhibit platelet aggregation in vitro and in vivo (Francischetti et al 1997, Kimura et al 1993, Tawata et al 1992). Whether the effect is clinically significant for licorice remains to be determined. Newer data indicate that GL is an effective thrombin inhibitor in vivo (Mendes-Silva et al 2003).

### Anticoagulation effect

Several components of licorice have been identified in vitro as having anti-coagulant activity. Following a 90-day oral toxicity study in rats, licorice flavonoid oil was found to prolong prothrombin time (PT) and activated partial thromboplastin time (APTT) at high doses (from 400 mg/kg) through reduction of vitamin K-dependent coagulation factors (Nakagawa et al 2008). GL has been shown to act as a direct inhibitor of factor XA, both in vitro and in vivo (Jiang et al 2014).

Isolated compounds licoricone, isotrifoliol, glycyrrhiza-isoflavone B from *Glycyrrhiza uralensis* Fisher have also been found to have significant anti-thrombotic effects (Tao et al 2012).

## OTHER ACTIONS

### Sex hormones

#### Testosterone

Whether licorice consumption affects testosterone levels is still unknown, as conflicting results have been obtained from clinical studies. Armanini et al (1999, 2003a) have conducted a series of trials investigating the effects of licorice on testosterone levels in males with mixed results.

One study showed that licorice (7 g/day equivalent to 0.5 g GA) was able to reversibly reduce testosterone levels within 7 days, by inhibiting 17,20-lyase (involved in the conversion of 17-hydroxyprogesterone to androstenedione) and 17-beta-hydroxysteroid dehydrogenase (involved in the conversion of androstenedione to testosterone) (Armanini et al 1999). Another study twice attempted to replicate these results but was unable to detect an effect on testosterone levels in either study. The authors suggest that inappropriate use of statistical tests in the first study may explain the varying results (Josephs et al 2001).

Anti-androgenic effects of licorice root extract (150–300 mg/kg/day) were examined in male rats, with rats found to have a significantly reduced prostate weight, total testosterone and ventral prostate/stroma ratio after 7 days treatment (Zamansoltani

et al 2009). There are limited studies that identify anti-androgenic effects of licorice outside of testosterone levels, therefore further studies are recommended to better elucidate these effects, and any clinical implications they may have.

More clinically promising are the results from a small trial of nine healthy women (22–26 years) in the luteal phase of their menstrual cycle. The women received 3.5 g licorice (containing 7.6% w/w of GL) daily for two cycles. Total serum testosterone decreased from 27.8 ( $\pm$  8.2) to 19.0 ( $\pm$  9.4) ng/dL in the first month and to 17 ( $\pm$  6.4) ng/dL in the second month of therapy (Armanini et al 2004). Further larger scale trials are required to confirm these effects in women with conditions of elevated testosterone such as hirsutism and polycystic ovary syndrome (PCOS).

### Oestrogen

The oestrogenic activity of different *Glycyrrhiza* species varies, with activity decreasing in the order *G. uralensis* > *G. inflata* > *G. glabra* (Hajirahimkhan et al 2013). Licorice contains isoflavones, including licochalcone A, which are also known as 'phyto-oestrogens' because they act as partial oestrogen agonists in the body (Setchell & Cassidy 1999). Additionally, in vitro studies suggest that stimulation of aromatase activity promotes oestradiol synthesis (Takeuchi et al 1991).

Liquiritigenin and isoliquiritigenin have displayed oestrogenic affinity to sex hormone-binding globulin and oestrogen receptors in vitro (Hillems et al 2005) and glabridin and glabrene have both demonstrated oestrogen-like activities similar to 17 $\beta$ -oestradiol in animal studies (Somjen et al 2004a). In vitro, glabrene-rich fractions of licorice root extract only exhibited agonistic responses, preferentially towards oestrogen receptor- $\alpha$  however glabridin (6 microM) was found to reduce the oestrogenic response of 17 $\beta$ -oestradiol by approximately 80% (Simons et al 2011).

### Anti-obesity

Glabridin has been shown to inhibit adipogenesis mouse fibroblast cells in vitro (Ahn et al 2013). This same study also found that a glabridin-rich supercritical fluid extract (SFE) of licorice (*Glycyrrhiza glabra* Linne) also showed a dose-dependent inhibitory effect on adipogenesis through inhibition of C/EBP- $\alpha$  and PPAR- $\alpha$ . When administered to rats fed a high-fat diet over 8 weeks, SFE significantly reduced weight gain, fat cell size and hypertrophy of white adipose tissue compared to untreated rats fed high-fat diets, suggesting a possible benefit of glabridin and glabridin-rich licorice extracts in reducing obesity.

Flavonoids isolated from *G. glabra* roots (isoliquiritigenin, 3,3',4,4'-tetrahydroxy-2-methoxychalcone, licuroside, isoliquiritoside) showed strong inhibition of pancreatic lipase in vitro, with isoliquiritigenin shown to bind to amino acid residues within the enzyme active site (Birari et al

2011). Within the same study, rats fed a high-fat diet who received isoliquiritigenin and licuroside gained significantly less weight ( $23.2 \pm 3.6$  g and  $28.2 \pm 1.6$  g respectively) compared to control high-fat diet rats ( $64.2 \pm 0.5$  g).

### Immunomodulation

Although immunostimulating effects have been observed in experimental models (Lin et al 1996), elevated cortisol levels, which are also induced by licorice, may theoretically reduce this effect (Padgett & Glaser 2003).

### Inhibition of aldolase reductase

In vitro studies show that licorice may suppress sorbitol accumulation in red blood cells by inhibiting aldolase reductase (Zhou & Zhang 1990). The isoliquiritigenin component appears to be responsible (Aida et al 1990a). This may have positive implications in diabetes.

### Antispasmodic

Isoliquiritigenin was found to exhibit concentration-dependent inhibition of spontaneous and pharmacologically-induced uterine contraction in the isolated rat uterus (Shi et al 2012). This relaxation was thought to be mediation through calcium channels, nitric oxide synthase and cyclooxygenase.

### Protection against cisplatin-induced toxicities

In vivo, oral GA treatment (75 mg/kg and 150 mg/kg daily) for 7 days prior to cisplatin exposure (7 mg/kg IP) attenuated the induction of oxidative stress, including lipid peroxidation, hydrogen peroxide generation and glutathione depletion (Arjmand & Sultana 2011). Additionally, the restoration of normal kidney histology and dose-dependent reductions in DNS fragmentation and nephrotoxic markers, BUN, creatine and lactate dehydrogenase were observed, suggesting GA may play a role in protecting against cisplatin-induced nephrotoxicity and genotoxicity.

### Cytochromes and P-glycoprotein

Several licorice components have been identified as possible cytochrome P450 modulators, including liquiritigenin, isoliquiritigenin, glycycomarin, semilicoisoflavone B, licoisoflavone A, licoricone, glycyrol, licoflavonol and licoisoflavone B (Qiao et al 2014). Licorice inhibits CYP3A4 in vitro (Budzinski et al 2000), the glabridin constituent inhibits CYP2B6, 2C9 and 3A4 in vitro (Kent et al 2002), GA inhibits expression of CYP2E1 in animal studies (Jeong et al 2002) and GL enhances the detoxifying activity of CYP1A1 (Chan et al 2003).

## CLINICAL USE

### Peptic ulcer and dyspepsia

The anti-inflammatory, mucoprotective and anti-ulcer activities of licorice make it an attractive

treatment for peptic ulcer. While these effects have been attributed to the GL and GA constituents, the DGL, which contains < 3% GL, has also been investigated and appears to produce the most promising results when used long term (Bardhan et al 1978, Larkworthy & Holgate 1975). DGL also promotes differentiation of undifferentiated cells to mucous cells and stimulates mucus production and secretion (van Marle et al 1981).

A placebo-controlled RCT ( $n = 100$ ) determined that GutGard (root extract of *Glycyrrhiza glabra*) significantly decreased *Helicobacter pylori* load compared to placebo as assessed through  $^{13}\text{C}$ -urea breath test and *H. pylori* stool antigen test (Puram et al 2013). Due to genetic differences in *H. pylori* strains, it is recommended that a similar trial be repeated at multiple centres and compared against gold standard treatment to help clarify any clinical benefit.

In an uncontrolled trial of 32 patients with chronic duodenal ulcer, 3800 mg/day of DGL (in five divided doses) produced signs of healing in all cases and total restoration of mucosa in a majority of subjects. Although treatment continued for 24 weeks, considerable improvement was seen in 56% of patients by week 12 and in 78% by week 16 (Larkworthy & Holgate 1975). A shorter 4-week trial of 96 patients with gastric ulcer failed to produce the same positive results (Bardhan et al 1978).

DGL plus antacid (Caved-S; two tablets chewed three times daily between meals) was as effective as cimetidine (200 mg three times daily plus 400 mg at night) after 6 weeks, according to one randomised single-blind trial of 100 volunteers with peptic ulcer. The two treatments continued to produce similar results after 12 weeks and recurrence rates after both medications were reduced were also similar (Morgan et al 1982).

Commission E approves the use of licorice for the treatment of gastric and duodenal ulcers (Blumenthal et al 2000).

### Dermatitis

The anti-inflammatory effect induced by GA provides a theoretical basis for its use as a topical anti-inflammatory agent (much like hydrocortisone) in the treatment of dermatitis.

In practice, GA has been used to potentiate the effects of weak steroids (such as hydrocortisone) in order to increase pharmacological effects without the need for stronger corticosteroids (Teelucksingh et al 1990). It is assumed that increasing corticosteroid activity in this way will not attract an increase in adverse effects; however, no studies have yet confirmed this.

An early study comparing the effects of hydrocortisone- and GA-containing ointments in dermatitis found that hydrocortisone was usually superior in acute and infantile eczemas, whereas GA was superior for chronic and subacute conditions (Evans 1958).

It should be noted that GA is a many times more powerful inhibitor of 11HSD than GL and therefore should theoretically induce far stronger anti-inflammatory effects. GA is not present in licorice but is produced in the gastrointestinal tract from GL; therefore, it is uncertain whether topical preparations containing pure licorice are likely to produce significant anti-inflammatory effects.

### Allergic conditions

The anti-allergic effects of licorice (Ram et al 2006, Shin et al 2007) provide a theoretical basis for the treatment of allergic conditions such as asthma and dermatitis; however, further research is required.

### Viral infections

In human trials, GL and its derivatives reduce the liver sequelae associated with hepatitis B and C viruses; animal studies demonstrate a reduction in viral activity for herpes simplex virus, encephalitis and influenza A virus pneumonia; and in vitro studies reveal antiviral activity against HIV-1, SARS-related coronavirus, respiratory syncytial virus, arboviruses, vaccinia virus and vesicular stomatitis virus (Fiore et al 2008). However, until controlled studies are available, the clinical effectiveness of this treatment remains unknown.

### Respiratory tract infections

Licorice increases mucus production within the respiratory tract and exerts an expectorant (Bradley 1992) and antitussive effect (Kamei et al 2005). When combined with its anti-inflammatory, antiviral and possible immune-enhancing effects, it is a popular treatment for upper and lower respiratory tract infections. In practice, it is often used to treat coughs (especially productive types) and bronchitis (Bradley 1992).

Commission E approves the use of licorice for catarrhs of the upper respiratory tract (Blumenthal et al 2000).

### Chronic stress

Traditionally, licorice is viewed as an 'adrenal tonic', most likely due to its ability to slow cortisol breakdown. It may be of benefit in patients experiencing allostatic load due to chronic stress and who are therefore unable to mount a healthy stress response. This is also known as adrenocorticoid insufficiency. Controlled trials are not available to determine its effectiveness in this situation.

Whether this effect is desirable in patients without adrenocorticoid insufficiency and for whom increased cortisol levels may prove problematic is open to conjecture. Chronically high cortisol levels have been associated with desensitisation of the hypothalamic-pituitary-adrenal (HPA) axis, insulin resistance, depression and immunosuppression (Blackburn-Munroe 2001, Jessop 1999, Mitchell & Mitchell 2003). In the initial stages of stress, increased cortisol levels trigger negative feedback mechanisms to keep stress under control and, therefore,

short-term use may be warranted but is unlikely to be beneficial unless some adrenocorticoid insufficiency exists.

(For more information see 'Clinical note — Allotaxis' in the Siberian ginseng monograph.)

### OTHER USES

Licorice has also been used traditionally as a sweetener and aromatic flavouring agent.

Although controlled trials are lacking, licorice is also used for a number of other conditions, largely based on evidence of pharmacological activity.

### Chronic fatigue syndrome

The ability of licorice to slow cortisol catabolism may provide a theoretical basis for its use in cases of chronic fatigue syndrome (CFS) accompanied by low cortisol levels. A case report exists of a patient experiencing improved physical and mental stamina and recovery from CFS following use of licorice dissolved in milk (2.5 g/500 mL/day) (Baschetti 1995, 1996).

### Polycystic ovary disease

The possibility that licorice may lower testosterone levels in women provides a theoretical basis for its use in PCOS (Armanini et al 2004). While trials using licorice as a stand-alone treatment are lacking, studies of licorice in combination with other herbal medicines such as peony have produced promising results, showing reductions in LH:FSH ratio, ovarian testosterone production and improvements in ovulation (Takahashi & Kitao 1994, Takahashi et al 1988).

### Preventing diabetic complications

In diabetic patients with neuropathy, retinopathy or nephropathy, sorbitol:glucose ratios are significantly higher than in those without these complications and ratios increase as complications become more severe (Aida et al 1990b). As licorice and its component isoliquiritigenin have been shown to inhibit aldolase reductase and suppress sorbitol accumulation in red blood cells in vitro (Aida et al 1990b, Zhou & Zhang 1990), a theoretical basis exists for its use in the prevention of diabetic complications.

### Menopause

Inhibition of serotonin reuptake and possible oestrogenic activity provide a theoretical basis for its use in pre- and postmenopausal women with mild to moderate depression (Ofir et al 2003, Takeuchi et al 1991).

Constituents in licorice may bind to oestrogen receptors, enhance osteoblast function and attenuate vascular injury and atherosclerosis (Choi 2005, Somjen et al 2004a, 2004b) suggesting a possible role in the prevention of bone disorders and cardiovascular diseases in postmenopausal women.

A pilot study found that administration of 330 mg licorice three times a day for 8 weeks reduced both severity and frequency of hot flushes in

postmenopausal women (Nahidi et al 2012). Studies with appropriate power and more thorough end-point evaluations are recommended to better understand this preliminary finding.

### Weight loss

The action of GA in blocking 11HSD type 1 at the level of fat cells may help to explain preliminary evidence suggesting an ability to reduce body fat mass and the thickness of thigh fat (Armanini et al 2003b, 2005). In vitro evidence suggests 18 $\beta$ -GA may also alter fat mass through direct effects on adipogenesis in maturing adipocytes and through lipolysis in mature adipocytes (Moon et al 2012).

An RCT of 84 participants found that in moderately overweight patients, 900 mg/day licorice flavonoid oil significantly decreased body weight, BMI, visceral fat area and LDL-cholesterol compared to placebo after 8 weeks (Tominaga et al 2009). Conversely, a small study investigating the effects of 300 mg/day licorice flavonoid oil supplementation over 8 weeks on body weight and body fat in both overweight/obese subjects ( $n = 22$ ) and in athletic subjects ( $n = 23$ ) found no significant effects on either parameter, suggesting the higher dose may be required for significant effects (Bell et al 2011). Further well-designed trials with appropriate power are recommended to clarify these findings.

### Addison's disease

The ability of licorice to reduce cortisol breakdown provides a theoretical basis for its use in Addison's disease, either as a stand-alone treatment, when adrenocortical function is not severely impaired, or as an adjunct to cortisone therapy. While studies in the 1950s confirm this use (Borst et al 1953, Calvert 1954, Pelser et al 1953), recent studies are limited. In patients with Addison's disease ( $n = 17$ ) on stable cortisone replacement therapy, a 3-day treatment of licorice significantly increased serum cortisol levels, with significant increase noticed within 3 hours of licorice ingestion (Methlie et al 2011). Based upon urinary cortisol excretion and the observed cortisol/cortisone ratio, this finding was attributed to licorice inhibiting 11 $\beta$ -HSD. A case report exists of an 11-year-old boy with hypoparathyroidism and Addison's disease developing hypermineralocorticoidism following excessive intake of licorice (300–400 g/day, equivalent to 600–800 mg GL) concurrently with hydrocortisone and 9-alpha-fluorocortisol. Pseudohyperaldosteronism persisted after treatment with 9-alpha-fluorocortisol was withdrawn and hydrocortisone was reduced; however, symptoms only diminished after the complete withdrawal of licorice. Similarly, it was also suggested that inhibition of 11HSD by licorice was responsible due to increased levels of free cortisol (Doeker & Andler 1999).

### Hypercholesterolaemia

Preliminary studies in rats suggest a possible role for licorice root powder in the treatment of

hypercholesterolaemia; however, clinical trials in humans need to be conducted to investigate this effect (Visavadiya & Narasimhacharya 2006).

### Depression

Licorice extract (150 mg/kg) appears to exert a monoamine oxidase-inhibiting effect in rats, increasing brain noradrenaline and dopamine, and resulting in an antidepressant effect comparable to that of imipramine (15 mg/kg IP) and fluoxetine (20 mg/kg IP) (Dhingra & Sharma 2006). Whether the effects are clinically significant remains to be tested.

### Hyperkalaemia

A 6-month prospective, double-blind, placebo-controlled crossover study ( $n = 10$ ) found that patients supplemented with GA had increased cortisol/cortisone ratio in plasma, had lowered serum potassium relative to baseline and experienced less frequent episodes of severe hyperkalaemia (Farese et al 2009).

The use of GA or licorice may be of benefit in dialysis patients at risk of hyperkalaemia and associated sequelae (Ferrari 2009). It is recommended that the chronic toxicity of GA be further evaluated prior to any clinical implementation of this treatment.

### DOSAGE RANGE

- Fluid extract (1:1): 2–4 mL three times daily or 15–40 mL/week (Australian manufacturer recommendations).
- Root: 5–15 g/day (equivalent to 200–600 mg of GL).
- Tea: pour 150 mL boiling water over one teaspoon (2–4 g) licorice root, simmer for 5 minutes and filter through a tea strainer after cooling.
- Chronic gastritis: one cup of licorice tea after each meal.

### According to clinical studies

- Chronic duodenal ulcers: 3800 mg/day of DGL (in five divided doses) before meals and at bedtime.
- Ideally, licorice extracts should contain > 30 mg/mL GL.

### ADVERSE REACTIONS

Many of the adverse effects attributed to licorice are due to GA at doses above 100–400 mg/day. For this reason, the DGL may be safer and more appropriate in cases where GL or GA is not required for efficacy.

Side effects may be more pronounced in people with essential hypertension who appear to be more sensitive to the inhibition of 11HSD by licorice than normotensive subjects (Sigurjonsdottir et al 2003).

- Hypercortisolism and pseudohyperaldosteronism — associated with sodium retention, potassium loss and suppression of the renin-angiotensin-aldosterone system and presenting as hypertension, fluid retention, breathlessness, hypernatraemia and

- hypokalaemia (Blachley & Knochel 1980, Dellow et al 1999, Kageyama et al 1997, Robles et al 2013, Ruiz-Granados et al 2012, Wash & Bernard 1975). A case of carpal tunnel syndrome following licorice-induced fluid retention has been reported (Tacconi et al 2009).
- Hypokalaemia — may present as hypotonia and flaccid paralysis, peripheral oedema, polyuria, proximal myopathy, lethargy, paraesthesiae, muscle cramps, headaches, tetany, breathlessness and/or hypertension (deKlerk et al 1997, Eriksson et al 1999). In practice, licorice is often mixed with the potassium-rich herb dandelion leaf, which also has mild diuretic effects.
  - Hypokalaemic arrhythmia — rare cases of ventricular arrhythmia associated with licorice-induced hypokalaemia have been reported (Crean et al 2009, Kormann et al 2012, Yorgun et al 2010). One case of recurrent torsade de pointes associated with severe hypokalaemia has been described (Panduranga & Al-Rawahi 2013).
  - Hypokalaemic paralysis — although rare, some cases have been reported as a result of chronic licorice use (Corsi et al 1983, Lin et al 2003, Shintani et al 1992, Templin et al 2009, van-den-Bosch et al 2005). A case report of a young female presenting with acute onset quadriplegia secondary to severe hypokalaemia has been attributed to a polyherbal preparation containing licorice (Mukherjee et al 2006).
  - Rhabdomyolysis — a number of cases are reported in the scientific literature (Firenzuoli & Gori 2002, Shah et al 2012, Templin et al 2009, van-den-Bosch et al 2005) as a result of severe hypokalaemia.
  - Thrombocytopenia — a case report of licorice-induced thrombocytopenia associated with hypokalaemia and oedema has been described. Following cessation of licorice, blood count returned to normal (Celik et al 2012).
  - Dropped head syndrome — a case report exists of dropped head syndrome (isolated weakness of the extensor muscles of the neck) due to licorice-induced hypokalaemia (Yoshida & Takayama 2003).
  - Hypertension encephalopathy — some cases associated with excessive licorice intake have been reported (Morgan et al 2011, van Beers et al 2011). This may occur even at low doses in susceptible patients with 11-beta-HSD deficiency (Russo et al 2000).
  - Increased sodium retention — reduced 11-beta-HSD activity may play a role in increased sodium retention in preeclampsia, renal disease and liver cirrhosis. Reduced placental levels may explain the link between reduced birth weight and adult hypertension (the Barker hypothesis) (Quinkler & Stewart 2003).
  - Juvenile hypertension — inhibition of 11HSD may also contribute to a rare form of juvenile hypertension (Chamberlain & Abolnik 1997, White et al 1997).

- Visual disturbance — ingestion of high doses of licorice (110–900 g) has been reported to elicit symptoms of visual disturbance in a case series of five patients. This may be attributed to the possible ability of licorice to 'stimulate retinal and occipital vasospasm and vasospasm of vessels supplying the optic nerve' (Dobbins & Saul 2000).
- Contact dermatitis — case reports of localised skin irritation with licorice-containing products have been reported, with patch testing confirming licorice as the causative irritant (Matsunaga et al 1995, Nishioka & Seguchi 1999, O'Connell et al 2008).

## SIGNIFICANT INTERACTIONS

Controlled trials exist that have identified drug interactions. However, in most cases, the interactions are based on evidence of pharmacological activity, case reports or theoretical reasoning. The DGL form is considered safer and less likely to result in drug interactions.

Glabridin is a substrate of P-glycoprotein (P-gp/MDR1) (Cao et al 2007); therefore, potential drug-glabridin interactions need to be considered until more clinical data are available (Yu et al 2007).

### Acetylsalicylic acid and other gastro-irritant anti-inflammatory drugs

Co-administration with licorice may reduce gastro-irritant effects induced by drug therapy — potentially beneficial interaction (Tawata et al 1992). Whether the effect is clinically significant for licorice remains to be determined — use high doses with caution.

### Anticoagulants / antiplatelets

Licorice has been documented as having an anticoagulant effect, therefore high quantities should be avoided in patients taking any form of blood-thinning medication (Tsai et al 2013).

### Antihypertensives

High-dose GL taken long term can lead to increased blood pressure, thereby reducing drug efficacy. Caution — monitor blood pressure when high-dose licorice preparations are taken for longer than 2 weeks.

### Chemotherapy (paclitaxel and vinblastine)

A constituent of licorice has demonstrated significant potentiation of paclitaxel and vinblastine chemotherapy in vitro (Rafi et al 2000). Observe.

### Cimetidine and other H<sub>2</sub> antagonists

Adjunctive licorice treatment may enhance ulcer-healing drug effects — potentially beneficial interaction.

### Corticosteroids

Concurrent use of licorice preparations potentiates the effects of topical and oral corticosteroids (e.g. prednisolone). Caution should be advised to patients on acute and chronic corticosteroid therapy due to

possible adverse additive effects (Liao et al 2010). Some practitioners employ licorice to minimise requirements for or aid in withdrawal from corticosteroid medications. Beneficial interaction is possible under professional supervision, but patients may require a reduction in corticosteroid dosage to avoid corticosteroid excess (Chen et al 1991, Homma et al 1994).

### Cyclosporin

An in vivo study found that GA induced P-glycoprotein and CYP3A4, resulting in reduced oral bioavailability of cyclosporin (Hou et al 2012) — monitor cyclosporin levels closely.

### Diclofenac sodium (NSAID)

In vitro studies have shown that the addition of GL enhanced the topical absorption of diclofenac sodium (Nokhodchi et al 2002), which may be a beneficial interaction.

### Digoxin

Hypokalaemia increases sensitivity to cardiac glycoside drugs, therefore increased digoxin toxicity is possible when licorice is used in high doses for more than 2 weeks. A case report exists of congestive heart failure caused by digitalis toxicity in an elderly man taking a licorice-containing Chinese herbal laxative (Harada et al 2002). Avoid long-term use of high-dose licorice preparations and digoxin concurrently.

### Diuretics (including loop, thiazide and potassium-depleting)

Case reports exist in which patients experience hypokalaemia and hypertension with concomitant use of licorice and diuretics (deKlerk et al 1997, Farese et al 1991, Folkerson et al 1996) due to increased potassium excretion. Avoid long-term use of licorice and diuretics concurrently unless under professional supervision — monitor potassium levels.

### Methotrexate

An in vivo study has suggested that concurrent administration of methotrexate and either GL or licorice decoction can significantly increase MRT and AUC (Lin et al 2009). Until clarification of this interaction occurs, use combination with caution and monitor for signs of methotrexate toxicity.

### Oral contraceptive pill

An increased risk of side effects such as hypokalaemia, fluid retention and elevated blood pressure due to increased mineralocorticoid effect exists. This has been demonstrated in case reports (Bernardi et al 1994, deKlerk et al 1997). Use this combination with caution when licorice is used in high dose or for more than 2 weeks and observe patients closely.

### Potassium

Licorice may reduce the effect of potassium supplementation. A case report exists of a 69-year-old

female developing hypokalaemia while taking potassium supplements and a mouth freshener containing licorice concurrently. The daily intake of GA was estimated at 6–10 mg/day (Kageyama et al 1997). In many cases potassium supplementation may be beneficial in reducing the hypokalaemic side effects of licorice.

### Testosterone

Licorice may decrease testosterone levels, although clinical tests have produced conflicting results (Armanini et al 1999, 2003a, 2004, Sakamoto & Wakabayashi 1988, Takeuchi et al 1991) — observe and monitor patients for reduced testosterone effects.

### Cytochrome P450 Substrates

In humans, GL has been shown to cause a moderate, clinically relevant, induction of CYP3A4 (Tu et al 2010). Other constituents have been found to affect various CYP P450 isoforms in vitro, including liquiritigenin, isoliquiritigenin, glycy-coumarin, semilicoisoflavone B, licoisoflavone A, licoricone, glycyrol, licoflavonol and licoisoflavone B (Qiao et al 2014). Until studies in humans come to light, the clinical significance of this remains unclear (See chapter 8 on Interactions for more information.)

## ❗ CONTRAINDICATIONS AND PRECAUTIONS

Licorice should be used with caution in people with hypertension (or a genetic predisposition to hypertension) or fluid retention, and is contraindicated in hypotonia, severe renal insufficiency, hypokalaemia, liver cirrhosis and cholestatic liver disease (Blumenthal et al 2000). The effects are likely to be dose-dependent and more likely in people with essential hypertension with a particular tendency to 11HSD inhibition by licorice (Sigurjonsdottir et al 2001, 2003). It is also contraindicated in people with a deficiency in 11HSD or with genetic mutation in the HSD11B2 gene (Harahap et al 2011, Russo et al 2000). A case report of severe hypokalaemia following low licorice intake was reported in a patient with anorexia nervosa, suggesting a possible increase in glycyrrhizin sensitivity in this population (Stoving et al 2011).

Long-term use (>2 weeks) at therapeutic doses should be monitored closely due to the potential side effects. Additionally, a high-potassium low-sodium diet should be consumed during treatment (Bradley 1992, McGuffin et al 1997).

As licorice may questionably reduce testosterone levels in men, it should be used with caution in men with a history of impotence, infertility or decreased libido (Armanini et al 1999, Zava et al 1998).

**Practice points/Patient counselling**

- Licorice has been used as a food, flavouring agent and medicine since ancient times.
- It exhibits mineralocorticoid, anti-inflammatory, antioxidant, mucoprotective and ulcer-healing activity in humans. Antiviral, antibacterial, anti-tumour, expectorant and hepatoprotective effects have also been demonstrated in animal or test tube studies. Significant effects on oestrogen and testosterone levels remain to be established in controlled trials as evidence is inconsistent.
- Licorice is a popular treatment for respiratory tract infections, gastrointestinal ulcers and dyspepsia. It is also used to treat chronic stress and numerous other conditions, largely based on evidence of pharmacological activity.
- GA has been used topically as an anti-inflammatory agent and also together with cortisone preparations to increase effects.
- High-dose licorice (>100 mg GL) used for more than 2 weeks can induce hypokalaemia and pseudoaldosteronism in susceptible individuals. As such, it should be used with caution and under professional supervision. Additionally, it interacts with numerous medicines. The DGL form is considered safer.

**PREGNANCY USE**

Licorice is contraindicated in pregnancy. A Finnish trial found that high consumption of licorice during pregnancy increased the likelihood of early delivery, but did not significantly affect birth weight or maternal blood pressure (Strandberg et al 2001). A study by the same group found that compared with zero-low glycyrrhiza exposure, children who experience high prenatal exposure (500 mg/week and higher) had significantly reduced verbal and visuospatial ability, reduced narrative memory and had significantly increased tendencies towards externalising symptoms, inattention, rule-breaking and aggression problems (Räikkönen et al 2009). An association between children exposed to high GL due to maternal consumption during pregnancy and altered diurnal and stress-induced HPA-axis function at age 8 years has also been reported (Räikkönen et al 2010).

**PATIENTS' FAQs****What will this herb do for me?**

Licorice has many effects in the body, the most well-established ones being reducing inflammation, enhancing healing of peptic ulcers and treating infections such as bronchitis and cough.

**When will it start to work?**

Beneficial effects in peptic ulcer occur within 6–12 weeks, although DGL is usually used to avoid side

effects. Symptoms of dyspepsia should respond within the first few doses. Effects in bronchitis will vary between individuals.

**Are there any safety issues?**

Used in high doses for more than 2 weeks, licorice can induce several side effects, such as raised blood pressure and fluid retention and may interact with a number of drugs. The DGL form is considered safer.

## L-Lysine

### BACKGROUND

L-Lysine is an amino acid which is absorbed from the small intestine and then transported to the liver via the portal circulation where it is involved in protein biosynthesis and is partly metabolised.

### CHEMICAL COMPONENTS

L-Lysine is the biologically active stereoisomer of lysine.

### MAIN ACTIONS

#### Essential amino acid

The human body cannot synthesise L-lysine so it must be taken through the diet. The richest sources of L-lysine are animal proteins such as meat and poultry. It is also found to lesser extents in eggs, beans and dairy products (Bratman & Kroll 2000).

#### Antiviral

L-Lysine has an inhibitory effect on the multiplication of herpes simplex virus (HSV) in cell cultures (Griffith et al 1981, Milman et al 1980). It appears to act as an antimetabolite and competes with arginine for inclusion into viral replicative processes (Griffith et al 1981). As such, lysine retards the viral growth-promoting action of arginine.

#### Calcium regulation

L-Lysine may be involved in the cellular absorption, regulation and use of calcium (Civitelli et al 1992). In vitro tests with human osteoblasts indicate that lysine has a positive effect on osteoblast proliferation, activation and differentiation (Torricelli et al 2003).

#### Inhibition of protein glycation and advanced glycation end products

L-Lysine inhibits protein glycation and the role of supplementary lysine has been investigated for the prevention of protein glycation and inhibition of the formation of advanced glycation end products. Under hyperglycaemic conditions, production of fibrin is increased by glycated fibrinogen and human studies report that lysine supplementation significantly

reduces fibrinogen activity in diabetic patients ( $P < 0.05$ ). As an inhibitor of glycation, lysine may therefore reduce fibrinogen's non-enzymatic glycation and rectify its structure and function (Mirmiranpour et al 2012).

### OTHER ACTIONS

L-Lysine is required for biosynthesis of collagen, elastin and carnitine. Studies in animal models have reported that lysine deficiency can have a negative impact on carnitine synthesis which results in a reduction in carnitine levels and an increase in lipid levels. The addition of lysine in a lysine-deficient diet improves both triglyceride and carnitine levels (Khan & Bamji 1979). However in human studies supplementation of 1 g lysine daily for 12 weeks has failed to demonstrate benefits for lipid profiles (Hlais et al 2012).

### CLINICAL USE

#### Herpes simplex — prevention and treatment

The most common use for oral lysine supplements in practice is to prevent and treat outbreaks of herpes simplex labialis. Most clinical research was conducted in the 1980s, generally producing positive results for reducing recurrences when used in high doses, long-term and possibly also reducing severity and improving healing time, but this is less consistent (Digiiovanna & Blank 1984, Griffith et al 1978, 1987, McCune et al 1984, Milman et al 1978, 1980, Simon et al 1985, Thein & Hurt 1984, Walsh et al 1983, Wright 1994).

#### Preventing an outbreak

The majority of double-blind, placebo-controlled randomised controlled trials have shown oral L-lysine supplementation to be effective for decreasing the frequency of outbreaks.

One randomised, double-blind crossover study found that supplementation with 1000 mg/day of L-lysine together with a low arginine diet over 24 weeks decreased the recurrence rate of HSV attacks in non-immunocompromised subjects (McCune et al 1984). A group taking a lower dose of 500 mg

daily experienced similar results to placebo. Another double-blind trial compared the effects of 1000 mg L-lysine three times daily for 6 months with placebo treatment in 52 subjects. Once again, oral L-lysine was found to decrease recurrence rates (Griffith et al 1987). An open study of 45 patients with recurring HSV infection found that L-lysine supplementation reduced recurrence when taken at concentrations between 312 and 1200 mg/day in single or multiple doses (Griffith et al 1978). Thein and Hurt (1984) conducted a 12-month, double-blind crossover trial involving 26 subjects with recurring herpes lesions and found that a dose of 1000 mg/day L-lysine in combination with dietary arginine restriction had protective effects against lesion formation. Furthermore, once supplementation ceased, an increase in lesion frequency occurred. This study went further than others, identifying that serum lysine levels need to exceed 165 nmol/mL in order for clinical effects to become significant.

An observational study of 1534 volunteers asking about the perceived effectiveness of lysine supplements to treat cold sores, canker sores or genital herpes over a 6-month trial period indicated positive results (Walsh et al 1983). Of those people with cold sores or fever blisters, 92% claimed lysine supplements were 'very effective' or 'an effective form' of treatment and 81% of those with genital herpes and who had tried other forms of treatment also claimed positive results.

A crossover study by Milman et al (1980) found that significantly more patients receiving treatment with L-lysine 500 mg twice daily for 12 weeks experienced a reduction in infection occurrence compared to placebo (27.7% versus 12.3%;  $P < 0.05$ ). However, the total number of recurrences was 12.5% lower in the active treatment group compared to the placebo group, but not statistically significant.

In contrast, a small double-blind study of 21 participants found oral lysine hydrochloride therapy (400 mg three times a day) did not reduce the frequency, duration or severity of herpes simplex infections (Digiovanna & Blank 1984). A later study by Simon et al (1985) suggests that there is a dose response. In their study, 31 people with diagnosed herpes labialis or genitalis took two capsules twice a day for 3 months (1000 mg/day), then 18 patients took 750 mg/day for 3 more months (Simon et al 1985). The group taking the higher dose had fewer recurrences than predicted while taking 1000 mg/day (17 recurrences versus 42.6 predicted) but during the second 3-month period (750 mg/day or placebo) there was no significant difference between actual and predicted recurrences (17 recurrences versus 16.8 predicted in the treatment group and 16 recurrences versus 21.8 predicted in the placebo group).

#### Reducing severity and/or healing time

Griffith et al (1987) found that a higher dose of 1000 mg three times daily significantly reduced

symptom severity and healing time. More specifically, healing time was reduced by a mean  $\pm$  SD of  $2.3 \pm 0.7$  days in the lysine group, versus  $0.2 \pm 0.6$  day with placebo ( $P < 0.1$ ). More patients in the lysine group than the placebo group reported their symptoms to be 'milder' (74% versus 28%;  $P < 0.01$ ). The treatment group had been taking L-lysine long-term as a means of reducing outbreak frequency.

Previously, Griffith et al (1978) showed that L-lysine taken at doses between 312 mg/day and 1200 mg/day accelerated recovery time during an outbreak, whereas a double-blind, placebo-controlled study by Milman et al (1978) showed that the lower dose of L-lysine 1000 mg taken at the first sign of an outbreak was no better than placebo for reducing severity or enhancing healing rate. McCune et al (1984) also did not find that a daily dose of 1000 mg/day reduced healing time during an outbreak in non-immunocompromised volunteers.

The effect of lysine on herpes may depend on variables such as the overall dietary ratio of lysine to arginine and the additional dose of supplemental lysine. In practice, doses of >3000 mg/day are used as treatment during an acute episode, based on the positive findings of the Griffith study. This is combined with a diet low in arginine-rich foods, such as chocolate, peas, nuts and beer, and high in lysine-rich foods, such as baked beans and eggs.

A small pilot study examined the use of a topical preparation SuperLysine Plus+ cream containing lysine plus other nutrients (zinc oxide, vitamins A, D and E and lithium carbonate 3X) and botanicals (extracts of propolis, calendula, echinacea and goldenseal) in relieving the symptoms of herpes simplex. Patients with signs and symptoms of an active cold sore of less than 24 hours duration applied the ointment to the lesions 2-hourly during waking hours. Symptoms, including severity of tingling, burning and tenderness, showed significant improvement by day 3 except oozing, and 40% of patients had full resolution; 87% of patients had full resolution after day 6 (Singh et al 2005).

## OTHER USES

### Diabetes/hyperlipidaemia

Mirmiranpour et al (2012) investigated changes in fibrinogen activity in 50 subjects with type 2 diabetes mellitus (aged  $\geq 40$  years). The subjects were randomised to receive either 3 g of L-Lysine monohydrochloride or placebo daily for 3 months. Patients also received the antidiabetic drugs metformin and glibenclamide. The authors reported that fibrinogen activity in the diabetic patients was significantly reduced ( $P < 0.05$ ) in the lysine-supplemented group compared to the placebo group, although there were no changes in the prothrombin time and partial thromboplastin time.

### Body composition

A high-lysine diet (80 mg/kg/day) for 8 weeks in well and undernourished healthy males resulted in

a small positive effect (~+7.5%) on muscle strength compared to those on low-lysine diets (Unni et al 2012). However most of the studies investigating lysine on body composition have used mixed formulations of amino acids.

Lysine has been reported to stimulate muscle protein anabolism; arginine stimulates whole-body protein synthesis and beta-hydroxy-beta-methylbutyrate has been shown to prevent excessive muscle proteolysis. A double-blind, randomised study (Flakoll et al 2004) investigated the effect of daily supplementation with lysine (1.5 g), arginine (5 g) and beta-hydroxy-beta-methylbutyrate (2 g) on strength, functionality, body composition and protein metabolism in 50 elderly women (mean age 76.7 years). The control group received an isocaloric isonitrogenous mixture (1.8 g of nitrogen) that contained non-essential amino acids (5.6 g of alanine, 0.9 g of glutamic acid, 3.1 g of glycine and 2.2 g of serine). The treatment group had increased measurements of functionality, lean tissue and protein synthesis ( $P < 0.05$ ) after 12 weeks. Similarly, a subsequent double-blind randomised 1-year-long study (Baier et al 2009) investigated the effects of daily consumption of the same supplement in elderly men and women ( $76 \pm 1.6$  years) over 1 year. Compared to the control group ( $n = 37$ ), there was a significant increase in protein turnover and fat-free mass ( $P = 0.05$ ) in the treatment group ( $n = 40$ ). Recently post hoc analysis of muscle strength based on the participants' vitamin D status was conducted because of the association of increased serum vitamin D levels with an increase in muscle function. The analysis revealed that vitamin D status did not affect fat-free mass, although muscle strength was increased significantly in the supplement group ( $P < 0.01$ ) but only in those with adequate ( $\geq 30$  ng 25OH-vitamin D<sub>3</sub>/mL) vitamin D levels (Fuller et al 2011). The role that lysine plays in this combination is unclear.

### Osteoporosis prevention

Two studies have investigated the effects of oral L-lysine supplementation on calcium use to determine whether L-lysine has a role in the prevention of osteoporosis. In these tests, oral L-lysine was shown to significantly increase intestinal absorption of calcium and decrease renal excretion in both healthy women and those with osteoporosis (Civitelli et al 1992).

### Anxiety and mood disturbances

A systematic review of nutritional and herbal supplements for anxiety and anxiety-related disorder reported that there is evidence for the use of supplemental L-lysine in combination with L-arginine (Lakhan & Vieira 2010). According to a randomised, double-blind trial, fortification of lysine in a wheat-based (L-lysine-deficient) diet significantly reduced anxiety score in males, but not females with high baseline anxiety. It is suspected that L-lysine's action as a 5-HT<sub>4</sub> receptor antagonist and benzodiazepine

receptor agonist is responsible for the observed effect (Smriga et al 2004). In a double-blind, randomised placebo-controlled study, Smriga et al (2007) evaluated the efficacy of combined lysine and arginine supplementation on reducing anxiety and stress response hormonal levels. Patients were given 1.32 g each of L-lysine and L-arginine twice daily for 1 week, estimated to be a 50% increase in total intake. Compared to placebo, long-term and stress-induced anxiety levels were reduced in both genders in the treatment group, and basal levels of salivary cortisol and chromogranin-A (a measure of sympathetic stress response) were significantly reduced in males (Smriga et al 2007). In contrast, a prospective study of 29,133 men (aged 50–69 years) found no association between L-lysine intake and depressed mood (Hakkarainen et al 2003).

It is believed that the brain's nitric oxide signaling system may be involved in the pathophysiology of schizophrenia. In a small, randomised single-blinded cross-over study, 10 patients with schizophrenia received L-lysine (6 g/day) or placebo in addition to their conventional antipsychotic medication for 4 weeks before being crossed over to the alternative phase of the study. During the lysine phase participants showed a significant decrease in positive symptoms, as assessed by the Positive and Negative Syndrome Scale. These encouraging results deserve further investigation in larger studies in future (Wass et al 2011).

### Cancer treatment (in combination)

Preliminary research has been conducted into the possible protective or treatment effects of lysine in combination with other nutritional components.

A formulation of lysine combined with other compounds (proline, arginine, vitamin C and green tea extract) has been used in several in vitro and in vivo studies, suggesting it may be beneficial in cancer treatment by inhibiting the growth, invasion and metastasis of tumour cells via inhibiting metalloproteinases which trigger extracellular matrix degradation (Roomi et al 2004, 2005a–e, 2006a–e, Roomi 2006). In contrast to this, however, an in vivo study conducted on mice found L-lysine and vitamin C Lysin C Drink, alone or in combination with epigallocatechin-gallate and amino acids Epican forte, was not effective as a prophylactic or treatment in reducing primary tumour growth (neuroblastoma model) or in preventing metastases (Lode et al 2008).

### Lysinuric protein intolerance

Lysinuric protein intolerance is an autosomal recessive transport disorder of the cationic amino acids which leads to decreased intestinal absorption and excessive renal loss of lysine, arginine and ornithine. Usual treatment involves restriction of protein and citrulline supplementation, which corrects many side effects except those related to lysine deficiency. Long-term low-dose lysine supplementation improves plasma lysine concentration in patients and

may help correct chronic lysine deficiency without causing side effects such as hyperammonaemia (Tanner et al 2007).

## DOSAGE RANGE

### Herpes simplex infections

- Prevention: 1000–3000 mg/day taken long-term (at least 6 months) together with a low-arginine diet.
- Acute treatment: minimum 3000 mg/day in divided doses taken between meals until lesions have healed.

### Osteoporosis prevention

- 400–800 mg L-lysine taken together with calcium supplementation.

## TOXICITY

Not known.

## ADVERSE REACTIONS

Doses greater than 10–15 g/day may cause gastrointestinal discomfort with symptoms of nausea, vomiting and diarrhoea.

### Practice points/Patient counselling

- L-Lysine is an essential amino acid found in foods such as animal proteins, eggs and milk.
- It has been shown to inhibit HSV multiplication in vitro.
- Supplemental L-lysine is popular as a prophylactic and treatment for HSV.
- Studies have yielded inconsistent results suggesting that there may be individual variation in responses. Due to its safety, a trial is worthwhile to determine individual response.
- Doses used as prophylaxis range from 1000 to 3000 mg/day, with treatment doses generally above 3000 mg/day.
- L-Lysine may also enhance intestinal absorption of calcium and reduces its renal excretion.

### CONTRAINDICATIONS AND PRECAUTIONS

Contraindicated in people with the rare genetic disorder hyperlysinemia/hyperlysinuria (Hendler & Rorvik 2001). High-dose lysine supplements should be used with caution in hypercalcaemic states, and by people with kidney or liver disease.

In children with pyridoxine-dependent epilepsy caused by antiquitin deficiency, a lysine-restricted diet as an adjunct to pyridoxine therapy appears to potentially decrease neurotoxic biomarkers and improve developmental outcomes (van Karnebeek et al 2012). As such lysine supplementation may not be suitable in such patients until more is known.

## SIGNIFICANT INTERACTIONS

### Calcium

Clinical tests have found L-lysine enhances intestinal absorption and decreases renal excretion of calcium (Civitelli et al 1992) — potentially beneficial interaction.

### PREGNANCY USE

Safety is unknown for high-dose supplements; however, dietary intake levels are safe.

### PATIENTS' FAQs

#### What will this supplement do for me?

L-Lysine supplements taken long-term appear to reduce the frequency of herpes simplex outbreaks and possibly reduce the severity and enhance healing. It may also improve the way the body absorbs and retains calcium.

#### When will it start to work?

Studies suggest that several months' treatment may be required, with a long-term approach recommended for prophylaxis against herpes simplex outbreaks.

#### Are there any safety issues?

L-Lysine appears to be a very safe supplement, although safety has not been established in pregnancy and lactation for high-dose supplements.

## Lutein and zeaxanthin

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Lutein and its isomer, zeaxanthin, are yellow-coloured, xanthophyll carotenoids that are not converted into vitamin A. The bioavailability of lutein and zeaxanthin from food sources is influenced by the food matrix and by the type and extent of food processing, but most notably by the presence of fat in the diet (Castenmiller et al 1999), with dietary fat intake being inversely related to serum levels (Nolan et al 2004). Cooking may increase their bioavailability by disrupting the cellular matrix and protein complexes, and supplemental sources may be significantly more bioavailable than food sources (Castenmiller et al 1999). It has also been observed that plasma responses to cholesterol and carotenoids are related (Clark et al 2006, Karppi et al 2010) and that the bioavailability of zeaxanthin from freeze-dried wolfberries is enhanced threefold when consumed in hot skimmed milk compared to hot water or warm

milk (Benzie et al 2006). One clinical study found that plasma lutein was higher when lutein was consumed with a high-fat spread (207% increase) than with a low-fat spread (88% increase) (Roodenburg et al 2000). This was supported by a small in vitro study showing that dietary lutein is absorbed more efficiently with 24 g of avocado oil or 150 g of avocado fruit (Unlu et al 2005). For each 10% increase in dietary lutein and zeaxanthin, serum levels are seen to increase by 1% (Gruber et al 2004).

When ingested, lutein and zeaxanthin are transported from the intestine to the liver via chylomicrons. They are then transported via low-density lipoproteins (LDL) and high-density lipoproteins (HDL) to various parts of the body (Yeum & Russell 2002). Lutein and zeaxanthin are present in the eye, blood serum, skin, cervix, brain, breast and adipose tissue. In the eye, lutein is more prominent at the edges of the retina and in the rods (Bernstein et al 2001, Bone et al 1997). Lutein

appears to undergo some metabolism in the retina to *meso*-zeaxanthin in most, but not all people. This accounts for lower retinal levels of lutein and higher relative levels of *meso*-zeaxanthin in the central macular and *visa versa* in the peripheral macular (Bone et al 1993). As such, *meso*-zeaxanthin and zeaxanthin are the predominant carotenoids in the foveal region, whereas lutein predominates in the parafoveal region (Bone et al 1988, Snodderly et al 1991). In particular, zeaxanthin is primarily concentrated in the centre of the retina and the cones, where it is present in concentrations nearly 1000-fold of those found in other tissues, thus giving the macula lutea or yellow spot of the retina its characteristic colour (Krinsky et al 2003). It is suggested, however, that during supplementation with xanthophylls, lutein is predominantly deposited in the fovea, while zeaxanthin deposition appears to cover a wider retinal area (Schalch et al 2007).

Lower serum concentrations of zeaxanthin have been associated with male gender, smoking, younger age, lower non-HDL cholesterol, greater ethanol consumption and higher body mass index (Brady et al 1996). Lutein and zeaxanthin, together with other carotenoids, have also been found to be lower in people with chronic cholestatic liver disease, which can be attributed to malabsorption of fat-soluble vitamins, as well as other mechanisms of hepatic release (Floreani et al 2000). In an epidemiological study involving 7059 participants, lower serum lutein and zeaxanthin levels were significantly associated with smoking, heavy drinking, being white, female, not physically active, having lower dietary lutein and zeaxanthin, a higher percentage of fat mass, a higher waist-hip ratio, lower serum cholesterol, a higher white blood cell count and high levels of C-reactive protein (Gruber et al 2004).

In a pharmacokinetic study involving 20 healthy volunteers, serum zeaxanthin levels were found to have an effective half-life for accumulation of 5 days and a terminal elimination half-life of around 12 days (Hartmann et al 2004). This was confirmed by another study that also found that lutein did not affect the concentrations of other carotenoids in healthy volunteers (Thurmann et al 2005). Similarly, high doses (50 mg) of beta-carotene over 5 years were not found to influence serum levels of lutein and zeaxanthin (Mayne et al 1998). It has been suggested that the associations between macula pigment density and serum lutein, serum zeaxanthin and adipose lutein concentrations are stronger in men (Broekmans et al 2002, Johnson et al 2000) and that the processes governing accumulation and/or stabilisation of zeaxanthin in fat tissue are different for males and females (Nolan et al 2004). This is supported by the finding that serum lutein and zeaxanthin concentrations vary with the menstrual cycle, with levels being higher in the late follicular than in the luteal phase (Forman et al 1998).

### CHEMICAL COMPONENTS

Lutein and zeaxanthin are isomers and have identical chemical formulas, differing only in the location

of a double bond in one of the hydroxyl groups. Lutein is known as beta, epsilon-carotene-3,3'-diol, whereas zeaxanthin is known as all-*trans* beta-carotene-3,3'-diol.

### FOOD SOURCES

Foods differ in their relative amounts of lutein and zeaxanthin, with lutein generally being more abundant. Lutein is found in dark green leafy vegetables such as spinach and kale, as well as in sweetcorn and egg yolks, whereas zeaxanthin is found in sweetcorn, egg yolk, orange peppers (capsicums), persimmons, tangerines, mandarins and oranges. Goji berries are a very rich source of zeaxanthin.

Lutein, zeaxanthin and *meso*-zeaxanthin are primarily extracted from marigold flowers (*Tagetes erecta*) for use in supplements and are available in either free or esterified form. The esters typically contain two fatty acid groups that must be cleaved by pancreatic esterases and their absorption requires higher levels of dietary fat (Roodenburg et al 2000); however, addition of omega-long-chain polyunsaturated fatty acids to oral supplementation of lutein/zeaxanthin has not been found to change serum levels of lutein and zeaxanthin (Huang et al 2008).

### DEFICIENCY SIGNS AND SYMPTOMS

Zeaxanthin and lutein can be considered conditionally essential nutrients because low serum levels or low dietary intakes are associated with low macular pigment density (Mares et al 2006) and increased risk of age-related macular degeneration (ARMD) (Semba & Dagnelie 2003).

Epidemiological studies have also found an association between low serum carotenoid levels, including lutein and zeaxanthin levels, with all-cause mortality (De Waart et al 2001), the risk of inflammatory polyarthritis (Pattison et al 2005), breast cancer (Tamimi et al 2005), prostate cancer (Jian et al 2005), colon cancer (Nkondjock & Ghadirian 2004), cervical cancer (Garcia-Closas et al 2005, Kim et al 2004), human papillomavirus persistence (Garcia-Closas et al 2005), type 2 diabetes and impaired glucose metabolism (Coyne et al 2005), chronic cholestatic liver diseases (Floreani et al 2000), Alzheimer's disease and vascular dementia (Polidori et al 2004) and low fruit and vegetable consumption (Al-Delaimy et al 2005).

Carotenoids have also emerged as an excellent tissue marker for a diet rich in fruit and vegetables, and measurement of plasma and tissue carotenoids is considered to have an important role in defining optimal diets (Al-Delaimy et al 2005, Brevik et al 2004, Handelman 2001).

### MAIN ACTIONS

#### Antioxidant

Lutein and zeaxanthin are both powerful antioxidants, with activity having been demonstrated in a number of *in vitro* and *in vivo* tests (Higashi-Okai et al 2001, Iannone et al 1998, Muriach et al 2008, Nagueib 2000). *In vitro* studies of human lens epi-

thelial cells also indicate that their antioxidant activity may protect the lens from ultraviolet (UV) B radiation (Chitchumroonchokchai et al 2004). According to animal studies, lutein increases glutathione levels and reduces retinal apoptosis following ischaemic reperfusion (Dilsiz et al 2005). Lutein was also found to significantly protect against injury associated with oxidative stress in rat intestinal tissues following ischaemia-reperfusion (Sato et al 2011).

Lutein supplementation of 20 mg daily over 12 weeks was shown to significantly reduce C-reactive protein levels and lipid peroxidation, as well as increase total antioxidant capacity, in a randomised placebo-controlled trial of healthy volunteers ( $n = 117$ ; Wang et al 2013). In contrast, a smaller study of 20 well-nourished adults aged 50–70 years found that supplementation of lutein (12 mg daily) for 112 days resulted in increased plasma antioxidant concentration but no significant changes in antioxidant activity or lipid peroxidation (Li et al 2010).

### Blue light filter

The yellow colour of lutein and zeaxanthin is due to their ability to absorb blue light, which is believed to contribute to their protective function because blue light is at the high-energy, and therefore the most damaging, end of the visible spectrum (Krinsky et al 2003). Lutein and zeaxanthin thus serve as ‘natural sunglasses’ (Rehak et al 2008) that act as an optical filter for blue light, reducing chromatic aberration and preventing damage to the photoreceptor cell layer (Krinsky et al 2003). An in vivo study confirmed that lutein afforded protection against light-induced retinal damage in mice, which was associated with reduced markers of DNA damage in photoreceptor cells, and upregulation of the prosurvival gene ‘eyes absent’ (Sasaki et al 2012). The reduction of light-induced oxidative stress was thought to contribute to protection against DNA strand damage.

### Macular pigment development

Lutein and zeaxanthin are entirely of dietary origin and are initially absent in newborns but gradually accumulate over time (Nussbaum et al 1981). It has been generally accepted that macular pigment density decreases with age; however, there are conflicting results. In one prospective, observational study involving 390 patients, macular pigment density was not found to change significantly with age, even when elderly subjects with cataracts and ARMD were considered (Ciulla & Hammond 2004). Other studies, however, have found that macular pigment does indeed decline with age in both normal eyes (Beatty et al 2001, Bernstein et al 2002) and those with ARMD (Bernstein et al 2002) and Stargardt macular dystrophy (Zhao et al 2003), but not in retinitis pigmentosa or choroideraemia (Zhao et al 2003).

Although lutein and zeaxanthin levels in the serum, diet and retina correlate, the nature of the relationships between lutein and zeaxanthin in foodstuffs, blood and the macula is confounded by many variables, including processes that influence digestion,

absorption and transport and accumulation and stabilisation of the carotenoids in the tissues (Beatty et al 2004). It is suggested, however, that lutein and zeaxanthin are transported into an individual’s retina in the same proportions found in his or her blood (Bone et al 1997). An in vitro study using retinal pigment epithelial cells found that both lutein and zeaxanthin modulate inflammatory responses to photo-oxidation, providing a possible mechanism for these compounds’ effects in ARMD (Bain et al 2012).

### Immunomodulation

Lutein modulates cellular and humoral-mediated immune responses, according to animal studies (Kim et al 2000a, 2000b). In particular, high levels of C-reactive protein and a high white blood cell count have been identified in individuals with low serum levels of lutein (Gruber et al 2004). In a case-controlled study, serum lutein and zeaxanthin, together with other carotenoids, were also found to be lower in children with acute-phase infections compared to healthy controls (Cser et al 2004).

### Anti-inflammatory

Lutein supplementation (20 mg daily) in early atherosclerosis patients ( $n = 65$ ) was found to significantly reduce serum cytokines interleukin-6 and monocyte chemoattractant protein-1 after 3 months compared to placebo (Xu et al 2013). This also correlated with reduced serum LDL and triglyceride levels in patients receiving lutein, though this study may be insufficiently powered to draw meaningful conclusions. Further studies are recommended to clarify lutein’s anti-inflammatory effects.

### Photoprotection

According to animal studies, lutein reduces the risk of sunburn, as well as local UVB radiation-induced immune suppression and reactive oxygen species generation (Lee et al 2004), and directly protects against photoageing and photocarcinogenesis (Astner et al 2007). A protective effect on skin cancer, however, has not been observed in human cohort studies. One prospective cohort study involving 43,867 men and 85,944 women found no significant inverse association between intake of lutein and squamous cell carcinoma (Fung et al 2003), while an increased risk of squamous cell carcinoma was observed for people with multiple prior non-melanoma skin cancers and high serum levels of lutein and zeaxanthin (Dorgan et al 2004).

While a protective effect against skin cancer is uncertain, there is evidence to suggest that supplementation with lutein and zeaxanthin may improve general skin health and simultaneously help to minimise signs of premature ageing (Maci 2007). A double-blind, placebo-controlled study that examined surface lipids, hydration, photoprotective activity, skin elasticity and skin lipid peroxidation found that oral and/or topical administration of either lutein or zeaxanthin provided antioxidant protection, with the greatest protection being seen with

combined administration of lutein and zeaxanthin (Palombo et al 2007). The clinical significance of these findings is uncertain.

### CLINICAL USE

Lutein and zeaxanthin supplementation is most often used for preventing and/or treating various ocular conditions.

### Age-related macular degeneration

ARMD is the leading cause of irreversible visual dysfunction in individuals over 65 years in Western society. People with ARMD are classified as having early-stage disease (early ARMD), in which visual function is affected, or late ARMD (generally characterised as either 'wet' neovascular ARMD or 'dry' atrophic ARMD, or both) in which central vision is severely compromised or lost (Bowes et al 2013). Atrophic ARMD accounts for 90% of all ARMD cases (Richer et al 2004).

The evidence that lifetime oxidative stress plays an important role in the development of ARMD is now compelling (Hogg & Chakravarthy 2004). ARMD is thought to be the result of free radical damage to photoreceptors within the macula, and therefore it is suspected that inefficient macular antioxidant systems play a role in disease development. After ageing, smoking is the next significant risk factor, most likely due to antioxidant depletion and increased oxidative stress. Smoking is also associated with lower levels of macular xanthophyll pigments such as lutein. Diets low in fruit and vegetables, excessive exposure to sunlight and blue light and use of photosensitising medicines are other factors known to increase the risk of developing ARMD (Richer et al 2004).

Epidemiological and autopsy studies have found an inverse relationship between lutein and zeaxanthin intake and macular pigment density (Bone et al 2001, Curran-Celentano et al 2001). The presence of unusually high levels of macular carotenoids in older donors who were regularly consuming high-dose lutein supplements further supports the hypothesis that long-term high intake of lutein can raise levels of macular pigment (Bhosale et al 2007). Similarly, clinical studies have also confirmed the association between macular pigmentation, dietary lutein intake and serum lutein levels (Burke et al 2005, Mares et al 2006, Yao et al 2013).

Lutein supplementation can also effectively increase plasma lutein and macular pigment density in most people with established ARMD (Bernstein et al 2002, Richer et al 2004, 2011, Wang et al 2007) and also in healthy controls (Koh et al 2004), demonstrating that both a diseased and a healthy macula can accumulate and stabilise lutein and/or zeaxanthin (Koh et al 2004). An increase in macular pigment density develops within 4 weeks of increasing lutein, according to clinical studies (Berendschot et al 2000, Hammond et al 1997). Interestingly, it was recently discovered that the variability in retinal macular pigment response to increased lutein intake

is due to underlying genetic variants (Yonova-Doing et al 2013). Clinical research further indicates that people with lower starting lutein levels experience greater protective effects when increasing lutein consumption in regard to age-related maculopathy (which precedes ARMD) (Cho et al 2004). There is also evidence from the Lutein Antioxidant Supplementation Trial (LAST) II that people with established atrophic ARMD starting with the lowest macular pigment optical density (MPOD) experience the greatest increases in MPOD when taking lutein or lutein + antioxidant supplements over 12 months (Richer et al 2007). These combined results are helping to clarify who is most likely to experience benefits from increased lutein intake and the variability in clinical trial results to date.

At least 16 epidemiological studies have reported a link between lutein and zeaxanthin and ARMD risk, supporting the theory that higher intakes and/or plasma levels of these macular pigments may be protective (Elliott & Williams 2012). A 2012 systematic review and meta-analysis concluded that, while dietary intake of lutein and zeaxanthin was not significantly associated with reduced risk of early ARMD onset, it was associated with protection in late ARMD (relative risk 0.74; Ma et al 2012). Joachim et al (2014) reported that dietary lutein-zeaxanthin intake was associated with decreased likelihood of progression from reticular drusen to late ARMD (adjusted odds ratio 0.5; 95% confidence interval 0.3–1.0), as based on the most recent results from the Blue Mountains Eye Study ( $n = 3654$ ), which involves 5-year, 10-year and 15-year follow-up examinations. Using data from the same study cohort together with data from the Rotterdam Study, Wang et al (2014) reported that people with a high ARMD genetic risk and the highest intake of lutein/zeaxanthin had a >20% reduced risk of early ARMD compared to people with a low genetic risk having a high intake of lutein/zeaxanthin.

For people with established ARMD, several important benefits have been reported with increased lutein intake, often when combined with other antioxidant nutrients. Improvements of up to 92% in visual acuity tests were observed when subjects with atrophic ARMD consumed a diet designed to contain approximately 150 g of spinach 4–7 times a week, according to an early pilot study (Richer 1999). A small pilot study by Falsini et al (2003) involving 30 patients with early ARMD and visual acuity of 6/9 or better experienced improved macular function with the use of daily lutein (15 mg) + vitamin E (20 mg) and nicotinamide (18 mg) for 180 days; this improvement was lost when supplementation was stopped (Falsini et al 2003).

Richer et al (2004) subsequently conducted a much larger study which found that lutein supplements (10 mg/day) improved some symptoms of atrophic ARMD after 12 months, such as contrast sensitivity, glare recovery and near vision acuity, while also increasing macular pigment density. The groups receiving lutein + antioxidants (including zinc)

demonstrated even broader effects compared to lutein alone or placebo. LAST, conducted by Richer et al (2004), was a double-blind, randomised, placebo-controlled study involving 90 subjects. In addition to improving most measures of quality of vision, both the lutein (FloraGloB, Kemin Foods International, USA) and lutein plus antioxidant (OcuPower, Nutraceutical Sciences Institute (NSI), USA) groups achieved an increase of 36% and 43%, respectively, in macular pigment density, whereas the placebo group experienced a slight decrease (Richer et al 2004). In other studies, lutein supplementation has been shown to increase macular pigment optical density and contrast and glare sensitivity compared to placebo (Yao et al 2013), and was seen to improve visual performance at low illumination, yet this was not correlated with macular pigment density (Kvansakul et al 2006).

More recently, a double-blind, placebo-controlled trial reported that macular pigment optical density and best-corrected visual acuity were significantly improved in patients with non-exudative ARMD ( $n = 172$ ) after taking a combination of lutein (10–20 mg) + zeaxanthin (1–2 mg) + omega-3 fatty acids (100–200 mg docosahexaenoic acid and 30–60 mg eicosapentaenoic acid) + antioxidants over 12 months (Dawczynski et al 2013). Two doses were used and both were as effective as each other but better than placebo, suggesting the lower dose saturated retinal levels and no further benefits could be achieved with a higher dose. A low dose of 6 mg daily of lutein is not effective according to a small double-blind, randomised controlled trial conducted over 60 weeks involving people with ARMD (Bartlett & Eperjesi 2007).

In regard to delaying the progression of ARMD, the AREDS2 study found that general antioxidant supplementation (original AREDS formula) was not enhanced by the addition of lutein (10 mg) and zeaxanthin (2 mg) (The AREDS2 Research Group 2013b). More recently, combinations of lutein and zeaxanthin combined with meso-xanthin have been tested in AMD. The Central Retinal Enrichment Supplementation Trials (CREST) are underway and will investigate the potential impact of macular pigment (MP) enrichment, following supplementation with a formulation containing 10 mg lutein (L), 2 mg zeaxanthin (Z) and 10 mg meso-zeaxanthin (MZ), on visual function in normal subjects and in subjects with early age-related macular degeneration (Akuffo et al 2014).

### Cataracts

Lens density has been found to inversely correlate with macular lutein and zeaxanthin levels (Hammond et al 1997) and numerous observational studies have found that increased consumption of foods high in lutein and zeaxanthin is associated with a decreased risk for cataracts (Brown et al 1999, Delcourt et al 2006, Tavani et al 1996). In one study involving 77,466 female nurses from the Nurses' Health Study, those with the highest quintile for

consumption of zeaxanthin and lutein were found to have a 22% reduction in the risk of cataract extraction (Chasan-Taber et al 1999). Similarly, a study of 1802 women aged 50–79 years found that women in the highest quintile category of diet or serum levels of lutein and zeaxanthin were 32% less likely to have nuclear cataract as compared with those in the lowest quintile category (Moeller et al 2008). A further epidemiological study of 3271 Melbourne residents found that, while cortical and posterior subcapsular cataracts were not significantly associated with lutein or zeaxanthin intake, high dietary lutein and zeaxanthin intake was inversely associated with the prevalence of nuclear cataract (Vu et al 2006). The link between lutein and cataracts is further supported by a small randomised, placebo-controlled trial of 17 patients with clinically diagnosed age-related cataracts that found that supplementation with lutein 15 mg three times weekly for up to 2 years resulted in improved visual performance (visual acuity and glare sensitivity) compared with placebo (Olmedilla et al 2003).

These results contrast with those from a cohort study of 478 women without previously diagnosed cataracts, which failed to detect a significant inverse relationship between lutein intake and lens opacities over a 13–15-year follow-up period (Jacques et al 2001). The AREDS2 randomised clinical trial also determined that daily supplementation with lutein (10 mg) and zeaxanthin (2 mg) had no statistically significant effects on rates of cataract surgery or vision loss in adults aged 50–85 years at risk for progression to advanced ARMD (The AREDS2 Research Group 2013a).

### Retinitis pigmentosa

In a double-blind, randomised, placebo-controlled crossover trial, supplementation with lutein (10 mg/day) for 12 weeks followed by 30 mg/day for 12 weeks was found to improve visual field and possibly visual acuity in 34 patients with retinitis pigmentosa (Bahrami et al 2006). A further study found that daily supplementation with 40 mg of lutein over 9 weeks followed by 20 mg for a further 16 weeks significantly improved visual acuity in 16 subjects with retinitis pigmentosa, many of whom were also taking other supplements (Dagnelie et al 2000).

#### Clinical note

The macula (central retina) contains a yellow pigment comprising the dietary carotenoids lutein (L), zeaxanthin (Z), and meso-zeaxanthin, known as macular pigment (MP). The concentrations of MP's constituent carotenoids in retina and brain tissue correlate, and there is a biologically plausible rationale, supported by emerging evidence, that MP's constituent carotenoids are also important for cognitive function (Nolan et al 2014).

### Retinopathy of prematurity

Supplementation of lutein and zeaxanthin in preterm infants did not prevent the occurrence of retinopathy of prematurity or outcome at hospital discharge compared to placebo in a randomised controlled trial of 114 infants of  $\leq 32$  weeks' gestation (Dani et al 2012).

### Cancer prevention

High dietary intake of lutein has been associated with reduced risk of some cancers, most notably endometrial and ovarian cancer, but not all cancers, according to epidemiological evidence (Freudenheim et al 1996, Fung et al 2003, Gann et al 1999, Giovannucci et al 1995, Huang et al 2003, Ito et al 2003, Lu et al 2001, McCann et al 2000, Michaud et al 2000, Nomura et al 1997, Schuurman et al 2002, Terry et al 2002).

### Lung cancer

Three large population studies of diet and lung cancer have revealed a non-significant association between high lutein intake and lower risk of lung cancer (Ito et al 2003, Michaud et al 2000, Ziegler et al 1996), and a significant trend was observed in another population-based case-control study (Le Marchand et al 1993). A nested case-control study also found that serum lutein and zeaxanthin were lower in those with lung cancer than in controls (Comstock et al 1997). These results are contrasted with those from a case-control study of 108 cases of lung cancer in a Chinese occupational cohort that found that higher serum carotenoid levels, including lutein and zeaxanthin, were significantly associated with increased lung cancer risk among alcohol drinkers, while having a possible protective association among non-drinkers (Ratnasinghe et al 2000).

### Cervical cancer

A 2005 systematic review suggests that lutein/zeaxanthin is likely to have a protective effect for cervical neoplasia and possibly for human papillomavirus persistence (Garcia-Closas et al 2005).

### Endometrial cancer

An epidemiological study involving 232 patients with endometrial cancer and 639 controls found that an intake of more than 7.3 mg/day of lutein was associated with a 70% reduced risk of endometrial cancer (McCann et al 2000).

### Ovarian cancer

A case-control study found that weekly intake of lutein of more than 24 mg was associated with a 40% reduction in the risk for developing ovarian cancer compared with weekly consumption of less than 3.8 mcg (Bertone et al 2001).

### Breast cancer

High lutein and zeaxanthin intake has been related to reduced risk of breast cancer (Dorgan et al 1998, Toniolo et al 2001). High lutein intake ( $> 7$  mg/day) was associated with a 53% reduction in the risk

of developing breast cancer compared with low consumption ( $< 3.7$  mg/day) in a population-based case-control study of 608 premenopausal women over age 40 (Freudenheim et al 1996). Similar risk reductions were found in a nested case-control study of 540 New York women (Toniolo et al 2001) and another nested case-control study of 969 cases of breast cancer and matched controls from the Nurses' Health Study found that the risk of breast cancer was 25–35% less for women with the highest quintile compared with that for women with the lowest quintile of lutein/zeaxanthin and total carotenoid intake (Tamimi et al 2005). Although this association is encouraging, another study of 4697 women followed over 25 years found no significant relationships between lutein intake and breast cancer risk (Jarvinen et al 1997).

### Gastric cancer

High serum lutein levels have been associated with a higher incidence of gastric carcinoma, according to a cohort study of 29,584 patients with oesophageal and stomach cancer (Abnet et al 2003); however, this association requires further investigation.

### Bowel cancer

The relationship between lutein and zeaxanthin intake and colon cancer is uncertain. A case-control study involving 1993 cases of colon cancer and 2410 controls found that lutein intake, as measured by a food frequency score, was inversely associated with colon cancer and another case-control study of 223 subjects with histologically confirmed colon or rectal cancer identified a non-significant inverse association with lutein (Levi et al 2000). A cohort analysis of 5629 women, however, found no such association (Terry et al 2002). A case-controlled study found that women with high intakes of long-chain polyunsaturated fatty acids had an inverse association between lutein and zeaxanthin intake and the risk of colon cancer (Nkondjock & Ghadirian 2004). Further investigation is required to clarify these findings because animal studies suggest low doses of lutein inhibit aberrant crypt foci formation, whereas high doses may increase the risk by 9–59% (Raju et al 2005).

### Prostate cancer

Overall, epidemiological evidence suggests that lutein and zeaxanthin intake has no influence over the risk of prostate cancer (Bosetti et al 2004, Gann et al 1999, Giovannucci et al 1995, Huang et al 2003, Lu et al 2001, Nomura et al 1997, Schuurman et al 2002). However, when lutein was included as part of a mixed carotenoid and tocopherol extract, the combination was effective in an *in vitro* study of prostate cancer cell lines (Lu et al 2005). A case-controlled study of 130 patients with adenocarcinoma of the prostate found that prostate cancer risk was seen to decline with increasing consumption of carotenoids, including lycopene, alpha-carotene, beta-carotene, beta-cryptoxanthin, lutein and zeaxanthin (Jian et al 2005).

### Laryngeal cancer

A case-control study involving 537 subjects identified an inverse relationship between dietary lutein and zeaxanthin intake, together with the intake of other carotenoids, and the risk of laryngeal cancer (Bidoli et al 2003).

### OTHER USES

Lutein and zeaxanthin may be used as part of a general antioxidant supplement, often taken in conjunction with other carotenoids in cases where there is known or suspected increased oxidative load.

### Sleep duration

Reduced lutein and zeaxanthin intake may be associated with reduced sleep duration; however more studies are needed to confirm this preliminary finding (Grandner 2013).

### Cognitive impairment

Dementia has been found to be associated with increased protein oxidative modification and the depletion of a large spectrum of antioxidant micronutrients, including lutein and zeaxanthin (Polidori et al 2004). In a clinical study of 25 subjects with mild cognitive impairment, 63 subjects with Alzheimer's disease and 56 healthy individuals found that serum lutein levels were lowest in the first two groups, particularly those with Alzheimer's disease (Rinaldi et al 2003), while a double-blind trial of 49 women aged 60–80 years found improved cognitive function after supplementation with a combination of docosahexaenoic acid and lutein (Johnson et al 2008).

A large, population-based study of adults aged over 50 years identified that low macular pigment density was associated with lower cognitive performance (Feeney et al 2013). This, however, was not an intervention-based study and therefore was not able to determine the effect of exogenous lutein supplementation in acutely improving cognitive parameters.

### Atherosclerosis

The relationship between lutein and zeaxanthin status and atherosclerosis is being investigated but remains unclear. Plasma levels of lutein, beta-cryptoxanthin and zeaxanthin were correlated to carotid intima media thickness in a 3-year case-controlled study of 231 subjects (Iribarren et al 1997), as well as in an 18-month epidemiological study of 573 subjects, suggesting that these carotenoids may be protective against early atherosclerosis (Dwyer et al 2004). Lutein intake has also been found to be inversely associated with the risk of ischaemic stroke in an observational study involving 43,738 males (Ascherio et al 1999), as well as being inversely associated with the risk of subarachnoid haemorrhage in a cohort study of 26,593 male smokers (Hirvonen et al 2000). Serum levels of lutein and zeaxanthin, however, were not associated with atherosclerosis risk in a case-control study involving 108 cases of aortic atherosclerosis in an elderly population (Klipstein-Grobusch et al 2000).

The foregoing findings contrast with those from two case-controlled studies that found a positive correlation between lutein and zeaxanthin levels and cardiovascular risk. A nested, case-control study of 499 cases of cardiovascular disease with matched controls taken from the Physicians' Health Study found that concentrations of plasma lutein, zeaxanthin and retinol corresponded to a moderate increase in cardiovascular disease (Sesso et al 2005). Similarly, myocardial infarction risk was positively associated with lutein and zeaxanthin levels in adipose tissue and diet in a case-controlled study of 1456 cases of first acute myocardial infarction and matched controls (Kabagambe et al 2005). The clinical significance of these findings is unclear and requires further investigation.

### DOSAGE RANGE

#### According to clinical studies

- Macular protection: lutein 6–20 mg/day; zeaxanthin 2–5 mg/day.
- The original AREDS formulation contained vitamin C, vitamin E, beta-carotene, zinc and copper.
- The successful AREDS2 formulation contained lutein and zeaxanthin instead of beta-carotene.
- Atrophic ARMD: improving visual quality — 10 mg lutein daily, ideally in combination with other antioxidants and possibly omega-3 essential fatty acids for better effects.
- Cataracts — improving visual performance: lutein 15 mg three times weekly.

### TOXICITY

Dietary amounts and those used in clinical studies are considered safe.

### ADVERSE REACTIONS

Lutein and zeaxanthin supplements are well tolerated.

### SIGNIFICANT INTERACTIONS

#### Vitamin C

Lutein showed increased antioxidant efficacy with vitamin C in an animal study (Blakely et al 2003). Further to this, a small in vivo study showed that 2000 mg of vitamin C enhanced the absorption of lutein (Tanumihardjo et al 2005).

#### Vitamin E

Vitamin E showed increased antioxidant efficacy with lutein according to an animal study (Blakely et al 2003).

#### Phytosterols

High dietary intake of phytosterol esters (6.6 g/day) reduced plasma levels of lutein by 14% in a small clinical trial; however, this was reversed by increasing fruit and vegetable intake (Clifton et al 2004).

#### Orlistat

Theoretically, long-term use of orlistat leads to reduced plasma levels of lutein due to reduced

gastric absorption ([Australian Medicines Handbook](#)) — increased dietary intake of lutein should be considered.

### Olestra

Lutein and zeaxanthin levels have been found to decrease with long-term use of olestra ([Tulley et al 2005](#)) — increased dietary intake of lutein should be considered.

### CONTRAINDICATIONS AND PRECAUTIONS

Lutein and zeaxanthin are contraindicated in people with a hypersensitivity to these carotenoids or their food sources.

### PREGNANCY USE

Eating dietary amounts of foods rich in lutein and zeaxanthin is likely to be safe. Women at risk of premature rupture of the membranes are cautioned against very high intake because one study observed a fourfold greater risk of membrane rupture with high serum lutein levels ([Mathews & Neil 2005](#)).

### Practice points/Patient counselling

- Lutein and zeaxanthin are antioxidant carotenoids found in spinach, corn, egg yolk, squash and greens. Goji berries are a particularly rich source of zeaxanthin.
- Lutein and zeaxanthin are essential for the development of macular pigment, which protects photoreceptor cells in the retina from free radical damage.
- Epidemiological studies have generally found an inverse relationship between lutein and zeaxanthin intake and macular degeneration; increased intakes will reduce the incidence of ARMD in some populations, but not all.
- People with established 'dry' macular degeneration may experience improved visual quality with lutein supplementation.
- Long-term use of lutein supplements may increase visual performance in people with pre-existing cataracts.
- High dietary intake of lutein has been associated with reduced risk of some cancers, most notably endometrial and ovarian cancer, but not all cancers, according to epidemiological evidence.
- Supplements containing lutein and zeaxanthin should be taken with food as dietary fat improves their absorption.

### PATIENTS' FAQs

#### What will this supplement do for me?

Lutein and zeaxanthin are important for eye health. They improve visual quality in people with established 'dry' ARMD and may reduce the risk of progressing to ARMD in some at-risk people. There may also be some protection against develop-

ing certain cancers when consumed over time.

#### When will it start to work?

Increased intake of lutein can improve macular health within 4 weeks; however, clinical effects develop slowly and may not be detected for 6 months. In regard to improving visual performance in people with pre-existing cataracts, effects take even longer ( $\approx 2$  years).

#### Are there any safety issues?

Lutein and zeaxanthin are generally considered safe.

# Maca

**HISTORICAL NOTE** Maca is a biennial plant native to the central Peruvian Andean plateaus that resembles a radish. It has thousands of years of cultivation and traditional use as a medicinal food. Its growing conditions are harsh, at altitudes of over 3300 m, with extreme weather conditions. It is a herbaceous plant with its flat and small overground leaves, an adaptation to the strong, cold winds of the mountains. The first written description about maca as a food was in 1553, and in 1653 its properties were recorded as fertility-enhancing and energy and mood-stimulating (Gonzales 2012). Other traditional uses include promoting mental clarity, regulating menstrual cycles and relieving menopausal symptoms (Cicero et al 2001). Legend has it that the Inca warriors used to eat maca to increase their energy for battle, but were prohibited from consuming it postconquest, as a measure to protect the women of the conquered city from the warriors' enhanced sexual impulses (Wang et al 2007).

## OTHER NAMES

Ayuk willku, Ayak chicira, *Maca maca*, maka, maino, Peruvian maca, Peruvian ginseng, maca peruvien, ginseng andin.

## BOTANICAL NAME/FAMILY

*Lepidium meyenii*; synonym: *Lepidium peruvianum* (family: Cruciferae/Brassicaceae)

There are many ecotypes of maca, characterised by their colour. Over 13 colours have been described, ranging from white, yellow, purple, red to black, and they possess different biological properties (Gonzales 2012). The yellow ecotype is the most common cultivar in the Peruvian Andes (Wang et al 2007).

## PLANT PARTS USED

The hypocotyl-root axis is used (radish-like tuber). This is 10–14 cm long and 3–5 cm wide. When dried, it is reduced in size to 2–8 cm in diameter. Traditionally, the root is naturally dried and can be stored for many years. To prepare for use, it is boiled or extracted in alcohol prior to consumption (Gonzales 2012).

## CHEMICAL COMPONENTS

Dried root contains 54.6–60% carbohydrates, 8.87–16% protein, 8.23–9.08% fibre and 1.09–2.2% lipids. The carbohydrate breakdown is 23.4% sucrose, 1.55% glucose, 4.56% oligosaccharides and 30.4% polysaccharides. Fatty acids include oleic, linolenic, palmitic and oleic acids, and both saturated (40%) and unsaturated (52.7%) fatty acids are present. It is a rich source of amino acids, containing up to 19 different ones: leucine, arginine, phenylalanine, lysine, glycine, alanine, valine, isoleucine, glutamic acid, serine, aspartic acid and others in lesser proportions. Mineral content includes significant levels of iron, calcium, manganese, sodium, potassium, copper and zinc. Maca has an energy content of 663 kJ/100 g (Gonzales 2012, Wang et al 2007).

Maca also has some unique secondary metabolites, including specific polyunsaturated fatty acids,

alkaloids, steroids, glucosinolates and isothiocyanates. Macaene and macamides are unique polyunsaturated fatty acids and their amides, often used as markers (Wang et al 2007, Wu et al 2013). Macaridine and other maca alkaloids are among the other unique constituents isolated and characterised (Muhammad et al 2002). Its sterol profile includes campesterol, beta-sisosterol, brassicasterol and stigmasterol. Maca root also contains nine different types of glucosinolates (Wang et al 2007). Most likely other compounds will be discovered in the future (Pino-Figueroa et al 2010).

Levels of macaene, macamides, sterols and glucosinolates, and their proportions, vary in different-coloured maca, which may explain the different biological properties of maca. The processing of the product affects the active secondary metabolites, particularly the glucosinolates. For example, sulfoxiphane formation is increased at boiling point, and epithiospecifier protein activity is decreased (Gonzales 2012).

Macamides are chemically neutral lipids in a carbohydrate-rich plant, which means they should easily cross the intestinal wall and the brain-blood barrier (Wu et al 2013).

Another identified compound is (1R,3S)-1-methyl-1,2,3,4-tetrahydro-B-carboline-3-carboxylic acid (MTCA), which is a member of the tetrahydro- $\beta$ -carboline, and a potential monoamine oxidase enzyme inhibitor. MTCA can accumulate in mammalian tissues and in the presence of nitrates becomes a mutagenic precursor. When consumed as a multi-component within the whole maca plant extract, MTCA loses its adverse drug reaction and has beneficial effects (Gonzales-Castaneda & Gonzales 2008). This inhibition of MTCA mutagenicity may in part be due to the polyphenol content.

## MAIN ACTIONS

Maca has many different active constituents, and thus its pharmacological activities are numerous. Antioxidant modulation appears to be a major action, contributing to its many demonstrated effects.

Schaeffer et al (2013) cite varying levels of evidence from animal and in vitro experiments for actions affecting the nervous system (antidepressant, energising, antistress, central nervous system stimulation, enhanced cognitive function), reproductive system (antierectile dysfunction, oestrogenic properties, female fertility, enhancement of progesterone levels and enhanced sexual function and spermatogenesis effects) and other systems (antioxidant, hepatoprotective activity, immunostimulant effects, joint disease effects, improved growth rates and prevention of postmenopausal osteoporosis). Wang et al (2007) summarised maca's actions as improving fertility, sexual performance and antiproliferative function, supporter of vitality and stress tolerance, improving growth rate (in rainbow trout) and reducing postmenopausal osteoporosis.

### Antioxidant

Maca has the capacity to scavenge free radicals and protect cells against oxidative stress. In vitro tests indicate that maca's antioxidant action contributes to adenosine triphosphate production and may help to maintain a balance between oxidants and antioxidants (Sandoval et al 2002).

Tests with preclinical models using traditionally prepared aqueous extracts of maca demonstrated epithelial cell protection from ultraviolet A, B and C radiation (Gonzales-Castaneda & Gonzales 2008). The MTCA component found in maca has significant antioxidant activity, considered greater than vitamin E and most likely contributes to the protective effect against ultraviolet radiation (Gonzales-Castaneda & Gonzales 2008). Maca polyphenols are also thought to be responsible for the antioxidant effect.

### Neuroprotection

Black maca exhibited a neuroprotective effect in an animal model of scopolamine-induced memory impairment. The activity was possibly due to the polyphenols, quercetin and anthocyanins (Rubio et al 2007). In vitro studies on crayfish neurons demonstrated potential neuroprotective properties in a dose-dependent manner. The same paper tested rats with a pentane extraction of maca, containing mostly liposoluble constituent alkaloids (macamides, macaenes and isothiocyanates) which indicated at low dose inhibitory, antioxidative or antiapoptotic mechanisms preventing the experimental ischaemic insult. High concentrations showed some deleterious effects (Pino-Figueroa et al 2010).

### Antiproliferative actions

Like other cruciferous vegetables, maca may be antiproliferative due to its high concentration of glucosinolates, as these are known to have both antiproliferative and proapoptotic actions and polyphenols (Gonzales 2012). The polyphenols, alkaloids and sterols in maca may further contribute to its proposed anticancer properties (Wang et al 2007).

### Reducing prostate size in benign prostatic hypertrophy

Both aqueous and hydroalcoholic extracts of red maca reduced prostate size but not yellow or black maca in a preclinical study. Interestingly, serum testosterone and oestradiol levels were not affected by any of the maca types assessed; however, red maca prevented an increase in prostate weight induced by testosterone treatment (Gonzales 2012). Previously, Gasco et al (2007b) suggested that red maca may inhibit dihydrotestosterone conversion by 5-alpha-reductase 2; however, this remains uncertain. A study investigating the mechanism further compared red maca to finasteride (a 5-alpha-reductase inhibitor), where it was shown to reduce prostate weight but not seminal vesicles, unlike finasteride, which reduced both. The study indicated a need for a direct measure of levels of reductase to clarify the mechanism of action (Gasco et al 2007b, Shrivastava & Gupta 2012).

### Aphrodisiac and sexual and reproductive enhancement

Traditionally, maca has been used to enhance fertility in livestock living at high altitudes, and also as an aphrodisiac for both men and women (Wang et al 2007).

Different variants of maca appear to affect reproductive function differently. Black maca significantly enhanced spermatogenesis, measured in daily sperm production in vivo (Gonzales et al 2006). While studies in both men (Dording et al 2008, Gonzales et al 2003, Stone et al 2009) and mice (Cicero et al 2001, Gonzales et al 2006, Yucra et al 2008, Zheng et al 2000) suggest an aphrodisiac action, the mechanism involved has not been fully elucidated. In particular, the lipid extracts of macaene and macamide seem to increase sexual activity and correct erectile dysfunction in experimental animals (National Medicines Comprehensive Database 2012).

Spermatogenesis studies in rats observed the greatest effect with the ethyl acetate fraction from the hydroalcoholic extract of black maca (Yucra et al 2008). The effect may be mediated via an oxidant/antioxidant homeostatic mechanism, possibly in the epididymis (Yucra et al 2008). Wang et al (2007) further suggest that maca does not act on the hypothalamic-pituitary axis to regulate secretion, nor does it activate human androgen receptors or influence genes regulated by androgens.

Studies in female animal models show that rats fed high doses of maca (more than 15 g/kg) had increased luteinising hormone serum levels during the pro-oestrus and the luteinising hormone surge occurred in a dose-dependent manner (Uchiyama et al 2013). This high dose is consistent with traditional intakes of up to 100 g a day. Similarly, in vitro tests reveal that maca extract exhibits oestrogenic activity (Valentova et al 2006).

### Adaptogenic action

Maca can reduce the effects of stress, including preventing increases in corticosterone and adrenal gland size, and exhibits an antitiredness effect (Wang et al 2007). The highly nutritious profile of maca is proposed as one reason for these effects; however it is likely that more specific mechanisms are at work. Lopez-Fando et al (2004) hypothesised that maca may lead to activation of the hypothalamic-pituitary-adrenal (HPA) axis to increase generalised resistance to various noxious and stressful stimuli, although no clear mechanism has been proven.

### Lipid and glucose metabolism

Experimentation on hereditary hypertriglyceridaemic rats administered maca with a high-sucrose diet showed decreased levels of very-low-density lipoprotein, low-density lipoprotein and total cholesterol, an improvement in glucose metabolism, enhanced glutathione levels in blood and liver and increased superoxide dismutase activity in the liver (Vecera et al 2007).

### Improving bone density

Maca increases bone density in ovariectomised rats and works in a different manner to hormone replacement therapy (HRT). Maca did not significantly increase uterine weight or oestrogen levels in the studies reviewed (Wang et al 2007). The effect of maca was more obvious in cancellous bone-rich regions than in cortical bone-rich ones. The exact mechanisms regulating the endocrine are unclear; some investigators suggest that the effect is not due to the phyto-oestrogens or plant hormones, but to the maca alkaloids acting on the HPA axis (Zhang et al 2006).

## CLINICAL USES

### Improvement in sexual function

Maca is used within Peru as a sexual stimulant, energiser and nutritional food. Due to the lack of large randomised controlled trials testing the effects of maca for sexual function, it is difficult to draw firm conclusions about its effectiveness (Bella & Shamloul 2014); however the available evidence is promising and supported by animal and human research (Gonzales 2012, Shin et al 2010).

A 12-week, double-blind placebo-controlled, randomised, parallel trial involving 57 healthy males aged 21–56 years, testing doses of 1.5 and 3 g maca gelatinizada/day, concluded that maca improves sexual desire in men. The self-reported increase in desire was 40% and 42.2% over 8 and 12 weeks respectively (Gonzales et al 2002). Another double-blind clinical trial of 50 Caucasian men with mild erectile dysfunction, using 2400 mg dried maca over 12 weeks, concluded that there was a small but significant effect of maca supplementation on subjective perception of general and sexual wellbeing (Zenico et al 2009).

Sportsmen taking 2 g/day of maca root extract for 14 days increased their sexual desire, and reduced their cycling time for 40 km, compared to placebo in a randomised crossover design (Stone et al 2009). Evaluation of reproductive hormones found that maca did not alter serum concentrations of testosterone, oestradiol or 17-hydroxyprogesterone throughout the 12-week trial (Gonzales et al 2003).

Maca root may help alleviate selective serotonin reuptake inhibitor (SSRI)-induced sexual dysfunction. A small trial of 10 remitting depressed patients showed improvement in sexual dysfunction and libido when taking 3 g/day over 12 weeks. No improvement was noticed at doses of 1.5 g/day (Dording et al 2008).

### Fertility

No randomised controlled trials are available to determine whether maca has any benefits in improving male or female fertility. Research with animal models is promising and suggests improvements in spermatogenesis in a number of models (Gasco et al 2007a, Gonzales 2012, Rubio et al 2006). Additionally, Peruvian researchers have shown that maca helps alleviate altitude-related compromises in sheep and guinea pig fertility through actions on both the female and the male reproductive systems (Sandoval et al 2002).

### Menopausal symptom relief

Maca has been used to reduce menopausal symptoms as an alternative to HRT and also when women are reducing their HRT dose (Meissner et al 2006). Two randomised controlled trials provide support for the use of maca in alleviating several menopausal symptoms (Brooks et al 2008, Meissner et al 2006).

A large ( $n = 124$ ) double-blind, randomised, placebo-corrected, outpatient, multicentre clinical study of early postmenopausal women taking maca ( $2 \times 1000$  mg/day with meals) resulted in significant reduction in menopausal symptoms over the 8-week trial (Meissner et al 2006). The symptoms most significantly improved were excessive night sweating, hot flushes, nervousness, excessive alertness, lack of energy, tiredness and, to a lesser degree, irritability and headaches. The second month of treatment magnified the positive effect, and the cessation of maca showed a 'residual effect' for 1 month. Maca treatment was found to stimulate production of oestradiol, suppress blood follicle-stimulating hormone and increase high-density lipoprotein cholesterol. The maca used in this study was pregelatinised organic maca, a combination of three main root ecotypes, 16% black, 48% yellow, 9% purple/red and 27% other colours, dried and processed at a Peruvian university.

A smaller double-blind, placebo-controlled, crossover randomised controlled trial of 14 postmenopausal women showed that treatment with 3.5 g/day powdered maca for 6 weeks significantly reduced psychological symptoms, including anxiety

and depression, together with measures of sexual dysfunction, when compared to placebo. Interestingly, the women's blood samples showed no differences in the concentrations of oestradiol, follicle-stimulating hormone, luteinising hormone and sex hormone-binding globulin. Additionally, the maca extracts were tested in *in vitro* yeast assays, and showed no androgenic or oestrogenic activity (Brooks et al 2008).

### OTHER USES

As a food, maca can be eaten baked, roasted, in soup or made into fermented drinks or coffee.

### DOSAGE RANGE

Traditionally, prepared maca was consumed at levels of 50–100 g/day.

### According to clinical trials

- Male libido enhancement: 2 g daily in three divided doses.
- SSRI-induced sexual dysfunction: 3 g/day.
- Menopausal symptom relief: 2–3.5 g daily for 8 weeks.

### TOXICITY

Toxicity studies showed safety for use at 7.5 g/kg (on rats) and 15 g/kg (on mice), suggesting maca is safe in high doses (Meissner et al 2006).

### ADVERSE REACTIONS

Peruvian highlanders state that fresh maca may have adverse effects on health (Valerio & Gonzales 2005); however this has not been scientifically validated (Gonzales 2012).

### SIGNIFICANT INTERACTIONS

Theoretical interactions have been suggested to be plausible in people taking antidepressants, blood thinners and blood pressure medications (Health Canada 2013).

No reported drug interactions.

### Practice points/Patient counselling

Maca is a traditional food and medicine from the Peruvian Andes used for thousands of years. Traditional uses include to enhance sexual behaviour in men and women, support fertility, enhance energy and reduce the adverse symptoms of menopause. It is rich in nutrients and contains many unique plant chemicals that have multiple benefits on health. There is still much scientific research needed to understand its actions and validate its effectiveness in humans. As with any natural medicine, the effect is gradual and subtle, so it may take 6–12 weeks of dosing before effect will be noted. Maca tastes slightly nutty when taken as a powder mixed in drinks. Other preparations are available (tablets and capsules). General dosage is 1.5–3 g/day for 6–12 weeks.

### CONTRAINDICATIONS AND PRECAUTIONS

Allergy to cruciferous family.

Some plants in the *Brassica* genus have goitrogenic effect, due to a range of constituents such as thiocyanates and isothiocyanates. To date there are no studies on whether maca exerts a goitrogenic effect. Goitrogens may become inactive after cooking (Srilakshmi 2006). Epidemiological surveys of the Andean region revealed endemic goitre and cretinism; however a wide range of factors contributed to this (Fierro-Benitez et al 1969). Ensure maca is correctly prepared and not used as a food staple.

### PREGNANCY USE

Insufficient information regarding use in pregnancy and lactation. Avoid use.

### PATIENTS' FAQs

#### What will this do for me?

Maca may improve libido and sexual function and also reduce menopausal symptoms; however more clinical research is required to be certain.

#### When will it work?

Most studies show that maca works after 6–8 weeks of dosing at the correct levels.

#### Are there any safety issues?

Maca has been used for centuries as a food at high doses with no safety issues.

## Magnesium

M

**HISTORICAL NOTE** 'Magnesium' comes from the name of the ancient Greek city Magnesia, where large deposits of magnesium were found. In the form of Epsom salts, magnesium has long been used therapeutically as a laxative although it is also used in many other ways, such as a foot soak to soften rough spots and absorb foot odour and as a bath additive to ease muscle aches and pains. Supplemental magnesium in recent years is commonly ingested to alleviate musculoskeletal pains and cramping.

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Magnesium is an essential mineral and critical cofactor for over 300 biochemical processes, such as adenosine triphosphate (ATP) manufacture, critical to phosphorylation reactions. It is also necessary for DNA, RNA protein synthesis, carbohydrate metabolism, bone formation and cellular signal transduction (Allen 2013, Hartwig 2001, Rude et al 2009). Magnesium may also serve as an immunomodulator regulating NF-κB activation and cytokine production. In this role it may limit systemic inflammation and corresponding general markers such as C-reactive protein (Chacko et al 2010, Song et al 2007). It is the fourth most abundant cation in the body, with 50–60% sequestered in the bone, the remainder distributed equally between muscle and non-muscular soft tissue. Only about 1% of total body magnesium is found in the extracellular fluid. Dietary intake, renal and intestinal function finely balance and maintain plasma magnesium concentrations.

Absorption of dietary magnesium starts within 1 hour of ingestion, and occurs along the entire length of the bowel, with salts of high solubility having the most complete absorption (e.g. magnesium citrate). Normal magnesium absorption occurs passively at a rate of approximately 90% through the paracellular pathway. Active transport may occur only where extremely low dietary magnesium intake is observed, i.e. it is thought that magnesium absorption may be enhanced in bowel disorders, which must be considered when suggesting magnesium supplementation for these conditions (Allen 2013, Swaminathan 2003, Topf & Murray 2003). Magnesium absorption requires selenium, parathyroid hormone (PTH) and vitamins B<sub>6</sub> and D and is hindered by phytate, fibre, alcohol, excess saturated fat and the presence of unabsorbed fatty acids, high phosphorus or calcium intake (Johnson 2001, Saris et al 2000). However, calcium is no longer perceived to be as antagonistic to magnesium uptake as previously

thought, while research using test meals may show negative interaction — in contrast to long-term balance studies (Andon et al 1996, Fine et al 1991, Gropper et al 2009, Lewis et al 1989). Some authors suggest that such nutrient interactions only become significant in situations of low magnesium intake (Gropper et al 2009, Lewis et al 1989). Healthy people absorb 30–50% of ingested magnesium; increasing to 70% bioavailability in cases of low intake or deficiency (Allen 2013, Braunwald et al 2003). Other research suggests that fructo-oligosaccharides may improve magnesium absorption, particularly in adolescent girls (Ellen 2009).

Although currently it is undisputed that magnesium metabolism is regulated, the identity of such regulators remains largely obscured (Gropper et al 2009). While a number of hormones affect magnesium homeostasis they fail to explain every facet. What is understood to date is that magnesium homeostasis is regulated via a filtration–reabsorption process in the kidneys. Magnesium conservation is facilitated when magnesium is deficient, and excreted when surfeit (Quamme 2008). Reabsorption occurs in the ascending loop of Henle mediated by mechanisms involving paracellin-1, where sodium-assisted transport is generated to enhance transepithelial transport. Therefore medications that impact sodium resorption, such as loop diuretics, osmotic diuretics and changes in extracellular fluid volume expansion, may enhance the excretion of magnesium (Allen 2013).

While hormones central to calcium homeostasis, e.g. PTH, play a role in magnesium metabolism, this is a greatly diminished one compared to calcium (Shils & Rude 1996). Additional regulators include adrenergic signalling pathways, insulin, oestrogen and growth hormone (Rude & Shils 2006). Some researchers suggest that the real locus of control over magnesium homeostasis may be independent of hormones; instead there may be a combination of fractional absorption, renal excretion and transmembranous cation flux (Gropper et al 2009).

Once absorbed, magnesium travels to the liver, enters the systemic circulation and is transported around the body, to be ultimately excreted via the kidneys, with urine representing the major excretory pathway. Consequently, the kidney is pivotal in homeostatic control, rapidly adjusting to changing dietary intake (Rude & Shils 2006). Renal handling of magnesium is subject to additional negative influences. For example, increased calcium ( $\approx 2600$  mg/day) (NHMRC 2005), sodium, protein, caffeine and alcohol consumption (Allen 2013, Gropper et al 2009, Rude 2010, Rude & Shils 2006),  $B_6$  depletion (Turnlund et al 1992), glycosuria, stress (Allen 2013, Khan et al 1999, Rude & Shils 2006, Turnlund et al 1992, Walti et al 2003), elevated thyroid hormones (Wester 1987), protein intakes either above or below recommended levels (Wester 1987) and increases in net endogenous acid production (Rylander et al 2006) all impair the kidney's capacity to reabsorb magnesium. Additional minor losses

occur through sweat and faeces (Gropper et al 2009, Rude & Shils 2006).

### Magnesium assessment

In spite of intense ongoing research, there is still no simple, rapid and accurate laboratory test to determine total body magnesium status in humans (Arnaud 2008, Feillet-Coudray et al 2000). In particular, as with many of the minerals, there is an urgent need to identify a functional or biological marker of magnesium status, similar to the role of ferritin in iron assessment (Arnaud 2008). While serum testing is still frequently performed, it is only indicative of severe depletion, as evidenced by values  $<0.75$  mmol/L and while some studies demonstrate a correlation between these values and the magnesium content of other tissues, many do not (Arnaud 2008). Some researchers suggest that serum values  $0.75$ – $0.85$  mmol/L warrant further investigation with more sensitive tests.

Erythrocytes naturally contain large amounts of magnesium and experimental depletion is reflected by declining red blood cell (RBC) concentrations within weeks. A criticism of this method relates to repletion studies which found greater increases in serum magnesium following supplementation than reflected in the RBC; however, one could argue that the diminished response is a more accurate reflection of delayed intracellular recovery. Both animal and human studies have shown magnesium concentrations in white blood cells, e.g. lymphocytes, to be a particularly accurate indicator of magnesium content of both skeletal and cardiac tissues, which, given their functional significance, represents an attractive option. Actual muscle biopsies are believed to be an excellent indicator of body status; however, due to their invasive nature, they are rarely used (Arnaud 2008).

Increasingly, however, magnesium loading tests are probably the best assessment (Allen 2013, Arnaud 2008). The procedure involves either oral or intravenous (IV) loading with magnesium (e.g.  $500$ – $700$  mg) followed by collection of 24-hour urine. Generally, excretion of  $<70\%$  is considered indicative of magnesium deficiency. One of the significant disadvantages of this method is the lack of standardisation, e.g. form and dose of magnesium administered, which is critical for ensuring its sensitivity and reproducibility. Additionally, this test should only be used in individuals with healthy renal function generally and absorptive capacity specifically in oral loading. Exchangeable magnesium pool tests requiring magnesium stable isotopes is a novel approach to magnesium assessment; more studies and human trials are needed (Allen 2013).

### FOOD SOURCES

Good dietary sources of magnesium include, in descending order, dark green leafy vegetables, legumes, wholegrain cereals, nuts, fruit, fish, most meat, whole full-fat milk, cheese, eggs, cocoa, soy flour, mineral water and hard water (Allen 2013).

In some communities, 'hard tap water' contains significant amounts of magnesium. Food processing and refining remove a substantial amount of naturally occurring magnesium from the food chain — up to 80% in refined grains (Insel et al 2013). High-fibre foods can limit the amount of magnesium absorbed from food but those containing fermentable carbohydrates (e.g. oligosaccharides, pectin) can improve magnesium absorption.

## DEFICIENCY SIGNS AND SYMPTOMS

When reduced intakes or increased losses of magnesium, potassium or phosphorus occur (the three major intracellular elements), losses of the others generally follow. As such, many deficiency symptoms are also due to alterations in potassium and/or phosphorus status and manifest as neurological or neuromuscular symptoms.

Symptoms of deficiency include:

- anorexia and weight loss
- nausea and vomiting
- muscular weakness and spasms
- numbness, tingling, cramps
- spontaneous carpal–pedal spasm
- vertigo, ataxia, athetoid, choreiform movements
- lethargy
- difficulty remembering things
- apathy and melancholy
- confusion
- dysregulation of biorhythms (some sleep and mental health disorders, including insomnia)
- depression
- mental confusion, decreased attention span and poor concentration
- personality changes
- hyperirritability and excitability
- vertigo
- cardiac arrhythmia, tetany and ultimately convulsions can develop if deficiency is prolonged.

Although magnesium deficiency is a common clinical problem, serum levels are often overlooked or not measured in patients at risk for the disorder. About 10% of patients admitted to hospitals and up to 65% of patients in intensive care units may be magnesium-deficient (Braunwald et al 2003).

Low magnesium states are associated with several serious diseases such as congestive heart failure, ischaemic heart disease, atherogenesis, atherosclerosis, cardiac arrhythmias, hypertension, mitral valve prolapse, metabolic syndrome, diabetes mellitus, hyperlipidaemia, pre-eclampsia (PE) and eclampsia and osteoporosis, although the latter demonstrates conflicting evidence (Allen 2013, Fox et al 2001, Guerrero-Romero & Rodriguez-Moran 2002, Rude & Shils 2006). Epidemiological evidence suggests that a low dietary intake of magnesium is also associated with impaired lung function, bronchial hyperreactivity and wheezing, and risk of stroke (Ascherio et al 1998, Hill et al 1997). Magnesium deficiency may also play a role in the pathophysiology of Tourette's syndrome (Grimaldi 2002).

## Primary deficiency

A primary deficiency is rare in healthy people as the kidneys are extremely efficient at maintaining magnesium homeostasis. Studies of experimental magnesium depletion demonstrate that it takes months of intentional magnesium deprivation to induce a deficiency and even then, its presentation is 'vague' and idiosyncratic (Shils & Rude 1996, Wester 1987).

Marginal deficiencies are far more common and very often undiagnosed. There is evidence that daily magnesium intake has declined substantially since the beginning of the last century, with dietary surveys showing the average intake in Western countries is often below the recommended dietary intake (RDI) (Ford & Mokdad 2003, Lukaski 2000, Rude & Shils 2006, Saris et al 2000). Those particularly susceptible to inadequate dietary intakes are institutionalised elderly and the elderly in general (McKeown et al 2008, Woods et al 2009).

## Secondary deficiency

In contrast to the low rates of reported primary magnesium deficiency, secondary deficiency is far more common and seen in both the acutely and the chronically ill (Gropper et al 2009, Shils 1964). Most magnesium deficiencies occur due to a combination of insufficient dietary intake and/or intestinal malabsorption and increased magnesium depletion or excretion. There are many factors that predispose to deficiency and the most common are listed in Table 1.

## Medicines increasing risk of deficiency

Many pharmaceutical drugs have the potential to cause hypomagnesaemia.

## MAIN ACTIONS

Magnesium plays an essential role in a wide range of fundamental biological reactions in the body. It is involved in over 300 essential enzymatic reactions and is necessary for every major biological process. It is especially important for those enzymes that use nucleotides as cofactors or substrates and plays a role in many processes that are of central importance in the biochemistry of each cell, particularly in energy metabolism. It is also required for many other important biological functions, such as:

- nerve conduction
- regulation of vascular tone
- muscle activity
- amino acid and protein synthesis
- DNA synthesis and degradation
- immune function
- ATP production
- blood clotting
- natural calcium antagonist.

## Interaction with other nutrients

Magnesium is extremely important for the metabolism of calcium, potassium, phosphorus, zinc, copper, iron, sodium, lead and cadmium and the

TABLE 1 RISK FACTORS FOR MAGNESIUM DEPLETION AND DEFICIENCY	
Dietary	Excessive intake of ethanol, salt, phosphoric acid (soft drinks), caffeine Sodium deficit (via drug administration) Protein-energy malnutrition. There is evidence that magnesium balance remains positive despite reduced recommended dietary intake as long as protein >30 g/day Chronic excessive magnesium intake
Endocrine disorders	Hyperaldosteronism Hyperparathyroidism with hypercalcaemia Hyperthyroidism Diabetes mellitus and glycosuria
Lifestyle	Profuse sweating Intense, prolonged stress Alcohol ingestion
Gastrointestinal disorders (gastrointestinal tract [GIT] absorptive surface pathology or reduced transit time or increased upper GIT loss)	Celiac disease Infections Inflammatory bowel disease Malabsorption syndromes Biliary and intestinal fistula Pancreatitis Partial bowel obstruction Vomiting/diarrhoea
Elevated cortisol levels	Chronic stress Sleep deprivation Athletes and high-frequency exercise
Pharmaceutical drugs	Aminoglycoside antibiotics Amphotericin B Antivirals (ribavirin, foscavir) Carboplatin, cisplatin Cetuximab, panitumumab Corticosteroids Cyclosporin Digoxin Loop diuretics Oestrogens Osmotic diuretics Penicillamine Pentamidine Proton pump inhibitors Tacrolimus Tetracycline antibiotics
Renal	Metabolic disorders Renal failure Acidosis Nephrotoxic drugs (e.g. cisplatin, cyclosporin)
Other	Hyperthermia Hypercatabolic states such as burns Phosphate depletion Potassium depletion Pregnancy Lactation (prolonged (>12 months) or excessive lactation) Excessive menstruation Long-term parenteral nutrition combined with loss of body fluids (e.g. diarrhoea) Parasitic infection (e.g. pinworms)

Source: Allen (2013), Braunwald et al (2003), Johnson (2001), McDermott et al (1991), Sanders et al (1999), Shils et al (1999).

intracellular homeostasis and activation of thiamine (Johnson 2001). It acts as a calcium antagonist and positively interacts with nutrients such as potassium, phosphorus, vitamin B<sub>6</sub> and boron.

### OTHER ACTIONS

In its macro form, oral inorganic magnesium salts have a laxative and antacid activity and are practically insoluble in water.

### CLINICAL USE

In practice, magnesium is administered by various routes, such as intramuscular injection and intravenous infusion. This review will focus only on oral magnesium, as this is the form most commonly used by healthcare professionals and the general public, outside the hospital setting.

### Deficiency: treatment and prevention

Magnesium supplementation is used to prevent and/or treat magnesium deficiency. This is achieved using either oral or parenteral administration forms. Ideally, forms of magnesium less likely to induce diarrhoea are recommended for long-term use. Table 1 lists the diet, lifestyle, comorbidities and pharmaceutical medications which can increase the risk of hypomagnesaemia. Sometimes, suboptimal magnesium states are associated with other electrolyte imbalances, such as calcium and potassium.

Healthy representation of total plasma magnesium levels are 0.86 mmol/L, between a reference value of 0.75–0.96 mmol/L. Low total plasma magnesium levels <0.7 mmol/L (1.8 mg/dL, 1.5 mEq/L) are indicative of magnesium deficiency, although symptoms occur when total plasma magnesium is <0.5 mmol/L (1.2 mg/dL, 1.0 mEq/L). It should be noted that total plasma magnesium may not be a good indicator of magnesium status, as low plasma levels may exist with low intracellular magnesium. Further investigation is needed to ascertain accurate measurement of magnesium status (Allen 2013, Braunwald et al 2003).

### Constipation

In high doses magnesium exerts a laxative effect, which is used in practice for the short-term treatment of constipation and in order to get the bowel ready for surgical or diagnostic procedures. It is often used in the form of magnesium hydroxide (milk of magnesia) or magnesium sulfate (Epsom salts) (Guerrera et al 2009).

### Dyspepsia

As magnesium hydroxide (milk of magnesia), oral magnesium is used to reduce symptoms of dyspepsia and gastric acidity and acts as an antacid by forming magnesium chloride in the stomach. Magnesium oxide is also used for its antacid properties, which are greater than magnesium carbonate and sodium bicarbonate (Coffin et al 2011, Reynolds et al 1982). Magnesium trisilicate is the form used when a prolonged antacid activity is required.

### Clinical note — Magnesium citrate and orotate: superior supplements?

Magnesium supplements come in a variety of salts (e.g. citrate, oxide, gluconate, acetate, orotate); however their bioavailability varies. Current evidence, although not clearly demonstrating superiority of one preparation over another, supports the use in general of organic over inorganic forms (Coudray et al 2005, Firoz & Graber 2001, Lindberg et al 1990, Walker et al 2003). In particular, investigations of magnesium orotate (Lindberg et al 1990), citrate (Walker et al 2003) and gluconate (Coudray et al 2005) demonstrate high solubility and bioavailability. Magnesium orotate has attracted further attention regarding its potential synergism with magnesium in terms of repair of damaged myocardium (Classen 2004, Zeana 1999).

According to one randomised, double-blind, placebo-controlled study, magnesium amino chelate and magnesium citrate are better absorbed than magnesium oxide in healthy individuals (Walker et al 2003). Of the three, magnesium citrate led to the greatest increase in mean serum magnesium, a result evident after acute dosing (24 hours) and chronic dosing (60 days). Furthermore, although mean erythrocyte magnesium concentration showed no differences among groups, chronic magnesium citrate supplementation resulted in the greatest mean salivary magnesium concentration compared with all other treatments.

M

### Cardiovascular disease (CVD)

Whether adequate magnesium intake has a protective effect against the development of CVD appears likely, based on the balance of evidence; however some studies remain inconclusive. This is largely based on epidemiological evidence which continues to strongly link magnesium deficiency to numerous CVD presentations, including congestive heart failure, ischaemic heart disease, cardiac arrhythmias, hypertension, mitral valve prolapse, stroke, non-occlusive myocardial infarction and hyperlipidaemia (Alon et al 2006, Flight & Clifton 2006, Fox et al 2001, Frishman et al 2005, Gropper et al 2009, Guerrero-Romero & Rodriguez-Moran 2002, Haenni et al 1998, Klevay & Milne 2002, Ma et al 1995, Rasmussen et al 1988, Rude & Shils 2006, Saris et al 2000, Song et al 2006, Xu et al 2012, Zhang et al 2012).

Xu et al (2012), in their meta-analysis of >210,000 people with cardiovascular history and CVD incidence and mortality, suggest that the evidence is weighted more towards protective factors in women than men. The Japan Collaborative Cohort study produced similar findings; however the authors state that this may be due to confounders such as a propensity of men to more risky lifestyle factors

such as high-energy drinks, smoking and alcohol consumption (Zhang et al 2012).

A protective effect from hard water consumption, and in particular magnesium intake from this source, against CVD has been hypothesised for many years, culminating in a meta-analysis which determined a pooled odds ratio of 0.75 for cardiovascular mortality (Catling et al 2008).

Although the pathophysiology of each condition is multifactorial, the multiple biological effects of magnesium in the cardiovascular system suggest an important cardioprotective role. In the heart, magnesium acts as a calcium-channel blocker and promotes resting polarisation of the cell membrane, thereby reducing arrhythmias (Shattock et al 1987). It also helps to prevent serum coagulation (Frishman et al 2005). Low magnesium selectively impairs the release of nitric oxide from the coronary endothelium, resulting in vasoconstriction and possibly coronary embolism. Magnesium plays a role in blood lipid levels with detrimental changes, e.g. increased oxidation of low-density lipoproteins (LDLs), as well as generally increased oxidation, evident in hypomagnesaemia (Rude & Shils 2006). In experimental animals, dietary magnesium deficiency exacerbates atherosclerosis and vascular damage because it has a modulatory role in controlling lipid metabolism in the arterial wall.

### Mitral valve prolapse

It has been suggested that hypomagnesaemia is common in patients with mitral valve prolapse and therefore supplementation to correct this deficiency could exert beneficial clinical effects (Kitlinski et al 2004). In 1997, one study of 141 subjects with symptomatic mitral valve prolapse confirmed this suspicion by identifying hypomagnesaemia in 60% of patients (Lichodziejewska et al 1997). A randomised, double-blind, crossover study followed those magnesium-deficient people and found that 5 weeks' magnesium supplementation significantly alleviated symptoms of weakness, chest pain, dyspnoea, palpitation and anxiety (Lichodziejewska et al 1997). The dose regimen used was three tablets of magnesium carbonate 600 mg (7 mmol elementary magnesium) daily for the first week followed by two tablets daily until the fifth week. New research in this area is sadly lacking; the most recent article was presented in a paediatric study of the prevalence of hypomagnesaemia in mitral valve prolapse syndrome. A small percentage of the patients had serum magnesium levels <1.5 mg/dL after therapy symptoms of chest pain decreased (Amoozagar et al 2012).

### Symptoms of coronary artery disease (CAD)

In 2003, the results from a multicentre, double-blind randomised controlled trial (RCT) showed that 6 months' oral magnesium supplementation in patients with CAD resulted in a significant improvement in exercise tolerance, exercise-induced chest pain and quality of life compared to placebo

(Shechter et al 2003). The study used oral magnesium citrate (15 mmol twice daily) as Magnosolv-Granulat (total magnesium 365 mg). Previously, randomised placebo-controlled studies have shown that oral magnesium supplementation in CAD patients is associated with significant improvement in brachial artery endothelial function and inhibits platelet-dependent thrombosis, providing several potential mechanisms by which magnesium could beneficially alter outcomes in these patients. Additionally, Shechter (2010) suggests magnesium supplementation has theoretical benefits in hospitalised and elderly patients as cardioprotective therapy in CAD (Shechter et al 1999, 2000, 2010).

### Hypertension

Epidemiological evidence suggests an inverse relationship between blood pressure and serum magnesium, while large well-designed prospective studies report that magnesium-rich diets may lower blood pressure, particularly in older individuals (Sontia & Touryz 2007). Magnesium modulates vascular tone and reactivity both directly, e.g. calcium-channel blocker, and indirectly, e.g. prostacyclin, and alters vascular responsivity to vasoactive agonists. However, magnesium deficiency does not appear universal amongst hypertensive patients and several subgroups have been identified as characteristically demonstrating both pathologies. These include individuals of African descent, obese patients, patients with severe or malignant presentations and those also diagnosed with metabolic syndrome.

This may partly explain the mixed findings produced from magnesium supplementation studies, as well as additional heterogeneities in study designs, such as the salts used, dose administered, sample size and trial duration (Sontia & Touryz 2007). Modest but significant success ( $\approx -2$  to  $-5$  mmHg), however, has been achieved, particularly in those patients deficient at baseline, African American individuals and those patients with diuretic-associated hypertension (Rude & Shils 2006, Sontia & Touryz 2007, Witteman et al 1994). Patients who are considered metabolically obese normal-weight people (also deficient at baseline) demonstrate lowered mean systolic ( $-2.1$  vs  $3.9\%$  mmHg,  $P < 0.05$ ) and diastolic ( $-3.8$  vs  $7.5\%$  mmHg,  $P < 0.05$ ) benefit from IV magnesium supplementation (equivalent: 382 mg magnesium) when compared to controls (Rodriguez-Moran & Guerrero-Romero 2014).

### Stroke protection

A prospective study of 43,738 men (Health Professional Follow-up Study) conducted over 8 years showed an inverse association between dietary magnesium intake and the risk of total stroke (Ascherio et al 1998). This association was stronger in hypertensive than normotensive men and was not materially altered by adjustments for blood pressure levels. This association was confirmed in a later study of male smokers (Larsson et al 2008). Following adjustment for age and other cardiovascular risks, high

magnesium intake was associated with a statistically significant reduced risk of cerebral infarct, with a relative risk of 0.85 across men of all ages or 0.76 in those men aged <60 years, while the dietary intake of other minerals did not appear to convey any protection. It is also interesting to note that low concentrations of magnesium in the serum or cerebrospinal fluid in acute ischaemic stroke patients at admission or within 48 hours of onset of the stroke predict both greater neurological deficits, e.g. paresis, and higher 1-week mortality (Bayir et al 2009, Cojocaru et al 2007). In a meta-analysis of eight cohort studies — 8367 stroke cases amongst 304,551 people — a significant inverse association between high magnesium intake (range 228–471 mg magnesium day) and risk of stroke was found. More specifically, the people with the highest magnesium intake experienced an 11% reduction in the relative risk of stroke (Nie et al 2012). Findings were confirmed by the National Institutes of Health Stroke Scale, appearing as a dose–response relationship between magnesium serum levels and risk of death, in an epidemiological study in China (Feng et al 2012).

### Dyslipidaemia

Oral magnesium supplementation (magnesium oxide 12 mmol/day) taken over 3 months effectively reduced plasma lipids compared with placebo in people with ischaemic heart disease (Rasmussen et al 1989). The double-blind study showed that magnesium produced a statistically significant 13% increase in molar ratio of apolipoprotein A1:apolipoprotein B, compared with a 2% increase in the placebo group. This was caused by a decrease in apolipoprotein B concentrations, which were reduced by 15% in the magnesium group as compared with a slight increase in the placebo group. Additionally, triglyceride levels decreased by 27% after magnesium treatment.

In a later study measuring serum lipids and insulin sensitivity (IS) in 48 patients with mild uncomplicated hypertension, oral magnesium (600 mg pidolate) was administered with concurrent lifestyle recommendations. In the control group there were no changes to oral glucose tolerance test-derived IS indices, nor serum lipids, whereas the active treatment group experienced increased IS indices and decreased triglycerides, LDL and total cholesterol, with elevated high-density lipoprotein (HDL) levels (Hadjistavri et al 2010).

A study of 50 healthy volunteers by Marken et al (1989) found no change in lipid profile in a double-blind, crossover RCT using magnesium oxide (400 mg twice daily) for 60 days. This may be due to the fact that participants had lipid levels within the normal range at baseline.

### Arrhythmia prevention

#### In congestive heart failure

Although magnesium is usually administered intravenously when indicated in this condition, one

controlled study using oral magnesium showed that it significantly reduced the incidence of arrhythmias in patients with stable congestive heart failure (Bashir et al 1993). The double-blind crossover study used magnesium chloride (3204 mg/day in divided doses). Its role in sudden cardiac death as a result of fatal ventricular arrhythmia was observed in a prospective women's cohort, where higher plasma magnesium from dietary intake was associated with lower risk of sudden cardiac death (Chiuve et al 2011).

### Postoperative recovery from cardiac surgery

An interesting Australian study employed a range of preoperative treatments addressing mental, physical and metabolic components, including magnesium. The results of this RCT, using 1200 mg magnesium orotate, together with 300 mg CoQ10, 300 mg alpha-lipoic acid and 3 g omega-3 essential fatty acids administered daily 1 month prior to surgery, suggest an enhanced postoperative recovery and improved quality of life (Hadj et al 2006). IV administration of magnesium sulfate is also used to reduce the risk of atrial fibrillation postsurgery (Burgess et al 2006).

### Postsurgical pain

Systemic magnesium has been used with some scepticism in the management of postoperative pain management. Magnesium was examined in both intraoperative and postoperative patient observations in a vast variety of surgical procedures. The perioperative meta-analysis of 20 RCTs suggests a use for magnesium to reduce opioid consumption and mitigate postoperative pain. In the cardiac patients (three studies) no adverse effects were noted (De Oliveira et al 2013).

### Migraine headaches: prevention

People who suffer with recurrent migraines appear to have lower intracellular magnesium levels (demonstrated in both red and white blood cells) than those who do not experience migraines. (See Feverfew monograph for more information about migraine aetiology.) The low magnesium level is believed to result in cerebral artery spasm and increased release of substance P and other pain mediators (Woolhouse 2005).

Two randomised, double-blind studies using high-dose oral magnesium have found it to be useful in migraine sufferers, reducing frequency and/or number of days with migraine headache (Peikert et al 1996, Taubert 1994). One placebo-controlled study using a lower dose found no benefit in reducing the frequency of migraine headaches (Pffaffenrath et al 1996).

A dose of 24 mmol/L magnesium (600 mg trimagnesium dicitrate) taken daily over 12 weeks produced a 42% reduction in frequency of attack compared with 16% with placebo in one study of 81 patients, with a mean attack frequency of 3.6 migraine headaches each month (Peikert et al 1996).

Effects were observed after week 9 and treatment also significantly decreased the duration of each migraine. Significant decreases in migraine frequency were also observed in a crossover study that used the same dose and form of oral magnesium (Taubert 1994). In a recent study, 300 mg magnesium, in combination with other B vitamins and a standardised extract of feverfew magnesium, was stated as probably prophylactic for migraine treatment (Holland et al 2012). However research on the use of single magnesium supplementation in the reduction of migraine headaches is limited.

**Clinical note — What is the link between magnesium and migraine?**

Magnesium seems to play a significant role in the pathogenesis of migraine, with low brain levels and impaired magnesium metabolism reported in migraine sufferers (Thomas et al 2000). Magnesium has an effect on serotonin receptors, nitric oxide synthesis and release and a variety of other migraine-related receptors and neurotransmitters. It is also essential for mitochondrial function within the cell. The available evidence suggests that up to 50% of patients during an acute migraine attack have lowered levels of ionised magnesium (Mauskop & Altura 1998). Pilot studies of migraine patients have suggested that disordered energy metabolism or magnesium deficiencies may be responsible for hyperexcitability of neuronal tissue in migraine patients (Boska et al 2002). As such, factors that decrease neuronal excitability, such as magnesium, may alter the threshold for triggering attacks (Boska et al 2002). The efficacy of magnesium is stated as probably effective for migraine prevention (Holland et al 2012).

**Menstrual migraine headache**

Oral magnesium supplementation decreases pain, premenstrual symptoms and the number of days with migraine headache, according to two double-blind, placebo-controlled studies (Facchinetti et al 1991a, Peikert et al 1996). In the earlier study, treatment consisted of 360 mg/day of magnesium (pyrrolidone carboxylic acid) starting on day 15 of the menstrual cycle and continuing until the onset of menses. In the second study 600 mg of trimagnesium dicitrate was administered every morning. Both studies suggest a benefit in the reduction of symptoms (Mauskop & Varughese 2012).

**Migraine prophylaxis in children**

Oral magnesium oxide (9 mg/kg/day) given in three divided doses with food may decrease headache frequency and severity, according to a multicentre, randomised, double-blind, placebo-controlled trial (Wang et al 2003). The 16-week study involved children aged 3–17 years who reported a 4-week history of at least weekly moderate to severe

headache with a throbbing or pulsatile quality, associated anorexia/nausea, vomiting, photophobia, sonophobia or relief with sleep, but no fever or evidence of infection. Of note, 27% of subjects ( $n = 42$  magnesium oxide;  $n = 44$  placebo) failed to complete the study, thereby hindering interpretation of the results. While promising, there has been little further investigation so the evidence to date can be described as limited, with further research required (Orr & Venkateswaran 2014).

**Attention-deficit hyperactivity disorder (ADHD)**

The role of magnesium status and supplementation in ADHD remains unclear.

Several studies have demonstrated a positive correlation between magnesium status and ADHD pathology. Reported prevalence of hypomagnesaemia varies between 50% and 95% (Kozielec & Starobrat-Hermelin 1997, Mousain-Bosc et al 2004). It has been hypothesised that a genetic mutation involving the TRPM6 gene, which is crucial for magnesium transport and homeostasis, may be implicated, therefore making deficiency possible irrespective of adequate dietary intake (Mousain-Bosc et al 2004). There have been three magnesium supplementation studies in combination with vitamin B<sub>6</sub> (6 mg/kg/day magnesium ± 0.6–0.8 mg/kg/day vitamin B<sub>6</sub>), producing significant behavioural improvement (Mousain-Bosc et al 2004). Magnesium–B<sub>6</sub> treatment led to a rise in erythrocyte magnesium levels; when treatment ceased, behavioural symptoms reappeared within a few weeks, concurrent with lowered erythrocyte magnesium levels (Mousain-Bosc et al 2006).

More recently, a systematic review of magnesium monotherapy in ADHD by Ghanizadeh (2013) concluded there are no well-controlled trials available to support the efficacy of magnesium in ADHD, even though preliminary reports are promising. Part of the difficulties arise from the fact that some pharmaceutical stimulants affect magnesium plasma levels, baseline levels of children with ADHD in the studies are unknown and confounders such as B<sub>6</sub> deficiency (which negatively affects magnesium balance), dietary intake and kidney/liver function are not usually taken into account.

**Autism spectrum disorders (ASD)**

Research suggests that people with ASD generally demonstrate RBC magnesium depletion (Mousain-Bosc et al 2006, Priya 2011, Strambi et al 2006). In spite of two negative reviews published 10 years apart (Nye & Brice 2005, Pfeiffer et al 1995), enthusiasm regarding the use of magnesium as an adjunct to high-dose vitamin B<sub>6</sub> therapy (6 mg/kg/day with 0.6–0.8 mg/kg/day vitamin B<sub>6</sub>) in ASD continues (Kidd 2002, Mousain-Bosc et al 2006). Whether magnesium ultimately proves to be a successful adjunctive treatment remains unclear as currently there are limited trials and poor methodological rigour (Ghanizadeh 2013, Kidd 2002, Nye & Brice 2005, Pfeiffer et al 1995).

It has been proposed by Yasuda and Tsutsui (2013) that the pathogenesis of autism may somehow relate to low zinc and magnesium levels coupled with high aluminium, cadmium, lead, mercury and arsenic. This complex interplay of nutritional factors needs further exploration to be confirmed.

### Kidney stone prevention

Magnesium deficiency is one of many risk factors for the development of kidney stones (Anderson 2002, Seiner 2005). Others include nutritional deficiencies of water, calcium, potassium and vitamin B<sub>6</sub>, excessive intakes of animal protein, fat, sugar, oxalates, colas, alcohol, caffeine, salt and vitamin D, lifestyle factors and a positive family history.

A prospective double-blind study of 64 patients who were randomly assigned to receive placebo or potassium–magnesium citrate (42 mEq potassium, 21 mEq magnesium and 63 mEq citrate) daily for up to 3 years showed that the combination supplement reduced the risk of developing recurrent calcium oxalate kidney stones by 85% (Ettinger et al 1997). In a recent epidemiological study (European Prospective Investigation into Cancer and Nutrition: EPIC), participants with higher levels of fresh fruit, wholegrain fibre and dietary magnesium (low range 282, higher range 481 mg/day) were found to have a lower risk of kidney stone formation (Turney et al 2014).

### Premenstrual syndrome (PMS)

Three early double-blind studies using oral magnesium supplements in women with PMS produced positive results for decreasing symptoms such as fluid retention and mood swings (Facchinetti et al 1991b, Rosenstein et al 1994, Walker et al 1998). According to these, clinical effects develop slowly, starting during the second menstrual cycle. More recently, an open-label study of magnesium (250 mg) in PMS showed a 35% reduction in symptoms as assessed by investigators and 33.5% improvement as assessed by participants (Quaranta et al 2007). The study of 41 women with PMS used a modified-release magnesium tablet taken at intermittent times over three menstrual cycles, beginning 20 days after the start of their last menstrual period and continuing until the start of their next menstrual period.

Although it is not clear what mechanism of action is responsible, some, but not all, studies have identified decreased magnesium concentrations in both RBC and mononuclear blood cells of women with PMS (Khine et al 2006, Rosenstein et al 1994).

To date, the evidence overall remains promising for magnesium supplementation for some women with PMS; however further studies are required for a definitive conclusion to be made (Whelan et al 2009).

### Dysmenorrhoea

A Cochrane review of seven RCTs investigating the effects of various treatments for dysmenorrhoea

included three trials comparing magnesium with placebo. Overall, magnesium was found to be more effective than placebo for pain relief and resulted in less extra medication being required (Doty & Attaran 2009, Wilson & Murphy 2001). It appears that decreased serum magnesium is associated with dysmenorrhoea in young female adults; however evaluation of effective dosing is not available (Kibirian 2011, Yakubova 2012).

### Osteoporosis prevention

Magnesium comprises about 1% of bone mineral and is involved in a number of activities supporting bone strength, preservation and remodelling. Epidemiological studies have linked increased magnesium consumption, as part of an alkaline diet, with improved bone mineral density (BMD) (Tucker et al 1999). Chronic magnesium deficiency compromises bone health by increasing the size and brittleness of the bone crystals, inducing hypocalcaemia and possibly increasing inflammatory cytokines (Rude & Shils 2006). Therefore, low magnesium states increase the risk of osteoporosis. Several studies have investigated the effects of supplemental magnesium on bone density, generally yielding positive effects in both men and women (Tucker 2009).

One long-term study has reported an increase in bone density for magnesium hydroxide supplementation in a group of menopausal women (Sojka & Weaver 1995). After the 2-year test period, fracture incidence was also reduced. Another 2-year study showed that magnesium supplementation in postmenopausal women with osteoporosis results in increased bone mass at the wrist after 1 year, with no further increase after 2 years of supplementation (Stendig-Lindberg et al 1993). The regimen used here was oral magnesium 750 mg/day for the first 6 months, followed by 250 mg/day thereafter. In the Women's Health Initiative Observational Study, observing risk factors for osteoporotic fractures and altered BMD, low magnesium intake was associated with lower-bone (whole body, including hip) mineral density, but this did not translate to increased risk of fracture. In women who consumed magnesium via food and supplementation, baseline hip BMD and whole-body BMD was 2–3% higher than controls (Orchard et al 2014).

#### Clinical note — Peak bone mass

The best opportunity to influence bone mass occurs early in life. It has been estimated that approximately 40% of peak bone mass is accumulated during adolescence, with peak bone mass in the hip achieved by age 16–18 years (Weaver 2000). The spinal vertebrae are still able to increase in mass until the third decade of life, when total peak bone mass reaches 99% by age 26.6 years ( $\pm$  3.7 years). As such, ensuring an adequate intake of calcium and magnesium early in life is essential for attaining optimal bone mass.

## Fibromyalgia

A study of 60 premenopausal women diagnosed with fibromyalgia according to the American College of Radiology criteria and 20 healthy women matched for age and weight found that oral magnesium citrate (300 mg/day) significantly reduced the number of tender points, tender point index and Beck depression scores by the end of the 8-week treatment period (Bagis et al 2013). Interestingly, the serum and erythrocyte magnesium levels were significantly lower in patients with fibromyalgia than in the controls and there was a negative correlation between the magnesium levels and fibromyalgia symptoms.

## Asthma

There is some evidence that asthmatics have low intracellular (both red and white blood cells) magnesium (Dominguez et al 1998, Mircetic et al 2001, Sedighi et al 2006). This has relevance in asthma because healthy magnesium concentrations inhibit calcium entering smooth muscles such as those in the airways and therefore potentially reduce bronchospasm (Dominguez et al 1998, Gropper et al 2009). In addition, magnesium influences pulmonary vascular muscle contractility, mast cell granulation and neurohumoral mediator release (Mathew & Altura 1988).

Results of two randomised, double-blind studies suggest that oral supplements may also significantly alleviate asthma symptoms (Bede et al 2003, Hill et al 1997). Hill et al found that treatment improved symptoms, although it failed to change objective measures of air flow or airway reactivity, and Bede et al found a significant decrease in bronchodilator use after 8 weeks compared with placebo. This was a 12-week study using oral magnesium citrate in 89 children (4–16 years) with mild or moderate persistent bronchial asthma. The dose used was 200 mg daily for children aged 7 years and 290 mg for those older than 7 years. Adding to this, a randomised double-blind trial of magnesium glycine (300 mg/day) in 37 subjects aged 7–19 years over 2 months resulted in a statistically significant reduction in bronchial reactivity, skin responses to recognised antigens and salbutamol use in the treatment group compared to placebo (Gontijo-Amaral et al 2007). Kasaks (2013) suggests magnesium supplementation may be a useful adjunct to medical management to reduce airway hyperresponsiveness and improve perceived quality of life and asthma control.

## Pregnancy

Six studies suggest magnesium intake in pregnant women is less than the recommended values and gene expression at week 37 of TRPM6 denotes higher urinary excretion of magnesium, indicating an increased demand in pregnant women (Rylander 2014).

### Pregnancy-induced hypertension

A double-blind RCT of pregnant primigravida women given an oral supply of 300 mg magnesium

citrate from pregnancy week 25 found that the average diastolic blood pressure at week 37 was significantly lower than in the placebo group ( $P = 0.031$ ) and the number of women with an increase in diastolic blood pressure of  $\geq 15$  mmHg was also significantly lower than with placebo ( $P = 0.011$ ) (Bullarbo et al 2013).

### Pregnancy-induced leg cramps

A 2002 Cochrane review of five RCTs of treatments for leg cramps in pregnancy concluded that the best evidence is for magnesium lactate or citrate taken as 5 mmol in the morning and 10 mmol in the evening (Young & Jewell 2002). According to a more recent double-blind RCT involving 45 women, short-term use of magnesium supplementation (120 mg magnesium citrate and magnesium lactate 360 mg daily) over 2 weeks was insufficient to modify the intensity or frequency of leg cramps compared to placebo (Nygaard et al 2008). Possibly another dose or longer-term use would be more beneficial; however this remains to be tested.

### Preterm birth and low birth weight

A 2001 Cochrane review of seven studies involving 2689 women concluded that, although not all trials were positive, oral magnesium taken before the 25th week of gestation was associated with a lower frequency of preterm birth, a lower frequency of low birth weight and fewer small-for-gestational-age infants. Additionally, fewer hospitalisations during pregnancy and fewer cases of antepartum haemorrhage were associated with magnesium use (Makrides & Crowther 2014).

### Pre-eclampsia and eclampsia

Parenteral magnesium is used for preventing and managing PE and eclampsia. In particular, magnesium sulfate administered intravenously or intramuscularly is used.

An interesting longitudinal study revealed that, while serum magnesium levels decline in both healthy and pre-eclamptic pregnant women, such a decrease occurs earlier in those women who later develop PE (Sontia & Touryz 2007). Lower measures of erythrocyte, brain and muscle magnesium have recently been observed in PE women compared to those with normal pregnancies. In addition, there was a lower risk of hypertension in PE women with higher magnesium intake. More specifically, the study of 50 patients with PE and 50 controls demonstrated severe PE with erythrocyte magnesium levels 0.62 mmol/L, mild PE with erythrocyte magnesium of 0.67 mmol/L, and normal with 0.79 mmol/L (Rylander 2014).

### Diabetes mellitus

A strong association between magnesium, diabetes and hypertension has been established (Ascherio et al 1998, Dasgupta et al 2012, Sontia & Touryz 2007). Deficiency aggravates insulin resistance and

contributes to an increased risk of CVD in people with diabetes.

### Type 1 diabetes mellitus (T1DM)

Hypomagnesaemia is present in 25–38% of all diabetic patients secondary to glycosuria and magnesium redistribution (Paolisso et al 1992). Such depletion may occur early in the pathology, with T1DM children demonstrating progressive deterioration of serum levels within 2 years of diagnosis in some (Tuvemo et al 1997), but not all, studies. Magnesium depletion in T1DM has also been linked to earlier atherosclerotic development (Atabek et al 2006, Djurhuus et al 1999), polyneuropathy (De Leeuw et al 2004), advanced retinopathy (de Valk et al 1999) and immunosuppression (Cojocaru et al 2006). Supplementation studies have produced mixed results (Eibl et al 1998); however, magnesium supplementation may reduce risks of secondary pathology.

Consistent with these findings, some researchers suggest T1DM patients receive a high dose in the first month of treatment to normalise RBC and serum magnesium and then remain on continuous lower-dose supplementation (e.g. 300 mg/day) in order to avoid a return to hypomagnesaemia (Eibl et al 1998). Lower serum magnesium levels are found in young patients with poor glycaemic control ( $0.79 \pm 0.09$  vs  $0.82 \pm 0.09$  mmol/L, respectively;  $P = 0.002$ ). In youths with T1DM, low magnesium levels provide inadequate glycaemic control ( $\text{HbA}_{1\text{C}} > 7.5\%$ ). Higher levels of magnesium concentration present a decrease of 1.7% in  $\text{HbA}_{1\text{C}}$  (Gallitsinopoulou et al 2014).

### Type 2 diabetes mellitus (T2DM)

Epidemiological studies have drawn a link between poor dietary and/or serum magnesium and an increased risk of T2DM (Chambers et al 2006, Dasgupta et al 2012, He et al 2006, van Dam et al 2006). In one large study those in the lowest tertile of magnesium and fibre intakes exhibited a three to four times greater risk (Bo et al 2006). Serum magnesium depletion is also evident in  $\approx 25$ –38% patients. Hypomagnesaemia in diabetic patients appears to exacerbate impaired insulin resistance, elevated fasting blood glucose and  $\text{HbA}_{1\text{C}}$  concentrations (He et al 2006, Walti et al 2003). Oral magnesium (magnesium chloride 2.5 g/day for 4 months) adjunctive to hypoglycaemic medication has produced reductions of fasting glucose (–37.5%),  $\text{HbA}_{1\text{C}}$  (–30.4%), homeostasis model assessment–insulin resistance index (–9.5%) and insulin (Rodríguez-Moran & Guerrero-Romero 2003), while other studies demonstrate increased insulin levels with improved action (Paolisso et al 1992). In another study, a combination of magnesium (200 mg/day), zinc (30 mg/day) and vitamins (C 200 mg/day and E 150 mg/day) over 3 months significantly increased levels of HDL and apo-A1 24% and 8.8%, respectively (Farvid et al 2004).

Several RCTs and a meta-analysis of prospective cohort studies investigating oral magnesium supplementation have shown improvements in diabetic control (Dong et al 2011, Paolisso et al 1992, Rodríguez-Moran & Guerrero-Romero 2003). A double-blind trial that involved 63 patients with T2DM and reduced serum magnesium levels (treated with glibenclamide) demonstrated that the addition of oral magnesium over 16 weeks significantly improves IS and metabolic control (Rodríguez-Moran & Guerrero-Romero 2003). In a meta-analysis of prospective cohort studies involving 536,318 participants, a dose-responsive relative risk for type 2 diabetes for 100 mg/day increment in magnesium intake was 0.86 (95% confidence interval 0.82–0.89) (Dong et al 2011).

### Chronic leg cramps

Two randomised, double-blind studies have investigated the use of oral magnesium supplements in people with leg cramps. Frusso et al (1999) conducted a crossover trial involving 45 individuals who had experienced at least six cramps during the previous month. Subjects were given 1 month of oral magnesium citrate (900 mg twice daily) followed by a matching placebo for 1 month, or vice versa. This treatment regimen failed to reduce the severity, duration or number of nocturnal leg cramps. In contrast, Roffe et al (2002) tested magnesium citrate equivalent to 300 mg magnesium in subjects suffering regular leg cramps and identified a trend towards fewer cramps with active treatment ( $P = 0.07$ ). Significantly more subjects thought that the treatment had helped after magnesium than after placebo — 36 (78%) and 25 (54%) respectively. Interestingly, in both studies patients improved over time regardless of the treatment they received.

Although two additional studies in athletes found no correlation between cramping incidence and serum magnesium, the authors suggest that the cramping was caused by increased neuromuscular excitability (Schwellnus et al 2004, Sulzer et al 2005), which is a classic feature of magnesium deficiency (Rude & Shils 2006). As is the case with much magnesium research, more accurate and validated assessment methods may be required to elicit the true relationship between magnesium status and this presentation.

### Cancer

#### Colorectal cancer (CRC)

A meta-analysis of prospective studies suggests that higher magnesium intake is inversely related to the risk of CRC. In dose-response analyses, summary relative risks for incremental magnesium intake of 50 mg/day in colorectal, colon and rectal cancer were 0.95, 0.93 and 0.93 respectively. In a case-control study on colorectal adenomas (three) and carcinomas (six prospective cohort studies) meta-analysis, for every 100-mg/day elevation in magnesium intake, there was an associated 13% lower risk

of colorectal adenomas and 12% lower risk of CRC (Chen et al 2012, Wark et al 2012).

### Lung cancer

There is limited evidence to suggest an association between risk of lung cancer and lower calcium and magnesium levels (Cheng et al 2012).

### Prostate cancer

There is a possible relationship between low blood magnesium levels and high calcium-to-magnesium ratio and high-grade prostate cancer. More studies are needed (Dai et al 2011).

### OTHER POSSIBLE USES

Oral magnesium supplements are used in a variety of different conditions, most notably those involving muscle spasm or tension, pain and/or psychological and physical symptoms of stress and hyperexcitability. This includes irritable bowel syndrome, restless legs syndrome, chronic fatigue syndrome, anxiety states, tension headaches and insomnia. Preliminary evidence suggests that it may be beneficial for women with detrusor muscle instability (incontinence) or sensory urgency.

### DOSAGE RANGE

#### Australian RDI for adults

##### Men

- 19–30 years: 400 mg/day.
- >30 years: 420 mg/day.

##### Women

- 19–30 years: 310 mg/day.
- >30 years: 320 mg/day.

##### Pregnancy

- ≤18 years: 400 mg/day.
- >19–30 years: 350 mg/day.
- >31–50 years: 360 mg/day.

##### Lactation

- ≤18 years: 360 mg/day.
- >18–30 years: 310 mg/day.
- >31–50 years: 320 mg/day.

### According to clinical studies

- ADHD: 6 mg/kg/day ± 0.6–0.8 mg/kg/day vitamin B<sub>6</sub>.
- Arrhythmia prevention in congestive heart failure: magnesium chloride 3204 mg/day in divided doses.
- ASD: 6 mg/kg/day ± 0.6–0.8 mg/kg/day vitamin B<sub>6</sub>.
- CAD symptoms: oral magnesium citrate (15 mmol twice daily as MagnoSolv-Granulat, total magnesium 365 mg).
- Cancer risk reduction CRC: >100 mg/day.
- Dyslipidaemia: 600 mg/day magnesium pidolate.
- Fibromyalgia: 300 mg/day.
- Hypertension: 360–600 mg/day.

- Kidney stone prevention: magnesium hydroxide 400–500 mg/day.
- Migraine: 600 mg trimagnesium dicitrate daily.
- Migraine prophylaxis in children: magnesium oxide (9 mg/kg/day).
- Mitral valve prolapse: three tablets magnesium carbonate 600 mg (7 mmol of elementary magnesium) daily for the first week followed by two tablets daily.
- Nocturnal leg cramps: magnesium citrate equivalent to 300 mg magnesium daily.
- Osteoporosis prevention: taken on an empty stomach, 250 mg three times daily for 6 months, followed by 250 mg/day for 18 months.
- Paediatric asthma: magnesium citrate 200–300 mg daily.
- PMS general symptoms: 260 mg/day.
- PMS fluid retention symptoms: 200 mg magnesium (as magnesium oxide) daily.
- PMS mood swings: magnesium pyrrolidone carboxylic acid (360 mg) taken three times daily, from day 15 of the menstrual cycle to the onset of menstrual flow.
- Postoperative recovery from cardiac surgery: 1200 mg magnesium orotate in combination with 300 mg CoQ10, 300 mg alpha-lipoic acid and 3 g omega-3 oils taken daily 1 month prior to surgery.
- Stroke prevention 228–471 mg/day.
- T1DM: initial high dose to normalise serum levels and then continuous 300 mg daily.
- T2DM: 2.5 g magnesium dichloride daily or 300 mg elemental magnesium in combination with 30 mg zinc, 250 mg vitamin C and 150 mg vitamin E daily.

### ADVERSE REACTIONS

The most common adverse effects of oral supplements are diarrhoea (18.6%) and gastric irritation (4.7%) (Peikert et al 1996). It can be found as a primary ingredient in some laxatives (magnesium hydroxide) providing 500 mg of elemental magnesium (Guerrera et al 2009). Typically, doses of inorganic preparations supplying above 350 mg/day (elemental) may be associated with adverse effects. Dividing total daily supplemental amounts over two to three separate doses may help to reduce this risk and maximise bioavailability.

### TOXICITY

The possibility of hypermagnesaemia is rare, and is seen mostly in the elderly, people with renal insufficiency, dialysis or with serious bowel disorders.

Mild hypermagnesaemia signs and symptoms are subtle, such as light-headedness, headache, nausea, flushing and warmth.

At levels between 6 and 12 mg/dL (5–10 mEq/L), electrocardiographic changes occur with prolonged reportedly similar changes to hyperkalaemia. Concentrations of 9–12 mg/dL may increase hypotension, loss of deep tendon reflex and somnolence. Levels >12 mg/dL (10 mEq/L) may initiate muscle paralysis, arrhythmias, hypoventilations, stupor,

sinoatrial and atrioventricular block and ventricular arrhythmias. Levels exceeding 15.6 mg/dL (13 mEq/L) may result in coma, respiratory arrest and cardiac asystole (Jhang et al 2013).

### SIGNIFICANT INTERACTIONS

The interactions included in this section are relevant for oral supplementation and do not refer to other administration routes, although there may be an overlap.

#### Alcohol

Alcohol consumption results in increased urinary losses of magnesium and therefore with higher chronic ingestion additional magnesium replacement may be necessary.

#### Aminoglycosides (e.g. gentamicin)

Drug may reduce absorption of magnesium — monitor for signs and symptoms of magnesium deficiency, as increased magnesium intake may be required with long-term therapy.

#### Calcium

Magnesium and calcium deficiencies usually coexist due to magnesium's key role in active PTH and vitamin D production (Gropper et al 2009, Rude & Shils 2006, Wester 1987). Conversely, if magnesium intakes are excessive, calcium levels decline due to inhibition of PTH release and increased renal excretion. There is additional redistribution with impaired calcium influx and release from intracellular stores. Magnesium can also bind calcium-binding sites and mimic its actions (Gropper et al 2009, Rude & Shils 2006).

#### Calcium-channel blockers

Magnesium may enhance the hypotensive effect of calcium-channel blockers: monitor patients and their drug requirements — possible beneficial interaction under supervision.

#### Fluoroquinolones

Magnesium may decrease absorption of fluoroquinolone antibiotics — separate doses by at least 2 hours before or 4 hours after oral magnesium.

#### Loop diuretics and thiazide diuretics

Increased magnesium intake may be required with long-term therapy because of increased urinary excretion — monitor magnesium efficacy and status with long-term drug use.

#### Potassium

Hypomagnesaemia results in hypokalaemia due to increased potassium efflux from cells and renal excretion (Gropper et al 2009, Rude & Shils 2006).

#### Potassium-sparing diuretics

May increase the effects of supplemental magnesium — observe patients taking this combination.

#### Tetracycline antibiotics

Tetracyclines form insoluble complexes with magnesium, thereby reducing absorption of both — separate doses by at least 2 hours.

#### Dasatinib

May increase magnesium blood levels — observe (Vest & Cho 2012).

#### Neuromuscular blockers

May potentiate effects of neuroblockers — observe (Amgen Inc 2012, Kim et al 2012).

#### L-thyroxine

Case studies suggest reduced effectiveness of levothyroxine with magnesium-containing antacids and laxatives (Pinard et al 2003) — observe.

### CONTRAINDICATIONS AND PRECAUTIONS

- Magnesium supplementation should be done cautiously in people with compromised renal function and is contraindicated in renal failure and heart block (unless a pacemaker is present).
- Hypermagnesaemia can develop in patients with renal failure and receiving magnesium-containing antacids or laxatives and with accidental Epsom salt ingestion.
- Overuse of magnesium hydroxide or magnesium sulfate may cause deficiencies of other minerals or lead to toxicity.

### PREGNANCY USE

Pregnant women and nursing mothers are advised to consume sufficient magnesium (see Australian RDI under Dosage range, above).

### PATIENTS' FAQs

#### *What will this supplement do for me?*

Magnesium is essential for health and wellbeing. Although used to prevent or treat deficiency states, it is also used to alleviate many conditions, such as CVD and PMS, and prevent migraine and muscular spasms.

#### *When will it start to work?*

This will depend on the indication it is being used to treat.

#### *Are there any safety issues?*

In high doses, some magnesium supplements can cause diarrhoea. High-dose supplements should not be used by people with severe kidney disease or heart block.

**Practice points/Patient counselling**

- Magnesium is an essential mineral in human nutrition with a wide range of biological functions.
- Low magnesium states are associated with several serious diseases, such as congestive heart failure, ischaemic heart disease, cardiac arrhythmias, hypertension, mitral valve prolapse, metabolic syndrome, stroke, diabetes mellitus, hyperlipidaemia, pre-eclampsia and eclampsia.
- Although supplementation is traditionally used to correct or avoid deficiency states, research has also shown a role in the management of numerous disease states, e.g. asthma, CVD, PMS, dysmenorrhoea, migraine prevention, diabetes, kidney stone prevention, osteoporosis prevention, dyspepsia and constipation. Preliminary research also suggests a possible benefit in ADHD, autism, women with detrusor muscle instability (incontinence) and pregnancy-induced leg cramps.
- Oral magnesium supplements are also used in a variety of different conditions, most notably those involving muscle spasm or tension, pain and/or psychological and physical symptoms of stress and hyperexcitability.
- Numerous drug interactions exist, so care should be taken to ensure safe use.

## Meadowsweet

**HISTORICAL NOTE** Meadowsweet is a medicinal herb indigenous to Europe that has been used traditionally as an anti-inflammatory agent. The health benefits of meadowsweet may be due to the polyphenol content, which is well known for its antioxidative and anti-inflammatory characteristics (Drummond et al 2013). Meadowsweet was one of the most sacred herbs used by ancient Celtic druid priests, hundreds of years ago (Blumenthal et al 2000). Modern-day aspirin owes its origins to the salicin content isolated from meadowsweet in the early 1800s. In fact, the name aspirin relates to this herb's former genus name 'Spiracea'.

**COMMON NAME**

Meadowsweet

**OTHER NAMES**

Bridewort, dolloff, dropwort, fleur d'ulmaire, gravel root, lady of the meadow, meadow-wort, queen of the meadow, spireaeflos.

**BOTANICAL NAME/FAMILY**

*Filipendula ulmaria* (family Rosaceae)

**PLANT PART USED**

Aerial parts

**CHEMICAL COMPONENTS**

Phenolic glycosides, essential oil, tannins, mucilage, flavonoids (up to 6% in fresh flowers) and ascorbic acid. Hydrolysable tannins (rugosins A, B, D, E) (Fecka 2009). The herb also contains various salicylate constituents, including methyl salicylate, salicin and salicylic acid. Fecka (2009) states that a dose of 3 g of meadowsweet flowers yielded an average of 394.9 mg of the polyphenols, of which 265.2 mg are ellagitannins and 107.9 mg are flavonoids.

**MAIN ACTIONS****Antibacterial**

Bacteriostatic activity has been reported in vitro against *Staphylococcus aureus*, *S. epidermidis*, *Escherichia coli*, *Proteus vulgaris* and *Pseudomonas aeruginosa* (Rauha et al 2000). The essential oil of *Filipendula vulgaris* has been found to inhibit the growth of *Aspergillus niger*, *Candida albicans*, *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Salmonella enteritidis* and *Staphylococcus aureus* (Radulović et al 2007). It seems the antimicrobial activity of *F. vulgaris* essential oil can be attributed to the synergistic interaction of the compounds within the oil rather than to the presence of a single inhibitory agent (Radulović et al 2007).

**Anti-inflammatory**

Meadowsweet has been shown to reduce complement activity and T-cell activation (Drummond et al 2013).

**Gastroprotective effects**

In vivo tests have identified protective effects against stomach ulcers induced by acetylsalicylic acid, but no protection was seen against ulcers produced under high-acid environments or due to stimulation by histamine (Barnaulov & Denisenko 1980). Based on these observations, it appears that the effect may involve a prostaglandin (PG)-mediated mechanism.

**Hepatoprotective**

An in vivo trial has demonstrated the hepatoprotective and antioxidant effects of meadowsweet (Shilova et al 2006). Meadowsweet extract (70% ethanol, 100 mg/kg) was shown to improve liver function in carbon tetrachloride (CCl<sub>4</sub>)-induced hepatitis in rats. In many parameters, the extract was shown to

be more effective than Carsil, a silymarin preparation well known for its hepatoprotective ability.

**OTHER ACTIONS**

In vitro tests have identified antioxidant and anti-coagulant activities (Calliste et al 2001, Liapina & Koval'chuk 1993).

Whether meadowsweet exerts anti-inflammatory and analgesic effects because of its high salicylate content is unknown and remains to be tested. The ethyl acetate extract of the petal of meadowsweet was investigated on whether it inhibited histidine decarboxylase (HDC) (Nitta et al 2013). HDC catalyses the formation of histamine and by controlling HDC, histamine-mediated symptoms, such as allergies and stomach ulceration, may be reduced. Future research is suggested in a clinical setting.

**CLINICAL USE**

Meadowsweet has not been significantly investigated under clinical trial conditions, so evidence is largely derived from traditional, in vitro and animal studies.

**Supportive therapy for colds**

Commission E approval for this condition is based on historical use in well-established systems of medicine, in vitro tests and animal studies (Blumenthal et al 2000).

**Acne**

Researchers believe that meadowsweet may stimulate the skin's natural immune mechanisms, reducing bacterial colonies and therefore limiting the complications of acne (Lenaers et al 2007). Volunteers used a meadowsweet preparation twice a day for 28 days and found a reduction in acne spots by 10%, an improvement in the homogeneity of the skin grain by 21% and a reduction of inflammatory lesions by 20%. Bacterial infiltration of lesions was also reduced by 22%.

**Gastrointestinal symptoms**

Meadowsweet is often used to treat gastrointestinal conditions associated with hyperacidity, such as gastritis, acidic dyspepsia and peptic ulceration. In vivo testing has found a decoction made from flowers of meadowsweet reduced experimentally-induced ulcers caused by acetylsalicylic acid. Additionally, it promoted healing of chronic stomach ulcers induced by ethanol (Barnaulov & Denisenko 1980). Currently, there is no evidence available to confirm an antacid activity.

**Conditions associated with mild-to-moderate pain**

Based on its significant salicylate content, meadowsweet is also prescribed for conditions associated with mild-to-moderate pain. However, no clinical research is available to confirm efficacy.

**OTHER USES**

Meadowsweet has traditionally been used as a treatment for diarrhoea based on the herb's appreciable

tannin content. It has also been used for conditions associated with mild-to-moderate pain (most likely due to the herb's significant salicylate content), fever and inflammation.

### DOSAGE RANGE

As no clinical trials are available to determine effective doses, the following doses are a general guideline.

- Fresh flowers: 2.5–3.5 g/day.
- Fresh herb: 4–5 g/day.
- Infusion: steep 2–3 g in 150 mL boiled water for 10 minutes and drink as hot as tolerable.
- Fluid extract (1:1) (g/mL): 2–3 mL/day.

### TOXICITY

Not known.

### ADVERSE REACTIONS

Although salicylates are present, they appear to cause less gastrointestinal irritation than acetylsalicylic acid. In fact, a meadowsweet preparation protected against acetylsalicylic acid-induced stomach ulcers in vivo (Barnaulov & Denisenko 1980).

### SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

### Aspirin and simple analgesics

Theoretically, meadowsweet may enhance anti-inflammatory and antiplatelet effects. Observe patients taking this combination — beneficial interaction possible.

### Iron

Separate doses of iron and meadowsweet by 2 hours — this is due to the tannin content of meadowsweet potentially forming an insoluble complex with iron and reducing its absorption.

### Warfarin

It is uncertain whether internal use of the herb will increase bleeding risk, so it is advised to observe patients taking warfarin concurrently. The herb has been shown to exert anticoagulant activity in vitro and in vivo, but human studies combining use with warfarin have not been conducted, so the clinical significance of this theoretical interaction remains unknown (Liapina & Koval'chuk 1993).

### CONTRAINDICATIONS AND PRECAUTIONS

Meadowsweet should not be taken by people with salicylate sensitivity. Suspend use of concentrated extracts 1 week before major surgery to avoid increasing bleeding risk.

### PREGNANCY USE

Safety unknown.

### Practice points/Patient counselling

- Meadowsweet is traditionally used as a herbal antacid, analgesic and antipyretic, antidiarrhoeal and treatment for urinary tract infections.
- Commission E approves its use as supportive therapy for the common cold.
- It contains several different salicylates that are thought to be responsible for much of its clinical activity; however, this remains to be proven.
- Although it contains salicylates, the herb does not appear to cause significant gastrointestinal irritation and may, in fact, have anti-ulcer activity.
- People who are salicylate sensitive should not take this herbal medicine.
- In practice, it is often combined with herbs such as chamomile and marshmallow in the treatment of gastrointestinal complaints.

### PATIENTS' FAQs

#### *What will this herb do for me?*

Traditionally, the herb has been used to treat gastrointestinal complaints such as dyspepsia and diarrhoea, urinary tract infections and joint aches and pains. It is also used as supportive therapy for the common cold.

#### *When will it start to work?*

Symptomatic relief should be experienced within the first few doses.

#### *Are there any safety issues?*

People who are salicylate-sensitive should not take meadowsweet. People taking anticoagulant medicines should use this herb with caution as increased bruising is theoretical possibility.

# Mullein

**HISTORICAL NOTE** Over the centuries mullein has been used in various ways. Taken internally, it has been used to treat respiratory conditions and tumours; applied topically, its use has been to relieve itch and dress wounds. It was also used to make candlewicks for casting out evil spirits. Due to its robust nature, mullein is now considered a serious weed pest of roadsides and industrial areas in countries such as the USA.

## **Clinical note — Natural mucilages found in herbs**

Mucilages are large, highly branched polymeric structures made from many different sugar and uronic acid units. They are hydrophilic and are capable of trapping water, causing them to swell in size and develop a gel-like consistency. The gels tend to have soothing properties and can be broken down by bowel flora when taken internally (Mills & Bone 2000). They are known to have beneficial effects on burns, wounds and ulcers when applied externally, and on gastric inflammation and irritation and diarrhoea when taken internally.

## **OTHER NAMES**

Aaron's rod, Adam's flannel, blanket herb, bunny's ears, candlewick plant, flannel-leaf, great mullein, Jacob's staff, flannelflower, gidar tamaku, gordolobo, hare's beard, hedge taper, longwort, Our Lady's flannel, rag paper, shepherd's club, shepherd's staff, torch weed, velvet plant, wild ice leaf, woollen, woolly mullein.

## **BOTANICAL NAME/FAMILY**

*Verbascum densiflorum* (syn *Verbascum thapsiforme*), *Verbascum phlomoides*, *Verbascum thapsus* (family Scrophulariaceae)

Note that although there are many species within the *Verbascum* genus utilised in various traditional medicinal systems (Akdemir et al 2011), this monograph focuses on the above three species as outlined in [British Pharmacopoeia \(2012\)](#).

## **PLANT PARTS USED**

Flower — dried petals, leaves

## **CHEMICAL COMPONENTS**

The constituents of the plant mullein include water-soluble mucilage, polysaccharides, flavonoids (including glycosides of quercetin, apigenin, luteolin, kaempferol and rutin), phenolic acids, iridoid glycosides (ajugol, harpagide and aucubin), phenylethanoid glycosides (including verbascoside), triterpene saponins (verbascosaponin) and sterols (Panchal et al 2010, Hussain et al 2009, Turker et al 2005, Georgiev et al 2011).

One of the most investigated constituents isolated from *Verbascum* spp. plants is verbascoside. Whether the pharmacological effects demonstrated for this

single constituent can be extrapolated to explain those for mullein is uncertain, as the effects of any herb are due to a number of phyto-constituents and their interaction with each other and the body. As such, information about verbascoside is included here in order to provide a further insight into the herb, but it should be interpreted accordingly.

Verbascoside has also been isolated from other herbs such as *Verbena officinalis*, *Echinacea purpurea* roots, *Euphrasia pectinata*, *Phlomis longifolia*, *Pedicularis plicata*, *Duranta erecta*, *Marrubium alysson*, *Leonurus glaucescens* and *Ballota nigra* (Calis et al 1992a, 1992b, Deepak & Handa 2000, Ersoz et al 2000, 2001, Liao et al 1999, Seidel et al 2000, Sloley et al 2001, Takeda et al 1995).

## **MAIN ACTIONS**

Mullein has not been significantly investigated under clinical trial conditions, so evidence is derived from traditional, in vitro and animal studies.

### **Demulcent and emollient**

Traditionally, these actions were thought to occur primarily within the respiratory system, especially the lungs. However, topical preparations of mullein also exert an emollient action on the skin (Blumenthal et al 2000). This is most likely due to the herb's high mucilaginous content.

### **Antiviral**

Mullein extract exhibits in vitro antiviral activity against fowl plague virus, several influenza A strains and influenza B strain, HSV and pseudorabies virus (Escobar et al 2012, McCutcheon et al 1995, Serkedjieva 2000, Slagowska et al 1987, Zanon et al 1999, Zgorniak-Nowosielska et al 1991). Antiviral activity has been demonstrated for both infusions and alcoholic extracts (Serkedjieva 2000).

### **Antibacterial**

In vitro studies have demonstrated antibacterial activity for mullein extracts (aqueous, ethanol and methanol) against *Klebsiella pneumonia*, *Staphylococcus aureus*, *Staphylococcus epidermidis* and *Escherichia coli* (Turker & Camper 2002). Of the three extracts tested, the aqueous extract exhibited the strongest antibacterial action.

### **Anthelmintic**

Crude methanolic extracts of *Verbascum thapsus* demonstrated in vitro anthelmintic activity against

*Ascaridia galli* (roundworm) and *Rallietina spiralis* (tapeworm) (Ali et al 2012).

### Antitumour

Some plants, such as mullein, were used in folk medicine as sources of antitumour remedies. An in vitro study has identified inhibitors of protein biosynthesis in *Verbascum thapsiforme* flowers. Researchers found that a saponin glycoside and its aglycon, isolated from the flowers, directly inactivates ribosomes (Galasinski et al 1996). The constituent, verbascoside, has been shown to inhibit telomerase activity in human gastric carcinoma cells in test tube studies, resulting in inhibition of tumour growth (Zhang et al 2002). Cytotoxic effects for verbascoside have also been identified against rat hepatoma and sarcoma cells, and cytostatic activity on human epithelial carcinoma cells (Saracoglu et al 1995).

### OTHER ACTIONS

The verbascoside constituent demonstrates antioxidant activity in vitro (Gao et al 1999). The saponins in mullein are thought to exert an expectorant activity; however, further investigation is required to confirm this.

### CLINICAL USE

Mullein has not been subjected to significant clinical investigation; therefore, information is generally derived from traditional usage, phytochemical research or evidence of pharmacological activity. In practice, this herbal medicine is often combined with other herbs in order to strengthen clinical effects.

### Chronic otitis media

To date, no controlled studies are available to determine the clinical effectiveness of mullein as a stand-alone treatment. However, two double-blind studies that tested a herbal combination ear-drop product (containing mullein) in children have produced positive results. The first study involved 103 children aged 6–18 years, and found that a naturopathic herbal ear drop, known commercially as Otikon (consisting of *Allium sativum*, *Verbascum thapsus*, *Calendula* flowers and *Hypericum perforatum* in olive oil), was as effective as local anaesthetic ear drops (containing amfetocaine and phenazone in glycerin) in the management of ear pain associated with acute otitis media. Treatment lasted for 3 days and produced a statistically significant improvement (Sarrell et al 2001). The second was a randomised, double-blind study involving 171 children aged 5–18 years who had otalgia and clinical findings associated with middle-ear infection (Sarrell et al 2003). Children receiving herbal ear drops containing *Allium sativum*, *Verbascum thapsus*, *Calendula* flowers, *Hypericum perforatum*, lavender and vitamin E in olive oil achieved better pain relief than controls; however, the pain appeared to be self-limiting with significant improvements seen in all groups over 3 days. The dose used was 5 drops three times daily.

### Productive and dry cough

Traditionally, mullein is combined with other demulcent or expectorant herbal medicines such as *Glycyrrhiza glabra*, *Tussilago farfara* and *Althaea officinalis* in the treatment of productive cough.

Commission E approves the use of mullein flowers for catarrhs of the respiratory tract (Blumenthal et al 2000). This is largely based on traditional use extending back to ancient times, and phytochemical investigation from in vitro and in vivo studies.

### Topical use

Mullein is used topically for wounds, burns, bruises, haemorrhoids and pruritus, and to soften the skin. The high mucilage and tannin content of the herb provides a theoretical basis for its use in these situations as an antipruritic and astringent agent. The leaves are used topically to soften and protect the skin. To date, no controlled studies are available to determine its effectiveness.

### OTHER USES

Mullein is included in herbal combination treatments for a variety of respiratory conditions such as bronchitis, asthma and tracheitis. Traditionally it is also used for diarrhoea, dysentery, haemorrhoids and laryngitis. In manufacturing, mullein is used as a flavouring component in alcoholic beverages.

### DOSAGE RANGE

- Fluid extract (1:1): 1.5–2 mL twice daily.
- Tincture (1:5): 7.5–10 mL twice daily.
- Dried leaf: 12–24 g/day.
- Decoction: 1.5–2 g of herb in 250 mL of cold water, brought to the boil for 10 minutes, taken twice daily.

### ADVERSE REACTIONS

A case of contact dermatitis has been reported (Romaguera et al 1985).

### SIGNIFICANT INTERACTIONS

Controlled studies are not available.

#### CONTRAINDICATIONS AND PRECAUTIONS

Insufficient reliable information is available.

#### PREGNANCY USE

Insufficient reliable information is available; however, Commission E states that no restrictions are known (Blumenthal et al 2000).

#### PATIENTS' FAQs

##### *What will this herb do for me?*

Mullein has been used since ancient times as a treatment for productive coughs and catarrhal states. In modern times, it is also used to treat chronic otitis

media, and has antiviral action against influenza virus and HSV. Currently, more scientific investigation is required to confirm efficacy for these indications.

#### **When will it start to work?**

Mullein has not been subjected to significant clinical investigation so it is unclear.

#### **Are there any safety issues?**

None are currently known.

#### **Practice points/Patient counselling**

- Mullein flowers have been used since ancient times as an expectorant and antitarrhal agent in conditions of productive cough and respiratory infections.
- It is most commonly used in combination with other demulcent and expectorant herbal medicines in the treatment of productive and dry cough.
- In vitro studies have identified antiviral and antibacterial activity.
- Mullein has not been subjected to significant clinical investigation; therefore, information is generally derived from traditional usage or evidence of pharmacological activity. As such, Commission E approves its use for catarrhs of the respiratory tract.
- Used in the form of a herbal combination ear drop, significant anaesthetic activity has been demonstrated.

## **Myrrh**

**HISTORICAL NOTE** Myrrh is the resin that seeps out of the secretory tissue in the bark of the *Commiphora* plant and has been considered an important medicinal product throughout the Middle East, China and India since biblical times. Because of its antimicrobial activity, myrrh has historically been used, alone and in combination with other herbs, to treat infections and inflammations of the oral cavity, in purification rituals, to embalm bodies, dress infected wounds and as a treatment for leprosy. Myrrh was one botanical ingredient in ocular applications from the Pharaonic pharmacopoeia of Egypt (Murube 2013) and in combination with aniseed, fennel, thyme and parsley, sweet myrrh was in one of the earliest formulations for a theriac (ointment or potion to antidote poisonous bites from wild animals), detailed on a stone in the Temple of Asclepius on the Kos island (Karaberopoulos et al 2012).

**COMMON NAME**

Myrrh

**OTHER NAMES**

Abyssinian myrrh, bal, bol, common myrrh, heer-abol, hirabol myrrh, gum myrrh tree, gummi myrrh, Somali myrrh, Yemen myrrh

**BOTANICAL NAME/FAMILY**

Genus: *Commiphora*

Species: There are over 150 species of *Commiphora*. The three species most used medicinally are:

- Commiphora molmol* (commonly farmed species)
- Commiphora myrrha* (native to Yemen, Somalia, Eritrea and Ethiopia)
- Commiphora mukul guggul* (native to India, used in Ayurveda)

Family: Burseraceae

**PLANT PARTS USED**

Essential oil (called oleoresin), gum resin, stem, leaves

**CHEMICAL COMPONENTS**

More than 300 molecules have been identified in this genus, including a diverse range of secondary metabolites, such as terpenoids, steroids, flavonoids, sugars and lignans (Shen et al 2012). Myrrh contains three main components: gum resin 30–60% (containing polysaccharides and proteins), alcohol-soluble resins 20–40% and volatile oils (2–10%) (composed of steroids, sterols and terpenes).

Sesquiterpenes have been identified as active constituents in the volatile oil. Resins are sticky, water-insoluble substances that are secreted where a plant is damaged by incision or natural causes. The viscous substance hardens shortly after secretion, but may be returned to a liquid state with heating. Resins tend to be soluble in alcohol. Each species has its unique constituent profile, which contribute to their specific therapeutic actions.

*C. molmol* oleo-gum resin contains volatile oils, resins and gum. Resins contain a wide range of constituents, including commiphoric acids and campesterol. The gum constituents include arabinose, galactose and xylose (Al-Harbi et al 1997). *C. molmol* is known for its anti-inflammatory, antipyretic and antihistamine effects (Al-Harbi et al 1997). *C. molmol* and *C. myrrha* are known for their antiparasitic actions.

Four new sesquiterpenes have been isolated from the resin of *C. myrrha*, called myrrhaterpenoids K-N(1-4) (Xu et al 2012). Triterpenoids have also been identified in *C. myrrha*.

Guggulipid is extracted from guggul, oleo-gum-resin exudate from *C. mukul*. It contains plant sterols (guggulsterones E and Z), thought to be its main pharmacologically active constituents (Ulbricht et al 2005). Diterpenoids, such as camphorene, and steroids have been identified in guggul (Shen et al 2012). This species is known for its actions as an

anti-inflammatory and lipid-lowering agent and for its role in obesity management.

**MAIN ACTIONS****Antiseptic**

Antifungal and antibacterial activities have been observed in vitro against standard pathogenic strains of *Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa* and *Candida albicans* (Dolara et al 2000). The oleo-gum-resin of *C. mukul* was shown to be comparable to kanamycin against both Gram-positive and Gram-negative bacteria in vitro (Saeed & Sabir 2004). Myrrh essential oil (species not identified in abstract) demonstrated some antifungal activity against *C. albicans* isolates in vitro (Carvalho et al 2012).

**Antiparasitic**

The use of *C. molmol* as an antiparasitic agent in Egypt resumed in the 1990s after numerous studies provided good evidence; however, the mode of action is still unclear (Abdul-Ghani et al 2009). The preparation called *Mirazid*, an oleo-resin containing 300 mg of purified *C. molmol*, has proven to be 100% effective against *Giardia lamblia* in rats, and had effect on hepatic coccidiosis induced by the parasite *Eimeria stiedae* in rabbits (Shen et al 2012). It was also considered to be effective against heterophyiasis with an animal study reporting a 100% reduction in worm load after 3 days (Fathy et al 2005).

Antiparasitic effects have been shown against *Schistosoma mansoni* in mouse livers in vitro (Hamed & Hetta 2005). Liver enzymes were significantly decreased after treatment with myrrh (*C. molmol*), while ova and worms' numbers were noticeably decreased. An in vivo study in the same year also produced promising results (Massoud et al 2005). Myrrh (500 mg/kg) was given for 5 days, 8 weeks postinfection. The animals were sacrificed after 12 weeks from the beginning of the experiment and myrrh was found to be comparable to cremophor EL, both producing approximate normal liver histology as compared to untreated animals. Another study compared the toxicity of myrrh to the commonly used antischistosoma drug Praziquantel. Praziquantel is well known for its toxicity and it would be a distinct advantage if another safer product could be found. The researchers reported that myrrh is a safe and promising alternative without hepatotoxic, genotoxic and carcinogenic consequences.

**Lipid-lowering effects**

Several mechanisms of action are responsible for this effect. The guggulsterones act as antagonists of the bile-acid receptor and of the farnesoid X receptor (FXR), which are involved in bile-acid regulation and cholesterol metabolism. Crude guggul contains ion-exchange resins that may remove bile from the intrahepatic circulation (Urizar et al 2002, Wu et al

2002). Additionally, two diterpenoids have been identified which act on pancreatic enzymes (PLA2) to control absorption of fat and cholesterol from the gastrointestinal tract (Shen et al 2012).

According to one review, 11 clinical studies have generally demonstrated that guggulipid from *C. mukul* significantly reduces triglyceride and total cholesterol levels; however, results from a recent double-blind randomised study were negative (Ulbricht et al 2005). Conflicting clinical results in the effects on total cholesterol, HDL, TG and LDL levels may be due to administration of different *C. mukul* materials (Shen et al 2012).

### Anti-diabetic

A recent review (Shen et al 2012) detailed the evidence for the use of *C. mukul* for diabetes. The ethanolic resin extract of *C. mukul* exhibited anti-hyperglycaemic and antioxidant effects in diabetic rat models. Guggulsterones 21 and 22 were identified as protective for the pancreatic beta cell function and prevented any impairment of glucose-stimulated insulin secretion. In vivo studies showed 21 and 22 reduced plasma insulin and blood glucose levels, and increased the glycogen content in induced DM2 models with high fat diets. Additionally, the antidiabetic target G6Pase has been inferred by 21 and 22 (Shen et al 2012).

### Anti-inflammatory

Myrrhanol A, a triterpene isolated from *C. mukul* gum resin, produces potent anti-inflammatory activity, as observed in an animal model of inflammation. In this study, anti-inflammatory activity was more marked than that of hydrocortisone (Kimura et al 2001). An animal model of rheumatoid arthritis (RA) confirmed significant anti-inflammatory effects with oral administration, also resulting in decreased joint swelling (Sharma & Sharma 1977). The essential oil of myrrh has also been shown to inhibit IL-6, probably due to down-regulating PGE<sub>2</sub> production, but not via nuclear factor kappaB inhibition in human gingival fibroblasts (Tipton et al 2006). Conversely, guggulsterone from *C. mukul* has demonstrated anti-inflammatory effects by decreasing nuclear factor kappaB and therefore tumour cell-induced osteoclastogenesis in vitro (Ichikawa & Aggarwal 2006).

Ethanolic and petroleum ether extracts of *C. myrrha* both demonstrated analgesic and anti-inflammatory activities in mice studies, providing some evidence to support the traditional use of myrrh for inflammatory pain (Su et al 2011). A water extraction of powdered resin of myrrh displayed anti-inflammatory and analgesic activities in mice models of inflammation. A combination of *C. myrrha* and *Boswellia carterii* (frankincense) demonstrated more potent anti-inflammatory and analgesic effect than the single herb. The suggested mechanism was the inhibition of inflammatory mediator overproduction, including nitrite and PGEs (Su et al 2012).

### Anti-oxidant

Essentially oil of *C. myrrha* showed potent antioxidant activity, and exceeded that of  $\alpha$ -tocopherol. The furano ring of *C. myrrha* constituents (namely furano sesquiterpenoids) reacted with singlet oxygen as the mechanism for the antioxidant activity. Three furano sesquiterpenoids showed significant radical scavenging activity (Shen et al 2012).

An emulsion of *C. molmol* displayed protective effects in rabbits poisoned with lead. The study showed that the rabbits given 50 mg/kg of *C. molmol* emulsion were protected from lead-induced hepatic oxidative damage and immunotoxicity, via reducing lipid peroxidation and enhancing antioxidant and immune defences (Ashry et al 2010).

### Local anaesthetic

Several compounds found within myrrh exert local anaesthetic activity, chiefly by blocking the inward sodium current across membranes (Dolar et al 2000).

### OTHER ACTIONS

#### Antispasmodic

One major component, T-cadinol, and several minor components possess smooth muscle-relaxing properties according to ex vivo tests (Andersson et al 1997, Claeson et al 1991).

#### Increases glucose tolerance

An extract of myrrh effectively increased glucose tolerance in both normal and diabetic rats (Al-Awadi & Gumaa 1987). Guggulipid (20 g/kg) improved glucose tolerance in another in vivo study (Cornick et al 2008). The purified ethyl ester of commipheric acid (150 mg/kg, twice daily) also lowered fasting blood glucose, insulin and triglycerides, leading researchers to propose that this constituent may be at least partly responsible for the antidiabetic effects; however, oral bioavailability is poor.

#### Local astringent and enhanced wound healing

Myrrh has astringent activity, promotes tissue granulation and enhances wound healing (Blumenthal 2000). In mice studies, myrrh (*C. molmol*) suspension promoted healing and repair of damaged (buccal) tissue over a 2-week period at low concentration (0.2% myrrh in sodium chloride solution). The mice had surgical incisions imposed on their buccal mucosa, which was irrigated every second day with the myrrh solution (Al-Mobeerick 2011).

#### Chemoprotective

In vitro tests of myrrh-terpenoids K-N 1 and 4 from *C. myrrha*, on dopaminergic neuroblastoma cells, exhibited some neuroprotective effects without any cytotoxicity (Xu et al 2012). Another study showed guggulsterone from *C. mukul* was cardioprotective through its antioxidative activity against a potent anti-neoplastic drug (doxorubicin) in vitro (Wang et al 2012).

### Antiproliferative/anticancer

A study of the protective effects of *C. molmol* against nitrosamine-induced hepatocarcinogenesis in rats showed that it did not prevent or delay the progression of hepatocarcinogenesis. Additionally, the study showed that, unlike earlier studies showing the contrary, *C. molmol* did not improve biochemical parameters nor the histological profile regarding antitumour efficacy, but actually negatively affected them (El-Shahat et al 2012).

### CLINICAL USE

#### Topical treatment of oral or pharyngeal inflammation

Often used as a component of gargles, mouthwashes or paints for these indications, there are few controlled clinical trials or in vitro studies on the effects of myrrh on cells derived from the human oral cavity. A 2003 in vitro study investigating the effects of myrrh oil on a number of key cells implicated in gingivitis found that low concentrations of myrrh oil reduced gingival fibroblast production of proinflammatory cytokines and, therefore, the participation of these cells in gingival inflammation associated with gingivitis and periodontitis (Tipton et al 2003). This is thought to be, at least in part, due to inhibition of PGE<sub>2</sub>. Taheri et al (2011) report that myrrh resin has potential use as a topical preparation in dentistry for small wound treatment, anodyne for the buccal cavity or for oropharyngeal infections, by soothing and astringing inflamed tissues of the oral cavity and throat (Taheri et al 2011). Commission E approved myrrh for these indications (Blumenthal 2000).

#### External treatment of minor inflammatory conditions and wounds

Myrrh is incorporated into salves and topical preparations for the treatment of bed sores, minor wounds and haemorrhoids. Although no clinical trials are available, the antimicrobial, anti-inflammatory, astringent and local anaesthetic activities of myrrh provide a theoretical basis for efficacy.

#### Osteoarthritis

A small, uncontrolled trial of *C. mukul* for patients with osteoarthritis ( $n = 30$ ) demonstrated that treatment with 500 mg (3.5% guggulsterones) of the herb, three times daily for 2 months resulted in reduced joint inflammation, swelling and pain (Singh et al 2003). Although this suggests that the effects may be clinically significant, further investigation is required.

#### Hyperlipidaemia, hypercholesterolaemia, hypertriglyceridaemia

Various RCTs have investigated the effects of guggulipid on high-blood levels of lipids, cholesterol and triglycerides with inconsistent results. Overall, effects seem to be more likely in Indian populations

than people eating Western diets; however, the reason for the discrepancy is unknown. A review of nonpharmacological treatments of cardiovascular diseases suggested that guggulipid (*C. mukul*) merits further clinical research; however, it was not recommended for the treatment of dyslipidaemia, due to the non-significant and often paradoxical results in Western populations according to double-blind trials and also due to concerns about bioavailability of concomitantly administered propranolol and diltiazem (Houston et al 2009).

Szapary et al (2003) conducted a double-blind, placebo-controlled, randomised trial with 103 subjects with LDL cholesterol levels of 3.37–5.19 mmol/L. A standardised dose of 1000 mg of guggulipid (containing 2.5% guggulsterones) was given to one treatment group, while a higher standardised dose of 2000 mg was given to the other, three times daily for 8 weeks. Results showed a decrease of LDL cholesterol in the placebo group of 5%, an increase of 4% in the 1000 mg group and an increase of 5% in the 2000 mg group. Overall, this constituted a 9% and a 10% increase in LDL cholesterol with guggulipid treatment. By comparison, several randomised clinical trials and in vivo tests using various extracts of guggul have reported significant lowering of total cholesterol, triglycerides and LDL cholesterol levels and increases in HDL cholesterol (Gopal et al 1986, Malhotra et al 1977, Nityanand et al 1989, Singh et al 1990). In two reports, the duration of the lipid-lowering effect continued for 6–20 weeks after discontinuation of therapy (Gopal et al 1986, Nityanand et al 1989). One clinical study showed that the lipid-lowering effects of a preparation of guggul fraction A (1.5 g/day) were similar to clofibrate (2 g/day) (Malhotra et al 1977). A larger study of 235 volunteers, conducted under double-blind randomised conditions, showed that patients with hypercholesterolaemia responded better to guggulipid (1.5 g/day) than to clofibrate (1.5 g/day). However, those with hypertriglyceridaemia responded better to clofibrate (Nityanand et al 1989). Many of these trials have been criticised for being small and methodologically flawed or poorly reported (Ulbricht et al 2005).

However, a more recent review stated a difference in opinion and concluded that the trials were of reasonable quality (Singh et al 2007). They found that over 80% of trials using guggul produced favorable results. A 2009 placebo-controlled RCT conducted in Norway ( $n = 43$ ) using 2160 mg guggul (4 caps) daily over 12 weeks resulted in a significant reduction in total cholesterol and HDL-C, with no significant changes to LDL-C, triglycerides and total cholesterol/HDL-C ratios over placebo. Authors concluded that the clinical significance of reducing total cholesterol or HDL-C around 3–6% was questionable, especially because the ratio between them remained unchanged. Additionally, there were reported side effects from 10 of the guggul users, including GIT discomfort, thyroid problems and generalised skin rash (Nohr et al 2009).

Again, more large-scale clinical trials need to be done to assess the efficacy of guggulipid in hypercholesterolaemia.

## OTHER USES

### Traditional indications

Myrrh has been used in traditional medicine in China, Tibet, Ayurveda, the Middle East and Europe and consequently has numerous traditional indications. Myrrh has been used to treat infections, respiratory conditions, mouth ulcers, gingivitis, pharyngitis, respiratory catarrh, dysmenorrhoea, amenorrhoea, menopausal symptoms, wounds and haemorrhoids. It has also been used to treat arthritis and as an embalming agent.

### Parasitic diseases

#### Schistosomiasis

Schistosomiasis is an important trematode infection affecting over 200 million people in the tropics and subtropics (Kumar & Clark 2002). After malaria, it is the next most important parasitic disease with chronic infection causing significant morbidity. Currently, the drug praziquantel is often recommended, but it does not affect the immature stage and may not abort an early infection. Additionally, a drug-resistant strain has developed (Beers & Berkow 2003). Due to these factors, there is great interest in discovering alternative treatments.

One clinical study involving 204 patients with schistosomiasis produced impressive results with a 3-day oral dose regimen producing a cure rate of 92% (Sheir et al 2001). Re-treatment of non-responders increased the overall cure rate to 98%. A field study produced similar results with 97.4% of subjects infected with the *Schistosoma haematobium* strain and 96.2% infected with the *S. mansoni* strain successfully clearing the parasite after ingesting 1200 mg of *Commiphora molmol* daily for 6 days (Abo-Madyan et al 2004a). However, two randomised trials, controlled with the drug praziquantel, have both shown little effectiveness of myrrh against the parasite (Barakat et al 2005, Botros et al 2005).

A 2009 review identified some discrepancies in the published clinical trials of myrrh's effect against schistosomes. One large open-label field trial ( $n = 1091$ ) found that a 600-mg dose of commercial myrrh preparation (Mirazid) on an empty stomach 1 hour before breakfast for 6 consecutive days was effective against both types of schistosomiasis in Egypt, with cure rates of 97.4% and 96.2% for *S. haematobium* and *S. mansoni* respectively. Despite many initial studies showing great success of myrrh, subsequent multicentre investigations and RCTs comparing commercial myrrh with the conventional drug praziquantel have suggested myrrh cure rates were not as efficient against worms and their eggs as originally believed. However, these clinical trials involved dosing regimens of two administrations of

a commercially-available myrrh product, over a 3-week period; significantly less than the earlier studies affirming its efficacy. A re-evaluation of myrrh as a schistosomicidal was recommended (Abdul-Ghani et al 2009).

#### Fascioliasis

Human fascioliasis occurs in Europe, Africa, China and South America and is an infection with *Fasciola hepatica*, which is acquired by eating contaminated watercress. The flukes mature in the bile ducts and cause biliary tract obstruction and liver damage (Beers & Berkow 2003).

A small study of seven infected patients found that treatment with myrrh over 6 consecutive days produced alleviation of all symptoms and signs, and a dramatic drop in egg count, with eggs no longer detected 3 weeks after treatment (Massoud et al 2001a). Furthermore, high-eosinophil counts elevated liver enzymes and *Fasciola* antibody titres returned to normal. A field study showed that myrrh (1200 mg daily for 6 days) cleared the parasite in 94.1% of infected people at the 3-month follow-up (Abo-Madyan et al 2004b). A 2009 review, drawing from promising results of myrrh in animal studies, clinical trials and field studies, concluded that myrrh is an excellent fasciolicidal drug free of side effects (Abdul-Ghani et al 2009).

#### Heterophycide

*Heterophyes heterophyes* is a common Egyptian parasite (fluke) which finds an intermediate host in snails and fish. A review detailed that, both clinically and experimentally, myrrh (in the commercial form of Mirazid made from *C. molmol*) was effective. The clinical study used a dose of 300 mg twice daily for 9 consecutive days after overnight fasting and had a 94% efficacy in the first instance (Abdul-Ghani et al 2009).

#### Dicrocoeliasis

*Dicrocoelium dendriticum* is a small liver fluke that infects animals and humans after ingestion of an infected second intermediate host (i.e. an ant) through raw vegetables or herbs or in drinking water. A number of both small and larger human studies, using 600 mg Mirazid/kg 1 hour before breakfast daily for 6 days, demonstrated efficacy in clearing the fluke in both stool analysis and clinical symptoms (Abdul-Ghani et al 2009).

#### Historical note — Myrrh and mummification

Chemical treatments were an essential part of the mummification process in ancient Egypt. Several different plant products were used in the process, one of which was oil of myrrh. Interestingly, modern-day research has discovered that the oil has molluscicidal properties against several Egyptian snail species, suggesting that it may have been a wise choice for protecting mummified remains against destruction (Allam et al 2001).

### Mosquitocidal

The oil and oleo-resin from the plant extract of *C. molmol* exhibit larvicidal activity against *Culex pipiens* larvae (Massoud et al 2001b).

### Acne

Three months' treatment with guggulipid (equivalent to 25 mg guggulsterone) was found to be as effective as tetracycline in the treatment of nodulocystic acne in a randomised clinical study of 20 patients (Thappa & Dogra 1994).

### Ulcerative colitis (UC) — in combination

Maintenance of UC remission was tested ( $n = 96$ ) using a blend of 100 mg myrrh (species not specified), 70 mg chamomile extract and 50 mg coffee charcoal ( $3 \times 4/\text{day}$ ) over 12 months in a randomised, double-blind, double-dummy, multicentre, non-inferiority study, comparing it with mesalamine 500 mg ( $3 \times 1/\text{day}$ ). The herbal blend demonstrated efficacy and safety comparable to gold standard pharmaceutical treatment, and is an alternative option for maintenance therapy of UC (Langhorst et al 2011).

### DOSAGE RANGE

#### Internal preparations — *Commiphora molmol*

- Fluid extract (1:1) (g/mL): 2 mL/day.
- Tincture (1:5): 0.5–2 mL three times daily.
- Commercial tablet Mirazid 300 mg twice daily.

#### Internal preparations — guggulipid

- Acne: a dose equivalent to 25 mg guggulsterone taken once to twice daily.
- Hyperlipidaemia — 500–1000 mg of standardised guggulipid administered two to three times daily.
- (Guggulipid preparations are often standardised to 2.5–5% of guggulsterones.)

#### External preparations

- Tincture (1:5) (g/mL) in 90% ethanol can be used in different concentrations to produce different therapeutic products.
- Mouthwash or gargle: 30–60 drops tincture in a glass of warm water.
- Paint: the undiluted tincture can be applied directly to gums or mucous membranes of the mouth two to three times a day.

### TOXICITY

A dose of 10 mg/kg/day was given to subjects in one study with no serious adverse effects (Sheir et al 2001). *C. myrrha* and *C. molmol* are considered free from hepatotoxic, genotoxic and carcinogenic effects, even after long-term use. However, high doses (3.139 mg/kg) of the preparation Mirazid was acutely toxic (Abdul-Ghani et al 2009). Combining *C. molmol* with nitrosamine (diethylnitrosamine (DNA)) increased the rate of hepatocarcinogenesis in rats.

### ADVERSE REACTIONS

Restlessness, mild abdominal discomfort and gastrointestinal symptoms, such as diarrhoea and nausea, have been reported, mainly with orally-administered extracts. Allergic dermatitis has also been reported for topical usage. Skin rash and possible thyroid problems were recorded in a small percentage of people in a trial using guggul internally (Nohr et al 2009). The standardised guggulsterone (guggulipid) preparations tend to be far better tolerated.

### SIGNIFICANT INTERACTIONS

Interactions are theoretical and based on in vitro and in vivo data; therefore, clinical significance is unclear and remains to be confirmed.

#### Diabetic medication

In vivo studies suggest myrrh (*C. mukul*) may have hypoglycaemic effects and therefore would have additive effects with diabetic medications. Changes in serum glucose in patients taking these medications should therefore be monitored.

#### Lipid-lowering medication

Guggul may have cholesterol-lowering activity and therefore have additive effects with other lipid-lowering medications — observe patients taking this combination and monitor drug requirements. Beneficial interaction is possible.

#### Anticoagulant and antiplatelet medication

Guggul inhibited platelet aggregation in vitro and in a clinical study; therefore, concurrent use may theoretically increase the risk of bruising and bleeding (Bordia & Chuttani 1979) and interfere with anticoagulant medications, particularly in geriatric clients (Zarowitz 2010). It is uncertain what implications this observation has for *C. molmol* use. Observe patients taking these combinations.

#### Diltiazem

Reduced efficacy possible. A clinical study confirmed that guggulipid reduces bioavailability of this medicine (Dalvi et al 1994). It is uncertain what implications this observation has for *C. molmol* use. Observe patients taking this combination.

#### Propranolol

Reduced efficacy possible. A clinical study confirmed that guggulipid reduces bioavailability of this medicine (Dalvi et al 1994). It is uncertain what implications this observation has for *C. molmol* use. Observe patients taking this combination.

### CONTRAINDICATIONS AND PRECAUTIONS

Do not use in cases of known allergy. Suspend use of guggul preparations 1 week before major surgery.

**PREGNANCY USE**

Safety is unknown.

**Practice points/Patient counselling**

- Myrrh has been used since ancient times in a variety of forms as an antiseptic, anti-inflammatory and analgesic medicine.
- It has been used as a topical preparation to reduce inflammation and enhance wound healing — in vivo evidence suggests that the anti-inflammatory activity of one of the main constituents is stronger than hydrocortisone and local anaesthetic activity is likely.
- Preliminary evidence suggests that it may be a useful treatment in gingivitis and periodontal disease.
- The preparation known as guggulipid, which comes from *Commiphora* species, may have lipid-lowering effects according to clinical studies; however, evidence is contradictory and further research is required to confirm this.
- Myrrh may interact with a number of medications when used orally.

**PATIENTS' FAQs****What will this herb do for me?**

Traditionally, the herb has been used as a mouthwash or topical paint to relieve symptoms of mouth ulcers, sore throats and gum disease. It has also been used as a topical application for inflamed skin conditions and wounds. Scientific research confirms antiseptic, anti-inflammatory and local anaesthetic effects and significant antiparasitic effects. The preparation known as guggulipid, which comes from *Commiphora* species, may lower total cholesterol levels.

**When will it start to work?**

A mouthwash or paint should provide rapid symptom relief.

Antiparasitic activity has been reported within 3 days' use in some parasitic infestations.

The lipid-lowering effects of guggulipid have been reported within 12 weeks.

**Are there any safety issues?**

The herb should not be taken during pregnancy until safety is confirmed. It may interact with some medications.

## New Zealand green-lipped mussel

**HISTORICAL NOTE** The Mytilidae are a family of bivalve molluscs that first appeared approximately 400 million years ago (Scotti et al 2001). In New Zealand, they include the green-lipped mussel, which is also known as *Perna canaliculus* and has the Māori name kuku. Green-lipped mussel forms an important component of the traditional diet of coastal Māori people in New Zealand. Interest in the potential therapeutic use of green-lipped mussel as a natural anti-inflammatory began about four decades ago when it was observed that coastal Māoris had a lower incidence of arthritis than those living inland.

### BACKGROUND AND RELEVANT PHARMACOKINETICS

There is insufficient reliable information available.

### CHEMICAL COMPONENTS

Green-lipped mussel contains a number of constituents, of which the protein (61%) and lipid content (5%) are considered the most important for pharmacological activity. Virtually all of the protein content is comprised of pernin, a self-aggregating glycoprotein rich in histidine and aspartic acid, while the lipid content is comprised of polyunsaturated fatty acids including omega-3 EFAs, free fatty acids, furan fatty acid, sterols, sterol esters and triglycerides. Other constituents include carbohydrates (13%), glucosaminoglycans (12%), minerals (5%) and water (4%) (Scotti et al 2001, Wakimoto et al 2011).

The green-lipped mussel also contain toxins, including BTXB<sub>4</sub>, a B<sub>4</sub> analogue of brevetoxin, yessotoxins, pectenotoxin and okadaic acid (Mackenzie et al 2002, Morohashi et al 1999). BTXB<sub>4</sub> has been associated with neurotoxic shellfish poisoning and has been identified as the most significant toxin in green-lipped mussel (Morohashi et al 1999).

### MAIN ACTIONS

Most investigation has been conducted with the commercial preparations: Seatone and Lyprinol.

#### Anti-Inflammatory

Significant anti-inflammatory activity has been observed with the New Zealand green-lipped mussel, which forms the basis of much of its clinical use (Halpern 2000, McPhee et al 2007, Miller & Ormrod 1980, Miller et al 1993). Multiple mechanisms of action have been demonstrated in preclinical tests and include inhibition of the 5-lipoxygenase pathway and synthesis of leukotriene B<sub>4</sub>, as well as inhibition of PGE<sub>2</sub> production by activated macrophages and prostaglandin inhibitor actions (Miller & Wu 1984, Miller et al 1993), and potent inhibition of the cyclo-oxygenase COX-1 and COX-2 enzyme pathways (Lawson et al 2007, Mani & Lawson 2006, McPhee et al 2007), with some findings suggesting preferential blockade of COX-2 enzyme activity over COX-1 activity (Efthimiou & Kukar 2010).

Inhibition of IgG, TNF- $\alpha$ , IL-1, IL-2 and IL-6 by green-lipped mussel extract has been demonstrated in an in vitro study by Mani and Lawson

(2006) and *in vivo* research indicates that green-lipped mussel decreases anti-collagen antibody levels, inhibiting production of pro-inflammatory cytokines (TNF- $\alpha$ , IL-12p40) and reduces superoxide release (Lawson et al 2007).

The most important constituents responsible for these mechanisms of action are the various fatty acids found in green-lipped mussel.

The omega-3 fatty acids EPA and DHA have been isolated in green-lipped mussel (Murphy et al 2003), in addition to a unique series of other omega-3 polyunsaturated fatty acids (C18:4, C19:4, C20:4, C21:5) which may confer a more potent anti-inflammatory action than DHA and EPA, via competitive inhibition of arachidonic acid metabolism, reducing both leukotriene and prostaglandin synthesis (Treschow et al 2007). Furan fatty acids (F-acids), compounds found only in algae and in a limited number of marine animals, are thought to be other key therapeutic components of green-lipped mussel, which exhibits more potent anti-inflammatory activity than the omega-3 fatty acid, EPA (Wakimoto et al 2011). These unstable fatty acids also have potent free-radical-scavenging activity, especially reducing lipid peroxidation.

### OTHER ACTIONS

In addition to anti-inflammatory and antioxidant activity, green-lipped mussel has demonstrated antihistamine activity and immunomodulatory properties, as well as endocrine actions and uterine effects (Ulbricht et al 2009). The protein, polysaccharide and lipid fractions are reportedly the bioactive components responsible for these actions (McPhee et al 2007).

### CLINICAL USE

In clinical practice, green-lipped mussel is chiefly used for indications characterised by inflammation.

#### Osteoarthritis

The clinical evidence to support the use of green-lipped mussel (GLM) in osteoarthritis is promising and supported by mechanistic studies demonstrating an effect on inflammatory pathways.

In 2013, a non-blinded randomised clinical trial (RCT) was conducted with 38 subjects diagnosed with knee osteoarthritis (OA) (Coulson et al 2013). Each volunteer received either 3000 mg/day of a whole GLM extract or 3000 mg/day of glucosamine sulphate (GS) orally for 12 weeks. A significant improvement was seen with GLM treatment using the Western Ontario McMaster Universities Arthritis Index (WOMAC) and the Lequesne algofunctional indices ( $P < 0.05$ ) after the test period.

Previously, an open study of 21 subjects with knee OA found that treatment with 3000 mg/day of green-lipped mussel extract for 8 weeks provided a significant improvement for the Lequesne and WOMAC ( $P < 0.001$ ), thereby demonstrating improvements in knee joint pain, stiffness and

mobility. The doses used by Coulson and colleagues exceeded those previously tested (maximum 1150 mg/day), which may have contributed to the positive findings.

A 2008 systematic review by Brien et al identified four RCTs where green-lipped mussel was used as an adjunct to standard therapy in mild to moderate osteoarthritis. In three studies, GLM was compared to placebo and in the fourth, a GLM lipid extract was compared to a stabilised powder extract. Results from the two studies considered to be of higher quality suggested that GLM may be superior to placebo for the treatment of mild to moderate OA (Brien et al 2008).

#### Rheumatoid arthritis (RA)

In contrast, evidence is less supportive of the use of GLM in RA as clinical studies with Seatone have produced inconsistent results. Whether the negative results are due to insufficient dosage or lack of any real effect remains to be tested further.

The first clinical trials testing Seatone in RA were conducted in the 1980s. Huskisson et al (1981) conducted a 4-week study of Seatone 300 mg three times a day as an adjunct to standard therapy in RA ( $n = 26$ ). It failed to show a significant benefit compared to placebo (Huskisson et al 1981). Another RCT using Seatone in 35 patients with RA found no significant difference in chemical or clinical parameters compared with placebo, after 6 months' use (Larkin et al 1985). A more recent RCT of 28 patients using Seatone over 3 months, with a follow-up phase of another 3 months, reported that active treatment was effective in reducing symptoms of RA in 68% of the treatment group (Gibson & Gibson 1998). This study was subsequently criticised as the subjects served as their own controls in the second phase of the study, and because treatment group were further subdivided into responders and non-responders making interpretation of the results difficult (Cobb & Ernst 2006).

#### Asthma

To date, two studies have investigated GLM in asthma, producing promising results. A 2002 study of 46 patients with asthma compared Lyprinol (2 capsules twice daily) to placebo twice daily over 8 weeks under double-blind randomised test conditions (Emelyanov et al 2002). Active treatment resulted in a significant improvement on several parameters, such as daytime wheeze, reduced concentration of exhaled  $H_2O_2$  (marker of airway inflammation) and an increase in morning peak expiratory flow (PEF), compared with placebo, but it did not improve night awakenings or reduce the use of beta-agonist bronchodilators or forced expiratory volume in 1-sec (FEV<sub>1</sub>). The Lyprinol product contains GLM oil as 50 mg per capsule.

More recently in 2013, treatment with a GLM product (Lyprinol/Omega XL) was tested for effects on airway inflammation and the bronchoconstrictor response to eucapnic voluntary hyperpnoea (EVH)

in asthmatics (Mickleborough et al 2013). The placebo controlled double-blind randomised cross-over trial involved 23 asthmatic volunteers with clinically treated mild to moderate persistent asthma and a resting forced expiratory volume in 1-sec (FEV<sub>1</sub>) of >65% predicted, and EIB as demonstrated by a greater than 10% drop in FEV<sub>1</sub> following a eucapnic voluntary hyperventilation (EVH) challenge. All subjects had a history of shortness of breath, chest tightness and intermittent wheezing following exercise, which was relieved by bronchodilator therapy and none were taking any maintenance medications (e.g. corticosteroids and leukotriene modifiers) at the time of the study.

Treatment consisted of 3 weeks of Lyprinol/Omega XL (8 capsules daily) or placebo followed by a 2-week washout period, before crossing over to the alternative arm. Additionally, all subjects were reviewed to ensure dietary intake was unchanged during the test period, in particular omega-3 EFA intake. Active treatment was found to significantly improve asthma symptom scores ( $P < 0.05$ ), reduce bronchodilator use ( $P < 0.05$ ) and reduce the maximum fall in post-EVH FEV<sub>1</sub> compared to usual and placebo ( $P < 0.05$ ). It appears that effects are slow-acting as a reduction in bronchodilator use was only evident after 1 week of treatment.

## OTHER USES

### Veterinary use for osteoarthritis

New Zealand GLM shows promise as a treatment option for dogs, cats and horses with joint disease. In dogs, the most common form of joint disease is OA, which has been successfully treated by green-lipped mussel powder in one double-blind RCT (Bierer & Bui 2002). Active treatment was shown to significantly improve total arthritic score, and alleviate joint pain and swelling at the end of week six compared with controls. More specifically, 83% of dogs in the active treatment group experienced a 30% or greater reduction in total arthritic scores and of these, 18% showed a 70% or greater improvement. Only 7% of controls showed a 30% or greater improvement, with no dogs showing a 50% or greater improvement. The doses of GLM powder ranged from 450 mg to 1000 mg/day, depending on body weight. Another randomised double-blind study of 45 dogs with OA reported that the dogs treated with green-lipped mussel showed significant improvements according to veterinary pain and mobility scales compared to placebo. However, these benefits were not as great as those observed in the dogs treated with carprofen, a non-steroidal anti-inflammatory drug (Hielm-Bjorkman et al 2009). A further study was conducted including 81 dogs with a diagnosis of mild-moderate degenerative joint disease. Daily oral consumption of an extract of green lipped mussel appeared to reduce clinical signs of disease (Pollard et al 2006).

GLM extract has also been evaluated in cats diagnosed with degenerative joint disease. In one study of 45 cats, the animals in the treatment group were given a diet high in EPA/DHA, green-lipped mussel extract and supplemental glucosamine/chondroitin. Although improvements in mobility were reported, it is unclear how much of this benefit can be attributed to green-lipped mussel (Lascelles et al 2010).

Lyophilised products from green-lipped mussel (*Perna canaliculus* [LPPC]) are also used in horses to treat OA. A double-blind, multi-centre RCT evaluating horses with primary fetlock lameness found treatment with oral LPPC 25 mg/kg bwt/day for 56 days produced a significant reduction in severity of lameness ( $P < 0.001$ ), improved response to the joint flexion test ( $P < 0.001$ ) and reduced joint pain ( $P = 0.014$ ) when compared with horses treated with placebo (Cayzer et al 2012).

### Inflammatory bowel disease

Findings from a preliminary animal study suggest green-lipped mussel may be of potential benefit in inflammatory bowel disease (IBD). A study compared the anti-inflammatory effects of green-lipped mussel (Lyprinol containing <1 mg omega-3 fatty acids/day) to that of fish oils (given at a dose 55 mg omega-3 fatty acids/day) in mice with experimentally induced IBD. The mice treated with Lyprinol showed significantly less weight loss, disease activity index scores and colonic damage than those treated with omega-3 fatty acids ( $P < 0.05$ ) after 13 days (Tenikoff et al 2005). Based on these results, the researchers proposed that GLM has a potential therapeutic benefit in IBD due to a mechanism or constituent unrelated to omega-3 fatty acids content (Tenikoff et al 2005). Human trials are now required to determine whether the effect is clinically significant.

### Muscle damage and soreness in athletes — no effect

A double-blind RCT found GLM was ineffective in reducing delayed onset muscle soreness, inflammatory markers or muscle damage after exercise. Twenty well-trained male athletes from various sports disciplines were randomly assigned to either Lyprinol 200 mg/day or placebo, taken for 8 weeks prior to an intense exercise intervention (Pumpa et al 2011).

### Cancer — no effect

Some research has been conducted with New Zealand GLM in the management of certain cancers as in vivo and in vitro studies suggest that inhibition of lipo-oxygenase pathways may arrest tumour growth in some cancers, especially prostate cancer and green-lipped mussel is a potent natural lipo-oxygenase inhibitor (Sukumaran et al 2010). An open-labelled clinical study involving 19 subjects found that GLM (Lyprinol) produced no clinical benefits in the management of advanced,

treatment-refractory, prostate or breast cancer (Sukumaran et al 2010).

## DOSAGE RANGE

Doses provided are based on the available clinical research. In addition, there is no well-known standardisation for green lipped mussel and efficacy may vary between manufacturers and between different batches (Ulbricht et al 2009).

- Asthma — Lyprinol/Omega XL taken as 8 capsules daily or Lyprinol taken as 4 capsules daily.
- Osteoarthritis — two studies showed significant symptomatic improvement at a dose of 3000 mg/day.

## TOXICITY

GLM contain the toxin brevetoxin B4 (BTXB4), which has been associated with neurotoxic shellfish poisoning (Morohashi et al 1999). Regular ingestion of New Zealand green-lipped mussels does not appear to lead to heavy metal toxicity according to traditional dietary use by Māori people, nor according to a preliminary laboratory investigation (Whyte et al 2009). Insufficient reliable information is available to determine toxicity of supplemental green-lipped mussel.

## ADVERSE REACTIONS

Gastrointestinal discomfort, nausea, gout and skin rashes have been reported (Ahern et al 1980, Brooks 1980). There have been three case reports in the literature suggesting that green-lipped mussel may be associated with rare incidences of liver dysfunction, however causality is difficult to ascertain (Abdulazim et al 2012). Raised liver enzymes were reported in two cancer patients participating in a small study ( $n = 17$ ) on the safety and tolerability of green-lipped mussel as adjunct therapy. One of the two patients had significant metastatic liver involvement and this was reported as the most likely reason for raised liver enzymes. The other patient had normal liver function at baseline and no liver cancer involvement. The dose of green-lipped mussel at which liver abnormalities were reported was not specified, nor were any other medications taken by the patients described (Sukumaran et al 2010).

## SIGNIFICANT INTERACTIONS

Insufficient reliable information exists regarding clinical interactions with green lipped mussel; however, in vivo studies suggest possible interactions with some medications.

### Anti-inflammatory agents

Due to the anti-inflammatory activity of GLM, concomitant use with these medications can theoretically result in enhanced anti-inflammatory effects or a reduction in drug dosage — beneficial.

## CONTRAINDICATIONS AND PRECAUTIONS

Contraindicated in people with allergies to shellfish. Rash, swelling of extremities and mouth, tingling, chest tightness and breathing difficulties have been reported (Ulbricht et al 2009). Lung dysfunction and a range of respiratory symptoms were reported in 32.3% of workers employed as New Zealand mussels openers, according to one study of 224 employees (Glass et al 1998). Whether the same effect is seen with manufactured GLM extracts taken orally remains to be seen.

Use with caution in people with hypertension, as the sodium content could theoretically raise blood pressure.

## PREGNANCY USE

Insufficient reliable information is available to assess safety.

### Practice points/Patient counselling

- New Zealand green-lipped mussel has been used to treat arthritis by the New Zealand Māoris for many years.
- Significant anti-inflammatory activity has been observed in both animals and humans.
- Several clinical trials have produced promising results for GLM in the symptomatic treatment of OA.
- Two clinical trials also suggest a possible role in asthma management.
- Significant symptom relief has been observed for GLM in dogs with osteoarthritis and cats and horses with joint disease.
- The most common side effects associated with GLM are gastrointestinal discomfort, nausea, gout and skin rashes.

## PATIENTS' FAQs

### What will this supplement do for me?

Some studies have shown that NZ green-lipped mussel exerts significant anti-inflammatory activity and is likely to relieve symptoms of OA when taken for several weeks. Two studies also suggest a possible role in the treatment of asthma.

### When will it start to work?

Effects in osteoarthritis are likely to be seen within 8 weeks of use. Effects with a combination of GLM and omega-3 EFAS developed within 3 weeks in the management of mild-to-moderate asthma.

### Are there any safety issues?

GLM should not be taken by people with allergies to shellfish and should be used with caution by people with high blood pressure due to the sodium content.

## Nigella

**HISTORICAL NOTE** Records suggest that black seed has been used medicinally for thousands of years, especially in the Middle East and Southeast Asia. Black seed (*nigella*) is referred to in the Old Testament in the Book of Isaiah, where Isaiah compares *nigella* to wheat (Isaiah 28:25, 27). It is also reported that the Islamic prophet Mohammed claimed that black seed (*kalonji*) was a remedy for all diseases except death. Black seed was used in Ancient Egypt, with extracts being found at various sites, including King Tutankhamun's tomb, and in Turkey, a Hittite flask of black seed dating back to 1650 BC was recovered by archaeologists. Black seed was also reportedly used by both Hippocrates (460–370 BC) and Dioscorides (40–90 AD) for a range of conditions.

**LATIN BINOMIAL/CLASS**

*Nigella sativa* (family Ranunculaceae)

**OTHER NAMES**

Nigella, black cummin, black caraway, blessed seed or seed of blessing, fennel flower, nutmeg flower, roman coriander, habbatul baraka, habat-ul-sauda, kalonji, nigelle de Crête, nigelle cultivée, Roman-coriander, Schwarzkummel.

**Plant part used**

Seed

**CHEMICAL COMPONENTS**

Thymoquinone, a component of the essential oil found in *Nigella sativa* seeds, has been identified as the main active constituent (Edris 2009). Other important constituents include dithymoquinone (nigellone), thymohydroquinone, *p*-cymene, carvacrol, 4-terpineol, *t*-anethol, sesquiterpene longifolene,  $\alpha$ -pinene, thymol,  $\alpha$ -hederin, isoquinoline and pyrazol alkaloids (Ahmad et al 2013). In addition, trace amounts are found of other compounds, including monosaccharides (glucose, rhamnose, xylose, arabinose), unsaturated fatty acids (linoleic acid, linolenic acid, oleic acid), alpha-spinasterol, arabic acid, aspartic acid, beta-sitosterol, campesterol, carvone, cholesterol, D-limonene, dehydroascorbic acid, eicosadienoic acid, melanthigenin, melanthin, myristic acid, palmitic acid, stearic acid, stigmasterol, various amino acids, vitamins and minerals.

**MAIN ACTIONS****Antiallergic**

Antihistamine effects have been demonstrated in human and animal study (Isik et al 2010, Kalus et al 2003, Nikakhlagh et al 2011). Decreased synthesis of proinflammatory leukotrienes via an inhibitory action on the arachidonic pathway has been described (Kalus et al 2003). Immunomodulatory effects were described by Isik and colleagues, with administration of black seed leading to an increase in phagocytic and intracellular killing activities of polymorphonuclear leucocytes in patients receiving allergen-specific immunotherapy (Isik et al 2010).

**Anticarcinogenic effects**

Thymoquinone, the main active constituent of black seed, has been shown to possess a number of anticancer properties, mediated through a number of different mechanisms. In vitro and in vivo studies have identified antiproliferative actions, induction of apoptosis, cell cycle arrest, reactive oxygen species generation and antimetastasis/antiangiogenesis. Thymoquinone also appears to modulate various molecular targets, including p53, p73, PTEN, STAT3, PPAR-g and activation of caspases (Ahmad et al 2013, Randhawa & Alghamdi 2011, Woo et al 2012).

Thymoquinone has been shown to inhibit proliferation of a variety of tumour cells, including neuroblastoma (Paramasivam et al 2012), human pancreatic adenocarcinoma, neoplastic keratinocytes (Worthen et al 1998), breast adenocarcinoma, ovarian adenocarcinoma (Shoieb et al 2003), colorectal cancer (Gali-Muhtasib et al 2004), human osteosarcoma (Roepke et al 2007), fibrosarcoma, lung carcinoma (Kaseb et al 2007) and myeloblastic leukaemia (El-Mahdy et al 2005). Researchers demonstrated that thymoquinone inhibited tumour growth and induced apoptosis via generation of reactive oxygen species in primary effusion lymphoma cell lines (Hussain et al 2011). According to the findings of laboratory research conducted using multiple myeloma cells, thymoquinone inhibited phosphorylation of the STAT3 signalling pathway, both constitutive and interleukin-6 (IL-6)-induced. Downregulation of the expression of STAT3-regulated gene products (cyclin D1, Bcl-2, Bcl-xL, survivin, Mcl-1 and vascular endothelial growth factor) were also observed (Li et al 2010). Thymoquinone was shown to attenuate haematological changes and oxidative stress in animal models with colon cancer (Harzallah et al 2012).

Use of thymoquinone in combination with other cytotoxic drugs to enhance drug efficacy is a promising area of research. One laboratory study demonstrated that thymoquinone induced apoptosis in doxorubicin-resistant human breast cells, primarily via upregulation of the tumour suppressor gene PTEN (El-Shaimaa et al 2011). Thymoquinone was also shown to be protective against doxorubicin-induced cardiotoxicity, which the authors proposed was due primarily to antioxidant activity (Nagi & Mansour 2000).

An animal study investigating thymoquinone in combination with 5-fluorouracil (5-FU) in gastric cancer cells demonstrated a significantly more effective antitumour benefit when the two agents were combined, than either used alone. It was proposed that this was due to thymoquinone enhancing the activation of caspase-3 and caspase-9 in gastric cancer cells, which resulted in the chemosensitisation of gastric cancer cells to 5-FU treatment (Lei et al 2012).

Synergistic effects were observed when thymoquinone was used in combination with cisplatin in lung cancer cells and in animal models (Jafri et al 2010).

Researchers also reported that thymoquinone significantly potentiated the apoptotic effects of thalidomide and bortezomib in multiple myeloma cells (Li et al 2010).

Banerjee et al (2009) report that thymoquinone potentiated the effects of gemcitabine and oxaliplatin in pancreatic cancer cells, possibly due to downregulation of NF-kappaB, which resulted in chemosensitisation.

Encapsulation of thymoquinone into nanoparticles appears to enhance the antiproliferative, anti-inflammatory and chemosensitising effects of

thymoquinone, according to findings of one study (Ravindran et al 2010). While thymoquinone appears to be the most promising anticarcinogenic constituent of black seed, other constituents such as  $\alpha$ -hederin and derivatives of both of these compounds have also been identified as holding therapeutic potential (Randhawa & Alghamdi 2011).

### Antidiabetic effects

Animal and preliminary human studies with black seed and the constituent thymoquinone have demonstrated improved glucose tolerance, antioxidant status, renal function, decreased blood glucose, serum insulin and glycated haemoglobin levels (Bamosa et al 2010, Fararh et al 2010, Kaleem et al 2006, Meddah et al 2009, Najimi et al 2006). The mechanism of action is yet to be elucidated, but decreased hepatic gluconeogenesis and inhibition of nitric oxide pathways have been proposed by researchers in this field (El-Mahmoudy et al 2005, Fararh et al 2005).

### Antihypertensive effects

Antihypertensive effects have been demonstrated in an animal study, and appeared to be centrally mediated via direct and indirect mechanisms involving muscarinic and 5-hydroxytryptaminergic action (El-Tahir et al 1993). Mild antihypertensive effects were reported in one clinical study, which the authors proposed may be related to the antioxidant properties of black seed.

### Antimicrobial actions

Antibacterial actions have been observed in vitro against *Staphylococcus aureus*, *Helicobacter pylori* and *Streptococcus* spp. Antiparasitic effects were identified in animal and human studies against *Schistosoma mansoni*, which may be due to antioxidant and immunomodulatory effects. In vitro study using methanolic extracts of *Nigella sativa* has shown antifungal activity against *Candida albicans*, and ether extracts showed activity against dermatophytes, supporting traditional folk use of black seed for fungal skin infections (Ahmad et al 2013).

### Antioxidant

Antioxidant effects have been reported in several in vitro and animal studies, mainly attributed to the constituent thymoquinone (Ahmad et al 2013). Black seed oil extracted by cold pressing has been shown to possess significant antioxidant properties, and appears to yield higher levels of thymoquinone than black seed oil extracted via other techniques (Lutterodt et al 2010). One preliminary clinical study of 30 postmenopausal women reported that black seed 3 g/day for 12 weeks increased levels of superoxide dismutase and glutathione peroxidase enzymes (Mostafa & Moustafa 2012).

### Hyperlipidaemic actions

Clinical studies have demonstrated that black seed reduces total cholesterol, low-density lipoprotein

(LDL) cholesterol and triglyceride levels, and induces a slight increase in high-density lipoprotein (HDL) cholesterol (Kaatabi et al 2012, Najmi et al 2008). One animal study suggests that this may be due to inhibition of the HMG-CoA reductase enzyme and of LDL lipoprotein receptor upregulation (Al Nageep et al 2009).

## OTHER ACTIONS

### Analgesic and neurological effects

Analgesic activity has been observed in experimental models and animal studies (Abdel-Fattah et al 2000, Al-Naggar et al 2003, Bashir & Qureshi 2010). Anxiolytic activity has been reported in animal study, with increased levels of gamma-aminobutyric acid, 5-hydroxytryptamine and tryptophan having been recorded (Ahmad et al 2013).

### Antiasthmatic effects

Tracheal relaxation has been observed in animal studies. The mechanism is unclear, but it has been proposed to be due to lipoxygenase inhibition of arachidonic acid metabolism and a non-selective histamine and serotonin blockade (Al-Majed et al 2001).

### Anticoagulant effects

Inhibition of platelet aggregation and blood coagulation has been demonstrated in vitro and in vivo (Al-Jishi & Abu Hozafa 2003, Enomoto et al 2001).

### Anti-inflammatory effects

Anti-inflammatory effects have been identified in vitro and in vivo. The main constituents involved are thymoquinone, carvacrol, dithymoquinone, thymohydroquinone and thymol. Observed anti-inflammatory effects according to various studies include inhibition of IL-1, IL-6, transcription factor, NF- $\kappa$ B, cyclooxygenase-1 and/or cyclooxygenase 2, nitric oxide release and leukotrienes (Ahmad et al 2013, El Gazzar et al 2007).

### Bone metabolism

A recent experimental laboratory study reported that the constituent thymoquinone induced proliferation and mineralisation of MC3T3-E1 osteoblastic cells, which the authors proposed was mediated by an increased expression of bone morphogenetic protein-2 (BMP-2), associated with phosphorylation of the ERK signalling pathway (Wirries et al 2013). Acceleration of bone formation with use of thymoquinone has been shown in an animal study (Kara et al 2012).

### Gastroprotective effects

Gastroprotective mechanisms have been observed in one animal study. Thymoquinone is reported to have inhibited proton pump activity and acid secretion, while increasing secretion of mucin and nitric oxide production (Mahmoud-Awny et al 2012).

### Hepatoprotective

Based on animal studies, black seed appears to confer hepatoprotective effects against a number of agents, including aflatoxin B<sub>1</sub> (Sabzevari et al 2011), D-galactosamine, carbon tetrachloride (El-Dakhkhny et al 2000, Ibrahim et al 2008), lead (Farraq et al 2007), isoniazid (Hassan et al 2012) and sodium valproate (Raza et al 2006). Conversely, one in vitro study cautions that the constituent thymoquinone may be metabolised to a reactive species and increase oxidative stress, leading to DNA damage in hepatocytes (Khader et al 2009). One laboratory study demonstrated that thymoquinone attenuated liver fibrosis via Toll-like receptor 4 blockade and phosphatidylinositol 3-kinase, suggesting a potential role in hepatic fibrosis (Bai et al 2013). Further study is required to determine the clinical significance of black seed in hepatic disorders or as a hepatoprotective agent.

### Heavy-metal toxicity

Animal studies have shown that thymoquinone, the active constituent of black seed, provides hepatoprotective effects against toxicity due to heavy metals such as cadmium and lead (Farraq et al 2007, Waseem et al 2012). Further research is required to confirm clinical significance.

### Immunomodulatory effects

Immunomodulatory effects have been identified in vitro and in vivo. Observed effects according to different studies include enhanced splenocyte proliferation; enhanced natural killer cytotoxic activity, including action against YAC-1 tumour cells, preferential secretion of Th2 over Th1 cytokines, suppression of proinflammatory mediator secretion (IL-6, tumour necrosis factor- $\alpha$  and nitric oxide), induction of IL-8, possibly due to involvement of Toll-like receptor 4, increased white blood cell count and radioprotective effects (Ahmad et al 2013, El-Obeid et al 2006, Majdalawieh et al 2010).

### CLINICAL USAGE

Most research regarding black seed has been done in vitro and with animal models and relatively few clinical trials are available. The clinical studies that are available suggest a potential therapeutic role in a range of conditions and warrant further investigation.

#### Asthma

Preliminary research with black seed aqueous extract suggests it may be beneficial as an adjunct therapy in asthmatic patients. A randomised double-blind study investigated the effect of black seed on asthma symptoms in 29 patients as adjunct therapy to their conventional asthma medication over a period of 3 months. The addition of black seed extract (15 mL/kg of 1 g% extract) resulted in a significant decrease in frequency of asthma symptoms, chest wheezing and lung function test values compared to baseline ( $P < 0.05$ ), allowing for a reduction in usage of drug

therapy in the treatment group (Boskabady et al 2007). A subsequent smaller study ( $n = 15$ ) compared the bronchodilatory effects of black seed aqueous extract (50 mg/kg and 100 mg/kg) to theophylline 6 mg/kg as adjunct therapy to inhaled corticosteroids in patients with diagnosed moderate to severe asthma. Analysis of lung function test results showed that onset of bronchodilatory action and duration of action were similar for both black seed and theophylline (30 min and 150 min respectively); however the magnitude of benefit was greater with theophylline. There was no significant difference in effect between the two doses of black seed used in the study (Boskabady et al 2010). These findings are suggestive of a beneficial effect for black seed as adjunctive asthma therapy; however further larger-scale research with more rigorous methodology is required before conclusions can be drawn. These preliminary human study data are supported by animal studies in which observations include tracheal-relaxant effects (Al-Majed et al 2001, Boskabady et al 2008) and inhibitory effects on inflammation, nitric oxide synthetase, tumour necrosis factor- $\alpha$ , immunoglobulin E levels and transforming growth factor- $\beta_1$  (El-Sayed et al 2011).

#### Allergies

Results from clinical studies suggest that oral use of black seed oil may be of benefit in the treatment of various allergic conditions. In a double-blind study of 66 patients, administration of black seed oil was shown to reduce symptoms of allergic rhinitis, including itching, nasal congestion, sneezing and runny nose, as determined by subjective questionnaires. The dose of black seed oil was not described in the research methodology (Nikakhlagh et al 2011). These findings support prior research in which black seed oil taken at doses ranging from 500 to 2000 mg three times a day (40–80 mg/kg/day) for up to 8 weeks provided subjective improvement of the symptoms of allergic rhinitis, atopic eczema and bronchial asthma (Kalus et al 2003). According to findings in another study, supplementation with black seed oil (2 g/day) increased the phagocytic and intracellular killing activities of polymorphonuclear leucocyte functions in patients with allergic rhinitis on allergen-specific immunotherapy (Isik et al 2010).

#### Diabetes mellitus

Clinical studies suggest a potential benefit of black seed as adjunct therapy in patients with type 2 diabetes mellitus within 6–12 weeks of oral use. In one study of 94 patients, black seed was administered as adjunct therapy in patients with diagnosed type 2 diabetes, given at doses of 1, 2 or 3 g/day. Optimal benefits were at the 2 g/day dose, with significant reductions reported in fasting blood glucose, 2 hours postprandial blood glucose and glycosylated haemoglobin levels. Improvements in  $\beta$ -cell function and insulin resistance were also reported after 12 weeks

of treatment (Bamosa et al 2010). An open, non-randomised, non-blinded study was conducted by Najimi et al to investigate potential benefits of black seed as adjunct therapy in 60 patients with hyperlipidaemia and type 2 diabetes mellitus and insulin resistance syndrome (Najimi et al 2006). The control group received atorvastatin 10 mg/day and metformin 500 mg twice daily for 6 weeks. The treatment group received the same drug therapy, as well as black seed oil 2.5 mL twice daily. Significant reductions in fasting blood glucose were reported ( $P < 0.05$ ), as well as reductions in total cholesterol and LDL cholesterol. In another open study, administration of black seed powder for 40 days to type 2 diabetic patients was reported to result in significant reductions in fasting blood glucose levels ( $P < 0.001$ ), LDL cholesterol ( $P = 0.001$ ) and triglyceride ( $P < 0.001$ ) levels, and to increase insulin ( $P < 0.001$ ) and HDL levels ( $P = 0.011$ ). These benefits reversed after withdrawal of black seed powder. Further data regarding research methodology are not available (Bilal et al 2008). Improved glucose tolerance and a reduction in blood glucose levels have also been reported in animal studies (Fararh et al 2010, Kaleem et al 2006, Meddah et al 2009).

### Epilepsy

Anticonvulsant properties have been observed in animal studies conducted with black seed and the constituent thymoquinone, suggesting a possible role in epilepsy (Hosseinzadeh et al 2005, Hosseinzadeh & Parvardeh 2004, Illhan et al 2005). To date, only one randomised study was located which has explored this in humans. The double-blind, randomised crossover study was conducted in 23 children with refractory epilepsy using an aqueous extract of black seed. This extract was given as a syrup, standardised to 0.5 mg/kg/12 h thymoquinone, and compared to a placebo syrup, as adjunct therapies to their regular anticonvulsant medication. One group of participants received thymoquinone for 4 weeks, while the other received placebo. After a 2-week washout period, the groups were crossed over and treatment continued for another 4 weeks. Seizure frequency was assessed during treatment periods for both groups. A 30% reduction in mean frequency of seizures was reported in both groups when treated with black seed extract ( $P \leq 0.04$ ), supported by a 75% parental satisfaction, compared to 30% satisfaction in the placebo group ( $P = 0.03$ ; Akhondian et al 2011). Further study is needed before conclusions can be drawn.

### Hyperlipidaemia

A clinical study ( $n = 94$ ) showed that ingestion of black seed 2 g/day for 12 weeks resulted in a significant reduction in total cholesterol, LDL cholesterol and triglyceride levels in type 2 diabetic patients. A slight increase in HDL cholesterol was also reported. Black seed was administered as 500 mg capsules containing ground black seed powder in this study (Kaatabi et al 2012). In another

small-scale randomised double-blind study ( $n = 73$ ), black seed (1 g/twice daily as encapsulated powder) was administered as adjunctive therapy to statin therapy in patients with hypercholesterolaemia over 6 weeks. Reductions in total cholesterol, LDL cholesterol and triglyceride levels were observed; however these effects were not clinically significant. No adverse renal or hepatic effects were reported and no significant reductions in either systolic or diastolic blood pressure were recorded (Qidwai et al 2009). Further study is needed before conclusions can be drawn.

### Hypertension

Hypotensive benefits were reported in animal study (Zaoui et al 2000) which have been demonstrated in humans. A subsequent randomised double-blind placebo-controlled clinical study ( $n = 108$ ) showed that administration of black seed extract (100 mg or 200 mg/day) for 8 weeks reduced both systolic and diastolic blood pressure slightly (2.8 mmHg and 1.1 mmHg respectively). However, in another study using a higher dose of 2 g/day for 6 weeks, no clinically significant reductions in blood pressure were observed (Qidwai et al 2009). Further study is needed to establish therapeutic doses and magnitude of benefit.

## OTHER USES

### Addiction

Preliminary evidence suggests that black seed may be of benefit in reducing the symptoms of withdrawal in opiate-dependent patients. A significant reduction ( $P \leq 0.05$ ) in opioid withdrawal symptoms was reported in a randomised single-blind study of 35 known male addicts administered dried black seed 500 mg three times a day for up to 12 days. There were no physiological changes to pulse rate, blood pressure or weight during treatment (Sangi et al 2008). Findings of a study conducted with mice suggest that black seed oil may protect against tramadol-induced tolerance and dependence (Abdel-Zaher et al 2011). Further well-designed study is required before conclusions can be drawn.

### Atopic dermatitis

In vitro study suggests that the constituent nigellone may inhibit histamine release; however results from one small clinical study found that an ointment made with 15% black seed oil did not reduce symptoms of atopic dermatitis compared to placebo (Stern et al 2002). There are also two case study reports where topical use of black seed oil caused allergic contact dermatitis (Ali & Blunden 2003). Further study is required, but a benefit seems unlikely.

### *Helicobacter pylori* eradication

One small-scale randomised study of non-ulcer dyspepsia patients found that a combination of *Nigella sativa* 2 g/day with omeprazole 40 mg/day resulted

in a 66.7% eradication of *H. pylori*, compared to a 82.6% eradication rate in the group treated with triple therapy (clarithromycin, amoxicillin, omeprazole) (Salem et al 2010).

## DOSAGE RANGE

Doses provided are suggestive, based on limited clinical study. There are insufficient data available at this stage to make conclusive recommendations.

According to clinical studies:

- Allergies: black seed oil at doses of 40–80 mg/kg/day in divided dose has been used for up to 8 weeks.
- Asthma: 50–100 mg/kg/day has been used as adjunct therapy.
- Hyperlipidaemia: 1 g twice daily for 12 weeks has been used as adjunct therapy.
- Hypertension: 100–200 mg/day for 8 weeks led to a minor reduction in systolic and diastolic blood pressure.
- Refractory paediatric epilepsy: aqueous extract, given as a syrup at a dose of 0.02 mL/kg/12 h (equivalent to 0.5 mg/kg/12 h of thymoquinone), has been used as adjunct therapy for 4 weeks.
- Type 2 diabetes mellitus: 2 g/day for 3 months has been used as adjunct therapy.

## ADVERSE REACTIONS

Insufficient reliable information exists about adverse reactions with black seed; however there are two case study reports of allergic contact dermatitis following topical use of black seed oil (Ali & Blunden 2003). One study suggests that doses exceeding 80 mg/kg/day may result in gastrointestinal adverse effects (Kalus et al 2003).

A review of the toxicological profile of black seed suggests a wide margin of safety at therapeutic doses, but cautions against potential changes in haemoglobin metabolism, platelet count and leucocyte levels (Zaoui et al 2002).

## SIGNIFICANT INTERACTIONS

### Analgesics

Theoretically, potentiation effects are possible when using black seed at high doses based on animal models (Abdel-Fattah et al 2000, Al-Ghamdi 2001) — interaction may be beneficial. Clinical significance unknown.

### Anticoagulants

Theoretical interaction predicted based on antiplatelet, anticoagulant and conversely coagulant effects observed in vitro and in vivo (Al-Jishi & Abu Hozaifa 2003, Asgary et al 2012, Awad & Binder 2005, Enomoto et al 2001). Clinical significance unknown — caution advised.

### Anticonvulsants

A small clinical study shows that black seed had anticonvulsant effects in epileptic children refractory to their antiepileptic medication (Akhondian 2007). The constituent thymoquinone was reported to

reduce sodium valproate-induced hepatotoxicity in one animal study (Raza et al 2006). Observe — however, interaction may be beneficial.

### Antidiabetic agents

Preliminary clinical studies suggest that black seed reduces blood glucose levels and improves glucose tolerance in type 2 diabetes mellitus patients (Bamosa et al 2010), including those with diabetes as a comorbidity in dyslipidaemic patients (Kaatabi et al 2012, Najimi et al 2006). Caution — however, interaction may be beneficial.

### Antihypertensives

A clinical study reported that black seed reduced blood pressure in patients with mild hypertension to a small extent (Dehkordi & Kamkhah 2008). Observe — however, interaction may be beneficial.

### Antineoplastic agents

A theoretical and speculative interaction exists between black seed when used in combination with antineoplastic agents. Cytotoxic, apoptotic and necrotic effects have been observed in laboratory studies with the constituents thymoquinone and alpha-hederin (El-Mahdy et al 2005, Gali-Muhtasib et al 2004). The anticancer activity of thymoquinone has also been observed in animal studies (Ahmad et al 2013, Banerjee et al 2010, Randhawa & Alghamdi 2011, Woo et al 2012). Thymoquinone potentiated the antineoplastic effects of gemcitabine and oxaliplatin in one animal study (Banerjee et al 2009) and of ifosfamide in another animal study (Badary 1999). Theoretically, beneficial interactions exist, but further research is required to determine significance in humans.

### Cisplatin

The constituent thymoquinone is theoretically protective against cisplatin-induced nephrotoxicity and deleterious drug effects on haemoglobin levels and leucocyte count, based on animal study findings (Badary et al 1997, Nair et al 1991). Synergistic effects were observed when thymoquinone was used in combination with cisplatin in lung cancer cells and in animal models (Jafri et al 2010). Observe — interaction theoretically beneficial. Clinical significance unknown.

### Cytochrome P450-metabolising agents

Preliminary animal study data suggest that black seed may be protective against carbon tetrachloride-induced downregulation of cytochrome P450 enzymes CYP2B, CYP3A2, CYP2C11 and CYP1A2 (Ibrahim et al 2008). A potential interaction with drugs with cytochrome P450-metabolising activity is theoretical and speculative. Further research is required to determine clinical significance.

### Doxorubicin

The constituent thymoquinone is theoretically protective against doxorubicin-induced cardiotoxicity

and renal toxicity based on findings in animal studies (Al-Shabanah et al 1998, Badary et al 2000, Nagi & Mansour 2000). Observe — interaction theoretically beneficial. Clinical significance unknown.

### Gentamicin

Black seed is theoretically protective against gentamicin-induced nephrotoxicity, based on findings in animal studies, but the clinical significance is unknown (Ali 2004, Sayed-Ahmed & Nagi 2007, Yaman & Balıkcı 2010). Observe — interaction theoretically beneficial.

### Hepatotoxic agents

Based on animal studies, black seed appears to confer hepatoprotective effects against a number of agents. A theoretically beneficial interaction exists, but further research is required to determine significance in humans and with other hepatotoxic drugs.

### Hypolipidaemic drugs

Black seed has been shown to modulate lipid levels according to clinical trials (Kaatabi et al 2012, Najmi et al 2008). Observe — however, interaction may be beneficial.

### Immunomodulatory agents

Based on laboratory and animal studies, black seed displays immunomodulatory activity and may theoretically interact with either immunostimulant or immunosuppressant drugs (Abbas et al 2005, El-Obeid et al 2006, Gali-Muhtasib et al 2006, Islam et al 2004). Human studies are not available, therefore interactions are currently speculative and based on evidence of pharmacological activity. Clinical significance unknown.

### Iron

Increased iron status possible with consumption of black seed, based on limited animal study (Jadayil et al 1999). Clinical significance is unknown, but theoretically beneficial in iron deficiency.

### Non-steroidal anti-inflammatory drugs and cyclooxygenase-2 inhibitors

Based on laboratory and animal studies, black seed displays anti-inflammatory activity and may therefore theoretically interact with non-steroidal anti-inflammatory agents and cyclooxygenase-2 inhibitors (Al-Ghamdi 2001, El-Dakhkhny et al 2002, Houghton et al 1995, Mansour & Tornhamre 2004, Marsik et al 2005, Tekeoglu et al 2006). Human studies are not available, therefore interactions are currently speculative and based on evidence of pharmacological activity, but may theoretically be beneficial.

### Methotrexate

Theoretically, the antioxidant properties of black seed may ameliorate the gastrointestinal adverse effects associated with methotrexate, according to preliminary animal studies (Labib et al 2009). Clinical studies

### CONTRAINDICATIONS AND PRECAUTIONS

Avoid if known allergy or hypersensitivity to plants of the Ranunculaceae family. There are case study reports of allergic contact dermatitis following topical use of black seed oil (Ali & Blunden 2003). Black seed has been shown to alter levels of inflammatory mediators and various cytokines, although the clinical significance is still to be fully investigated (El-Obeid et al 2006, Gali-Muhtasib et al 2006). Caution is advised in patients with immune disorders, although dietary intake appears safe.

### PREGNANCY USE

When taken in usual dietary amounts, black seed is likely to be safe; however the safety of larger doses has not been scientifically evaluated.

Animal studies suggest that the volatile oil of *Nigella sativa* seeds may suppress uterine contractions (Aqel & Shaheen 1996) and may also confer some contraceptive properties (Keshri et al 1995). There are insufficient data to extrapolate these data to humans; however it is suggested that large doses should be avoided in women trying to conceive.

### Practice points/Patient counselling

- Black seed has been used for thousands of years to flavour food and for medicinal purposes, mostly in the Middle East and Southeast Asia.
- It has been referred to as a 'miracle herb' and has been used traditionally as a natural remedy for a range of conditions, including asthma, hypertension, diabetes, inflammation, cough, bronchitis, headache, eczema, fever, dizziness and influenza, as a carminative, a diuretic, a galactagogue, a vermifuge and for general wellbeing.
- A wide spectrum of pharmacological actions has been identified, including antiallergic, antidiabetic, antihypertensive, antimicrobial, antioxidant, lipid-lowering, antiepileptic, anti-inflammatory, immunomodulatory and anticancer properties.
- Currently, traditional folk use is supported by limited clinical evidence, but preliminary research suggests a potential role of black seed as adjunct therapy in asthma, allergy, type 2 diabetes mellitus, hyperlipidaemia and epilepsy.
- Appropriate therapeutic doses and potential for interactions and adverse effects are still to be confirmed.
- There is considerable interest in the potential of black seed as an innovative anticancer therapy and this is an area of current research.

are not yet available — however, beneficial interaction is possible.

### Respiratory agents

Black seed has been shown to have antiasthmatic effects according to preliminary human study (Boskabady et al 2007, 2010). Observe — adjunctive use may be beneficial.

### Warfarin

Theoretically, black seed may interact with warfarin, based on an in vitro study in which warfarin binding was displaced by the constituent thymoquinone (Lupido et al 2010). Caution — monitor concurrent use.

## ! PATIENTS' FAQs

### What will this herb do for me?

Black seed has a long history of traditional use as a folk medicine. It may be used in combination with drug therapies to support the treatment of a range of conditions, including allergy, asthma, diabetes and high cholesterol.

### When will it start to work?

Benefits have been reported after 6 weeks of use, although further scientific evidence is required to confirm this and to determine suitable therapeutic doses.

### Are there any safety issues?

Black seed is generally considered to be a very safe treatment based on historical use as a food and traditional medicine, although further research at therapeutic doses is required to confirm safety of black seed.

# Noni

**HISTORICAL NOTE** Noni has been used throughout Southeast Asia and Polynesia for more than 2000 years as a food source, a medicine and a dye. Noni fruit was traditionally used by Polynesians to combat fatigue (Ma et al 2007) and legends tell of Polynesian heroes and heroines that used noni to survive from famine (Wang et al 2002). Based on existing Bishop Museum records, it has been stated that the juice of the ripe fruit boiled is used as a remedy for diabetes, and fermented, as a tonic for cardiac complications and high blood pressure (Brown 2012).

## COMMON NAME

Noni

## OTHER NAMES

Ba Ji Tian, cheese fruit, Indian mulberry, meng-kudu, nhau, nono, nonu.

## BOTANICAL NAME/FAMILY

*Morinda citrifolia* (family Rubiaceae)

## PLANT PARTS USED

Roots, stems, bark, leaves, flowers, fruit and juice.

## CHEMICAL COMPONENTS

Noni contains terpenoids, alkaloids, anthraquinones (e.g. damnacanthal, morindone and rubiadin), the coumarin scopoletin, beta sitosterol, carotene, vitamin A, flavone glycosides, linoleic acid, the orange-red pigment alizarin, L-asperuloside, caproic acid, caprylic acid, ursolic acid, octanoic acid, potassium, vitamin C, rutin (Hiramatsu et al 1993, Wang et al 2002), as well as a natural precursor for serotonin named proseronine (Heinicke 1985, 2001). In vitro studies suggest that the antioxidant activity is due to several compounds such as coumarin derivatives (Ikeda et al 2009) and phenolic compounds (Liu et al 2007) that may contribute individually or synergistically.

Scopoletin has been suggested as a bioactive marker and a candidate for product standardisation and pharmacokinetic studies (Issell et al 2008).

## MAIN ACTIONS

Noni is purported to have many different effects including analgesic, anti-inflammatory, antioxidant, anticancer, antimicrobial, immune enhancement and antihypertensive activity.

### Analgesic and anti-inflammatory

Noni root extract has exhibited opioid-like properties, with dose-dependent analgesic properties in mice that were reversible by naloxone, together with sedative effects at higher doses (Younos et al 1990). Analgesic activity has also been reported in controlled trials using rats and mice (Wang et al 2002). The analgesic effect of noni is also due to its ability to inhibit cyclooxygenase and may be as potent as some NSAIDs (McKoy et al 2002).

### Antioxidant

Fruit, leaf and root extracts have all been shown to exhibit antioxidant activity (Kamiya et al 2004, Zin et al 2006) and NO scavenging activity in vitro (Jagetia & Baliga 2004), with some extracts showing comparable antioxidant activity to tocopherol (Zin et al 2002, 2006), grape seed powder and pycnogenol (Wang et al 2002). The neolignan, americanin A, has shown to be a particularly potent antioxidant in vitro (Su et al 2005).

A 1-month double-blind, randomised, placebo-controlled trial involving 68 smokers found that 50 mL of noni juice twice daily significantly reduced plasma superoxide radicals and lipid peroxides (Wang et al 2002). Noni juice has also been shown to reduce oxidative stress and liver damage in carbon tetrachloride-treated rats (Wang et al 2002, 2008a, 2008b), as well as inhibit the in vitro enzymatic activity of cyclooxygenase-1 (COX-1) (Li et al 2003) and cyclooxygenase-2 (COX-2) (Wang et al 2002). The clinical significance of these findings is yet to be determined.

### Gastroprotective

One in vivo study which evaluated the effect of an aqueous extract of dried noni fruit as well as its biomarker (scopoletin) demonstrated that noni may be beneficial as a potential preventive and therapeutic agent for gastro-oesophageal inflammation, mainly through its ability to enhance the mucosal defensive mechanisms via suppression of serotonin, free radicals and cytokine-mediated inflammation. Moreover, the efficacy was comparable to that of a standard potent anti-secretory proton pump inhibitor (lansoprazole) (Mahattanaadul et al 2011). Further research is required to establish efficacy in humans with GORD.

### Antitumour/anticancer

A review by Brown et al (2012) investigated 19 (both in vitro and in vivo) studies related to cancer. Of these studies, noni was tested in various forms (extract, powder and precipitate). Only nine studies were conducted on noni extract and the results suggest a bioactive component in noni juice extract (not leaves, roots or other plant parts) may be effective against cancer up to 30% of the time in laboratory rodents. However, the noni precipitate or

extract was injected into these animals, so the results may not be clinically relevant.

Several *in vitro* studies found anti-proliferative compounds in the leaves and roots of noni. Furthermore, the polysaccharide ethanol precipitate of noni has been shown to stimulate the immune system through macrophages, which were reported to release cytokines, nitric oxide (NO), interleukin-1 and interleukin 12 (IL-1, IL-12) and tumour necrosis factor (TNF) (Furusawa et al 2003, Hirazumi et al 1994). More recent *in vitro* data suggests that noni juice can enhance treatment responses in women with existing HER2/neu breast cancer as it significantly reduces tumour weight and volume, and has the ability to inhibit the growth of this aggressive form of cancer at an equivalent human dose of between 45 and 80 mL/day (Clafshenkel et al 2012).

In another study, cisplatin, an antitumour agent, showed only a slightly higher cell-killing activity against human cervical carcinoma HeLa and SiHa cells when compared to noni juice *in vitro* (Gupta et al 2013). The combination of noni juice and cisplatin showed additive effects through the upregulation of pro-apoptotic members and down-regulation of the anti-apoptotic members suggesting noni may be a potential adjuvant agent for chemotherapy.

Older research reveals that an alcoholic precipitate of noni juice significantly prolonged the life of mice with implanted tumours (Furusawa et al 2003, Hirazumi et al 1994). It is suggested that this antitumour activity is due to immunostimulatory activity because the noni precipitate was not directly cytotoxic to tumour cells, but did activate immune cells *in vitro* with its activity reduced by immunosuppressant drugs (Furusawa et al 2003, Hirazumi et al 1996). Noni juice has also been observed to increase the wet weight of thymus tissue in animals (Wang et al 2002) and to protect against 7,12-dimethylbenz(*a*)anthracene (DMBA)-induced DNA adduct formation in rats (Wang & Su 2001).

Noni improved survival times in cancer-implanted mice when combined with suboptimal doses of standard chemotherapeutic agents (Hirazumi & Furusawa 1999) and this is supported by *in vitro* studies demonstrating synergistic effects with chemotherapeutic agents (Furusawa et al 2003, Wang et al 2002).

*In vitro* studies have also found that noni fruit has antiproliferative activity against SKBR3 human breast adenocarcinoma cells (Moongkamdi et al 2004), and that glycosides extracted from noni inhibit cell transformation (Liu et al 2001) and ultraviolet-B (UVB)-induced activator protein-1 activity (Sang et al 2001, 2003). The anthraquinone, damcanthal, is reported to stimulate UV-induced apoptosis *in vitro* (Hiwasa et al 1999).

### Antimicrobial

Constituents of noni show activity against *Escherichia coli* *in vitro* (Duncan et al 1998) and *Mycobacterium tuberculosis* (National Library of Medicine 2001), as

well as the parasite *Ascaris lumbricoides* (Raj 1975); however, the clinical significance of this is undetermined. *In vitro* testing found that noni juice was as effective as sodium hypochlorite in reducing the smear layer when used as an endodontic irrigant (Murray et al 2008).

### Hepatoprotective

*In vivo* evidence (Lin et al 2013) suggests that noni juice significantly ameliorates ( $P < 0.05$ ) the increased liver size and visceral fat levels in hamsters fed a high-fat diet compared to hamsters fed a normal-fat diet over a 6-week period. The hamsters were put into five groups (including the control group), and the high-fat diet hamsters received distilled water, and 3, 6 and 9 mL of noni juice/kg of body weight, respectively. Supplementation with noni juice decreased serum and liver lipid levels, and also lipid deposits in hepatohistological examination, and diminished overall liver damage induced by a high-fat diet.

### Anti-psychotic

Studies have demonstrated that a methanolic extract of noni fruit, which was orally administered to mice (at doses of 1, 3, 5, 10 g/kg) significantly decreased methamphetamine and apomorphine-induced behaviour (licking, biting, gnawing and sniffing) and climbing time in mice in a dose-dependent manner (Pandy et al 2012). Conversely, when noni juice was made freely available in drinking water at a volume concentration of 50% and 100%, there were significant reductions in apomorphine-induced climbing behaviour and time. This data demonstrates the anti-dopaminergic effect of noni juice in mice, and supports anecdotal evidence which suggests that noni is effective in the treatment of CNS disorders. Further studies are required to identify the actions responsible for the observed antipsychotic activity of noni.

### Ergogenic

Animal studies in aged mice have shown that noni juice improved endurance, balance and flexibility (Ma et al 2007).

### Antihypertensive

The antihypertensive effects of the root extract of noni were first investigated in the 1950s (Ho 1955) and a hot-water extract of noni root is reported to have lowered the blood pressure of an anaesthetised dog (Youngken 1958). Antispasmodic and vasodilator activities of noni root extract are believed to be mediated through a blockade of voltage-dependent calcium channels (Gilani et al 2010). However, the root is not a component of commercial preparations, and this study used a vacuum-dried 70% aqueous-ethanolic extract.

### Antidiabetic

In experimental diabetic models, noni extract displayed antihyperglycaemic as well as antioxidant

effects (Kamiya et al 2008, Mahadeva Rao & Subramanian 2008). When fermented as a soybean paste, noni has shown benefit in murine models as a functional food for the management of type 2 diabetes (Lee et al 2012). Over a 90-day period the fermented noni paste reduced blood glucose levels to 211.60–252.20 mg/dL (11.8 mmol/L–14.0 mmol/L) after 90 days, while those in the control group were in excess of 400 mg/dL (22.2 mmol/L) after 20 days. In addition, supplementation with the fermented noni paste reduced glycosylated haemoglobin (HbA<sub>1c</sub>) levels, enhanced insulin sensitivity and significantly decreased serum triglycerides and low-density lipoprotein (LDL) cholesterol (Lee et al 2012).

### Cardioprotective

In vitro evidence suggests that noni juice exerts a cardio-protective effect in hamsters consuming a high-fat/cholesterol diet (Lin et al 2012). In this study, noni juice supplementation decreased serum triacylglycerol, cholesterol, atherogenic index, malondialdehyde levels and hepatic lipids, while glutathione and faecal lipids were increased ( $P < 0.05$ ).

### OTHER ACTIONS

Noni has been shown to inhibit gastric emptying in male rats via a mechanism involving stimulation of cholecystokinin (CCK) secretion and CCK1 receptor activation (Pu et al 2004) and in vitro studies demonstrate inhibition of lipoprotein lipase suggesting potential use in weight management (Pak-Dek et al 2008).

### CLINICAL USE

In recent years noni juice has been touted as a 'super juice' that enhances wellbeing. Noni has been reported to be of benefit for people with arthritis, diabetes, hypertension, muscle aches and pains, menstrual difficulties, headache, heart disease, atherosclerosis, AIDS, cancers, gastric ulcers, poor digestion, depression, senility and drug addiction (Wang et al 2002). Since noni has not been significantly investigated in human studies, uncertainty remains about its potential benefits in these conditions and diseases. At this stage, evidence for its use is mostly derived from traditional, in vitro and animal studies and a handful of trials of varying quality.

### Osteoarthritis

Based on its demonstrated anti-inflammatory and analgesic properties, a benefit in osteoarthritis seems possible. Wang et al (2011) have investigated this further in an open label pilot study of 82 patients with diagnosed knee or hip osteoarthritis (OA), which revealed that Tahitian Noni Juice (TNJ, produced by Morinda Holding Inc.) improved both quality of life and symptoms as measured by two validated scales, SF-36 and the Arthritis Impact Measurement Scales (AIMS 2).

The 21 male and 61 female participants (aged 40–75 years) received 88 mL of TNJ per day for 90 days, and were not taking any other prescription medication for arthritis. The results indicated that there were statistically significant improvements in OA patient satisfaction with mobility, walking and bending, hand and finger functions, arm function, self-care, household tasks, social activity, arthritis pain, work, level of tension and mood (Wang et al 2011). Since the study lacked a placebo arm, it can only be described as suggestive of a benefit. Double-blind, placebo-controlled studies are now warranted.

### Primary dysmenorrhoea

A prospective, randomised, double-blind placebo-controlled trial of 100 university students (aged 18 years or older) found that 3 months treatment with noni capsules (400 mg twice daily; Vitamin World, USA) provided no benefits for primary dysmenorrhoea (Fletcher et al 2013). Interestingly, the placebo group had a greater decrease in mean pain scores than the noni group after 3 months and there were no significant differences in the mean bleeding score. The fact that the subjects using noni had a better decrease in their ESR (an acute phase reactant) suggests that it does have some anti-inflammatory effects; however, this was not manifested in clinically improved pain or bleeding scores during the time of the study. The authors suggested that poor treatment compliance may have been a limitation of the study. Whether a higher dose or longer treatment term may have produced different results remains to be tested.

### Smoking-induced dyslipidaemia

Noni juice has been shown to mitigate cigarette smoke-induced dyslipidaemia (Wang et al 2012). A randomised, double-blind, placebo-controlled clinical trial investigated the antioxidant activity of noni juice in 100 heavy smokers who smoked more than 20 cigarettes per day. The study, which used a blend of grape and blueberry juices as placebo, found that noni juice (29.5–188 mL/day for 30 days) significantly reduced cholesterol levels, triglycerides and high-sensitivity C reactive protein. It is theorised that noni juice inhibits cigarette smoke-induced oxidative stress by increasing the activity of glutathione-utilising enzymes (Wang et al 2012).

### Hearing and mental health

A small placebo-controlled pilot study involving nine hearing-impaired osteopenic or osteoporotic women found that ingestion of approximately 50 mL of noni juice over 3 months resulted in improved mental health and a mild protective effect on hearing. Further studies are required to determine the clinical significance of these findings (Langford et al 2004).

**Practice points/Patient counselling**

- Noni has been traditionally used as food and medicine for a wide range of medical conditions.
- Noni has not been significantly investigated in clinical studies, so its use is based on traditional evidence and laboratory and animal studies demonstrating various actions.
- Although it is likely to be safe, it is prudent to avoid using noni in amounts greater than those ingested as a food during pregnancy and to monitor clotting profiles if noni is used with anticoagulant medications.

**OTHER USES**

Noni fruit may be used as a food source.

**DOSAGE RANGE**

There is little human research upon which to make accurate dosage recommendations, however, successful studies have used in the vicinity of 30–190 mL/day (Wang et al 2012).

Noni juice can also be used to create freeze-dried pills, concentrated extracts, powders, tinctures and even fruit leather similar to dried fruit strips (Brown 2012).

**TOXICITY**

Human clinical trials have shown the maximum tolerated dose of noni was 12 g (tablet form) with no dose-limiting toxicity found in seven of eight patients who ingested 14 g (Issell et al 2009). No toxic effects have been found in rats (Mancebo et al 2002), even when given doses up to 80 mL/kg (Wang et al 2002).

Idiosyncratic adverse events have been reported for noni juice; however, these appear to be rare.

Several cases of hepatotoxicity related to noni juice consumption have been reported, with one case requiring urgent liver transplantation (Millonig et al 2005, Stadlbauer et al 2005, Yu et al 2011), and others spontaneously recovering after ceasing noni consumption (Millonig et al 2005, Stadlbauer et al 2005). More recently, a case was reported of a 38-year-old woman who developed acute liver injury and jaundice associated with noni juice (cumulative amount approximately 400 mL) in a patient on long-term (9 months) anticonvulsant therapy (Mrzljak et al 2013). It is unknown whether this toxic effect is a result of the synergistic effect of both the medication prescribed and noni juice consumption. Such case reports are in contrast to studies that indicate that the no-observed-adverse-effect level (NOAEL) for freeze-dried noni fruit puree is greater than 6.86 g/kg body weight, equivalent to approximately 90 mL of noni fruit juice/kg (West et al 2009).

More safety data is required before clinical conclusions can be made.

**ADVERSE REACTIONS**

Noni appears to be well tolerated. A safety study conducted on 96 healthy volunteers who consumed up to 750 mL Tahitian Noni Juice per day revealed no adverse effects (West et al 2009). Similarly no adverse events were reported in a clinical trial using 29.5 to 188 mL daily for 30 days (Wang et al 2012). Allergenicity studies using guinea pigs report no allergic responses (Wang et al 2002).

**SIGNIFICANT INTERACTIONS**

There is one case report of noni juice consumption causing resistance to warfarin (Carr et al 2004). Further investigation is required to determine the certainty of this causal association.

**? CONTRAINDICATIONS AND PRECAUTIONS**

Noni juice is high in potassium and use needs to be monitored in patients with kidney, liver or heart problems (Brown 2012).

**! PREGNANCY USE**

Likely to be safe when consumed in dietary amounts; however, safety is not known when used in larger quantities. In vivo studies suggest the possibility of reproductive toxicity in rats (Muller et al 2009) while prenatal toxicity in developing rat embryos or fetuses revealed no evidence of toxicity (West et al 2008).

**! PATIENTS' FAQs****What will this herb do for me?**

Noni has not been significantly investigated under clinical trial conditions, so its use is largely based on traditional evidence and laboratory and animal studies. Preliminary research suggests it may be useful in osteoarthritis and reducing cholesterol levels in heavy smokers, but benefits remain unclear and further clinical studies are required to confirm effects.

**When will it start to work?**

There is little published evidence to indicate its speed of action, which will depend on the clinical use.

**Are there any safety issues?**

Noni is generally considered safe and can be consumed as a food; however, the safety of large intakes is unknown. The available human studies show it is well tolerated.

# Oats

**HISTORICAL NOTE** Culpeper (1652) recommended that ‘a poultice made of meal of oats and some oil of bay helpeth the itch and the leprosy’. By the end of the 18th century oats was the main grain used by all levels of the population in Scotland. Students would arrive at university after the summer with a bag of oatmeal to live on during the term. The older Scottish universities still call the autumn midterm break ‘Meal Monday’ because traditionally at that time the students would return home to replenish their supplies. In recent years oats has gained a reputation as a superfood due to its high nutritional content and cardiovascular benefits. It is a good source of B-complex vitamins, protein, fat and minerals as well as the heart-healthy soluble fibre known as beta-glucan, which appears to improve blood glucose and cholesterol levels (Sadiq Butt et al 2008).

## OTHER NAMES

Groats, green oats, green tops, haver, oat herb, oatmeal

## BOTANICAL NAME/FAMILY

*Avena sativa* (family Poaceae [Graminaceae])

## PLANT PARTS USED

The whole flowering plant, including the oat straw and the seed (also used for porridge). Oat bran is also used in some clinical trials.

## CHEMICAL COMPONENTS

Beta-glucan (soluble fibre), triterpenoid saponins (including avenacosides A and B), phenolic compounds (avenanthramides A, B, C), alkaloids (including indole alkaloid, gramine, trigonelline, avenine), sterol (avenasterol), flavonoids, starch, phytates, protein (avenalin, a water-soluble globulin; avenin, a prolamine protein) (Mahmood et al 2013) (including gluten) and coumarins.

Nutrients such as silicic acid, calcium, potassium, phosphorus, iron (39 mg/kg), manganese (8.5 mg/kg), zinc (19.2 mg/kg) (Witchl & Bisset 1991), vitamins A, B-complex, C, E and K and amino acids.

## MAIN ACTIONS

The actions of oats, oatbran and key constituents such as beta-glucan have been investigated in various models.

### Lipid lowering

Beta-glucans increase bile acid synthesis and thus decrease serum cholesterol (Andersson et al 2002). The fibre binds to cholesterol, preventing initial absorption and enterohepatic recirculation of cholesterol, and the two are excreted together. A recent animal study examining the lipid-lowering properties of oats reported that increased bile acid production occurs by upregulating cholesterol-7  $\alpha$ -hydroxylase and sterol-12  $\alpha$ -hydroxylase (Andersson et al 2012). This study also noted that intestinal microbial flora may alter bile acid or cholesterol metabolism (Andersson et al 2012).

Clinical trials have shown that oat bran contains soluble fibres, such as beta-glucan (e.g. 75 g extruded oat bran, equivalent to 11 g beta-glucan), which nearly double the serum alpha-HC (7 alpha-hydroxy-4-cholesten-3-one) concentration within 8 hours, indicating increased bile acid synthesis and thus decreased serum cholesterol (Andersson et al 2002). Recent human studies using 75 g extruded oat bran breakfast cereal daily (containing 11.6 g native beta-glucans) have confirmed similar effects. Administration of oat bran significantly increased median excretion of bile acids by 144%, decreased cholesterol absorption by 19%, increased the sum of bile acid and cholesterol excretion by 40% and increased alpha-HC concentration (reflecting bile acid synthesis) by 57% within 24 hours of consumption (Ellegard & Andersson 2007).

Beta-glucan added to a fruit drink appears to significantly reduce both total and low-density lipoprotein (LDL) cholesterol in human subjects without affecting fat-soluble antioxidant levels (Naumann et al 2006). Triglyceride levels may also be reduced. In a randomised crossover study, 27 healthy men added oat (providing 5.7 g/day beta-glucan) or wheat (control) cereal products to their usual diet for 2 weeks. Peak triglyceride concentration was significantly lower in the oats group compared to controls (Maki et al 2007a).

### Antiatherogenic effects

In vitro studies suggest that the polyphenolic antioxidants known as avenanthramides, present in oats, may exert anti-inflammatory and antiatherogenic effects (Andersson & Hellstrand 2012, Liu et al 2004). Avenanthramides have been shown to decrease the expression of endothelial proinflammatory cytokines. This is in part due to inhibition of nuclear factor-kappaB activation via inhibiting phosphorylation of IkappaB kinase and IkappaB, and suppressing proteasome activity (Guo et al 2008). Additionally, avenanthramide C inhibits the serum-induced proliferation of vascular smooth-muscle cells and increases nitric oxide production (Nie et al 2006a, 2006b). As chronic inflammation and proliferation of vascular smooth-muscle cells are involved

in the initiation and development of atherosclerosis, these mechanisms may reduce atherogenesis.

### Antihypertensive effects

Reviews report that supplementation of oat  $\beta$ -glucan daily reduces systolic and diastolic blood pressure as well as the need for antihypertensive medication (Daou & Zhang 2012). Oats are known to contain angiotensin-converting enzyme-inhibiting dipeptides and tripeptides (Pihlanto & Mäkinen 2013). While a reduction in blood pressure has been observed in clinical trials, the mechanism of action has not been fully elucidated (Keenan et al 2002, Pins et al 2002, Saltzman et al 2001).

### Blood glucose control

Oats have been shown in clinical trials to reduce the postprandial glycaemic response (Brummer et al 2012, Jenkins et al 2002, Pins et al 2002, Tapola et al 2005). This is most likely to be due to the ability of beta-glucans to slow stomach emptying and increase the viscosity of food in the small intestine, resulting in delayed glucose absorption (Rakel 2003, Regand et al 2011). The fat content of rolled oats does not appear to be responsible for either the glycaemic or the insulinaemic response (Tuomasjukka et al 2007).

While some studies have suggested that a minimum of 4 g of beta-glucans is required to produce a significant decrease in glucose and insulin responses in healthy people (Granfeldt et al 2008), other studies suggest this dose may not exert a significant response (Biorklund et al 2008). The effect is likely to be dependent not only on the amount of beta-glucan but on the amount of extractable beta-glucan in oat products (Makelainen et al 2007). In humans this extraction is dependent upon the solubility of beta-glucans, and a recent study noted that beta-glucans of higher molecular weight were more soluble than beta-glucans of lower molecular weight (Kwong et al 2013, Regand et al 2011). This may explain inconsistent results in clinical studies using different formulations of oats (Tosh et al 2008).

### Antioxidant

In human trials, avenanthramides (A–C) in oats have been found to be bioavailable and increase antioxidant capacity in healthy older adults. A randomised controlled trial (RCT) of healthy adults who received daily supplementation of 3.12 mg oat-extracted avenanthramides for 1 month reported potent antioxidant activity. The intervention resulted in an increase in serum superoxide dismutase of 8.4% ( $P < 0.05$ ); a reduction in glutathione hormone of 17.9% ( $P < 0.05$ ); and a decrease in malondialdehyde of 28.1% (Liu et al 2011). After consumption of an avenanthramide-enriched mixture extracted from oats, plasma-reduced glutathione was elevated by 21% at 15 minutes ( $P \leq 0.005$ ) and by 14% at 10 hours ( $P \leq 0.05$ ) in another study (Chen et al 2007). In a further study whole oat grains

(seven different varieties) showed superior antioxidant activity compared to other whole grains but the antioxidant capacity did not correlate with avenanthramide content, suggesting that other compounds in oats may potentially contribute to synergistic or matrix effects (Chu et al 2013).

### Antipruritic/anti-inflammatory effects

External application of oat preparations has been shown to relieve itch (Matheson et al 2001). These effects are most likely to be due to the potent anti-inflammatory effects of the avenanthramide constituents (Sur et al 2008). Experimental studies demonstrate that avenanthramides can inhibit the activity of nuclear factor- $\kappa$ B and the release of proinflammatory cytokines and histamine (Cerio et al 2010). Topical application of 1–3 ppm avenanthramides has been shown to alleviate inflammation in experimental models of contact hypersensitivity, neurogenic inflammation and itch (Sur et al 2008). The high concentration of starch and beta-glucan in colloidal oatmeal (produced by finely grinding the oats and boiling to extract the colloidal material) is responsible for the protective and water-holding functions of oats (Kurtz & Wallo 2007).

### Anticarcinogenic

The consumption of oats and oat bran has been shown to reduce the risk of colon cancer, not only because of their high fibre content, but also because in vitro studies suggest that avenanthramides attenuate the proliferation of colon cancer cells (Guo et al 2010). The beta-glucans in oats have demonstrated anticarcinogenic, antimutagenic and antitumorogenic activity (Mantovani et al 2008). An in vitro study using an inflammation-related cancer model in mice demonstrated that whole oats reduced aberrant crypt foci and colon tumours, indicating a protective effect of oats against colon cancer and the potential to act as a chemoprotective agent (Wang et al 2011). However, further investigation is needed to confirm these effects.

### OTHER ACTIONS

Due to its vitamin, mineral and amino acid content, oats are a nutritious food. Internally, oats also act as a bulk-forming laxative. Wholegrain oat-based breakfast cereals may also act as prebiotics, increasing the proliferation of the *Bifidobacterium* genus (Connolly et al 2012).

### CLINICAL USE

Oats are sometimes used in clinical practice in tincture form, often as part of an overall management program, combined with other herbal medicines. It is also used in topical preparations and, most recently, the beta-glucan component in oats has received a lot of attention, whereby dietary oats are used as a means of increasing beta-glucan uptake and conferring health benefits.

## Hyperlipidaemia

In 1997 the US Food and Drug Administration approved a health claim for  $\beta$ -glucan soluble fibre from oats for reducing plasma cholesterol levels and risk of heart disease, and this was followed by similar approvals in 2004 from the UK Joint Health Claims Initiative. Recent reviews have confirmed that intake of oat  $\beta$ -glucan at daily doses of at least 3 g may reduce plasma total and LDL cholesterol levels by 5–10% in normocholesterolaemic or hypercholesterolaemic people (Othman et al 2011, Tiwari & Cummins 2011).

A Cochrane review estimating the effect of wholegrain foods on risk factors for coronary heart disease summarised the results of eight RCTs, which had used an oatmeal-based intervention in individuals with raised cholesterol levels (Kelly et al 2007). The duration of the studies varied between 4 and 12 weeks. The review found evidence that oatmeal-based foods lower total cholesterol and LDL-cholesterol. Combined results from the eight studies showed a weighted mean difference of  $-0.19$  mmol/L (95% confidence interval [CI]  $-0.30$  to  $-0.08$ ,  $P = 0.0005$ ) in the reduction of total cholesterol. The combined result for reduction in LDL showed a weighted mean difference of  $-0.18$  mmol/L (95% CI  $-0.28$  to  $-0.09$ ,  $P < 0.0001$ ).

Several clinical trials have shown a marked reduction in total and/or LDL cholesterol using oat-based beta-glucan-containing products (Karmally et al 2005, Queenan et al 2007, Saltzman et al 2001).

In a double-blind, randomised crossover study in 24 young adults (age  $25.2 \pm 2.7$  years; body mass index [BMI]  $24.9 \pm 2.9$  kg/m<sup>2</sup>), the addition of oat bran (6 g soluble fibre/day) to a low-fibre diet for 2 weeks lowered total cholesterol by 14% compared with 4% during the control period ( $P < 0.001$ ) (Kristensen & Bugel 2011). There were also decreases in non-high-density lipoprotein (HDL) cholesterol (16% vs 3%;  $P < 0.01$ ), total triacylglycerol (21% vs 10%,  $P < 0.05$ ), very-low-density lipoprotein triacylglycerol (33% vs 9%,  $P < 0.01$ ), plasminogen activator inhibitor-1 (30 vs 2.3%,  $P < 0.01$ ) and factor VII (15 vs 7.6%,  $P < 0.001$ ). Faecal volume and dry matter were greater when consuming the oat bran diet ( $P < 0.001$ ), and energy excretion was increased by 37% ( $P < 0.001$ ); although changes in body weight were not significantly different.

In a randomised, controlled, parallel-arm study of 166 Asian adults with mild to moderate hypercholesterolaemia, participants received 100 g of instant oat cereal or 100 g of wheat flour-based noodles daily for 6 weeks. Total, LDL-cholesterol and waist circumference decreased significantly and dietary fibre intake increased significantly in the oat group compared to the control group at the end of the 6-week intervention. Conversely, HDL-cholesterol decreased significantly in the control group compared to the oat group (Zhang et al 2012). Oat bran has been shown to reduce LDL-cholesterol by 16%

in 140 hypercholesterolaemic subjects consuming 56 g oat bran/day for 12 weeks (Davidson et al 1991). In overweight men consuming an oat-based cereal (14 g dietary fibre) for 12 weeks, LDL-cholesterol was most significantly affected, with a reduction in concentrations of small, dense LDL-cholesterol and LDL particle number. No adverse changes occurred in blood triacylglycerol or HDL-cholesterol concentration (Davy et al 2002). In another clinical trial, a group consuming wholegrain oat-based cereals experienced a 24.2 mg/dL reduction in total cholesterol levels and a 16.2 mg/dL decrease in LDL-cholesterol levels (Pins et al 2002).

In a controlled trial 75 hypercholesterolaemic subjects were randomised to receive 6 g/day of concentrated oat beta-glucan or placebo (dextrose) for 6 weeks. Oat beta-glucan significantly reduced total cholesterol ( $-0.3 \pm 0.1$  mmol/L) and LDL-cholesterol ( $-0.3 \pm 0.1$  mmol/L), but only the reduction in LDL-cholesterol was significantly greater than in the control group. In an intestinal fermentation model the concentrated oat beta-glucan also produced higher concentrations of the short-chain fatty acid known as butyrate than guar gum and inulin, suggesting it may have benefits for colonic health (Queenan et al 2007).

A clinical trial of 38 normotensive males (mean age 59.8 years) with mild to moderate hypercholesterolaemia and a mean BMI of 28.3 kg/m<sup>2</sup> was conducted over 8 weeks. The study investigated the effects of adding high levels of monounsaturated fatty acids plus bread formulated with 6 g of beta-glucan to the American Heart Association Step II diet plus 60 min walking per day. While results were impressive, it is unclear what part the beta-glucan played in isolation (Reyna-Villasmil et al 2007).

The lipid-lowering effects of a hypocaloric diet containing oats have been shown in a clinical trial to result in significantly greater decreases in total and LDL-cholesterol than a hypocaloric diet alone (Saltzman et al 2001). In addition, an RCT of moderately hypercholesterolaemic men consuming oat milk, deprived of insoluble fibre but still containing 0.5 g/100 g beta-glucan (750 mL/day) for 5 weeks, also showed a 6% reduction in total and LDL-cholesterol (Onning et al 1999). Effects on serum lipid levels in people without hypercholesterolaemia are not well supported in clinical trials (Chen et al 2006). (See Clinical note: Major lipids affecting cardiovascular disease risk, in monograph on vitamin B<sub>3</sub>.)

## Hypertension

Daily consumption of three portions of wholegrains, including oats, has been shown to significantly reduce systolic blood pressure (SBP) and pulse pressure (Tighe et al 2010). Results of RCTs suggest that consumption of oat-based cereals may reduce SBP and reduce or eliminate requirements for anti-hypertensive medications in some people (Pins et al 2002, Saltzman et al 2001).

The inclusion of wholegrain oat-based cereals was found in an RCT to decrease blood pressure in hypertensive patients and reduce requirements for antihypertensive medications. 'Seventy-three percent of participants in the oats group versus 42% in the control group were able to stop or reduce their medication by half. Treatment group participants whose medication was not reduced had substantial decreases in blood pressure' (Pins et al 2002). In another RCT, overweight subjects consuming a hypocaloric diet containing oats (45 g/4.2 MJ dietary energy/day) for 6 weeks experienced a reduction in SBP that was more significant than a hypocaloric diet alone (oats  $-6 \pm 7$  mmHg, control  $-1 \pm 10$  mmHg,  $P = 0.026$ ). Lipid-lowering effects were also noted (Saltzman et al 2001). In another double-blind, multicentre clinical trial, 97 hypertensive patients were randomly assigned to receive a control diet or one containing oat beta-glucan for 12 weeks. Subgroup analysis revealed that only obese patients with a BMI  $> 31.5$  kg/m<sup>2</sup> experienced a significant decrease in blood pressure (SBP  $-8.3$  mmHg, diastolic blood pressure  $-3.9$  mmHg) compared to controls (Maki et al 2007b). Overall, results appear to suggest greater benefits for overweight or obese individuals.

### Blood sugar regulation

The ability of oats to delay glucose absorption, and therefore reduce the postprandial glycaemic response, provides a theoretical basis for their use as part of an overall treatment protocol in diabetes and hypoglycaemic conditions.

In a crossover RCT, 35 patients with type 2 diabetes and dyslipidaemia received a breakfast consisting of 250 g of oat bread (50% oat flour, 50% white flour) or barley bread (50% barley flour, 50% white flour) daily for 3 weeks (with a washout period of 3 weeks). Both oat and barley bread reduced fasting blood sugar (FBS) ( $P < 0.0001$ ) and improved HDL-cholesterol ( $P < 0.01$ ). However, the beneficial effect of oat bread on reducing serum FBS (mean difference  $6.2 \pm 9.2$  mg/dL) and improving HDL-C (mean difference  $1.34 \pm 0.2$  mg/dL) was greater than for barley bread (mean difference in FBS,  $32 \pm 2.7$  mg/dL; HDL-C,  $9.2 \pm 1.8$  mg/dL). Neither of the interventions demonstrated significant differences for LDL-C, insulin sensitivity or triglycerides (Hajifaraji et al 2012). Animal studies have also reported that the effects of oat bran are superior to barley bran (El Rabey et al 2013). An RCT of 12 patients with type 2 diabetes demonstrated that 30 g oat bran flour, high in beta-glucan, had a low glycaemic response and decreased the postprandial glycaemic response of an oral glucose load in a series of 2-hour meal glucose tolerance tests (Tapola et al 2005).

Another trial showed a 15.03 mg/dL drop in plasma glucose levels versus controls when consuming wholegrain oat-based cereals (Pins et al 2002). Processing methods may affect the benefits of oats, with a small study demonstrating that processing oat beta-glucan through enzymatic, rather than aqueous,

methods preserves the viscosity and improves postprandial glycaemic control (Panahi et al 2007). In a 50 g portion of carbohydrate, each gram of beta-glucan reduces the glycaemic index by 4 units, making it a useful adjunct to reduce the postprandial glycaemic response without affecting palatability (Jenkins et al 2002).

In an uncontrolled pilot study, 14 hospitalised patients with metabolic syndrome were given a diabetes-adapted hypocaloric diet (1500 kcal/day; 50–55% carbohydrate, 15–20% protein, 30% fat) for 5 days with or without a 2-day period (third and fourth day), where the diet included 15 carbohydrate units of oatmeal (1200 kcal/day; 63% carbohydrate, 12% protein, 6% fat and 16.2 g fibre). The oatmeal intervention reduced insulin requirements by 42.5% and the effect persisted after a 4-week outpatient period (Lammert et al 2008). The differences in calorie intake and nutritional breakdown make it difficult to attribute the observed effects to oatmeal alone and more controlled studies are warranted.

Recent studies suggest that porridge made from pinhead oats compared to rolled oats may have better effects on glycaemic control and sense of fullness (Gonzalez & Stevenson 2012). In addition different food formats that deliver similar amounts of soluble  $\beta$ -glucan may have similar effects. For instance, 1.5 g/day  $\beta$ -glucan from ready-to-eat oat flakes was reported to be as effective in lowering cholesterol as 3.0 g/day from oats porridge in a 6-week RCT of 87 mildly hypercholesterolaemic adults ( $\geq 5$  mmol/L and  $< 7.5$  mmol/L) (Charlton et al 2012).

### Obesity

In a recent RCT of 34 adult participants with a BMI  $\geq 27$ , beta-glucan-containing oat cereal was compared to placebo daily for 12 weeks. Consumption of the oat cereal reduced body weight, BMI, body fat and the waist-to-hip ratio. Liver function tests revealed a reduction in aspartate transaminase, and especially alanine transaminase, with oat consumption. Oats were well tolerated and the authors concluded that consumption of oats reduced obesity and abdominal fat and improved lipid profiles and liver function (Chang et al 2013). Further research is required to confirm and elucidate these effects.

### Pruritus

Topical oatmeal has been used traditionally to relieve the itch and irritation associated with various dry, itchy skin conditions. Colloidal oatmeal lotion, Aveeno (Johnson & Johnson, Maidenhead, Berkshire, UK) has been shown to be an effective treatment for pruritus (Talsania et al 2008). These effects may be explained by the avenanthramides, potent anti-inflammatory agents that appear to mediate the anti-irritant effects of oats (Sur et al 2008). In addition, the beta-glucan and starch in colloidal oatmeal are thought to possess water-holding effects (Kurtz & Wallo 2007).

A clinical trial assessing the itch experienced by burns patients found that the group using a product with 5% colloidal oatmeal reported significantly less itch and requested significantly less antihistamine treatment than the control group (Matheson et al 2001).

Commission E approves topical use in baths for inflammatory and seborrhoeic skin disease, especially with itch (Blumenthal et al 2000).

### Atopic dermatitis

Daily use of moisturisers and/or cleansers containing colloidal oatmeal appears to improve many clinical outcomes of atopic dermatitis, including the size and severity of the affected area, itch and dryness (Fowler et al 2012). In a controlled trial, an emollient treatment (containing oat extract) for 6 weeks significantly reduced high-potency topical corticosteroid consumption (−42%;  $P < 0.05$ ) in infants with atopic dermatitis. Significant effects were not demonstrated for moderate-potency corticosteroids (Grimalt et al 2007). However, it should be noted that percutaneous sensitisation to oats used in emollients and moisturisers has been reported and one study found that 32% of children with atopic dermatitis using oat-based creams had an oat-positive atopy patch test vs 0% of non-users (Boussault et al 2007). Given the hyperpermeability of infant skin, topical products containing potentially allergenic food proteins should be used cautiously (Codreanu et al 2006).

### OTHER USES

Traditionally, oats are considered a nervous system nutritive and therefore used during times of convalescence. More specifically, the straw is prescribed for nervous debility and exhaustion, whereas the seed is considered more stimulating and said to gently improve energy and support an overly stressed nervous system (Chevallier 1996). An animal study on rats showed that beta-glucan enhanced endurance and significantly improved recovery from fatigue (Xu et al 2013).

Preliminary trials have suggested an improvement in sexual interest and performance in people taking oats in combination with nettles. The effects were more consistent in males than females. Further trials are required to confirm the benefits of oats in isolation (Haroian et al 1987).

Interestingly, oats are also used as supportive therapy during nicotine (Beglinger et al 1977, Schmidt & Geckeler 1976) and morphine withdrawal; however, reliable clinical evidence is currently limited and does not fully support these recommendations.

Due to its high soluble fibre content, oats are also used as an aid to weight loss. Taken before meals, they increase satiety and therefore enable smaller food portions to satisfy hunger.

### DOSAGE RANGE

- 1–4 g three times daily of oatmeal or straw (Mills 1991).

- Australian manufacturers recommend 20–40 mL/week 1:2 tincture.
- Topically for itch: 5% colloidal oatmeal in a suitable carrier (Matheson et al 2001) or 100 g cut herb in a bath (Blumenthal et al 2000).
- The inclusion of wholegrain oat-based cereals or oat bran may be a useful adjunct to the treatment of hyperlipidaemia and hypertension and to delay glucose absorption — 75 g dried oatmeal (equivalent to  $\approx 3$  g soluble fibre daily) (Rakel 2003). Some research indicates 6 g/day of concentrated oat beta-glucan is required for lipid-lowering effects.

### ADVERSE REACTIONS

Excessive oral intake of fibre from oats or oat bran may cause flatulence and anal irritation.

### SIGNIFICANT INTERACTIONS

Controlled studies are largely unavailable; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

### Antihypertensives

Additive effects are theoretically possible (Pins et al 2002); beneficial interaction is possible — observe.

### Lipid-lowering medications

Additive effects are theoretically possible — beneficial interaction is possible.

### Insulin and diabetic medications

In an uncontrolled pilot study, an oatmeal intervention reduced insulin requirements by 42.5% in hospitalised patients with metabolic syndrome; the effect persisted after a 4-week outpatient period (Lammert et al 2008). Insulin requirements should be monitored in patients taking oat beta-glucans as a change to medication dose could be required. Beneficial interaction possible under supervision.

### CONTRAINDICATIONS AND PRECAUTIONS

Given the hyperpermeability of infant skin, topical products containing potentially allergenic oat proteins should be used cautiously (Codreanu et al 2006). Dietary oats should not be used in cases of intestinal obstruction (Skidmore-Roth 2001).

### **Clinical note — Do oats interfere with nutrient absorption?**

Although the high phytate content of oats would indicate a potential for reduced absorption of trace elements such as zinc, calcium and iron, one clinical trial investigating the effects of oat bran on zinc absorption found no evidence of reduced absorption (Sandstrom et al 2000).

## Coeliac disease and oats consumption

In the past oats were generally contraindicated in people with coeliac disease due to their gluten content. Recent studies however have demonstrated that oats appear to be well tolerated by the majority of adults (Cooper et al 2013, Guttormsen et al 2008, Kempainen et al 2007, Lundin et al 2003, Pulido et al 2009) and children (Benkebil & Nydegger 2007, Hogberg et al 2004, Holm et al 2006) with coeliac disease. For instance, a recent study of 46 patients with coeliac disease who consumed oats for 1 year reaffirmed the lack of oats immunogenicity and toxicity (Cooper et al 2013).

However, some patients display a specific small intestinal T-cell response to oat peptides that cannot be explained by contamination with other cereals (Ellis & Ciclitira 2008) and may experience intestinal discomfort, diarrhoea, bloating and subtotal villous atrophy (Lundin et al 2003, Peraaho et al 2004, Storsrud et al 2003).

Food-processing techniques such as kilning do not appear to either increase or decrease the antigenic potential (Kempainen et al 2008); however some species such as the Italian variety, Astra, and the Australian variety, Mortlock, may be more reactive (Silano et al 2007).

Two recent reviews of the literature concluded that oats are well tolerated by most patients with coeliac disease (Garsed & Scott 2007, Haboubi et al 2006) but recommended the avoidance of oat products that may have been contaminated by wheat (Garsed & Scott 2007) and regular follow-up, including small-bowel biopsy (Haboubi et al 2006). The Canadian Coeliac Association recommends

consumption of uncontaminated oats up to 70 g ( $\frac{1}{2}$ – $\frac{3}{4}$  cup)/day for adults and up to 25 g ( $\frac{1}{4}$  cup)/day for children (Rashid et al 2007).

## ! PATIENTS' FAQs

### *What will this herb do for me?*

Oats are a concentrated nutrient source and also contain soluble fibre. They not only provide a range of vitamins and minerals, but can reduce blood pressure and cholesterol and improve blood sugar regulation.

### *When will it start to work?*

Scientific studies have shown that oatbran and oat-based cereals containing beta-glucan may reduce cholesterol levels and blood pressure within 5–6 weeks.

### *Are there any safety issues?*

Dietary oats should be avoided in cases of intestinal obstruction.

## PREGNANCY USE

Oral use is considered to be safe in pregnancy and lactation.

## Practice points/Patient counselling

- Oats are a rich source of nutrients, such as calcium, potassium, phosphorus, iron, manganese and zinc, vitamins A, B-complex, C, E and K and amino acids. Dietary oats also contain a significant amount of soluble fibre.
- Regular intake of wholegrain oat-based beta-glucan-containing cereals may have positive effects on cardiovascular disease risk factors such as hypertension, hyperlipidaemia and glucose regulation.
- Topical use of the cut herb in the bath or 5% colloidal oatmeal in a suitable carrier is used to relieve itch.
- Traditionally, oats are viewed as a nervous system nutritive and therefore used during times of convalescence.
- Patients with coeliac disease should be able to tolerate moderate amounts of oats in the diet.

## Passionflower

**HISTORICAL NOTE** Legend has it that this herb received its name because the corona resembles the crown of thorns worn by Christ during the crucifixion. A popular sedative medicine in the early 20th century, it was listed in the US National Formulary until 1936.

### COMMON NAME

Passionflower

### OTHER NAMES

Apricot vine, granadilla, Jamaican honeysuckle, Maypop passion flower, maracuja, passion vine, water lemon

### BOTANICAL NAME/FAMILY

*Passiflora incarnata* (family Passifloraceae)

### PLANT PARTS USED

Aerial parts, particularly leaves

### CHEMICAL COMPONENTS

Flavonoids and related compounds (including apigenin, quercetin, kaempferol and chrysin), maltol, coumarin derivatives, indole alkaloids (mainly harman, harmaline, harmine), phytosterols (stigmasterol), sugars and small amounts of essential oil.

Note: Some research trials use other species of *Passiflora*, notably *P. edulis*, *P. alata* or *P. caerulea*. Each species contains similar, but not equivalent, constituents and may have different pharmacological properties and effects.

### Harmine

Research has been conducted with several key constituents found in passionflower, in particular harmine and harman. Harmine is a  $\beta$ -carboline alkaloid, a compound class known to be strong inhibitors of monoamine oxidase which metabolises catecholamine neurotransmitters. Harmine exhibits various pharmacological effects both in vitro and in vivo, such as improvement of insulin sensitivity, a vasorelaxant effect and an antidepressant effect. In vitro and ex vivo models also show that harmine inhibits osteoclast differentiation and suppresses

bone loss. In vivo studies on mice have demonstrated that harmine was able to prevent bone loss in osteoporosis models (Yonezawa et al 2011).

### Harman

Numerous in vitro and in vivo trials have been conducted on the constituent known as harman suggesting mild monoamine oxidase A inhibitory activity (Adell et al 1996), inhibition of HIV replication (Ishida et al 2001), vasorelaxant activity (Shi et al 2000) and effects on gamma-aminobutyric acid (GABA) release (Dolzhenko & Komissarov 1984).

However, harman is not considered to be one of the main active constituents in the herb and is not present in biologically active concentrations in the dosage range used for passionflower. As such, results obtained using isolated harman in vitro and in vivo cannot necessarily be extrapolated to the use of passionflower in humans.

Harman has also been identified in beer, and to a lesser extent in wine, both of which contain levels far in excess of those found in passionflower at therapeutic doses.

### MAIN ACTIONS

#### Anxiolytic and sedative activity

Several in vivo studies have demonstrated the anxiolytic effects of *Passiflora* extract (Della Loggia et al 1981, Dhawan et al 2001, Soulimani et al 1997). Behavioural tests in mice have also demonstrated that high doses have a sedative effect (Soulimani et al 1997).

The mechanism of action has been unclear until recently, as some research suggested stimulation of GABA release or an interaction with GABA receptors, and other research observed no interaction with GABA benzodiazepine receptors (Zanolli et al

2000). This may be due to different *Passiflora* species being used in research, as well as different routes of administration.

In 1999, an in vitro study showed inhibition of GABA-A binding with *Passiflora* extract (Simmen et al 1999). A more recent study has determined that, indeed, the anxiolytic effects of *P. incarnata* are mediated via the GABAergic system (Grundman et al 2008). This was confirmed yet again in 2011, whereby numerous pharmacological effects of *Passiflora incarnata* were shown to be mediated via modulation of the GABA system including affinity to GABA-A and GABA-B receptors, and effects on GABA uptake in vitro (Appel et al 2011).

### Anticonvulsant

A hydroalcoholic extract of *Passiflora* (Pasipay 0.4 mg/kg) has demonstrated anticonvulsant activity in vivo (Nassiri-Asl et al 2007). The extract was shown to delay onset and decrease the duration of seizures compared to placebo. It appeared to work through GABAergic and opioid pathways; however more research is needed to confirm the mechanism.

### OTHER ACTIONS

Recent in vitro and rat studies demonstrated that *Passiflora* enhances the potency of St John's wort's antidepressant action (Fiebich et al 2011).

### Antiepileptic

*Passiflora* significantly reduced the severity of seizures in vivo, and ameliorated postictal (the period immediately after a seizure) depression, possibly due to its ability to retain serotonin and noradrenaline levels of the brain. This is worthy of further consideration as the standard anticonvulsive therapies such as diazepam tend to worsen postictal depression (Singh et al 2012).

### Aphrodisiac

Tests in mice have identified significant aphrodisiac properties associated with high doses of *Passiflora* extract (Dhawan et al 2003a). A benzoflavone moiety may be chiefly responsible, as tests with this isolated compound were found to increase libido and fertility of male rats after 30 days' treatment (Dhawan et al 2002a).

### Antitussive and antiasthmatic activity

*P. incarnata* was as effective as codeine phosphate in suppressing a sulfur dioxide-induced cough in mice (Dhawan & Sharma 2002). Passionflower (100 mg/kg) was also able to prevent dyspnoea-related convulsions in guinea pigs with acetylcholine-induced bronchospasm (Dhawan et al 2003b).

### Antidiabetic

In the Ayurvedic system, the leaves of *P. incarnata* are used for their antidiabetic properties. Recent tests using mice confirm hypoglycaemic and hypolipidaemic effects, with improvement in glucose

tolerance and lipid profile as well as regeneration of pancreatic islets of Langerhans (Gupta et al 2012).

### Nicotine withdrawal

Promising new in vivo research suggests that passionflower extract has the potential to ameliorate the signs of nicotine sensitisation (Breivogel & Jamerson 2012). This builds on previous research which identified a benzoflavone moiety in *Passiflora* which, when given acutely to test animals as a single 20 mg/kg dose, prevented some of the nicotine withdrawal effects (Dhawan et al 2002c).

### CLINICAL USE

Preclinical research and traditional evidence suggest *Passiflora* can play a role in the symptomatic relief of anxiety. The clinical evidence currently available supports this and shows benefits for anxiety and possibly insomnia and opiate withdrawal. However, evidence comes from only a handful of randomised controlled trials, so ideally, larger controlled trials are required to further clarify its role in practice.

### Anxiety and nervous restlessness

*Passiflora* extract is a popular herb for nervousness and anxiety and is most often prescribed in combination with other herbs such as valerian and St John's wort.

At least three clinical trials have confirmed the efficacy of passionflower treatment for symptoms of anxiety. Two trials found that treatment with *passiflora* before surgery relieved anxiety and one trial investigated its use in generalised anxiety disorder (GAD), finding positive results (Lakhan & Vieira 2010).

Treatment with passionflower extract (45 drops/day) was compared to oxazepam (30 mg/day) in a double-blind study involving 36 volunteers with GAD and found both treatments were equally effective anxiolytics in this population. Both treatments were used for 4 weeks. Passionflower treatment had a slower onset of action compared to oxazepam; however, the herbal group also reported less job impairment (Akhondzadeh et al 2001a).

Commission E approved passionflower for this indication (Blumenthal et al 2000).

### Presurgery use

Two studies have investigated the use of *passiflora* to relieve anxiety before surgery. In the first study, 60 patients were randomised to two groups and given passionflower (500 mg; Passipay Iran Darouk) or placebo 90 minutes before surgery (Movafegh et al 2008). Anxiety scores were significantly lower in the active treatment group compared to the placebo group, while other parameters such as psychological and physiological recovery were the same for both groups.

Anxiolytic activity was confirmed in a more recent randomised, double-blind, placebo-controlled study involving 60 patients about to undergo spinal anaesthesia. Thirty minutes before the procedure,

patients were randomly assigned to receive either oral *Passiflora incarnata* extract or placebo. The passiflora extract was found to reduce the increase in anxiety before spinal anaesthesia without changing psychomotor function test results, sedation level or haemodynamics (Aslanargun et al 2012).

#### IN COMBINATION

A formulated extract containing passionflower, St John's wort and valerian was tested on 16 healthy adults in a randomised, placebo-controlled crossover study. Electroencephalogram (EEG) recordings were performed 0.5, 1.5, 3 and 4 hours after administration of the preparation and analysis revealed a difference to placebo 3 and 4 hours after intake. Analysis of the neurophysiological changes following the intake of the preparation showed a similarity of brain frequency changes on the EEG to those of calming and antidepressive drugs without impairment of cognition (Dimpfel et al 2011).

Previously, an anxiolytic effect was observed in a randomised, placebo-controlled study of 182 people diagnosed with adjustment disorder and anxious mood who were treated with a combination of *Crataegus oxyacantha*, *Ballota foetida*, *Valeriana officinalis*, *Cola nitida* and *Paullinia cupana* in a commercial product known as Euphytose, taken as two tablets three times daily for 28 days (Bourin et al 1997).

#### Opiate withdrawal

A randomised double-blind study involving 65 subjects with opiate addiction compared the effects of clonidine and placebo with clonidine and passiflora extract over a 14-day period. The fixed daily dose was 60 drops of passiflora extract and a maximum daily dose of 0.8 mg of clonidine administered in three divided doses.

The combination treatment of clonidine and passiflora extract was significantly better at alleviating the psychological symptoms associated with withdrawal; however, no differences in physical symptoms were seen between the groups (Akhondzadeh et al 2001b).

#### Insomnia

Currently, in vivo evidence supports the sedative activity of passiflora when used in high doses. There has been only one small randomised controlled trial ( $n = 41$ ) that compared 2 g of passionflower tea to placebo before sleep and demonstrated an improvement for subjective sleep quality but no other significant findings on other sleep outcomes (Ngan & Conduit 2011). Preclinical research suggests it should have potential for this indication.

#### IN COMBINATION

A herbal combination consisting of standardised extracts of *Valeriana officinalis* (300 mg; standardised to 0.8% total valeric acid), *Passiflora incarnata* (80 mg; standardised to 4% isovitexin) and *Humulus lupulus* (30 mg; standardised to 0.35% rutin) may be a suitable alternative to zolpidem as a treatment for primary insomnia, according to a recent randomised, double-blind study

(Maroo et al 2013). The study of 91 people with primary insomnia identified that the herbal combination was as effective as zolpidem in significantly improving total sleep time, sleep latency, number of nightly awakenings and insomnia severity index scores. Interestingly, the Epworth sleepiness scores did not change significantly over the study period for either group.

In regard to safety, 12 people in the herbal group and 16 treated with zolpidem reported side effects, with drowsiness the most common. Most were mild and not serious.

#### OTHER USES

##### Traditional uses

Traditionally, passionflower has been used to treat neuralgia, generalised seizures, hysteria and insomnia. It has also been used to treat diarrhoea, dysentery and dysmenorrhoea by acting on the nervous system.

##### DOSAGE RANGE

- Dried herb: 2 g three to four times daily.
- Infusion of dried herb: 0.25–2 g three to four times daily.
- Fluid extract (1:1) (g/mL): 2 mL three to four times daily in 150 mL of water.
- Tincture (1:5) (g/mL): 10 mL three to four times daily.

##### TOXICITY

Not known.

##### ADVERSE REACTIONS

Drowsiness is the most common side effect according to the available clinical research.

One human study found that *Passiflora* extract has a significantly lower incidence of impairment of job performance compared with oxazepam (Akhondzadeh et al 2001b). One case reports a 34-year-old woman who developed severe nausea, vomiting, drowsiness and episodes of non-sustained ventricular tachycardia following administration of passionflower at therapeutic doses (Fisher et al 2000).

##### SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of pharmacological activity and are theoretical.

##### Benzodiazepines

Additive effects are theoretically possible at high doses. There has been one case report of a patient taking passiflora and valerian while also taking lorazepam and developing shaking hands, dizziness, throbbing and muscular fatigue (Carrasco et al 2009). It is not known if the treatment was tested for authenticity or contamination, so causality is difficult to ascertain.

Use with caution and monitor drug dosage — possible beneficial interaction under medical supervision.

Note: *Passiflora* may be a useful support during benzodiazepine withdrawal.

### Barbiturates

Additive central nervous system sedation is theoretically possible. Use with caution and monitor drug dosage — possible beneficial interaction under medical supervision.

#### Practice points/Patient counselling

- Both human and animal studies confirm passionflower has significant anxiolytic activity and reduces the symptoms of anxiety.
- When used 30 minutes before surgery, it appears to reduce nervousness.
- One randomised study found that it has significantly less negative effects on performance than 30 mg oxazepam, yet is as effective for GAD.
- Maximal effects may require several days of regular intake.
- It is not known whether physical tolerance develops.
- One study has shown it improves psychological symptoms during opiate withdrawal when used together with clonidine.
- In practice, it is often prescribed with other herbs for stronger effects in anxiety and insomnia.

#### CONTRAINDICATIONS AND PRECAUTIONS

Whether concomitant use of high doses of passionflower adversely affects people's ability to drive a car or operate heavy machinery should be evaluated on an individual case-by-case basis.

#### PREGNANCY USE

Passionflower has demonstrated the ability to increase uterine contractions in an isolated rat uterus model when compared to control tissue (Sadraei et al 2003). Whether this has any adverse effects in pregnancy remains unknown. Caution is advised until safety is better established.

#### PATIENTS' FAQs

##### What will this herb do for me?

Passionflower has anxiolytic effects that help reduce symptoms of anxiety. It might also be useful for insomnia, especially when used as part of a herbal combination. There is some research suggesting it may help ease the symptoms of opiate withdrawal.

##### When will it start to work?

When being used for anxiety, it may take 3–4 weeks before significant effects are seen.

##### Are there any safety issues?

Overall, passionflower does not appear to impair job performance but some people have reported

drowsiness. However, it may theoretically interact with other sedative medicines when used in high doses. Other interactions are theoretically possible, so use should be monitored by a healthcare professional.

## Pelargonium

**HISTORICAL NOTE** *Pelargonium sidoides* DC. (Geraniaceae) is an important traditional medicine in South Africa where it has been used to treat diarrhoea, dysentery, coughs and colds, tuberculosis and gastrointestinal conditions. This and other South African traditional medicines were often referred to by their original Khoi-Khoi name *rabas*, and were amongst the first to be recorded by early explorers such as van der Stel (1685) and Thunberg (1773). The most detailed account of the value and uses of *P. sidoides* is that of Smith (1895), who listed *P. reniforme*/*P. sidoides* as the first of five species used in the treatment of dysentery (Brendler & van Wyk 2008). The herb was introduced to Europe by the Englishman Charles Henry Stevens and is now a popular, commercially produced herbal medicine, listed in the European Pharmacopoeia (Brendler & van Wyk 2008).

### Clinical note — Is it *P. sidoides* or *P. reniforme*?

*P. sidoides* is predominantly found over large parts of the interior of southern Africa, but also occurs in coastal mountain ranges. The product may be adulterated with the very similar-looking *P. reniforme* and the two species often grow side by side. The phytochemical composition of the roots of *P. sidoides* is similar to *P. reniforme*, reflecting the close botanical relationship between the two species (Brendler & van Wyk 2008, Kolodziej 2007). Morphological distinction of the dried product is extremely difficult and chemical analysis is the only reliable method of telling them apart.

### COMMON NAME

South African geranium

### OTHER NAMES

Geranium, EPs 7630, Geranien, geranium root, Ikhubalo, Icwayiba, i-Yeza lezikali, Kaloba, Kalwerbossie, Pelargonien, pelargonium root, Rabas, Rabassam, silverleaf geranium, Umckaloabo, Uvendle

### BOTANICAL NAME/FAMILY

*Pelargonium sidoides* (family: Geraniaceae)

### PLANT PARTS USED

Root

### CHEMICAL COMPONENTS

Oligomeric and polymeric proanthocyanidins are present in significant amounts: the putative precursors afzelechin, catechin and galocatechin have been isolated; and highly oxygenated coumarins. Gallic acid is consistently found in high concentrations in the plant material and the minerals calcium and silica (Kolodziej 2007, Kolodziej et al 2003).

Coumarins and phenolic compounds, including simple phenolic acids and proanthocyanidins, are the principal compounds found in the special extract, EPs 7630 (Kolodziej 2007). Gallic acid occurs in low amounts in EPs 7630 (Kolodziej 2007).

### MAIN ACTIONS

#### Antibacterial activity

Different in vitro evaluations of the herbal preparation from the roots of *P. sidoides* and its isolated constituents demonstrated pharmacological activities, including moderate, direct antibacterial effects against a panel of pathogenic bacteria that are responsible for numerous respiratory tract infections (RTIs), several multiresistant strains of *Staphylococcus aureus*, also *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis* and *Mycobacterium tuberculosis* (Kolodziej et al 2003, Lizogub et al 2007, Mativandlela et al 2006).

#### Antiadhesion properties

Antiadhesive properties of pelargonium have been demonstrated for several bacteria, including *Helicobacter pylori*, and is thought to be one of the

mechanisms responsible for its antimicrobial activity (Beil & Kilian 2007, Wittschier et al 2007).

### Immune enhancement

The root extract also exhibits notable immune modulatory capabilities. The immune modulatory activities are mediated mainly by the release of tumour necrosis factor- $\alpha$  and nitric oxides, the stimulation of interferon- $\beta$ , the increase of natural killer cell activity and interferon-like activity (Kolodziej et al 2003, Lizogub et al 2007). Improved phagocytosis has also been demonstrated in vitro.

### Antiviral activity

Direct antiviral activity against herpesvirus 1 and 2 has been demonstrated (Schnitzler et al 2008). *P. sidoides* extract affects the virus before penetration into the host cell and reveals a different mode of action when compared to aciclovir; it might be suitable for topical therapeutic use as antiviral drug in both labial and genital herpes infection. Through induction of the interferon system and upregulation of cytokines, important in protecting host cells from viral infection, the herb can be expected to exhibit antiviral activity in vivo (Engler et al 2009).

### OTHER ACTIONS

A variety of mechanisms account for its symptom-relieving effects in RTIs.

The liquid extract acts as an expectorant and reduces sputum production, allowing the body to expel mucus, thereby making conditions less suitable for the multiplication of the bacteria and viruses. It has also been shown to increase cilia beat frequency in nasal epithelia.

### CLINICAL USE

Most research has been conducted with a standardised liquid herbal extract of the roots of *P. sidoides* (1:8–10), extraction solvent: ethanol 11% (wt/wt) produced by Willmar Schwabe Pharmaceuticals, Karlsruhe, Germany, also known as EPs 7630 (Umckaloabo, marketed by Spitzner Arzneimittel, Ettlingen, Germany). It has been approved for use in over 30 countries, including Australia.

### Respiratory tract infections — bronchitis, common cold, sinusitis

In the light of inappropriate antibiotic use and increasing drug resistance rates worldwide, the need for an alternative, effective remedy for respiratory tract conditions is crucial. *P. sidoides* has been investigated as one such medicine and represents a promising treatment for the management of RTIs. It has achieved widespread popularity in Germany over the last 50 years, where it is approved for the treatment of acute bronchitis, acute tonsillopharyngitis and acute sinusitis. The standardised, liquid extract is now a registered medicine on the Australian Register of Therapeutic Goods and has been given an AUST R number, signifying claims have been

### Clinical note — The difficult and winding road to successful commercialisation

It is believed that the medicinal properties of *Pelargonium sidoides* were first recognised and applied by traditional tribal healers in South Africa many centuries ago. It first came to the attention of Europeans in the early 1900s, as a result of a serendipitous meeting between an Englishman, Charles Henry Stevens, and a traditional Zulu healer. In 1897, Stevens was sent to South Africa by his doctor to recover from pulmonary tuberculosis. While there, he was treated by a traditional Zulu healer with a root concoction that successfully cured his condition (Bladt & Wagner 2007). Seeing the need for such a medicine back home and no doubt the commercial opportunity, Stevens called the tuberculosis treatment 'Umckaloabo', which he commercially manufactured once back in England. The treatment also became known as the 'Stevens' cure' and caused controversy amongst the medical establishment, which sought to discredit him by labelling Stevens a 'quack'. After his death in 1942, Stevens' son sold the business to a drug manufacturer in Germany. The exact herbal ingredient in the remedy and its source were kept secret and shrouded in mystery until well into the 1970s, when the plant ingredient was finally identified as *P. sidoides* by S. Bladt, while undertaking research for her thesis in Germany (Bladt & Wagner 2007). After the conduct of scientific and clinical trials, the herb was once again commercially manufactured in Europe with great success, with an annual turnover in Germany of 80 million Deutschmark in 2006 (Brendler & van Wyk 2008).

evaluated by the Therapeutic Goods Administration for which there is good supportive scientific evidence.

Overall, the available evidence indicates that pelargonium is likely to be beneficial in the treatment of acute, mild to moderate bronchitis, acute rhinosinusitis and the common cold in adults. Paediatric trials suggest a potential benefit in acute bronchitis and in alleviating several common RTI symptoms, in particular, nasal congestion.

The scientific investigation of *P. sidoides* in the treatment of various RTIs really began in earnest in the 1990s (Brendler & van Wyk 2008). The earliest trials were mainly observational studies, whereas more recent studies tend to be placebo-controlled randomised trials and focus on acute bronchitis, although observational studies are still performed. The results of the individual research reports are compelling, particularly as there are no good treatment options for viral RTIs and bacterial RTIs are becoming increasingly difficult to treat.

One of the largest adult studies published to date was a randomised, double-blind, placebo-controlled, multicentre study of 406 adults with acute bronchitis published in 2010 (Matthys et al 2010). Patients were randomly assigned to one of four parallel treatment groups to receive different doses of EPs 7630 tablets (10 mg EPs 7630 tablets three times a day (30 mg group), 20 mg EPs 7630 tablets three times a day (60 mg group), 30 mg EPs 7630 tablets three times a day (90 mg group)) or placebo three times a day for a treatment period of 7 days. Bronchitis-specific symptoms were measured from baseline to day 7 and the groups were compared. Overall, the participants receiving EPs 7630 tablets had a statistically significant improvement in symptoms compared to the placebo group. The best results were obtained for the two higher-dosage regimens. When the incidence of side effects was considered, the optimal dose was 20 mg tablets of EPs 7630 taken three times daily.

Two new paediatric studies have been published since 2009, both in 2012. They continue to build the supportive evidence base for *Pelargonium sidoides* as a medicine for the treatment of common symptoms associated with RTIs, in particular, nasal congestion.

A randomised, placebo-controlled study by Patiroglu et al (2012) involved 28 children aged between 1 and 5 years with transient hypogammaglobulinaemia of infancy, one of the more common immune deficiencies of childhood. In this study, 14 participants were treated with *Pelargonium sidoides* for 1 week (10 drops three times a day), while 14 were given placebo during an episode of upper RTI. Active treatment with *P. sidoides* resulted in significantly improved appetite by day 5, a good representative factor in terms of indicating the general state of health of children. A highly relevant improvement was observed for nasal congestion in the *P. sidoides* extract group, compared to no improvement in the placebo group. On day 7, 71.4% of children taking active treatment had no nasal congestion compared with 21.5% in the placebo group. In contrast, no improvements were detected between the *P. sidoides* extract group and the placebo group for daily and nocturnal cough, fever or pain.

The prevention of an asthma attack during an upper RTI by 5 days of pelargonium treatment was tested in a randomised study of 61 children (Tahan et al 2012). This is based on the fact that viral infections have been implicated in most (>80%) asthma exacerbations in children. When the active treatment and placebo groups were compared, those receiving liquid *P. sidoides* had a significant decrease in cough frequency and nasal congestion and a statistically significant reduced frequency of developing an asthma attack. No significant changes were reported for fever or muscle aches and pains. The dosage schedule used was: for 1–5 years, 10 drops three times a day; for 6–12 years, 20 drops three times a day; for 12 years and above, 30 drops three times a day.

Previously, in 2008 a Cochrane systematic review was published in which authors evaluated data from eight randomised control trials (RCTs) and concluded that *P. sidoides* may be effective in alleviating symptoms of acute bronchitis, rhinosinusitis and the common cold in adults, but the findings were not yet definitive (Timmer et al 2008). The authors identified two RCTs that showed *P. sidoides* was effective in relieving all symptoms, and in particular cough and sputum production in adults with acute bronchitis, although a third study showed that the preparation was only effective for treating sputum reduction. Similarly, *P. sidoides* was effective in resolving symptoms of acute bronchitis in two out of three paediatric studies. One RCT of 104 adults was included in the review, showing significant treatment effects in acute rhinosinusitis for the resolution of all symptoms as well as the key symptoms of nasal discharge and headache resolution.

The results obtained by studies using tablet preparations included in this review were different from those using the liquid preparation. Based on this, the authors stated that the liquid preparation (alcoholic solution) may be associated with improvement in some symptoms of acute bronchitis in both children and adults — in particular sputum production and cough — but tablet preparations produced fewer or no potential beneficial effects in both children and adults. The cause of this difference is unknown and may be due to chance or differences in constituent bioavailability or in the product's phytochemical constituents. Another caution expressed by the review authors was of the use of non-validated symptom scales as a primary end point and the subjective nature of the results.

The same year, a review was published in *Phyto-medicine* that analysed six RCTs, of which four were suitable for statistical pooling (Agbabiaka et al 2008). One study compared EPs 7630 against conventional non-antibiotic treatment (acetylcysteine); the other five studies tested EPs 7630 against placebo. All RCTs reported findings suggesting the effectiveness of EPs 7630 in treating acute bronchitis. When a meta-analysis of the four placebo-controlled RCTs was conducted, the results confirmed that EPs 7630 significantly reduced bronchitis symptom scores in patients with acute bronchitis by day 7.

### Common cold

A multicentre, randomised, double-blind trial by Lizogub et al (2007) involved 107 participants with cold symptoms present for between 24 and 48 hours. It demonstrated that treatment with liquid extract of *P. sidoides* significantly hastened recovery from the common cold, and markedly improved individual symptoms, most notably nasal congestion and drainage, sneezing, sore throat, hoarseness and headache. The group receiving active treatment also experienced significantly higher remission and improvement in rates of other cold-related symptoms compared to placebo, such as limb pain (95.5% vs 74%), general weakness (79% vs 35%), exhaustion

(85% vs 43%) and fatigue (89% vs 60.5%) (Lizogub et al 2007). The study compared 30 drops (1.5 mL) of liquid herbal pelargonium three times daily to placebo for a maximum of 10 days. After 10 days, substantially more people receiving the herbal treatment were considered clinically cured than the placebo group (78.8% vs 31.4%;  $P < 0.0001$ ). All (100%) of patients receiving pelargonium judged tolerability of treatment as good or very good.

### Immune modulation in athletes

Exhaustive physical exercise is associated with increased frequency of upper RTIs, probably due to a compromised immune response. A double-blind, placebo-controlled study involving male marathon runners found that treatment with *P. sidoides* extract modulated the production of secretory immunoglobulin A in saliva, both interleukin-15 (IL-15) and IL-6 in serum, and IL-15 in the nasal mucosa after an intense running session. Secretory immunoglobulin A levels were increased, while levels of IL-15 and IL-6 were decreased, thereby indicating a strong modulating influence on the immune response (Luna et al 2011). The treatment schedule consisted of umckaloabo or placebo (3 × 30 drops/day) for 28 consecutive days before training and testing.

### OTHER USES

The traditional uses of tuberous *Pelargonium* species mainly involve ailments of the gastrointestinal tract (diarrhoea and dysentery) and respiratory tract, although Smith (1895) made a case for it being used as a general tonic.

It is also used as a gripe water for infants ('upset stomach', 'air in the intestine'). The crushed root is mixed with water and a teaspoonful of the red infusion is taken orally (Brendler & van Wyk 2008).

The aerial parts have also been used traditionally as a wound-healing agent. This may be due to their high tannin content that would contribute to its astringent effect (Kolodziej 2007).

### DOSAGE RANGE

Dried herb: 0.4 g/day

#### According to clinical studies

Treatment of acute bronchitis

General dosage: Adults and children over 12 years: 30 drops (1.5 mL) of liquid extract herbal pelargonium three times daily before meals for up to 10 days.

Adults — for acute bronchitis symptoms: 20 mg tablets of EPs 7630 taken three times daily.

Children aged 6–12 years: 20 drops (1.0 mL) three times per day.

Children aged 2–5 years: 10 drops three times a day.

Treatment for the common cold

Adults: 30 drops (1.5 mL) of liquid herbal pelargonium three times daily.

#### Practice points/Patient counselling

- *P. sidoides* is a traditional herbal medicine originating from South Africa and now extremely popular in Europe, particularly Germany, and available in Australia.
- The herb demonstrates antibacterial and antiviral activity and enhances non-specific immune function; it also has activity against herpesvirus 1 and 2.
- Observational and randomised studies indicate *Pelargonium sidoides* liquid extract EPs 7630 may provide benefits in the treatment in acute, mild to moderate bronchitis, acute rhinosinusitis and possibly the common cold in adults, acute bronchitis in children and in alleviating several common RTI symptoms, in particular, nasal congestion.
- It appears to hasten recovery from the common cold, reduce symptoms and improve associated fatigue and weakness and may have a role in the acute treatment of other, uncomplicated respiratory infections.
- It is generally well tolerated; however, gastrointestinal side effects and allergic skin reactions have been reported with use.

#### Acute sinusitis treatment

Adults: 60 drops three times a day.

#### Reducing the frequency of an asthma attack during respiratory tract infection in children with mild asthma

1–5 years: 10 drops three times a day.

6–12 years: 20 drops three times a day.

Over 12 years of age: 30 drops three times a day.

### TOXICITY

Not known.

### ADVERSE REACTIONS

Evidence from clinical trials and postmarket surveillance studies indicates few serious adverse events, all found to be unrelated to the medicine, and only mild side effects, which tended to be limited to gastrointestinal symptoms such as nausea, vomiting, diarrhoea or heartburn, and rashes. Allergic skin reactions with pruritus and urticaria have been reported in trials.

### SIGNIFICANT INTERACTIONS

Controlled clinical studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

### Immunosuppressant drugs

Theoretically, use of this herb may reduce the effectiveness of immunosuppressant medication — avoid until safety can be established.

**CONTRAINDICATIONS AND PRECAUTIONS**

People with an allergy to the geranium family of plants should avoid this herb.

**PREGNANCY USE**

It appears safe in pregnancy based on studies using animal models of reproduction and development whereby no effects on fertility or development were detected at up to 2700 mg/kg body weight/day EPs 7630.

**PATIENTS' FAQs****What will this herb do for me?**

*Pelargonium sidoides* has antibacterial and antiviral actions and will enhance immune function. It may provide benefits in the treatment in acute, mild to moderate bronchitis, acute rhinosinusitis and possibly the common cold in adults, acute bronchitis in children and in alleviating several common RTI symptoms, in particular, nasal congestion.

**When will it start to work?**

It should be started at the first sign of infection and a course of treatment is 6–10 days. When used as acute treatment for the common cold, symptom relief may be noticeable within 3 days and significant after 5 days. Symptom relief may take longer to fully establish in cases of acute bronchitis and rhinosinusitis.

**Are there any safety issues?**

It is generally well tolerated; however; gastrointestinal side effects and allergic skin reactions have been reported with use.

# Peppermint

**HISTORICAL NOTE** The written record of mint dates back to an ancient Greek myth in which the Greek god Pluto was said to have affections for a beautiful nymph named Minthe. His jealous wife Persephone cast a spell on the nymph, transforming her into a plant. When Pluto could not reverse the spell, he gave her a sweet scent that would emanate throughout the garden (Murray & Pizzorno 1999). Peppermint has been used medicinally for generations as a digestive aid and carminative. More recently, enteric-coated peppermint oil capsules have been widely prescribed for the relief of irritable bowel syndrome (IBS).

**BOTANICAL NAME/FAMILY**

*Mentha × piperita* (family [Labiatae] Lamiaceae)

**PLANT PARTS USED**

Leaf or stem — essential oil is distilled from the aerial parts.

**CHEMICAL COMPONENTS**

Peppermint leaves contain about 2.5% essential oil, 19% total polyphenolic compounds, 12% total

flavonoid compounds (eriocitrin, luteolin-7-O-rutinoside and hesperidoside) and 7% total hydroxycinnamic compounds (including rosmarinic acid) (Duband et al 1992). The biochemistry, organisation and regulation of essential oil metabolism in the epidermal oil glands of peppermint have been defined, and research is underway to create ‘super’ transgenic peppermint plants with improved oil composition and yield (Wildung & Croteau 2005).

### Essential oil

Over 100 constituents have been identified in peppermint oil. The principal constituents are terpenes; menthol (35–55%), menthones (10–35%), isomenthone, menthyl acetate, menthofuran and cineole. To comply with the European Pharmacopoeia, the oil must not contain more than 4% pulegone and not more than 1% carvone.

### MAIN ACTIONS

The actions of the leaf as an infusion (tea) or liquid extract are largely dependent on the essential oil content. Other compounds, such as the flavonoids, also contribute to the overall activity, especially the antioxidant activity. Peppermint oil is relatively rapidly absorbed after oral administration and eliminated mainly via bile (Grigoleit & Grigoleit 2005a).

#### Antispasmodic

Peppermint essential oil, ethanol extracts and flavonoids isolated from the leaf have all shown antispasmodic effects in vitro (ESCOPE 1997). The antispasmodic effect of various peppermint preparations has been confirmed in human clinical trials. An antispasmodic effect on gastric smooth muscle was demonstrated for peppermint oil when used topically (intraluminal) or ingested orally in doses of 0.1–0.24 mL (Grigoleit & Grigoleit 2005). According to a double-blind RCT, oral administration of 182 mg peppermint oil significantly reduced intragastric pressure, proximal phasic contractility and appetite, but had no effect on gastric sensitivity, tone and nutrient tolerance (Papathanasopoulos et al 2013). In healthy volunteers, intragastric administration of a dose equivalent to 180 mg peppermint oil reduced intraoesophageal pressure within 1–7 minutes of infusion (Kingham 1995). Investigation with a peppermint leaf extract found it reduced the frequency of slow wave motion in the small intestine but not the amplitude (Sibaev et al 2006).

Gastric smooth muscle relaxation was also seen for a combination product, Enteroplant, an enteric-coated capsule containing 90 mg peppermint and 50 mg caraway oil (Micklefield et al 2003).

The antispasmodic activity is believed to be mediated via activation of sensory neurons of transient receptor potential (TRP) channels, in particular melastatin8 (TRPM8) (Farco & Grundmann 2013). The active constituent menthol induces Ca<sup>2+</sup> ion influx through the TRPM8 channels expressed in sensory neurons, the dorsal root ganglia, vagal afferent neurons, the gastric fundus, colon and small intestine (Papathanasopoulos et al 2013). Although menthol has been shown to induce Ca<sup>2+</sup> release from intracellular stores in several TRPM8-expressing cell types, a TRPM8-independent pathway of Ca<sup>2+</sup> release, originating from the endoplasmic reticulum and the Golgi compartments, has also been postulated (Kim et al 2009, Mahieu et al 2007).

#### Carminative

Peppermint has a carminative activity, which refers to its ability to relax the gastrointestinal sphincters. Carminatives are thought to alleviate symptoms of bloating and gas by facilitating eructation and passage of flatus and by inducing relaxation of the lower oesophageal sphincter (LES) (Massey 2001). An early study demonstrated that peppermint oil canalised into the gall bladder and duodenal areas was able to counteract morphine hydrochloride-induced constriction of the sphincter of Oddi (Giachetti et al 1988). In patients with diffuse oesophageal spasm, peppermint oil orally (10 drops in water) did not affect lower oesophageal sphincter contractile pressure but completely eliminated simultaneous oesophageal contractions in all patients (Pimentel et al 2001).

#### Choleretic

Choleretic activity has been demonstrated for peppermint tea, flavonoids and the essential oil (ESCOPE 1997). Hydrophilic compounds may contribute to the gastrointestinal effects, with aqueous extracts from peppermint leaves having antiulcerogenic and choleretic effects (Grigoleit & Grigoleit 2005c, Van Rensen 2004). Peppermint oil has a relaxing effect on the gall bladder and small intestine, inhibiting gall bladder emptying and prolonging oro-caecal transit time in a manner comparable to *N*-butylscopolamine (Goerg & Spilker 2003). Peppermint oil strongly promotes bile acid secretion and decreases cholesterol levels in bile. The oil has been shown to up-regulate bile acid synthesis-related genes CYP7A1, and FXR mRNA levels, suggesting that the molecular mechanisms are related to gene expression involved in bile acid synthesis (Zong et al 2011).

#### Antimicrobial

Peppermint oil and its main constituent menthol have significant antibacterial, antifungal and antiplasmod activity and are able to potentiate the effect of some antibiotics (Schelz et al 2006).

#### Antibacterial

Peppermint oil has significant antibacterial activity (Mimica-Dukic et al 2003), as has the juice of peppermint leaves (Rakover et al 2008, Saeed & Tariq 2005). Peppermint oil has been shown to inhibit *Helicobacter pylori*, *Staphylococcus aureus* (Betonj et al 2006, Imai et al 2001, Mohsenzadeh 2007, Yadegarinia et al 2006), *Escherichia coli* (Mohsenzadeh 2007, Pattnaik et al 1995, Yadegarinia et al 2006), *Salmonella enteritidis*, *Listeria monocytogenes* and multi-resistant strains of *Shigella sonnei* and *Micrococcus flavus* (Mimica-Dukic et al 2003). Peppermint oil has further been shown to have a significant antimycobacterial activity in vitro, and inhalation of peppermint oil has been used successfully as a supplement to combined multidrug therapy for pulmonary tuberculosis (Shkurupij et al 2002). In a recent

study, peppermint oil showed stronger antimicrobial and antibiofilm properties than chlorhexidine against *Streptococcus mutans* and *Streptococcus pyogenes* (Rasooli et al 2008).

Peppermint oil has been tested in conjunction with various antibiotics to determine whether antimicrobial effects are enhanced. The notion that concurrent use may be beneficial began with the observation that peppermint extract produced a synergistic antibacterial effect against *Staphylococcus aureus* when used in conjunction with a variety of antimicrobial drugs (Betoni et al 2006). More recently, peppermint oil was tested with piperacillin and meropenem, which resulted in a substantial increase in the susceptibility of *Escherichia coli* to antibiotic therapy. There was also a considerable reduction in the minimum inhibitory concentrations (MIC) of the antibiotics (Yap et al 2013).

### Fungistatic, fungicidal

Peppermint is also fungistatic and fungicidal (Patnaik et al 1996, Positive Health News 1998) with its activity against *Trichophyton tonsurans*, *Candida albicans* being considerably greater than the commercial fungicide bifonazole (Mimica-Dukic et al 2003, Sokovic et al 2009, Yadegarinia et al 2006). Fungicidal activity similar to lavender and clove oil was reported for peppermint oil against *Trichophyton mentagrophytes* when used in combination with salt and heat (Inouye et al 2007). Peppermint oil showed high antifungal activity against *Candida albicans* (Yigit et al 2008), with one study reporting a 74% *Candida albicans* (strain CA I) biofilm reduction due to the effects of peppermint oil (Agarwal et al 2008). Moderate antifungal activity was observed for peppermint oil against *Rhizopus stolonifer*, *Botrytis cinerea*, *Aspergillus niger*, *Aspergillus candidus*, *Penicillium* spp and *Fusarium culmorum* (Behnam et al 2006, Magro et al 2006). Moreover, peppermint oil at various concentrations has been shown to inhibit aflatoxin B production by 85–90% when evaluated for activity against *Aspergillus parasiticus* and *Aspergillus flavus* (Bluma et al 2008).

### Antiviral

Peppermint oil also has virucidal activity against herpes simplex virus (HSV)-1 and -2, including activity against an aciclovir-resistant strain of HSV-1 (ACV<sub>res</sub>) with a 50% inhibitory concentration determined at 0.002 and 0.0008% for HSV-1 and HSV-2, respectively. The oil was also found to affect the virus before, but not after, penetration into the host cell indicating it acts on free HSV (Schuhmacher et al 2003). This suggests the potential for topical use against recurrent herpes infections (Nolkemper et al 2006). Aqueous extract (Geuenich et al 2008, Nolkemper et al 2006) and 80% ethanolic extract of peppermint (Reichling et al 2008) at maximum non-cytotoxic concentrations reduced plaque formation of HSV-1, HSV-2 and ACV<sub>res</sub> significantly following exposure of free virions as well as host cells to the extracts prior to infection.

### Insecticidal

Peppermint oil shows moderate repellent activity against *Culex pipiens* (Erler et al 2006), and menthol and its derivatives show mosquitocidal activity against *Culex quinquefasciatus*, *Aedes aegypti* and *Anopheles tessellatus* (Samarasekera et al 2008). This preliminary research shows promise for the development of insecticidal and repellent agents. Peppermint oil was shown to only exert some repellence against head lice (*Pediculus humanus* var. *capitis*), which was due to the slippery nature of the oil rather than specific repellent activity (Canyon & Speare 2007). However, a combination product of 5% eucalyptus and 5% peppermint oil in 50% ethanol showed effectiveness against the head lice (Gonzalez Audino et al 2007).

### Antiparasitic

Aqueous extracts of peppermint showed activity against gastrointestinal nematodes in goats and pigs (De Almeida et al 2007, Lans et al 2007). In vitro, dichloromethane extracts, but not water extracts, of peppermint showed anti-giardial activity by causing alterations on the plasma membrane surface of the parasite and inhibiting its adhesion (Vidal et al 2007). The anti-giardial action is comparatively weaker than other essential oils of plants with high levels of phenolic compounds (Machado et al 2010). Research on the anthelmintic action of peppermint remains limited to in vitro testing and suitable doses appear to have no effect when administered in vivo (Carvalho et al 2012).

### Antioxidant

The polyphenolic compounds in peppermint, such as luteolin-7-O-rutinoside, eriocitrin and rosmarinic acid, have been shown to have antioxidant and free radical scavenging activity (Sroka et al 2005). Peppermint oil and its constituents menthone and isomenthone exert antioxidant activity (Mimica-Dukic et al 2003). Interestingly, peppermint and lemon balm exerted the strongest antioxidant and radical scavenging effects when examining all individual herbs from a herbal combination preparation (STW 5 — Iberogast: 9 plant extracts from *Mentha piperita*, *Iberis amara*, *Chelidonium herba*, *Cardui mariae fructus*, *Melissae folium*, *Carvi fructus*, *Liquiritiae radix*, *Angelicae radix*, *Matricariae flos*) (Germann et al 2006, Schempp et al 2006).

### Stimulant

Intraperitoneal and intravenous injections of peppermint oil and its constituents, 1,8-cineol, menthone, isomenthone, menthol, pulegone, menthyl acetate and caryophyllene, dramatically increased ambulatory activity in mice, which may explain the traditional use of peppermint for mental fatigue (Umezu & Morita 2003, Umezu et al 2001). A recent study suggests that this effect exerted by menthone is mediated via dopamine (Umezu 2009). Inhalation of peppermint oil has also been shown

to have a stimulant effect on mice in a forced swimming test (Lim et al 2005).

### Coolant

The active constituent menthol is considered responsible for the cooling sensation brought about by peppermint, and is achieved via the same mechanism responsible for its antispasmodic action. Activation of sensory neurons TRPM8 and transient receptor potential subfamily A, member 1 (TRPA1) rapidly increases intracellular calcium and mobilises calcium flux through the channels to induce cold response signals at the application site (Farco & Grundmann 2013). In the peripheral nerves, this effect may be responsible for the characteristic cooling sensation experienced on oral ingestion of mint. Interestingly, menthol's cold sensitivity response mechanism has been shown to inhibit mucosal recognition of nicotine and cigarette toxins common in mentholated cigarette brands. Menthol has been investigated for its action on airway epithelium and was found to regulate cAMP-activated anion transporters on the apical and basolateral membranes, independent of the transient receptor potential (TRP) channels. This action directly relates to the airway lumen forming low viscosity mucus and contributing to overall mucociliary clearance (Morise et al 2010). A second proposed mechanism of action is the antioxidant action of peppermint oil.

### IN COMBINATION

A combination of essential oils (soy oil — 69.18%; coconut oil — 20.00%; orange oil — 4.90%; aloe vera oil — 4.90%; peppermint oil — 0.75%; vitamin E — 0.27%) was shown to effectively reduce inflammation associated with oxidant stress-related challenge to the nasal mucosa (Gao et al 2011), however the role of peppermint alone is unclear. A double-blind randomised controlled trial (RCT) investigated a spray containing aromatic essential oils of five plants (*Eucalyptus citriodora*, *Eucalyptus globulus*, *Mentha piperita*, *Origanum syriacum*, and *Rosmarinus officinalis*) applied five times a day for 3 days and compared with a placebo spray. The treatment group reported a significantly greater improvement in symptom severity compared to participants in the placebo group ( $P = 0.019$ ) after 20 minutes; however, there was no difference in symptom severity between the two groups after 3 days of treatment (Ben-Arye et al 2011).

### Analgesic

Peppermint and caraway oil have been shown to synergistically modulate post-inflammatory visceral hyperalgesia in a rat model (Adam et al 2006). A significant analgesic effect, with a reduction in sensitivity to headache, was observed in a double-blind, placebo-controlled, randomised, 7-day crossover study that used a combination of peppermint oil and ethanol applied externally in 32 healthy males undergoing artificial pain stimulation (Gobel et al 1994). Research reports menthol engages in synergistic excitation of GABA receptors and sodium ion

channels resulting in analgesia (Farco & Grundmann 2013).

### OTHER ACTIONS

A spray-dried peppermint infusion has been found to be mildly diuretic and produce weak sedative action in several tests when administered orally to mice (Della et al 1990). Peppermint tea has been found to significantly increase follicle stimulating hormone (FSH) and luteinising hormone (LH) levels and reduce total testosterone levels in rats (Akdogan et al 2004). Concomitant topical exposure to low concentrations of peppermint oil reduced the percutaneous penetration of benzoic acid; however, with increased peppermint oil doses, penetration of benzoic acid increased (Nielsen 2006). Peppermint extract was shown to reduce the side effects of arsenic-induced hepatopathy (Sharma et al 2007). In a more recent study, peppermint oil displayed acetylcholinesterase and butyrylcholinesterase inhibitory activities, which was more than the activity exerted by individual components of the oil (Orhan et al 2008).

*Mentha piperita* protects against radiation-induced lethality, lipid peroxidation and DNA damage (Jagetia 2007) through its antioxidant and free radical scavenging activities (Samarth et al 2006b). The same authors suggest that these activities are also responsible for a significant reduction in the number of lung tumours observed in mice following oral administration of peppermint extract (Samarth et al 2006a). It has also been reported that peppermint protected against radiation-induced haematopoietic damage in bone marrow of mice by increasing erythropoietin.

### CLINICAL USE

In practice, peppermint and its derivatives are used in many forms and administered by various routes. This review will focus only on those methods that are commonly used by the public and preparations that are available over the counter (OTC), such as oral dose forms, topical applications and inhalations. In many cases, peppermint is used as part of a multi-herbal combination, which is reflected in some of the studies presented here.

### Irritable Bowel Syndrome (IBS)

Since the late 1970s, clinical studies have been conducted to determine the role of various peppermint preparations in the treatment of IBS (Dew et al 1984, Rees et al 1979). Generally, the oil was used in the early studies with more recent research utilising other forms such as pH-triggered, enteric-coated peppermint oil capsules that prevent dissolution of the capsules until they have reached the small intestine, and release into the colon over 10–12 hours (Grigoleit & Grigoleit 2005c). Enteric coating also has the advantage of allowing administration of a higher dose than would otherwise be possible to tolerate and, importantly, avoids the risk of excessively relaxing the lower oesophageal sphincter and causing reflux.

Multiple systematic reviews and meta-analyses have been published since 1998, concluding that peppermint oil is a worthwhile symptomatic treatment in IBS (Pittler & Ernst 1998, Grigoleit & Grigoleit 2005a, Khanna et al 2014, Ruepert et al 2011). One systematic review of 16 clinical trials investigating peppermint oil in IBS showed statistically significant effects in favour of peppermint oil, with an average response for 'overall success' being 58% for peppermint oil and 29% for placebo. Three studies that compared peppermint oil to smooth muscle relaxants showed no difference between these treatments (Grigoleit & Grigoleit 2005a).

In 2013, a more recent meta-analysis of nine RCTs ( $n = 726$  patients) concluded that peppermint oil was significantly superior to placebo for global improvement of IBS symptoms (five studies, 392 patients, relative risk 2.23) and improvement in abdominal pain (five studies, 357 patients, RR 2.14) using a minimum treatment time-frame of 2 weeks (Khanna et al 2014). When side effect incidence was compared, the group receiving active treatment was more likely to experience mild transient adverse events, most commonly heartburn; however, the treatment is considered safe and effective for the short-term treatment of IBS.

#### **Clinical note — Pathophysiology of IBS**

The pathophysiology of IBS is poorly understood, but it is believed to occur when the intestinal muscles are contracting faster or more slowly than normal. Colonic contractions cause abdominal pain, cramping, wind and diarrhoea or constipation. It has been proposed that IBS may result from dysregulation of gastrointestinal motor and enhanced sensory functions, as modulated by the central nervous system (CNS). However, clinical and laboratory investigations have failed to uncover any histological, microbiological or biochemical abnormalities in patients with IBS. Patients with IBS demonstrate increased motility and abnormal contractions of the intestinal muscles when faced with an emotionally or physically stressful situation (Greenberg et al 2002). It is likely that IBS is also associated with dietary habits, poor upper digestion and intestinal dysbiosis (bacterial overgrowth of the bowels).

Common symptoms of IBS are (Greenberg et al 2002) as follows:

- cramping pain in the lower abdomen
- bloating and excess gas (wind)
- changes in bowel habits
- diarrhoea or constipation, either one dominant or both alternating
- immediate need for a bowel movement on awakening or during or after meals
- relief of pain after bowel movements
- feeling of incomplete emptying after bowel movements
- mucus in the stool.

#### **IN COMBINATION**

An early placebo-controlled trial of 223 patients with nonulcer dyspepsia and IBS tested a caraway (*Carum carvi*) and peppermint oil combination which was found to significantly reduce pain compared to placebo ( $P < 0.001$ ) (Freise & Kohler 1999). The herbal combination commercially available as Iberogast contains peppermint leaf in addition to other herbs and has also been tested in IBS.

A 2013 systematic review of RCTs concluded that Iberogast produces symptomatic relief in IBS and is well tolerated (Ottillinger et al 2013). Since peppermint is only one component of this multi-component herbal product, it is uncertain what contribution this herb made to achieving the beneficial outcomes.

#### **Dyspepsia**

A two-way crossover study with 10 healthy male volunteers showed that peppermint oil enhances gastric emptying during the early phase, suggesting the potential use of peppermint oil in functional gastrointestinal disorders (Inamori et al 2007).

#### **IN COMBINATION**

Peppermint is often combined with other herbal ingredients, such as caraway (*Carum carvi*) in the treatment of dyspepsia. As a reflection of practice, nearly all studies have tested a herbal combination containing peppermint oil or leaf as one of the ingredients and there is little research available that has used peppermint as a stand-alone treatment.

A popular herbal combination preparation (STW 5 — Iberogast) that includes peppermint leaf extract and eight other plant extracts (*Iberis amara*, *Chelidonii herba*, *Cardui mariae fructus*, *Melissae folium*, *Carvi fructus*, *Liquiritiae radix*, *Angelicae radix* and *Matricariae flos*) has been demonstrated to significantly relieve dyspepsia in a number of RCTs, including a meta-analysis of three trials (Melzer et al 2004), with a fourth RCT showing similar effects to cisapride (Rosch et al 2002). In a newer study, it was shown that STW 5 lowered gastric acidity as effectively as commercial antacid preparations (i.e. Rennie, Talcid and Maaloxan), prevented secondary hyperacidity more effectively and additionally inhibited serum gastrin levels in rats (Khayyal et al 2006). A more recent 2013 systematic review of RCTs further concluded that Iberogast produces symptomatic relief in functional dyspepsia and is well tolerated with a side effect incidence of 0.04% when considering worldwide spontaneous reporting schemes (Ottillinger et al 2013). Since peppermint is only one component of this multi-component herbal product, it is uncertain what contribution this herb made towards achieving the beneficial outcomes.

The combination of peppermint and caraway has also been the subject of numerous trials. Previously, in a systematic review of herbal medicines for functional dyspepsia, Coon and Ernst (2002) identified four RCTs of a fixed combination of peppermint and caraway oils; five which tested the herbal combination known as Iberogast; one trial of a combination of extracts of peppermint

leaves, caraway fruit, fennel fruit and wormwood herbs; and one trial of a combination of peppermint oil and ginger extract. Various clinical benefits were found for all treatments.

The commercial peppermint and caraway combination products tested were found to produce significant symptomatic relief. These were Enteroplant products delivering 180 mg/day peppermint oil and 100 mg/day caraway oil; 270 mg/day peppermint oil and 150 mg/day caraway oil; or an enteric soluble formulation providing 108 mg/day peppermint oil and 60 mg/day caraway oil (Dr Willmar Schwabe, Karlsruhe, Germany).

One of the studies included in the review was by [May et al \(2000\)](#), which involved 96 outpatients and used Enteroplant (180 mg/day peppermint oil and 100 mg/day caraway oil; (Dr Willmar Schwabe GmbH, Karlsruhe, Germany), which significantly improved symptoms of functional dyspepsia. After 4 weeks the average intensity of pain was reduced by 40% versus baseline in the active group and by 22% in the placebo group. The peppermint combination also reduced pressure, heaviness and fullness ([May et al 2000](#)). A subgroup analysis from this study revealed that *Helicobacter pylori*-positive patients had a substantially better treatment response ([May et al 2003](#)). In a further double-blind, placebo-controlled trial, the same oil combination was found to significantly improve disease-specific quality of life (QOL), as measured by the validated Nepean Dyspepsia Index compared to placebo ([Holtmann et al 2003](#)).

The peppermint oil and caraway oil product (Enteroplant; 180/100 mg) has been compared to cisapride (30 mg/day) in a double blind RCT involving 120 people with functional dyspepsia and moderate pain and one other gastric symptom over the last 14 days. In the 4-week study, the peppermint and caraway oil combination (Enteroplant, 2 capsules daily) was shown to be as effective as cisapride in reducing both the magnitude and the frequency of epigastric pain and dyspeptic discomfort. Doctors rated the two treatments comparable in regard to other dyspeptic symptoms, in addition to intestinal and extraintestinal autonomic symptoms. Corresponding results were also found in *H. pylori*-positive patients and patients who initially presented with intense epigastric pain in the two treatment groups. Both medications were well tolerated ([Madisch et al 1999](#)).

### Infantile colic

Peppermint (1 drop/kg body weight) was compared with simethicone in a double-blind crossover study of 30 infants experiencing infantile colic for a period of 14 days. At the end of the treatment period, the number of daily episodes of colic fell and the crying duration decreased in both groups. All mothers reported a decrease in frequency and duration of episodes of infantile colic, and both treatments seemed to be as effective as each other. The extract of peppermint was not specified in this report. These preliminary findings justify further clinical trials using peppermint for the treatment of infantile colic ([Alves et al 2012](#)).

### Diffuse oesophageal spasm

Diffuse oesophageal spasm (DES) is a relatively rare motor disorder. Associated manometric abnormalities may include hypertensive and repetitive contractions. The lower oesophageal sphincter (LES) may also be hypertensive. Although LES relaxation with deglutition is generally normal, disturbances in LES function are often seen. These abnormalities are, however, not required for the diagnosis ([Massey 2001](#)). In a study of eight DES patients with chest pain or dysphagia, peppermint oil had no effect on LES pressures or contractile pressures and durations in the oesophagus, yet completely eliminated simultaneous oesophageal contractions in all patients ( $P < 0.01$ ). The number of multiphasic, spontaneous and missed contractions also improved. Two of the eight patients had their chest pain resolved after taking the peppermint oil ([Pimentel et al 2001](#)).

### Aid for endoscopic procedures

Results from double-blind RCTs suggest that the antispasmodic properties of peppermint oil can be utilised intraluminally during upper endoscopy with superior efficacy and fewer side-effects than hyoscine-N-butylbromide (Buscopan) administered by intramuscular injection ([Hiki et al 2003a, 2003b](#)). The use of peppermint oil solution was used to successfully extend an endoscope past an area of severe antral stenosis in a case that was unresponsive to Buscopan. In a study of 383 patients receiving double-contrast barium enemas, which compared peppermint oil in the barium, peppermint in the enema tube, Buscopan and no treatment, found that peppermint oil in the barium or the enema tube could be safely and effectively used instead of Buscopan and that the oil had a stronger antispasmodic effect in the caecum and the ascending colon than a Buscopan injection ([Asao et al 2003](#)). Similarly, orally-administered peppermint oil was an effective and safe antispasmodic agent for double-contrast barium meal examination in a controlled study with 420 participants ([Mizuno et al 2006](#)). In another study ( $n = 40$ ) peppermint oil (20 mL, 1.6%) was effective and safe in inhibiting duodenal motility during endoscopic retrograde cholangiopancreatography, but additional administration was recommended for future procedures. The effect was identical to that of glucagon ([Yamamoto et al 2006](#)). A non-randomised prospective study compared the anti-spasmodic scores between non-elderly patients (younger than 70) and elderly patients (70 years old or older) treated with buscopan, peppermint oil or glucagon, while undergoing an oesophago-gastro-duodenoscopy procedure. A total of 8269 procedures were performed and analysis revealed peppermint oil in the elderly was as effective as Buscopan and more effective than glucagon in providing antispasmodic relief ([Imagawa et al 2012](#)).

### Headache/migraine

Topical application of a solution of 10% peppermint oil in ethanol has been shown in a randomised,

placebo-controlled, double-blind, crossover study to efficiently alleviate tension-type headache. The study analysed 164 headache attacks in 41 patients of both sexes ranging from 18 to 65 years of age, suffering from tension-type headache. The peppermint oil was spread largely across forehead and temples and repeated after 15 and 30 minutes. Using a headache diary, the headache parameters were assessed after 15, 30, 45 and 60 minutes. Compared with the application of a placebo, the peppermint oil significantly reduced the intensity of the headache after 15 minutes ( $P < 0.01$ ). The analgesic effect of the peppermint oil was comparable to 1000 mg paracetamol (acetaminophen). Simultaneous ingestion of 1000 mg of paracetamol and application of 10% peppermint oil in ethanol solution led to a slight additive effect (Gobel et al 1996).

One of the main active constituents in peppermint is menthol, which has been investigated as a stand-alone, topical treatment in migraine headache. A randomised, triple-blind, placebo-controlled, crossover study found cutaneous application of menthol 10% as a treatment for migraine without aura produced an acute and significant effect on pain. Thirty-five patients were involved and a total of 118 migraine attacks were reported. The menthol solution was statistically superior to the placebo on 2-hour pain-free ( $P = 0.001$ ), 2-hour pain relief ( $P = 0.000$ ), sustained pain-free and sustained pain relief end-points ( $P = 0.008$ ). The menthol solution was also more efficacious in alleviating nausea and/or vomiting and phonophobia and/or photophobia ( $P = 0.02$ ). No significant difference was observed between the adverse effects of the drug and the placebo groups ( $P = 0.13$ ). The authors report that menthol may inhibit the transmission of nociceptive impulses from the pain-producing cranial vessels, via branches of the trigeminal nerve, to higher brain centres (Borhani Haghghi et al 2010).

## Nausea

A review of scientific evidence of essential oils for the alleviation of nausea and vomiting found that the inhaled vapour of peppermint or ginger essential oils not only reduced the incidence and severity of nausea and vomiting but also decreased antiemetic requirements. However, the authors did acknowledge methodological flaws in the existing research articles and determined the results were not yet fully substantiated (Lua & Zakaria 2012). Furthermore, a Cochrane review of aromatherapy for the treatment of postoperative nausea and vomiting found no reliable evidence for the use of peppermint oil (Hines et al 2012).

### Postoperative nausea

Inhalation of peppermint oil vapours has been shown in a study to reduce postoperative nausea in gynaecological patients in a placebo-controlled trial in which patients were able to inhale peppermint oil as frequently as desired (Tate 1997). A more

recent study examined peppermint spirits (ethyl alcohol 82%, peppermint oil, purified water, peppermint leaf extract) for the treatment of nausea following postoperative C-section. The women who inhaled peppermint had significantly lower nausea levels compared with controls after 2 and 5 minutes, indicating a quick-acting effect (Lane et al 2012).

In another placebo-controlled trial, a reduction in postoperative nausea was seen equally with inhalation of isopropyl alcohol, peppermint oil or saline, with the authors attributing the effect to the controlled breathing used during inhalation (Anderson & Gross 2004).

A hot peppermint oil compress is used in China to prevent abdominal distension in postoperative gynaecological patients (Feng 1997).

### Nausea in cancer treatment

Inhalation of peppermint significantly reduced the intensity and number of emetic events in the first 24 hours following chemotherapy treatment in cancer patients when compared with a control group (Tayarani-Najaran et al 2013).

### Nausea in pregnancy

In a double-blind RCT, peppermint essential oil was shown to have no significant effects on nausea and vomiting during pregnancy when compared to saline (Pasha et al 2012).

## Respiratory tract infections

Peppermint and menthol have an established tradition in the treatment of respiratory infections. Chest rubs containing menthol are frequently used to treat coughs and bronchitis. Inhalation of various antiseptic and anti-inflammatory essential oils is often used in the treatment of respiratory infections, including bronchitis (Shubina et al 1990). In a recent study conducted with 18 healthy volunteers, it was shown that menthol inhalation did not affect nasal mucosal temperature and nasal airflow but supported the fact that menthol leads to direct stimulation of cold receptors modulating the cool sensation, thus inducing a feeling of clear and open nasal passages (Lindemann et al 2008).

Peppermint oil has been found to have a pronounced antimycobacterial effect *in vitro*, and long-term use of peppermint oil in a humidifier has been used in Ukraine as an adjunctive treatment to multidrug therapy for pulmonary tuberculosis (Shkuru-pii et al 2002). A more recent study shows that inhaling peppermint oil by patients with infiltrative pulmonary tuberculosis in the penitentiary system was most effective in the phase of resorption of infiltrates and/or closure of decay cavities (Shkuru-pii et al 2006).

### Exercise performance

Peppermint oil was investigated for its ability to enhance sports performance in 12 healthy male students. The students consumed a 500-mL bottle of

mineral water, containing 0.05 mL peppermint essential oil for 10 days, after which there were significant changes to forced vital capacity (FVC), peak expiratory flow rate (PEF) and peak inspiratory flow (PIF). Exercise performance evaluated by time to exhaustion, work and power also significantly increased. In addition, the results of respiratory gas analysis exhibited significant differences in  $\text{VO}_2$  and  $\text{VCO}_2$ . Authors referred to a number of possible explanations for peppermint's action on exercise performance including: a stimulating effect on the CNS including cognitive performance, perceived physical workload and analgesic effects. They also suggested peppermint may improve muscular energy metabolism, lower heart rate and systolic BP and reduce arterial smooth muscle tonicity (Meamarbashi & Rajabi 2013). While these results are interesting, the absence of a placebo group make it difficult to interpret.

### Enhance cognitive performance

Peppermint odour has also been shown to reduce daytime sleepiness (Norris & Dwyer 2005) and fatigue and to improve mood (Goel & Lao 2006), as well as significantly improve performance in difficult tactile tasks (Ho & Spence 2005) and promote a general arousal of attention with improved typing speed and accuracy (Barker et al 2003). Similarly, in a recent study with healthy volunteers ( $n = 144$ ), peppermint oil inhalation enhanced memory and alertness when measured by the Cognitive Drug Research computerised assessment battery (Moss et al 2008).

### IN COMBINATION

A combination of peppermint oil, eucalyptus oil and ethanol was shown in a crossover double-blind study to increase cognitive performance and promote relaxation in 32 healthy subjects (Gobel et al 1994). A randomised, double-blind pilot trial determined the effectiveness of a combination of essential oils (peppermint, basil and helichrysum) on mental exhaustion, or moderate burnout (ME/MB) using a personal inhaler. While both groups had a reduction in perception of ME/MB, the aromatherapy group had a much greater reduction compared to placebo (Varney & Buckle 2013).

### Traditional uses

Traditionally, peppermint was believed to increase libido and used to stop hiccups, relieve pain in childbirth, reduce bleeding and treat menorrhagia (Fisher & Painter 1996). It was also used externally to repress lactation, to treat dermatological conditions, as a mouthwash for painful gums and mouth and applied to the temples to relieve headaches.

### OTHER USES

Peppermint or pure menthol is commonly used in heat rub ointments for arthritis, fibromyositis, tendonitis and other musculoskeletal conditions. Commission E approved peppermint oil externally for neuralgia and myalgia (Blumenthal et al 2000). A case report describes the treatment of postherpetic

neuralgia with the direct application of undiluted peppermint oil containing 10% menthol to the affected area. The pain relief persisted for 4–6 hours after application of the oil. At a 2-month follow-up, the patient had only minor side effects and continued to use the medication (Davies et al 2002). An aromatherapy acupressure intervention using peppermint oil displayed positive effects on hemiplegic shoulder pain, compared to acupressure alone, in patients with stroke (Shin & Lee 2007).

An oral spray or gargle containing a range of essential oils including peppermint oil is reported to reduce snoring in one double-blind study (Prichard 2004). A mixture of tea tree, peppermint and lemon oil seemed effective in reducing malodour and volatile sulphur compounds in intensive care unit patients (Hur et al 2007).

Two studies conducted with breastfeeding women found that topical application of peppermint water and peppermint gel prevented nipple cracks and associated pain more effectively than lanolin and placebo (Melli et al 2007a, 2007b).

A small study ( $n = 44$ ) conducted with patients undergoing breast cancer treatment showed that 18 of them (41%) chose peppermint and neroli hydrolat spray over plain water spray to manage their hot flushes (Dyer et al 2008).

Antimicrobial and antibiofilm properties of peppermint oil against *Streptococcus mutans* and *Streptococcus pyogenes* were evident, when an in vivo study with healthy volunteers showed that brushing teeth with peppermint oil-blended toothpastes was more effective than using a chlorhexidine mouthwash (Shayegh et al 2008).

### DOSAGE RANGE

#### Leaf

- Infusion: 3–6 g three times daily (Blumenthal et al 2000).
  - Liquid extract (1:2): 1.5–4.5 mL/day.
- These dosages are for adults; adjust according to size for children.

#### Essential oil

- Digestive disorders: 0.2–0.4 mL three times daily in dilute preparations or in suspension (ESCOP 1997). Often used in combination with caraway and other herbs.
- IBS: Most studies report doses of approx. 0.2–0.5 mL two to four times daily in enteric-coated capsules or tablets (Ruepert et al 2011).
- Inhalation: 3–4 drops added to hot water.
- Lozenge: 2–10 mg.
- External use (for analgesic, anaesthetic or antipruritic activity): 0.1–1.0% m/m (ESCOP 1997).
- External use (counterirritant): 1.25–16% m/m (ESCOP 1997).

### ADVERSE REACTIONS

A single dose of 4000 mg/kg of a spray-dried infusion did not produce any macroscopic signs of

toxicity in mice (Della et al 1990). Peppermint oil taken orally has been shown to be well tolerated at the commonly recommended dosage but may cause significant adverse effects at higher doses (Kligler & Chaudhary 2007).

Short-term and subchronic oral studies reported brain lesions in rats that were given very large doses of peppermint oil containing pulegone, pulegone alone or large amounts (>200 mg/kg/day) of menthone. Pulegone is also a recognised hepatotoxin, and large doses of peppermint oil have been shown to be hepatotoxic in cultured human hepatoma cells (Vo et al 2003). Peppermint oil was negative in an Ames test and a mouse lymphoma mutagenesis assay, but gave equivocal results in a Chinese hamster fibroblast cell chromosome aberration assay. There is a case report of acute lung injury following intravenous injection of peppermint oil (Behrends et al 2005).

Although sensitisation to peppermint oil and/or its constituents has been reported, a solution containing 8% peppermint oil was shown not to be a sensitiser (Nair 2001). Cases of allergic contact dermatitis to peppermint and menthol have been reported following intraoral application (Morton et al 1995, Tamir et al 2005), with one case reporting vulval allergic contact dermatitis following long-term (6 years) high oral consumption of peppermint tea (Vermaat et al 2008). Moreover, the application of a transcutaneous patch (Foti et al 2003) or foot spray (Kalavala et al 2007) caused allergic contact dermatitis. However, the incidence of allergic contact dermatitis due to peppermint and its components is low considering its widespread use and seems to be more common in patients with a history of allergic reactions (Kalavala et al 2007, Vermaat et al 2008). As long as the pulegone content is kept to a minimum, peppermint oil and peppermint extract are considered to have a very good safety profile.

### SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

#### Felodipine

Peppermint oil has been shown to increase the oral bioavailability of felodipine in animal studies (Dresser et al 2002b) — use this combination with caution.

#### Simvastatin

Peppermint oil has been shown to increase the oral bioavailability of simvastatin in animal studies (Dresser et al 2002b). Observe the patient and monitor drug requirements — possible beneficial interaction.

#### Cyclosporin

Peppermint oil has been shown to increase the oral bioavailability of cyclosporin in animal studies

### Practice points/Patient counselling

- Peppermint oil and/or peppermint leaf extracts can be used for IBS, dyspepsia, flatulence, intestinal colic and biliary disorders as it exerts an antispasmodic and carminative effect.
- Although enteric-coated peppermint oil capsules may prevent side effects such as reflux and allow higher doses to be used, traditional extracts of peppermint, including hydroethanolic extracts and infusions, may also be effective.
- Peppermint leaf extract combines well with chamomile, caraway, licorice, lemon balm, angelica, St Mary's thistle and the bitter candytuft (*Iberis amara*) in the treatment of functional dyspepsia (Madisch et al 2001).
- Peppermint oil can be used as an inhalation or chest rub for coughs, sinusitis and bronchitis. Commission E approved peppermint oil for internal use in the treatment of respiratory tract inflammation (Blumenthal et al 2000), and hot peppermint leaf infusion is used as a diaphoretic tea in the treatment of colds and influenza.
- Peppermint oil can be inhaled to reduce nausea and may enhance cognitive performance and tactile tasks.
- Ten per cent peppermint oil in ethanol solution can be applied externally for tension headaches and over affected areas for postherpetic neuralgia.

(Dresser et al 2002b) — avoid concurrent use, unless under medical supervision.

### Drugs metabolised by CYP3A4 liver enzyme

Peppermint may increase the oral bioavailability of certain drugs by inhibition of CYP3A4-mediated drug metabolism, which has been demonstrated *in vitro* but not in test animals (Dresser et al 2002a, Maliakal & Wanwimolruk 2001). Although these studies seem to suggest that peppermint may modulate drug-metabolising enzymes, the clinical significance of this is unknown and requires further investigation. Observe.

### CONTRAINDICATIONS AND PRECAUTIONS

**?** Hypersensitivity to peppermint oil (Morton et al 1995).

Non-enteric-coated peppermint may be best avoided in patients with gastro-oesophageal reflux symptoms (McKay & Blumberg 2006). Avoid chewing enteric-coated capsules as it may cause heartburn (Liu et al 1997). Avoid the use of peppermint oil on the face of infants and small children. Capsules containing peppermint oil are contraindicated in biliary duct occlusion, gall bladder inflammation and severe liver damage (Blumenthal et al 2000). Similarly, caution has been urged in patients with hiatal hernia and kidney stones (McKay & Blumberg 2006).

**PREGNANCY USE**

Safe dosages in pregnant women have not been determined; however, external use and inhalation is likely to be safe.

**PATIENTS' FAQs****What will this herb do for me?**

Peppermint is a safe herb for gastrointestinal disorders, including dyspepsia and IBS. It is also safe for children, particularly as a herbal tea.

**When will it start to work?**

Peppermint will generally have an immediate effect, with the condition continuing to improve with long-term use.

**Are there any safety issues?**

Concentrated peppermint oil preparations may theoretically interact with a number of different medications. It is unlikely that any interaction will occur with peppermint tea or simple liquid extracts. Avoid the use of peppermint oil on the face of infants and small children. Allergic reactions may occur in hypersensitive individuals.

## Perilla

**HISTORICAL NOTE** Perilla is an annual plant native to Eastern Asia. It was introduced to Japan from China and is now cultivated extensively in Japan, India and Korea. The seed is mainly used for its high oil content (*Perilla frutescens* var. *frutescens*), and the leaves of *Perilla frutescens* var. *crispa* are used as a vegetable and food colouring in gourmet cooking. The salty umeboshi plum is coloured by the addition of special red perilla leaves. The leaves of var. *crispa* are also used medicinally. In China, perilla has been used to reduce the risk of food poisoning by cooking seafood with the leaf (Bensky & Gamble 1986). In recent times, certain compounds (monoterpenes) isolated from the oil are being investigated as an anticancer treatment, and the defatted seed extract is used in the treatment of allergies.

### COMMON NAME

Perilla

### OTHER NAMES

Different names are used for the different varieties of perilla. *Perilla frutescens* var. *frutescens*: Chinese: Ren; Korean: Deulggae; Japanese: Egoma. *P. frutescens* var. *crispa* — Chinese: Zisu; Korean: Cha-Jo-Ki; Japanese: Shiso. In English, wild sesame refers

to var. *frutescens*, while beefsteak plant refers to var. *crispa*.

### BOTANICAL NAME/FAMILY

*Perilla frutescens* (L.) Britt.

There are several botanical variants: *P. frutescens* var. *frutescens* and *P. frutescens* var. *japonica* are used interchangeably; the use is for the seed and oil crop, as well as a traditional vegetable and is the most

important crop in Korea; *P. crispata* represents another variety, and the leaf is used for nutritional and medicinal purposes. (family Lamiaceae [mint family]).

### PLANT PARTS USED

Leaf, stem and the fruit (seed) are used.

Some genotypes of perilla are not suitable for consumption as they contain a toxic perilla ketone.

### CHEMICAL COMPONENTS

A study of the five most common genotypes of var. *frutescens* and var. *crispata* found that the phenolic content and corresponding antioxidant capacity of perilla is relatively high compared to other vegetables. In particular, they contain high concentrations of carotenoids, especially lutein and  $\beta$ -carotene, with concentrations up to five-fold higher than in other carotenoid rich vegetables.

A study of eight cultivars of the two *Perilla frutescens* varieties showed variations in major phenolic acids and flavones were quite marked between green and red cultivars (Meng et al 2009). No obvious relationships between genotypes and geographical origin of *P. frutescens* were noted by the authors.

As different parts of the plant are used, the rest of this section will deal with each part individually.

### Raw oil

Perilla seed contains 25–51% lipids. The raw perilla oil has been used as a drying oil in paints, varnishes, linoleum, printing ink and lacquers and for protective waterproof coatings on cloth. It has also been used for cooking and as a fuel.

### Refined oil

The purified oil is rich in fatty acids including palmitic acid, linoleic acid, alpha-linolenic acid, stearic acid, eicosanoic acid and arachidic acid. The omega-3 essential fatty acid, alpha-linolenic acid, comprises over 60% of the oil (Tan et al 1998).

### Defatted perilla seed extract

Defatted perilla seed extract is a concentrated ethanolic extract rich in polyphenolic compounds including rosmarinic acid and rosmarinic acid methyl ester and the flavones apigenin, luteolin and chrysoeriol. Normally, flavonoids exist as glycosides in plants; however, in perilla seed extract, they occur as aglycones (free flavonoids), which have more potent activity. The defatted extract is free of perillyl ketone, perillyl aldehyde and perillyl alcohol (Oryza Co 2003). Individual and total phenolic content in the seed varies significantly between *Perilla frutescens* cultivars and therefore affects antioxidant activity (Lee et al 2013).

### Leaf

The leaf contains flavones, including apigenin and luteolin; flavone glycosides, anthocyanins, phenolic

compounds, including rosmarinic acid, and aldehydes including perillyl aldehyde (Makino et al 2003a).

### Essential oil

The volatile oil is distilled from the dried foliage of perilla. It contains perillyl aldehyde, elsholtzia ketone, perillyl ketone, citral and perillene, in addition to more than 70 other compounds (Ito et al 1999). Notably, rosmarinic acid is one of the major polyphenolic ingredients of perilla leaf. Perillyl aldehyde is used as a sweetener and flavouring agent. One of the aldehyde isomers is 2000-fold sweeter than sugar and four–eight-fold sweeter than saccharin. Perillyl alcohol, prepared from perillyl aldehyde, is used in fragrances (Misra & Husain 1987). There are different chemotypes of perilla; one genotype lacks perillyl aldehyde but has perillyl ketone (Brenner 1993).

### MAIN ACTIONS

The herb has several different actions demonstrated in vitro and in vivo, and the part of the plant used will determine which is exhibited. As such, this review specifies which part of the herb is responsible for the activity listed. Additionally, much research has been conducted with the rosmarinic acid and luteolin components isolated from perilla.

### Anti-inflammatory action

Both the refined oil and seed extract demonstrate anti-inflammatory activity in vitro and in vivo.

### Refined oil

The pharmacological effects of the refined oil are associated with its high level of alpha-linolenic acid, which is metabolised in the body to eicosapentaenoic acid (EPA) and docosahexaenoic acid. EPA is a precursor of the series 3 prostaglandins, the series 5 leukotrienes and the series 3 thromboxanes, which have anti-inflammatory and anti-atherogenic properties. The effects have been shown clinically, as perilla seed oil significantly suppressed the generation of leukotrienes in patients with asthma in an observational study comparing two groups of patients with asthma, one of whom received perilla oil for 4 weeks. Ventilatory parameters, such as peak expiratory flow (PEF), forced vital capacity (FVC) and forced expiratory volume (FEV<sub>1</sub>), increased significantly after 4 weeks' dietary supplementation in the treated group (Okamoto et al 2000). In vivo dietary perilla oil has been shown to alleviate inflammation in mice by decreasing the secretion of pro-inflammatory cytokines (Chang et al 2008).

### Seed extract

Perilla seed extract, as well as its constituents luteolin, rosmarinic acid and chrysoeriol, has been shown to inhibit 5-lipoxygenase in vitro and therefore leukotriene synthesis. Leukotrienes are associated with both allergic and inflammatory disorders, including hay fever, asthma and inflammatory bowel disorders.

### Anti-allergic activity

In both in vitro and animal models of allergy, perilla preparations have demonstrated anti-allergic effects. Luteolin and rosmarinic and caffeic acids are chiefly responsible for this activity.

### Seed extract

The defatted seed extract has been shown to inhibit chemically induced type IV allergy and inflammation in vivo, with the luteolin constituent exhibiting the most potent activity.

Perilla seed extract has also been shown to inhibit histamine release from mast cells in a dose-dependent manner. The effect is more potent than for isolated flavonoids including catechin, quercetin and caffeic acid. Additionally, in a case report of perilla seed extract, 150 mg/day for 2 weeks selectively inhibited the production of serum IgE in two human subjects suffering allergic symptoms including sneezing, nasal obstruction and itchy eyes (Oryza Co 2003).

### Leaf

Perilla leaf extract is thought to down-regulate Th2-type cytokine production and prevent the Th1/Th2 balance from shifting towards Th2-type immune responses. A study on the effects of perilla leaf extract on cytokine production in allergic reaction in mice found that it suppressed IgE and IgG antibodies as well as IL-4, IL-5 and IL-10 (Ishihara et al 1999).

An aqueous extract of perilla leaf was shown in vitro and in vivo to inhibit local and systemic reactions in a mast cell-mediated immediate-type allergic reaction. Plasma histamine levels and cyclic adenosine monophosphate (AMP) were reduced in a dose-dependent manner. Perilla also inhibited IgE-induced tumour necrosis factor (TNF)-alpha production (Shin et al 2000). Oral administration of a hot water extract of perilla leaf was also shown to inhibit histamine release from mast cells and reduce scratching in an animal model of dermatitis (Wakame et al 2000).

Oral administration of a perilla leaf extract inhibited the inflammatory response in an induced allergic reaction in animals. Luteolin, rosmarinic and caffeic acids were isolated and identified as active constituents. Luteolin has been shown in vivo to inhibit TNF-alpha and arachidonic acid and reduce oedema (Ueda et al 2002). In another inflammatory model, perilla dose-dependently reduced the allergic response in mice by over 40%. Rosmarinic acid was identified as the main active constituent (Makino et al 2001) and has been shown to decrease the inflammatory response and increase superoxide radical scavenging in vivo (Osakabe et al 2004a). An extract of perilla leaf with high levels of rosmarinic acid decreased cytokine activity in asthma-induced rats (Sanbongi et al 2004). A perilla leaf decoction was found to suppress IgA nephropathy in genetically predisposed rats, possibly through modulation

of the intestinal mucosal immune system. Perilla suppressed proteinuria, proliferation of glomerular cells, serum levels of IgA, glomerular IgA and IgG depositions in the mice. Rosmarinic acid seems to produce this effect synergistically with other constituents (Makino et al 2003b).

### Antioxidant activity

A methanolic extract of roasted defatted perilla seed has been shown to exert strong antioxidant activity, and upon fractionation, luteolin was identified as one of the active antioxidant constituents (Jung et al 2001). Rosmarinic acid inhibits NO and nitric oxide synthase (iNOS) in vitro (Qiao et al 2005, Renzulli et al 2004). Aqueous extract of perilla significantly inhibits free radical production by neutrophil leucocytes (Zekonis et al 2008). In vitro, isolated luteolin from *P. frutescens* showed non-competitive inhibition of aldose reductase (involved in diabetic complications and  $\alpha$ -glucosidase) (Ha et al 2012).

A small study of eight healthy non-smoking females showed that a water extract of a red cultivar of *P. frutescens* var. *crispa* standardised at 1000 mg of polyphenols prolonged LDL peroxidation lag time by 5 minutes at 4 hours post-ingestion indicating a clinical effect (Saita et al 2012). In vitro, the comparative study of red and green perilla showed the red cultivar had a higher polyphenol content and increased antioxidant activity in endothelial cells (Saita et al 2012).

### Neuroprotective

Oral ingestion of perilla seed oil caused brain cells to be significantly less sensitive to reactive oxygen species, reactive nitrogen species and mitochondrial dysfunction according to an animal model. Furthermore, an increase in oleic and linoleic acid brain content was observed, as well as increased in-situ biosynthesis of arachadonic acid (AA) and DHA (Eckert et al 2010). Despite these changes in fatty acid content, synapse membrane fluidity was unchanged.

### Immunostimulant

Perilla leaf extract stimulates phagocytosis in vitro and in vivo (Simoniene et al 2005). An increase in neutrophil phagocytosis was noted after 7 days, but was strongest after 4 weeks of treatment. A polysaccharide extract from perilla leaf has also demonstrated phagocytic ability both in vitro and in vivo (Kwon et al 2002).

### Antimicrobial activity

Perilla may help prevent dental caries and periodontal disease. Perilla seed extract has been shown to have antimicrobial activity against oral cariogenic streptococci and periodontopathic *Porphyromonas gingivalis*. The luteolin constituent showed the strongest antimicrobial effect among the phenolic compounds tested (Yamamoto & Ogawa 2002).

### Hepatoprotective effects

Perilla extract and its constituent rosmarinic acid showed hepatoprotective activity against lipopolysaccharide-induced liver damage in mice, possibly due to an antioxidant mechanism (Osakabe et al 2002).

### Lipid lowering activity

Perilla and perilla flavonoids demonstrate lipid lowering activity in vivo. Perilla oil lowers cholesterol by suppressing hepatic beta-hydroxy-beta-methylglutaryl-CoA (HMG-CoA) reductase activity (Du et al 2003). Perilla oil also lowers plasma triacylglycerol by suppressing fatty acid synthase (Kim et al 2004) and stimulating acyl-CoA oxidase (Kim & Choi 2005) in the liver. Perilla oil mixed with borage and evening primrose oil has been shown to reduce cholesterol in older rats (Fukushima et al 2001). Similarly, a dose of 200 mg/kg of perilla flavonoids given to test animals over 30 days and fed a high fat diet for 4 weeks was shown to normalise lipid levels (Feng et al 2011).

### Anticancer effects

Several constituents found in perilla have demonstrated anticancer effects in vitro and in experimental cancer models. This has prompted phase I and phase II clinical testing with one key active constituent, perillyl alcohol.

Conjugated alpha-linolenic acid from perilla oil has been shown to reduce the rate of carcinogenesis in a chemically-induced rat mammary cancer model (Futakuchi et al 2002). The fibrinolytic and antioxidative activities of rosmarinic acid suppress the proliferation of mesangial cells in vivo (Makino et al 2002, Osakabe et al 2004b). Animal studies have demonstrated the ability of perillyl alcohol to inhibit tumorigenesis in the mammary gland (Yuri et al 2004) and skin (Lluria-Prevatt et al 2002). The precise mechanism of action is unclear, but it is thought that compounds other than the rosmarinic acid stimulate apoptosis (Lin et al 2007). Perillyl alcohol has been shown to inhibit part of the signal transduction cascade involved in uncontrolled cell proliferation, upregulate the mannose-6-phosphate receptor and induce apoptosis (Liston et al 2003, Xu et al 2004). Perillyl alcohol has also demonstrated an ability to decrease the release of vascular endothelial growth factor from cancer cells and encourage the expression of angiopoietin-2 by endothelial cells (Loutrari et al 2004). This indicates that perilla may play a role in decreasing the vascularisation of tumours and inducing regression. The effects of perillyl alcohol and its metabolite perillic acid on the proliferation of non-small cell lung cancer cells were investigated in vivo. Both elicited dose-dependent cytotoxicity, induced cell cycle arrest and apoptosis in a dose-dependent manner (Yeruva et al 2007).

Perillyl alcohol increases the sensitivity of cancer cells in vitro to radiation treatment of prostate

cancer (Rajesh & Howard 2003), glioma (Rajesh et al 2003) and certain neck and head cancers (Samaila et al 2004).

### Antidepressant activity

Several different constituents within perilla leaf have demonstrated effects on behaviour in vivo, most notably antidepressant effects. Perilla demonstrated an antidepressant-like property in animal models of depression, possibly through cell proliferation in the hippocampus (Ito et al 2008b). Rosmarinic acid and caffeic acid have demonstrated antidepressant activity in a forced swimming test in mice. The activity is thought to be via some mechanism other than the inhibition of monoamine transporters and monoamine oxidase (Takeda et al 2002a). Apigenin from perilla significantly reduced immobility in a forced swimming test in mice, an effect mediated by dopaminergic mechanisms (Nakazawa et al 2003). Inhalation of L-perillaldehyde, a major component in the essential oil, shows antidepressant-like activity in mice through the olfactory nervous function (Ito et al 2008a).

Rosmarinic acid and caffeic acid have been shown to decrease the duration of the defensive freezing behaviour caused by fear and stress in animals (Takeda et al 2002b).

### OTHER ACTIONS

Perilla oil has been shown to reduce the excessive growth of visceral adipose tissue in rats by down-regulating adipocyte differentiation in animals (Okuno et al 1997). This has direct relevance to obesity, as a high-fat diet not only accelerates the filling process of preexisting preadipocytes but also stimulates the proliferation of adipose precursor cells. Adipocyte differentiation, from adipoblasts to adipocytes, is a key factor underlying obesity.

A glycoprotein isolated from perilla oil has been shown to inhibit an early stage of HIV-1 replication without blocking viral adsorption in vitro (Kawahata et al 2002, Yamasaki et al 1998).

Perilla aldehyde has demonstrated vasodilatory activity in isolated rat aorta and appears to work by blocking Ca<sup>2+</sup> channels (Takagi et al 2005). The clinical significance of this is currently unknown.

### CLINICAL USE

The form most commonly used at the moment is the extract of defatted perilla seed; however, this review will also include information regarding other forms.

#### Cancer

The main form tested is the perillyl alcohol in various vehicles such as topical creams and intranasal delivery.

#### Perillyl alcohol (POH)

Phase I clinical trials have shown a favourable toxicity profile, and preliminary data have suggested some chemotherapeutic efficacy in cancer, but no

definitive conclusions can be made just yet as to the potential use of POH as there are few clinical trials and results to date have been disappointing.

In vitro studies suggest that POH inhibits the expression and function of androgen receptors in human prostate cancer cell line, suggesting that POH could be useful for intervention of prostate cancer (Chung et al 2006). Another in vitro study of a combination of POH with a virally delivered therapeutic cytokine shows promise for both preventing and treating human pancreatic cancer without toxic effects (Lebedeva et al 2008). In a small pilot study of eight patients with adenocarcinomas of the exocrine pancreas treated perioperatively with POH 1200 mg/m<sup>2</sup> four times daily, there was a non-statistical increase in survival time and greater local apoptosis; however, tumour size and CA 19.9, a commonly used pancreatic cancer marker, remained unchanged (Matos et al 2008).

Similarly, POH (1200 mg/m<sup>2</sup> four times daily) failed to extend the time-to-progression in three phase II studies in patients with advanced ovarian carcinoma (Bailey et al 2002), refractory metastatic breast cancer (Bailey et al 2008), prostate cancer (Liu et al 2003) and colorectal cancer. All trials were very small and had to contend with high dropout rates due to intolerability of the medicine. Despite encouraging preclinical results, perilla does not appear to be an effective treatment for advanced cancer based on the small amount of clinical investigation conducted thus far.

Topical POH inhibits ultraviolet B-induced skin carcinogenesis in vivo so has been tested clinically for activity. A 1-month, double-blind, phase 1 trial of topically administered perillyl alcohol cream was tested in 25 human subjects. They were monitored for toxicity and underwent histopathological evaluation. The topical cream was well tolerated and no serious cutaneous toxicities, systemic toxicities or histopathological abnormalities were observed. However, there was no significant difference between lesions appearing on the treated forearm versus the placebo-treated forearm (Stratton et al 2008). In a phase IIa trial comparing placebo against a low dose POH (0.3%) cream and a high dose POH (0.76%) topical cream for chemoprevention on participants with sun damaged skin, there was a borderline statistical significance in histopathological score in the groups using 0.3% cream but no change with use of 0.76% cream, although a decrease in nuclear abnormalities was demonstrated in karyotyping analysis (Stratton et al 2010).

The 6-month treatment of recurrent malignant glioma in a phase I/II study of 37 patients with intranasal POH spray demonstrated antitumour activity and decrease in peritumoral brain oedema. While no toxicity was noted, nausea, early satiety, eructation and fatigue side effects interfered with compliance (Da Fonseca et al 2008). Further research is required to further investigate the effects of intranasal POH in this cohort.

## Allergy

Based on traditional use, in vitro and in vivo studies and human trials, perilla leaf and defatted seed extracts are used for allergic respiratory disorders including hay fever, asthma and sinusitis. The refined oil may also help allergic and inflammatory respiratory conditions by regulating the arachidonic acid metabolism pathways and suppressing leukotriene generation.

A double-blind, randomised, placebo-controlled clinical trial showed a significant reduction in symptoms such as watery eyes, itchy eyes and itchy nose in 29 patients with seasonal allergic rhinoconjunctivitis, taking 50 or 200 mg of rosmarinic acid-enriched perilla for 21 days (Takano et al 2004). Responder rates were 55.6 and 70%, respectively. A drastic reduction in the number of neutrophils and eosinophils in nasal fluid was also demonstrated.

In an open clinical trial, 20 human subjects suffering allergic symptoms, including sneezing, nasal obstruction and itchy eyes and skin, were treated with 100–150 mg perilla seed extract daily (higher dose for persons over 60 kg) for 2 weeks. The subjects themselves evaluated changes in the severity of symptoms. Significant improvement was noted in 80% of the subjects for nasal obstructive symptoms, 40% reported a significant improvement in sneezing and half reported a significant reduction of itchy eyes (Oryza Co 2003).

A systematic review of double-blind randomised trials evaluating various herbal medicines in patients with allergic rhinitis concluded that perilla (part used not specified) showed promising results (Guo et al 2007).

## Perilla leaf extract cream and dermatitis

Open studies of more than 100 children with atopic dermatitis found that perilla leaf extract cream improved symptoms in 80% of cases after 3 months' treatment (Yu et al 1997). Another open study with 20 allergic patients, using perilla leaf cream topically and perilla leaf extract orally, showed a general improvement in 90% of the patients after 2 months, with 30% reporting significant improvements (Yu et al 1997).

## Dental caries and periodontal disease

Perilla seed extract inhibits the growth of cariogenic and inflammatory microorganisms including oral streptococci and *Porphyromonas gingivalis* (Yamamoto & Ogawa 2002). Perilla seed extract also reduces inflammation through inhibition of leucocyte production and radical scavenging activity. As such, application of the extract in the oral cavity is used to reduce dental caries and pericoronitis.

## OTHER USES

Refined perilla oil is a good source of omega-3 series alpha-linolenic acid.

**Clinical note — Perilla and traditional medicine systems**

Perilla is an important ingredient of several traditional Chinese medicine (TCM) formulas. Perilla leaf is a key ingredient in Saiboku-to, a traditional Chinese formulation used in the treatment of type 1 hypersensitivity disorders, including asthma (Nishiyori et al 1985). Saiboku-to contains *Bupleurum falcatum*, *Pinellia ternata*, *Poria cocos*, *Scutellaria baicalensis*, *Magnolia officinalis*, *Zizyphus spinosa*, *Panax ginseng*, *Glycyrrhiza uralensis*, *Zingiber officinale* and perilla. Another TCM formula containing perilla, Sam So Eum, is used to treat asthma and has been shown in an animal model to decrease airway hyperresponsiveness by restoring the immunomodulating cytokines. The anti-inflammatory effects of this formula are similar in effectiveness to prednisolone (Cho et al 2008). Perilla is also a component of the Banxia Houpu Decoction used for depression. It contains *Pinellia ternata*, *Poria cocos*, *Magnolia officinalis*, *Perilla frutescens* and *Zingiber officinale* (Luo et al 2000). Perilla leaf has been prescribed as one of the component herbs in certain Kampo (Japanese herbal) medicines that are used clinically for the improvement of depressive mood. These formulae demonstrate antidepressant-like effect in mice models through suppressing the hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis (Ito et al 2006).

**DOSAGE RANGE**

- Perilla leaf: extract equivalent to 4–9 g/day (Bensky & Gamble 1986).
- Refined perilla oil: 1000 mg capsules taken three to six times daily.
- Perilla seed extract (containing a minimum of 3.0% polyphenols): 100–150 mg/day (Oryza Co 2003).
- External use (dental caries and periodontal disease): 80–160 mg defatted perilla seed daily delivered directly into the oral cavity in the form of toothpaste, chewing gum or mouth rinse.

**ADVERSE REACTIONS**

Defatted perilla seed extract has very low toxicity. After administering 2000 mg/kg to mice for 2 weeks, no toxic effects were observed (LD<sub>50</sub> for mice is therefore more than 2000 mg/kg). Dosage of 7.0 g/kg for 2 weeks did not produce any toxic effects in humans.

In Japan, 20–50% of long-term workers in the perilla industry develop dermatitis on their hands due to contact with perillyl aldehyde (Brenner 1993).

A 13-week subchronic oral toxicity study of perilla leaf extracts in drinking water did not show any acute toxicity. There were no treatment-related

changes in body weight gain or in haematological or blood biochemistry values. Nor were there any treatment-related histopathological changes observed in the highest dose group (Yun et al 1999).

Phase I and II clinical trials of perillyl alcohol for certain cancers have shown that gastrointestinal side effects and fatigue are the most common adverse reactions (Azzoli et al 2003, Bailey et al 2002, 2004, Liu et al 2003, Meadows et al 2002). Gastrointestinal effects are usually mild and include nausea, vomiting, bloating and belching. Doses were usually between 1200 and 1600 mg/m<sup>2</sup> four times daily.

The refined perilla oil is clear golden yellow. It is fully refined (neutralised, bleached and deodorised) and should be free of perillyl ketone, which is a potent lung toxin that causes increased microvascular permeability and pulmonary oedema in grazing animals (Waters et al 1993).

There has been a report of lipoid pneumonia in a 57-year-old man who had a history of ingesting green perilla oil, and there was also residual neurological deficit of cerebral infarction with right hemiparesis (Kwang et al 1999).

Anaphylactic reactions to *Perilla frutescens* seeds were reported in 2006 (Jeong et al) in two atopic subjects with high serum-specific IgE response.

A separate report of a 21-year-old atopic man who presented with bronchospasms and periorbital urticaria after ingestion of Shiso leaves (botanical name and chemotype not supplied) concluded the reaction was mediated by direct histamine release from basophils; there was no detection of serum IgE antibodies (Shin et al 2009). None of these reports gave specific information about the variety, cultivar or PK content taken.

**SIGNIFICANT INTERACTIONS**

Controlled studies are not available, so interactions are based on evidence of activity and are largely theoretical and speculative.

**Antihistamine agents**

Theoretical additive effect is possible. Patients taking perilla concurrently with antihistaminic should be observed and drug doses modified if required.

**CONTRAINDICATIONS AND PRECAUTIONS**

None reported for perilla seed extract or refined oil; however, perilla leaf extract is contraindicated in diarrhoea (Bensky & Gamble 1986).

**PREGNANCY USE**

Insufficient information is available to determine the safety of perilla during pregnancy.

**Practice points/Patient counselling**

- Perilla exhibits anti-inflammatory, anti-allergic, antioxidant and anticarcinogenic activity. Preliminary evidence also suggests hepatoprotective and behavioural effects.
- Perilla leaf and defatted seed extracts are specifically used for allergic respiratory disorders including hay fever, asthma and sinusitis.
- Perilla leaf and defatted seed extract may down-regulate Th2-type cytokine production and prevent the Th1/Th2 balance from shifting towards Th2-type immune responses that may be associated with a range of allergic reactions and autoimmune disorders.
- Refined perilla oil is a good source of omega-3 series alpha-linolenic acid, and extracts should be free of perillyl ketones and aldehydes.

**! PATIENTS' FAQs****What can this herb do for me?**

Perilla leaf and defatted seed extracts are used in the treatment of allergic respiratory conditions, such as hay fever, asthma and sinusitis. Preliminary evidence suggests that it may be beneficial; however, more rigorous studies are still required to confirm effectiveness.

**When will it start to work?**

Relief of allergic symptoms should be noticed within the first week, although it may take a couple of weeks to show a significant effect. For hayfever, it would be beneficial to start taking perilla at least 1 month before the onset of the hayfever season.

**Are there any safety issues?**

Perilla is generally well tolerated and nontoxic. It can be used long term if indicated.

## Policosanol

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Policosanol is isolated from the waxes of plants such as sugar cane. The main component, octacosanol, has variable absorption from the small intestine and is chiefly metabolised by the liver and excreted in the faeces.

### CHEMICAL COMPONENTS

Policosanol is a mixture of long-chain primary aliphatic alcohols (Arruzazabala et al 1993a). The alcohols have a chain length ranging from 24 to 34

carbons and the major components of the mixture are octacosanol (60–70%, w/w), triacosanol (10–15%, w/w) and hexacosanol (4–10%, w/w) (Francini-Pesenti et al 2008). Octacosanol is regarded as the main active constituent.

### MAIN ACTIONS

#### Lipid lowering — questionable

Cuban sugar cane policosanol (CSP), derived from the waxy coating of stems and leaves of sugar cane and other plant materials, has been shown to exert

significant lipid-lowering effects in animals and humans in numerous studies conducted by a single laboratory and using a CSP product manufactured by Dalmer Laboratories (Havana, Cuba). Tests investigating CSP with experimental models, including rats, rabbits, dogs and monkeys, have demonstrated reductions in circulating total cholesterol levels consistently greater than 13% (Kassis et al 2007). Early human studies using CSP showed significant reductions in total cholesterol and low-density lipoprotein (LDL)-cholesterol; however, these findings are being questioned because there has been a plethora of negative clinical and experimental studies published since 2006 which have been unable to detect lipid-lowering activity for CSP and other policosanols preparations.

#### **Reduces oxidation of LDL-cholesterol**

This has been demonstrated *in vitro* at an equivalent dose of 5 and 10 mg/day (Menendez et al 2000).

#### **Reduces platelet aggregation**

This has been confirmed in animal models and randomised double-blind studies, with effects starting at 10 mg/day (Arruzazabala et al 1993b, 2002, Castano et al 1999a). One clinical study found that a dose of 20 mg/day policosanols produces the same inhibitory effects on platelet aggregation as 100 mg aspirin daily (Arruzazabala et al 1997). A higher dose of 40 mg policosanols does not appear to produce any further antiplatelet effects according to another double-blind study (Arruzazabala et al 2002). Thromboxane, but not prostacyclin, generation induced by collagen is also inhibited by policosanols in clinical studies (Carbajal et al 1998a).

### **OTHER ACTIONS**

#### **Endothelial protection**

Oral administration of policosanols to spontaneously hypertensive rats resulted in a significant reduction in circulating endothelial cells compared with controls. Moreover, comparison between groups revealed a lower frequency of aortic lesions in policosanols-treated animals than in untreated animals (Noa et al 1997).

#### **Antihypertensive effects at very high doses**

Tests in animal models have identified enhancement of propranolol-induced hypotensive effects with pretreatment at 200 mg/kg policosanols (Molina et al 1999), which is an extremely high dose and clinically irrelevant in humans.

#### **Reduces atherosclerotic lesion development**

According to one animal study, most policosanols-treated animals did not develop atherosclerotic lesions compared with an untreated group, and the thickness of fatty streaks that did develop with treatment had fewer foam cell layers than in controls (Arruzazabala et al 2000).

### **CLINICAL USE**

Policosanols is most often used in the management of hyperlipidaemia and was sold as a lipid-lowering agent in over 40 countries worldwide.

#### **Hyperlipidaemia**

Policosanols has been the focus of multiple clinical trials in an attempt to clarify its role as a potential treatment in hyperlipidaemia. Initial results published prior to 2006 and conducted with CSP, manufactured by Dalmer Laboratories (Havana, Cuba), supported its use and indicated significant lipid-lowering activity. However, studies conducted by other research groups outside Cuba have not been able to reproduce the results obtained in the original studies, casting doubt on the product's lipid-lowering activity. Since 2007 several new double-blind studies have been published with policosanols producing negative results again, thereby confirming that policosanols is not an effective treatment for hyperlipidaemia.

#### **Prior to 2006**

Numerous randomised, double-blind clinical trials conducted prior to 2006 demonstrated significant cholesterol-lowering effects of oral policosanols (Castano et al 2001b, Mas et al 1999, Menendez et al 2000, Pons et al 1994, Torres et al 1995). Several previous studies conducted with postmenopausal women confirmed benefits in this population (Castano et al 2000, Mas et al 1999, Menendez et al 2000, Mirkin et al 2001, Pons et al 1994, Torres et al 1995). Overall, these early results showed that a daily dose of 5 mg policosanols may: reduce LDL-cholesterol by 11–18%, reduce total cholesterol by 8–15% and increase high-density lipoprotein (HDL) by 8–15%, whereas a higher dose of 20 mg policosanols daily can: reduce LDL-cholesterol by 31%, reduce total cholesterol by 23% and increase HDL by 27%. These studies used the same specific policosanols product.

#### **Since 2006 the body of evidence has shifted significantly**

In 2006 five negative clinical studies were published which were conducted by different research teams around the world, using either Cuban or non-Cuban policosanols products.

In Germany, Berthold et al (2006) conducted a 12-week randomised study of 143 Caucasian subjects with hypercholesterolaemia or combined hyperlipidaemia. The multicentre study used CSP at doses of 10, 20, 40 and 80 mg/day. In contrast to previous studies, policosanols failed to significantly reduce LDL-cholesterol, total cholesterol, HDL-cholesterol, triglycerides and other lipid parameters at all test doses. In a US double-blind, placebo-controlled trial of 40 healthy adults with mild hypercholesterolaemia, conducted by Dulin et al (2006), subjects were assigned to receive oral

policosanol 20 mg or placebo once daily for 8 weeks. No significant changes were seen for LDL-cholesterol, total cholesterol, HDL-cholesterol, triacylglycerol, C-reactive protein and nuclear magnetic resonance spectroscopy-determined profiles. Also in the United States, [Cubeddu et al \(2006\)](#) divided subjects with LDL-cholesterol levels from 140 to 189 mg/dL into four groups and compared policosanol 20 mg to atorvastatin 10 mg, combination therapy or placebo for 12 weeks ([Cubeddu et al 2006](#)). In total, 99 patients took part and groups were well matched at baseline. Yet again, policosanol failed to have a significant effect on any lipid parameter and produced no additional lipid-lowering effects when added to atorvastatin. In Canada, [Kassis and Jones \(2006\)](#) compared policosanol 10 mg/day to placebo in 21 people over a period of 28 days. The double-blind, crossover study also failed to find significant changes to plasma lipid levels for total, LDL-cholesterol, HDL-cholesterol and triacylglycerol concentrations with policosanol treatment. In South Africa, [Greyling et al \(2006\)](#) conducted a double-blind study involving 19 hypercholesterolaemic and familial hypercholesterolaemic subjects who received either policosanol 20 mg/day or placebo for 12 weeks. After a 4-week wash-out period, the interventions were crossed over and treatment recommenced. No significant differences in total cholesterol and LDL-cholesterol from baseline to end or between policosanol and placebo were seen in the hypercholesterolaemic or familial hypercholesterolaemic groups.

Since 2006, the negative evidence has continued to accumulate as studies using animal models and clinical trials consistently fail to find significant lipid-lowering activity for either CSP or its other forms ([Backes et al 2011](#), [Francini-Pesenti et al 2008](#), [Kassis 2008](#), [Kassis & Jones 2008](#), [Kassis et al 2007](#), [Marinangeli et al 2007](#), [Martino et al 2013](#), [Swanson et al 2011](#)).

In 2011, two more negative clinical trials were published. [Backes et al \(2011\)](#) used a modified policosanol (MP) product in an attempt to improve the absorption of policosanol and determine if this new form would produce better results. MP was administered as stand-alone treatment (20 mg/daily) or together with statins and compared to a placebo group over an 8-week test period. In both groups receiving MP there were no significant changes to major lipoproteins.

[Swanson et al \(2011\)](#) found that a dose of 20 mg daily of standard policosanol failed to normalise any of the dyslipidaemic parameters measured (LDL-cholesterol, HDL-cholesterol, triglycerides) in their randomised, double-blind, crossover study. The study involved 54 people with HIV who received either 20 mg of policosanol or placebo for 12 weeks, followed by a 4-week washout period and 12 more weeks of the alternative treatment ([Swanson et al 2011](#)). No adverse effects were reported.

#### **Clinical note — Policosanol controversy**

It is now certain that policosanol does not have significant lipid-lowering activity as the more recent clinical trials have failed to confirm earlier positive results. Several theories may explain the discrepancy, such as differences in the purity and composition of different policosanol products, insufficient test timeframes, differences between test subjects and, of course, researcher bias or contamination of product.

Researchers external to the original Cuban research groups began testing these different theories to uncover the answer. Theories proposing differences in octacosanol content have been discounted as the various policosanol products tested externally have contained similar concentrations to the original Cuban blend. Another suggestion is that products may have differed in minor alcohol content, explaining the disparate results. To test this theory, Cuban policosanol has been directly compared to other policosanol products in various animal models. Using a hamster model, [Kassis et al \(2007\)](#) compared Dalmer Cuban policosanol to an alternative Degussa policosanol mixture and found that neither treatment had a significant effect on lipids. A second research team, headed by [Marinangeli](#), also compared Cuban policosanol to another product with a similar amount of octacosanol and found no differences between them for tissue, plasma and faecal policosanol levels in an animal model ([Marinangeli et al 2007](#)). In regard to timeframes, Cuban clinical studies indicate that lipid-lowering activity can be observed by 4 weeks of treatment and reaches a maximal effect between 6 and 8 weeks. Studies conducted by [Berthold et al \(2006\)](#), [Greyling et al \(2006\)](#) and [Cubeddu et al \(2006\)](#) lasted 12 weeks and still found no significant activity, so this theory can also be discounted.

More recently, a modified form of policosanol with improved absorption was tested by [Backes et al \(2011\)](#), but no significant lipid-lowering activity was observed. Finally, genetic differences between test subjects and differences in dietary habits could account for the varied responses between test subjects; however this appears unlikely.

#### **Wheatgerm-derived policosanol**

No beneficial effects on blood lipid profiles were observed in a double-blind, randomised study of 58 subjects with normal to mildly elevated plasma cholesterol who were given 20 mg wheatgerm policosanol in a short, 4-week study ([Lin et al 2004](#)).

#### **Intermittent claudication**

Policosanol treatment for intermittent claudication has produced encouraging results in several randomised studies ([Castano et al 1999b, 2001a, 2003a](#)).

Policosanol 10 mg/day taken for 6 months significantly increased initial claudication walking distance by approximately 70 metres and absolute claudication by approximately 140 metres in one double-blind study, whereas placebo produced no changes (Castano et al 1999b). A single-blind study using 20 mg policosanol daily showed significant improvements after 6 months' treatment, which further increased after 12 months (Castano et al 2001b). In both studies patients in the policosanol group reported improvements in lower-limb symptoms that were greater than those in the placebo group.

More recently, policosanol (10 mg twice daily) was shown to be as effective as ticlopidine (250 mg twice daily) for improving walking distances of claudicant patients (Castano et al 2004b). In the 20-week double-blind, randomised study of 28 subjects, policosanol significantly increased mean values of initial and absolute claudication distances from 162.1 to 273.2 metres and from 255.8 to 401.0 metres, respectively, which was not significantly different to ticlopidine. Both treatments were well tolerated.

In 2008, a randomised, double-blind study comparing policosanol (10 mg/day) to aspirin (100 mg/day) was published showing that policosanol modestly but significantly increased the initial and absolute claudication walking distances whereas no change occurred with aspirin (Illnait et al 2008). The study involved 39 volunteers and treatment lasted for 10 weeks.

Until these results can be confirmed by other research groups, these results remain uncertain.

#### Practice points/Patient counselling

- Policosanol can no longer be considered an efficacious lipid-lowering treatment because of a spate of negative studies showing no significant effect.
- It is a potentially useful treatment in claudication; however, more research is required to confirm its effects.
- Policosanol may have platelet aggregation inhibitor activity.
- Safety studies indicate that it is well tolerated and has a wide safety margin.

## OTHER USES

### Pre-existing coronary heart disease

A randomised double-blind study of 45 subjects with documented coronary heart disease found that a dose of 10 mg policosanol daily increased maximum oxygen uptake and exercise electrocardiograph responses. The effects were further enhanced by co-administration of 125 mg aspirin (Stusser et al 1998).

### Cerebrovascular disease

In two different experimental models, policosanol had anti-ischaemic activity when administered after

induction of cerebral ischaemia, suggesting a possible therapeutic effect in cerebrovascular disease (Molina et al 1999).

## DOSAGE RANGE

The doses tested in clinical trials range from 5 to 20 mg/day.

### More specific doses

- Hypercholesterolaemia: 5–20 mg/day has been tested (recent evidence now indicates it is ineffective).
- Intermittent claudication: 10–20 mg/day — 3 months' continual use may be required before effects are observed (uncertain efficacy).

## TOXICITY

Studies using several animal models have confirmed no carcinogenic effects and no signs of toxicity at doses as high as 500 mg/kg (Aleman et al 1994a, 1994b). This dose is hundreds of times greater than the maximal recommended therapeutic dose (20 mg/day), thereby indicating an excellent safety profile (Mesa et al 1994).

## ADVERSE REACTIONS

A pharmacovigilance study of 2252 subjects aged 60 or more years with coronary, cerebrovascular and peripheral artery disease and treated with policosanol (5, 10 or 20 mg/day) at seven major medical centres found that long-term tolerability of policosanol in elderly patients at high vascular risk was very good (Fernandez et al 2004).

## SIGNIFICANT INTERACTIONS

### Aspirin

Increased antiplatelet effects may develop — patients taking aspirin and policosanol concurrently should be observed for increased bleeding or bruising.

### Warfarin

Current evidence suggests that there is no interaction between policosanol and warfarin. One clinical study confirmed that the addition of policosanol to warfarin therapy does not enhance the prolongation of the bleeding time induced by warfarin alone (Carbajal et al 1998b). Caution with doses > 10 mg/day.

## CONTRAINDICATIONS AND PRECAUTIONS

Suspend use of high doses 1 week before major surgery.

## PREGNANCY USE

Safety has been investigated in animal tests with no evidence of teratogenicity or any other embryonal toxicity (Rodriguez & Garcia 1994, 1998, Rodriguez et al 1997).

## ! PATIENTS' FAQs

### *What can this supplement do for me?*

It now appears unlikely that policosanol can significantly lower cholesterol levels. Early studies suggested this effect was as strong as conventional cholesterol-lowering medications; however, more recent studies have found no effect. It may also be useful in intermittent claudication but confirmation is required by other researchers before this is certain.

### *When will it start to work?*

Early studies suggest that maximal lipid-lowering effects are seen after 6–8 weeks of continuous use; however, new evidence casts doubt over its efficacy.

### *Are there any safety issues?*

Policosanol has a wide safety margin and is well tolerated.

# Prebiotics

**HISTORICAL NOTE** Gibson & Roberfroid (1995) introduced the concept of prebiotic as ‘a non-digestible food ingredient that beneficially affects the host by selectively stimulating the growth and/or activity of one or a limited number of bacteria in the colon and thus improves health’. This concept has been further developed to define prebiotics as ‘selectively fermented ingredients that allow specific changes, both in the composition and/or activity of the gastrointestinal microflora that confer benefits upon host wellbeing and health’ (Roberfroid 2007b).

## BACKGROUND AND RELEVANT PHARMACOKINETICS

Numerous components appear to have prebiotic characteristics, but some will not be classified as prebiotics because they may not meet all the criteria, i.e. not metabolised (hydrolysed or absorbed) in the upper gastrointestinal tract (GIT), demonstrate selective fermentation by one or a limited number of potentially beneficial intestinal bacteria and change the colonic microflora to a healthier composition (Gibson & Roberfroid 1995, Roberfroid 2007b). To date, the most well-researched prebiotics are inulin, lactulose, fructooligosaccharides (FOS) and galactooligosaccharides (GOS) (Roberfroid 2007a).

One of the key characteristics of prebiotics is to stimulate the selective growth of intestinal microorganisms and, in particular, the growth of lactobacilli and bifidobacteria.

Studies have demonstrated that the intestinal microflora of breastfed infants is characterised by high levels of bifidobacteria and lactic acid bacteria because oligosaccharides occur naturally in breastmilk. Formula-fed infants were found to have more *Bacteroides*, clostridia and Enterobacteriaceae and lower levels of the beneficial microorganisms (Coppa et al 2006).

Bifidobacteria are well-known defences against pathogenic bacteria and are significant for promoting gut health (Brunser et al 2006, Cummings & Macfarlane 2002, Gibson 1998, Gibson & Roberfroid 1995). In addition to stabilising the gut microflora, prebiotics may have a role in allergy: reports indicate that infants with allergy had lower levels of lactobacilli and bifidobacteria (Bjorksten et al 2001) and feeding prebiotics was able to rectify this. Increasingly, prebiotics have been added to infant milk formulas in order to simulate the composition of human breastmilk prebiotic oligosaccharides.

In recent years, there has been a focus on using multiple prebiotics together rather than a single component; combinations of long-chain FOS and short-chain GOS have been utilised mainly because different gastrointestinal microorganisms may require different substrates for optimal growth.

In both adults and the young, prebiotics are reported to have other health-promoting properties and they may have a role in the management of a

number of diseases and conditions. Altered gastrointestinal microflora and abnormal colonic fermentation are also noted in some conditions, such as inflammatory bowel disease (IBD) and irritable bowel syndrome (IBS) (King et al 1998); treatment with prebiotics or synbiotics may normalise the altered microflora.

Prebiotics as indigestible components are known to have laxative properties and are used as bulking agents for gastrointestinal health. The end products of the prebiotic fermentation in the colon are short-chain fatty acids (SCFAs), while have direct effects on the intestinal cells and stimulate intestinal peristalsis (Gibson 1998, 1999, Gibson & Roberfroid 1995, Gibson et al 1995).

Both lactobacilli and bifidobacteria species in the colon have important roles in immune stimulation and prevention of infection and diarrhoea (Gorbach et al 1987, Macfarlane et al 2006, Saavedra et al 1994). Some bifidobacteria and lactobacilli strains may have antimutagenic and antitumour properties; prebiotics such as inulin appear to inhibit colonic cancer cell growth (Pool-Zobel & Sauer 2007).

Prebiotics also demonstrate anti-inflammatory activity in the GIT, with lactulose, inulin and FOS all demonstrating GIT anti-inflammatory activity in animal models and/or human research (Cherbut et al 2003, Koleva et al 2012, Lara-Villoslada et al 2006, Looijer-Van Langen & Dieleman 2009, Yasuda et al 2012).

## CHEMICAL COMPONENTS

Prebiotics are principally oligosaccharides or disaccharides, of which there are various types: oligofructose, inulins, isomaltooligosaccharides, lactosucrose, GOS, lactulose, pyrodextrins and xylooligosaccharides. Potential prebiotics, their food sources and their targeted microorganisms are highlighted in Table 1.

Inulins are multiple fructose units and inulin degradation results in oligofructose. GOS occur naturally in breastmilk. Fructans are linear or branched fructose polymers and the GOS are synthesised from lactose by the action of beta-galactosidase. FOS are the inulin-type fructans that can be readily obtained from plant sources. Both GOS and FOS are widely used in the food industry (Yang & Silva 1995).

**TABLE 1 PREBIOTIC SUBSTANCES AND THE ORGANISMS WHOSE GROWTH THEY PROMOTE (HUDSON & MARSH 1995, TERAMOTO ET AL 1996, TEURI & KORPELA 1998, VAN LOO ET AL 1995, 1998)**

Prebiotic compound	Food sources	Targeted microorganisms
β-glucooligomers	Oats	<i>Lactobacillus</i> spp.
Fructooligosaccharides and inulin	Jerusalem artichokes, garlic, onions, chicory roots, asparagus, wheat	<i>Bifidobacterium</i> spp.
Galactooligosaccharides	Cow's milk, yoghurt, human milk	<i>Bifidobacterium</i> spp.
Galactosyl lactose	Human milk	<i>Bifidobacterium</i> spp.
Lactitol	None known	<i>Lactobacillus</i> spp.; <i>Bifidobacterium</i> spp.
Lactosucrose	None	<i>Bifidobacterium</i> spp.
Lactulose	UHT milk	<i>Lactobacillus</i> spp.; <i>Bifidobacterium</i> spp.
Polydextrose	None known	<i>Lactobacillus</i> spp.; <i>Bifidobacterium</i> spp.
Raffinose	Legumes, beets	<i>Lactobacillus</i> spp.; <i>Bifidobacterium</i> spp.
Xylooligosaccharides	Oats	<i>Bifidobacterium</i> spp.

**Clinical note — The hygiene hypothesis**

The intestinal microflora is crucial for the development of the immune system (Ouwehand et al 2002) and the 'hygiene theory' suggests that exposure to microorganisms is required for this. The consumption of foods containing microorganisms for health-promoting properties has a long history. Probiotics are microorganisms that can 'beneficially affect the host physiology by modulating mucosal and systemic immunity, as well as improving nutritional and microbial balance of the intestinal tract' (Gibson & Roberfroid 1995, Salminen et al 1998).

**Clinical note — Synbiotics**

Synbiotics are products that contain both probiotic and prebiotic agents (Schrezenmeir & de Vrese 2001). The combination is supposed to enhance the survival of the probiotic bacteria through the upper GIT, improve implantation of the probiotic in the colon and have a stimulating effect on the growth and/or activities of both the exogenously-provided probiotic strain(s) and the endogenous inhabitants of the bowel (Casiraghi et al 2007). In recent years, there has been a trend to increasingly use synbiotics for a synergistic health-promoting effect, but this also makes it difficult to evaluate the individual effects of each component.

**FOOD SOURCES**

Low levels of prebiotic compounds can be found in artichokes, asparagus, bananas, chicory root, garlic,

leek, onions and wheat. Inulin and oligofructose occur naturally in these foods. Commercially produced prebiotics are extracted from chicory roots or Jerusalem artichokes or synthesised from sucrose and are used widely in the food industry. Dietary intake of prebiotics is variable, with the intake for Americans being in the range 1–4 g/day and on average a higher intake among Europeans, who consume 3–10 g/day (Delzenne 2003).

**DEFICIENCY SIGNS AND SYMPTOMS**

Clear deficiency signs are difficult to establish because the symptoms may vary enormously. Local signs and symptoms of disruption of the intestinal microflora leading to an imbalance (intestinal dysbiosis) include bloating, flatulence, abdominal pain, diarrhoea and/or constipation and fungal overgrowth (such as *Candida*). An imbalance in the gastrointestinal microflora can be caused by the use of antibiotics, GIT infections, stress and dietary factors (Hawrelak & Myers 2004). Administration of prebiotics, probiotics or synbiotics is used as a means of restoring this microflora imbalance.

**MAIN ACTIONS**

The health benefits claimed for prebiotics mainly stem from their ability to increase numbers of beneficial organisms in the colon, modulate the immune response, reduce numbers of potentially pathogenic microorganisms (PPMs) in the GIT and stimulate SCFA production.

**Stimulation of beneficial bacteria and prevention of GIT infections**

Many animal and human studies have demonstrated that prebiotics modulate the gut microflora by

increasing bifidobacteria and lactobacilli levels (Bouhnik et al 1997, Gibson & Wang 1994, Langlands et al 2004).

Prebiotics are fermented by the microflora in the proximal colon, resulting in the production of SCFAs (acetic, propionic and butyrate acids) and gas (CO<sub>2</sub> and H<sub>2</sub>). Consequently, the lower intraluminal pH inhibits the growth of PPMs while simultaneously creating an atmosphere more conducive to the growth of lactobacilli and bifidobacteria (Walker et al 2005). As a result of prebiotics stimulating the growth of beneficial bacteria, these microorganisms secrete antimicrobial compounds and can inhibit colonisation of the pathogenic bacteria and prevent their adherence to the intestinal epithelium (Shoaf-Sweeney & Hutkins 2009). Adherence can also be limited as a result of the oligosaccharide's terminal sugars interfering with the receptors on the pathogenic bacteria (Hopkins & Macfarlane 2003, Zopf & Roth 1996); reduced adherence of enteropathogenic *Escherichia coli* in HeP and Caco-2 cells has been noted with GOS, for example (Shoaf et al 2006). GOS have also been shown to inhibit binding of *Vibrio cholerae* toxin to its receptor in the human GIT (Sinclair et al 2009) and reduce colonisation and pathology associated with *Salmonella typhimurium* infection in a murine model (Searle et al 2009).

### Immunomodulation and enhanced mucin production

The mechanisms whereby prebiotics have immunomodulatory effects (modulate cytokine and antibody production) are largely unknown and the proposed mechanisms include beneficial changes in the intestinal microflora and increased production of both mucin and SCFAs. There may also be changes in the gut-associated lymphoid tissues (GALT) as a result of prebiotic fermentation in the colon (Forchielli & Walker 2005). The SCFAs are beneficial to the host as an energy source and enhance mucosal integrity with increased production of mucin, binding to receptors on immune cells within GALT and limiting translocation. Mucin may limit bacterial translocation and acts as a barrier against luminal contents by protectively covering the intestinal epithelial cells. There is little information about the effects of prebiotics on mucin production, but both animal and human research has noted increased mucin production associated with inulin and FOS supplementation (Fontaine et al 1996, Ten Bruggenate et al 2006). This increase appears to be mediated via increases in mucin 3 gene expression, as well as increases in colon crypt depth with more mucin-secreting goblet cells per crypt (Paturi et al 2012).

Both prebiotics and probiotics are reported to have beneficial effects in reducing the effects of colitis by altering the gastrointestinal microflora due to stimulating growth of the protective bacteria and reducing colonisation with potentially hazardous bacteria (Sartor 2004). Prebiotics (mainly inulin and FOS) may also ameliorate inflammation as a result

of reducing the activity of proinflammatory transcription factors (e.g. NF-κB), and by the increased production of SCFAs (Cavin et al 2005, Holma et al 2002, Kinoshita et al 2002, Millard et al 2002). Animal studies show conflicting findings, with the majority reporting a reduction in inflammation with prebiotic supplementation (Cherbut et al 2003) and others reporting that there is no protection from FOS or GOS in rat models of colitis (Looijer-Van Langen & Dieleman 2009). In recent years, some human studies have been undertaken and mixed results are reported. Butyrate is a major source of energy for colonocytes, and in vitro studies indicate that butyrate has anti-inflammatory effects (Saemann et al 2000, Segain et al 2000); butyrate and acetate also enhance mucin secretion.

### Cancer prevention

Various in vitro and animal studies have been conducted to investigate the role of prebiotics and synbiotics for their anticancer effects, but there are only a limited number of studies in humans (Pool-Zobel & Sauer 2007). Animal studies have shown that prebiotic treatment is beneficial in reducing precancerous aberrant crypt foci and the effects may be more pronounced with synbiotics. Rowland et al (1998) reported that the effect is enhanced with synbiotics such as inulin plus *Bifidobacterium longum* in their study of azoxymethane-induced aberrant crypt foci in rats. Oligofructose-enriched inulin plus *Lactobacillus rhamnosus* and *B. lactis* treatment prevented azoxymethane-induced suppression of natural killer (NK) cell activity in Peyer's patches (Roller et al 2004) and, similarly, a study (Le Leu et al 2005) demonstrated increased apoptotic response with resistant starch plus *B. lactis* treatment.

### OTHER ACTIONS

#### Mineral metabolism

Animal studies have indicated that prebiotics such as inulin and oligofructose can affect calcium bioavailability and increase calcium absorption. A number of mechanisms have been proposed for this action, including the increased production of SCFAs, which increase the solubility of minerals and also facilitate the colonic absorption of calcium and magnesium (Demigne et al 2008).

#### Improved bioavailability of phyto-oestrogens

An interesting animal (rat) study has found that concurrent consumption of FOS and the soy isoflavones, genistein and daidzein, significantly improved the bioavailability of these compounds. The relative absorption of genistein was ~20% higher in FOS-fed rats than in controls. In addition, the presence of both phyto-oestrogens in serum was maintained for longer in FOS-fed rats than in controls, suggesting that FOS enhanced colonic absorption of these compounds (Uehara et al 2001).

This result may be especially relevant to women postantibiotic therapy, where the metabolism and

subsequent absorption of phyto-oestrogens appear to be impaired (Kilkinen et al 2002). Bifidobacteria have been shown to possess  $\beta$ -glucosidase activity, and FOS administration has resulted in enhanced  $\beta$ -glucosidase activity in animal models (Rowland et al 1998) as well as improved phyto-oestrogen bioavailability (Ohta et al 2002). FOS consumption not only aids in the re-establishment of a healthy GIT microflora, but its consumption also increases colonic  $\beta$ -glucosidase activity, resulting in enhanced deglycosylation and thus increased colonic concentrations of the medicinally active aglycones.

The synergistic effect of FOS supplementation with soy isoflavones on bone health has been observed in an osteopenic rat model, where coadministration of the two agents was found to exert the strongest effect in inhibiting bone loss in rats. This was due, at least in part, to FOS-induced increases in calcium absorption and equol production (Kimira et al 2012). Another study utilising an ovariectomised rat model of osteoporosis also found a strong synergistic effect between soy isoflavones and FOS supplementation in preventing bone loss (Hooshmand et al 2010).

## CLINICAL USE

### Irritable bowel syndrome

A multicentre, double-blind randomised controlled trial (RCT) by Olesen and Gudmand-Hoyer (2000) did not find benefits for the use of FOS in the treatment of IBS, similar to the findings of Hunter et al (1999), who utilised oligofructose in their double crossover study investigating IBS.

Conversely, in a randomised, single-blind, placebo-controlled, crossover trial, supplementation of 3.5 g/day of GOS to subjects with IBS significantly improved stool consistency, flatulence scores, bloating scores and overall IBS symptom scores compared to placebo (all  $P < 0.05$ ) over a 4-week treatment period. Supplementation of 7 g/day resulted in significant improvements in overall IBS symptom scores and a reduction in anxiety levels compared to placebo (both  $P < 0.05$ ). However, there was also a significant increase in bloating scores relative to baseline when subjects were taking the higher dosage ( $P < 0.05$ ) (Silk et al 2009).

### Inflammatory bowel disease

In a study of patients with active IBD, 14 patients presenting with ulcerative colitis (UC) and 17 patients presenting with Crohn's disease (CD) received either standard medication treatment or the medications with an additional 10 g/day lactulose dose for 4 months. At the end of the study there were no differences in the clinical or endoscopic score, although the UC group receiving the lactulose treatment reported an improved quality of life compared to the control group ( $P = 0.04$ ) (Hafer et al 2007).

### Crohn's disease

At present, the role of prebiotics in the management of CD remains unknown due to a limited number of studies.

A small open-label study of 10 patients with active ileocolonic CD who were treated with FOS (15 g/day for 3 weeks) reported a significant reduction in disease activity scores (30% reduction;  $P < 0.01$ ) and inflammation, with an increase in interleukin-10 (IL-10)-positive dendritic cells and Toll-like receptor 2 and Toll-like receptor 4 expression. It is noteworthy that patients entering remission had increased mucosal-associated bifidobacteria (Lindsay et al 2006).

This positive, but small, open-label trial was followed up with a double-blind, placebo-controlled RCT. One hundred and three subjects with active CD were supplemented with 15 g/day FOS or placebo for 4 weeks in conjunction with standard medications. While there was an increased percentage of IL-10-positive dendritic cells ( $P = 0.035$ ), there was no significant difference in response rate or rate of remission. Surprisingly, there were no changes in faecal bifidobacterial concentrations in the FOS-treated group. It is also worth noting that 19% of the FOS-treated group withdrew from the trial due to adverse gastrointestinal effects (flatulence, borborygmi and abdominal pain) (Benjamin et al 2011).

In a small, randomised, open-label trial, Hafer et al (2007) investigated the efficacy of lactulose therapy (10 g/day for 4 months) compared to standard care in patients with CD ( $n = 17$ ). No significant improvements in clinical activity index, endoscopic score or immunohistochemical parameters were observed in CD patients receiving lactulose, in comparison to controls (Hafer et al 2007).

A RCT of 30 patients with CD postoperative ileocaecal resection, who were treated with Synbiotic 2000, a combination of four prebiotic components plus a probiotic mixture of four lactic acid strains (*Pediococcus pentosaceus*, *Lactobacillus raffinolactis*, *Lactobacillus paracasei* subsp. *paracasei* F19, *Lactobacillus plantarum*, 2.5 g beta-glucans, 2.5 g inulin, 2.5 g pectin, 2.5 g resistant starch), did not show prevention of relapse 24 months later (Chermesh et al 2007). In another study (duration:  $13.0 \pm 4.5$  months) (Fujimori et al 2007), 10 non-hospitalised patients with active CD were treated with high-dose synbiotic therapy consisting of bifidobacterium and lactobacillus (75 billion colony-forming units (CFU)/day) plus psyllium (9.9 g/day); only three patients did not experience any benefit.

These differing results may be due to the variation in fibres used in the trials, as well as differences in the probiotic strains utilised.

### Ulcerative colitis

The results from a number of animal studies have indicated that prebiotics may be of therapeutic value in UC and preliminary human studies appear to show similar results. A small randomised,

double-blind, placebo-controlled trial evaluated 19 patients with active UC (mild/moderate). Subjects received prebiotic treatment (12 g/day of oligofructose-enriched inulin, ratio 1:1) or placebo plus 3 g/day of mesalazine for 2 weeks. Subjects in the prebiotic group experienced significantly fewer dyspeptic symptoms and a reduction of intestinal inflammation, as determined by faecal calprotectin levels, which decreased after 1 week of treatment (from 4377 to 1033;  $P < 0.05$ ). However, there was no change in prostaglandin E<sub>2</sub> secretion and IL-8 production (Casellas et al 2007).

The effectiveness of lactulose therapy in UC was evaluated in a small, randomised, open-label trial. Seven subjects consumed 10 g/day of lactulose in conjunction with their standard medications for 4 months, while another seven received standard care only. There was a significant improvement seen in the clinical activity index in the lactulose-treated group (54% reduction;  $P = 0.047$  compared to baseline). The decrease in the clinical activity index was not significant when compared to controls, however ( $P = 0.09$ ). Four patients in the lactulose group achieved remission versus none in the control group. Quality-of-life scores significantly improved in the lactulose group compared to controls ( $P = 0.037$ ) and there was also a trend for a reduction in steroid dose ( $P = 0.063$ ) in this group (Hafer et al 2007).

In a double-blind RCT of 18 patients with active UC, synbiotic treatment with 12 g oligofructose-enriched inulin (1:1) plus *Bifidobacterium longum* for 4 weeks resulted in reduced colonic inflammation, decreased human beta-defensin mRNA, tumour necrosis factor- $\alpha$  and IL-1 $\alpha$ , and improved sigmoidoscopy scores, although there was no difference in clinical measures (Furrie et al 2005).

In another RCT, the efficacy of synbiotic therapy was compared to either prebiotics or probiotics and involved 120 outpatients with UC in remission (Fujimori et al 2009). Each group of patients enrolled in the study were treated with either one capsule per day consisting of *B. longum*  $2 \times 10^9$  CFU (probiotic group) or  $2 \times 4$  g doses of psyllium (prebiotic group) or both the probiotic plus prebiotic (synbiotic group) for 4 weeks. At the end of the study, C-reactive protein decreased significantly ( $P = 0.04$ ) and the quality-of-life scores in the Inflammatory Bowel Disease Questionnaires were also significantly improved for the synbiotic treated group; the score for bowel function was significant in the prebiotic group ( $P = 0.04$ ).

### Pouchitis

There are only a limited number of studies that have investigated the role of prebiotics or synbiotics in pouchitis.

A small open-label study of 10 patients with pouchitis (antibiotic-refractory or antibiotic-dependent) treated with a synbiotic mixture of FOS plus *Lactobacillus rhamnosus* GG reported complete remission as determined by clinical and endoscopic

criteria (Friedman & George 2000). In a crossover study of 20 patients with ileal pouch-anal anastomosis, daily treatment with 24 g of inulin or placebo for 3 weeks did not change the clinical activity scores, although there was a reduction in inflammation ( $P = 0.01$ ) and increased faecal butyrate concentrations. Lactobacilli and bifidobacteria levels were not affected, although a significant reduction in faecal levels of *Bacteroides fragilis* was reported (Welters et al 2002).

### Constipation

The use of lactulose has a long history and it has been used successfully as an osmotic laxative to treat constipation (de Schryver et al 2005, Petticrew et al 1997). Likewise, FOS and GOS also have laxative effects: Gibson et al (1995) demonstrated that feeding 15 g of FOS or 15 g inulin per day could significantly increase stool output. Utilising 9 g GOS/day, one study found an increase in defecation frequency (from 5.9 to 7.1 movements/week) in elderly subjects over a 2-week treatment period. There was also a trend for easier defecation ( $P = 0.07$ ) during the GOS phase of the trial (Teuri & Korpela 1998).

Two RCTs evaluated the laxative effects of GOS in healthy adult subjects with a tendency to constipation. At a daily dose of 5 and 10 g there were significant improvements in defecation frequency — from 0.92 to 1.07 movements daily ( $P < 0.05$ ) and from 0.85 to 0.97 times per day ( $P < 0.05$ ), respectively (Niittynen et al 2007).

### Diarrhoea

Various prebiotic components have been utilised in clinical trials to evaluate their efficacy in diarrhoea of different origins.

#### Traveller's diarrhoea

A double-blind RCT of 244 people travelling to medium-high-risk destinations and at risk of traveller's diarrhoea reported that those subjects who were treated with FOS (10 g) experienced increased wellbeing and less severe diarrhoea, although there was no significant difference in the incidence of diarrhoea (Cummings et al 2001).

A more recent double-blind RCT evaluated the potential of GOS administration to prevent traveller's diarrhoea. Subjects ingested 2.6 g GOS once daily starting 7 days before reaching their holiday destination and continued taking it daily throughout their holiday. Compared to the placebo group, subjects in the GOS group experienced a 40% decrease in the incidence ( $P < 0.05$ ) and a 48% reduction in duration of traveller's diarrhoea ( $P < 0.05$ ). Additionally, they suffered less abdominal pain ( $P < 0.05$ ) and experienced improved quality of life ( $P < 0.05$ ) (Drakoularakou et al 2009).

#### *Clostridium difficile*-associated diarrhoea (CDAD)

In a double-blind RCT, 142 patients with CDAD in hospital were randomised to receive oligofructose

or placebo as well as the standard antibiotic treatment for 30 days and followed up 30 days later. It was found that the prebiotic-treated patients had increased bifidobacteria levels and reduction in the rate of relapse and experienced significantly less diarrhoea compared to placebo (8% vs 34%,  $P < 0.001$ ) (Lewis et al 2005a).

In another double-blind RCT of 435 hospitalised patients who were receiving antibiotics, treatment with oligofructose for 7 days was compared to placebo. After a 7-day follow-up period, there was a significant increase in bifidobacteria concentrations in the prebiotic group, although there was no difference in the incidence of *Clostridium difficile* (Lewis et al 2005b).

### Allergic disease and food hypersensitivity

Clinical trials confirm that prebiotic-enhanced infant formula ingested during the first 6 months of life reduces the risk of atopic disease. The effect is not limited to the 6-month treatment period but seems to provide longer-term protection.

In a double-blind RCT, Moro et al (2006) evaluated the effects of a prebiotic-enhanced infant formula (FOS and GOS combination) on the incidence of atopic dermatitis during the first 6 months of life in formula-fed infants at high risk of atopy development. Atopic dermatitis developed in 23% of infants in the control group compared to 10% in the prebiotic group ( $P = 0.014$ ) over the 6-month intervention period. Subjects in the prebiotic group were also found to have significantly reduced plasma levels of total IgE ( $P = 0.007$ ), IgG<sub>2</sub> ( $P = 0.029$ ) and IgG<sub>3</sub> ( $P = 0.0343$ ), as well as cow's milk protein-specific IgG<sub>1</sub> ( $P = 0.015$ ), suggesting that FOS and GOS supplementation induces an antiallergic antibody profile (Nauta et al 2008).

These same infants were followed up over the next 18 months. Those infants who received the prebiotic-enhanced formula for the first 6 months of life were at reduced risk of developing atopic disease over the follow-up period. Infants in the control group experienced a significantly higher rate of atopic disease, such as atopic dermatitis (27.9% vs 13.6%), recurrent wheezing (20.6% vs 7.6%) and allergic urticaria (10.3% vs 1.5%) compared to infants in the prebiotic group (all  $P < 0.05$ ) (Arslanoglu et al 2010).

A Cochrane systematic review (Osborn & Sinn 2013) investigated the effectiveness of prebiotics for the prevention of allergic disease or food hypersensitivity in infants. Four studies including 1428 infants were eligible for inclusion. Meta-analysis of two studies (226 infants) found no significant difference in rates of infant asthma, although significant heterogeneity was observed between the two studies. Meta-analysis of four studies found a significant reduction in eczema incidence in the prebiotic-treated groups (1218 infants, typical risk ratio 0.68;  $P = 0.03$ ), with no statistically significant heterogeneity found between studies.

### Improved immune response

Prebiotics, like FOS, have long been suggested to have immune-enhancing effects (Bornet & Brouns 2002, Watz et al 2005). It is, however, only recently that human trials with hard end points have been completed, in both children and adults.

### Use in children

Various studies have evaluated whether long-term prebiotic use reduces the incidence of various infections and reduces the use of antibiotic medication, overall producing positive results.

One of the first of these trials investigated the effects of a prebiotic mixture (containing a combination of FOS and GOS) in protecting against infection during the first 6 months of life in formula-fed infants. In this randomised, double-blind, placebo-controlled trial, infants allocated to the prebiotic group experienced significantly fewer episodes of all types of infections combined ( $P = 0.01$ ) compared to those in the placebo group. There was also a trend for fewer episodes of upper respiratory tract infection ( $P = 0.07$ ) and fewer infections requiring antibiotic treatment ( $P = 0.10$ ) in the prebiotic group. Additionally, the cumulative incidence of recurring infection and recurring respiratory tract infection was 3.9% and 2.9% in the prebiotic group versus 13.5% and 9.6% in the placebo group, respectively ( $P < 0.05$ ) (Arslanoglu et al 2008).

This same infant cohort was followed up over the next 1.5 years. Those infants who received the prebiotic-enhanced formula for the first 6 months of life experienced significantly fewer episodes of medically-diagnosed respiratory tract infections ( $P < 0.01$ ), fever episodes ( $P < 0.00001$ ) and fewer antibiotic prescriptions ( $P < 0.05$ ) compared to those in the placebo group (Arslanoglu et al 2010).

In an open-label, placebo-controlled, randomised study, Bruzzese et al (2009) also investigated the efficacy of a prebiotic-enhanced infant formula (a combination of GOS and FOS) on infection incidence in infants. The prebiotic-enhanced formula or a standard infant formula was consumed over the initial 12 months of life. During this period, the incidence of gastroenteritis was 59% lower in the prebiotic group ( $P = 0.015$ ). Additionally, the number of children suffering from recurrent upper respiratory tract infections tended to be lower in the prebiotic group (28% vs 45%;  $P = 0.06$ ) and the number of children prescribed multiple antibiotic courses per year was also lower (40% vs 66%;  $P = 0.004$ ).

A shorter double-blind RCT was conducted involving children (aged 7–19 months) attending day-care centres. The authors found that 21 days of treatment with FOS significantly reduced the number of infectious diseases requiring antibiotic treatment ( $P < 0.001$ ), episodes of diarrhoea and vomiting ( $P < 0.001$ ) and episodes of fever ( $P < 0.05$ ) compared to controls (Waligora-Dupriet et al

2007). In another RCT investigating the effects of FOS in toddlers (4–24-month-olds) attending day care, FOS administration was found to significantly reduce antibiotic use (32% reduction;  $P = 0.001$ ) and day-care absenteeism (61% decrease;  $P = 0.025$ ) compared to those in the control group. There was also a 34% reduction in episodes of fever in combination with any cold symptoms ( $P = 0.001$ ) and a 61% decrease in episodes of fever in association with diarrhoea ( $P < 0.05$ ) in the FOS-supplemented group (Saavedra & Tschernia 2002).

#### Use in adults

Treatment with GOS for 8 weeks around exam time had multiple beneficial effects according to a double-blind RCT involving 427 academically stressed undergraduate students. Students received placebo, 2.5 or 5.0 g GOS daily for 8 weeks. Active treatment resulted in a significant reduction in stress-induced gastrointestinal symptoms such as diarrhoea ( $P = 0.0298$ ) and constipation ( $P = 0.0003$ ). Additionally, the lower dose of GOS was associated with lower cold and flu symptom intensity. The higher dose was found to reduce the probability of having a sick day by 40% in normal-weight individuals ( $P = 0.0002$ ). However, this protective effect was not observed in overweight or obese patients. The authors theorised that the lack of efficacy in overweight patients was due to differences in the baseline microbiota (e.g. fewer bifidobacteria) (Hughes et al 2011).

In another randomised, double-blind, placebo-controlled, crossover trial, the impact of GOS supplementation (2.75 g/day) on immune parameters in healthy elderly subjects was assessed. Forty-four subjects took part in this 24-week trial ( $2 \times 10$ -week treatment periods with a 4-week washout in between). Ten weeks of GOS supplementation was found to not only significantly increase faecal populations of bifidobacteria and decrease the quantity of less beneficial bacteria (*E. coli*, *Bacteroides* spp., *Clostridium* spp. and *Desulfovibrio* spp.) compared to the control period, but also significantly increase NK cell activity, phagocytic activity of leucocytes and the production of the anti-inflammatory cytokine IL-10. GOS supplementation also resulted in a significant reduction in the production of proinflammatory cytokines (IL-6, IL-1 $\beta$  and tumour necrosis factor- $\alpha$ ) (Vulevic et al 2008).

Prebiotic supplementation has also been tested in an HIV-positive population, showing benefits. In a double-blind RCT, 57 highly active antiretroviral therapy (HAART)-naïve HIV-1-infected adults received either a unique prebiotic mixture (GOS, long-chain FOS and pectin hydrolysate-derived acidic oligosaccharides) or placebo for 12 weeks. Subjects in the prebiotic group demonstrated significant improvements in the gut microbiota composition, a reduction of soluble CD14 and CD4<sup>+</sup> T-cell activation and increased NK cell activity compared to controls (Gori et al 2011).

#### Cancer of the colon

Administration of lactulose or oligofructose-enriched inulin to healthy volunteers resulted in a significant decrease in colonic beta-glucuronidase activity, which is considered protective against colon cancer development (De Preter et al 2008). A randomised, double-blind, placebo-controlled study investigated the effects of a synbiotic mixture on immune modulation in patients with colon cancer ( $n = 34$ ) post 'curative resection' and polypectomised patients ( $n = 40$ ). The synbiotic-treated group received encapsulated *Lactobacillus rhamnosus* GG  $1 \times 10^{10}$  CFU + *Bifidobacterium lactis* Bb12  $1 \times 10^{10}$  CFU plus 10 g of inulin enriched with oligofructose on a daily basis for 12 weeks. Overall, both groups receiving the synbiotic treatment demonstrated minor effects on some of the immune markers (Roller et al 2007). Likewise, in another randomised, double-blind, placebo-controlled study of 80 patients (37 colon cancer and 43 polypectomised) by this group, a number of colorectal cancer biomarkers were positively affected by 12 weeks' synbiotic treatment (Rafter et al 2007).

A randomised clinical trial conducted by Roncucci et al (1993) demonstrated the ability of lactulose to prevent the growth of resected colorectal polyps. Lactulose administration (20 g/day) reduced the recurrence rates of colonic polyps by 66% ( $P < 0.02$ ) as compared to controls.

#### Prevention of urinary tract infections

Two human studies have demonstrated the efficacy of lactulose therapy in the prevention of urinary tract infections. McCutcheon and Fulton (1989) conducted a retrospective study using 45 elderly, long-term hospital patients as subjects. The study found that daily lactulose therapy for 6 months (30 mL lactulose syrup/day) resulted in a significant reduction in urinary tract infections compared to controls ( $P < 0.025$ ). Sixteen of the 17 lactulose-treated patients (94%) remained infection-free over the 6 months, compared to 16 of the 28 control patients (57%) ( $P < 0.005$ ). In addition, there was a significant reduction in the number of antibiotic prescriptions ( $P < 0.05$ ) and in the number of patients receiving antibiotics ( $P < 0.005$ ) in the lactulose group.

In the second study, Mack et al (cited in Conn 1997) enrolled 75 elderly, hospitalised patients in a randomised, placebo-controlled trial. Thirty-eight patients received the placebo and 58 received lactulose therapy. Twelve per cent of the lactulose group developed urinary tract infections during the period of follow-up, compared to 32% in the control group ( $P < 0.01$ ).

#### Bone health

Calcium absorption was significantly increased ( $P = 0.04$ ) in women ingesting a yoghurt drink ( $2 \times 200$  mL/day) rich in GOS (20 g/day) according to a double-blind, crossover RCT. The study used a

9-day intervention period and involved 12 menopausal women (van den Heuvel et al 2000).

Griffin et al (2002) conducted a larger, randomised, crossover study of 59 young girls to investigate the effect of either inulin or inulin plus oligofructose (8 g/day) taken for 3 weeks in addition to 1500 mg/day calcium (two glasses of calcium-fortified orange juice); at the end of the study, the inulin plus oligofructose-treated group was reported to have significantly higher calcium absorption. Research by Abrams et al (2005) has supported these findings.

### Promotion of satiety

FOS supplementation affects satiety and hunger, according to a single-blind, crossover, placebo-controlled trial (Cani et al 2006). Subjects who ingested 8 g of FOS twice daily (with breakfast and dinner) experienced a significant increase in satiety at both meals (both  $P = 0.04$ ), but not at lunch. At dinner, FOS supplementation was also found to reduce hunger ( $P = 0.04$ ) and prospective food consumption ( $P = 0.05$ ). Energy intake at breakfast ( $P = 0.01$ ) and lunch ( $P = 0.03$ ) was also found to be significantly reduced after FOS supplementation, resulting in a 5% decrease in total energy intake per day.

A later double-blind RCT investigated the effects of a higher dose (21 g/day) of FOS over a 12-week period and found that active treatment resulted in a mean reduction of 1.03 kg bodyweight compared to a 0.45 kg increase in weight in the placebo group ( $P = 0.01$ ). FOS consumption was also associated with a lower area under the curve (AUC) for ghrelin ( $P = 0.004$ ) and a higher AUC for peptide YY ( $P = 0.03$ ), suggesting an upregulation of satiety hormone secretion. These changes coincided with a reduction in self-reported caloric intake ( $P < 0.05$ ). Serum glucose concentrations and insulin levels also significantly improved in the FOS group compared to baseline measures (both  $P < 0.05$ ) (Parnell & Reimer 2009).

### Metabolic syndrome

Treatment with GOS (2.75 g/day) for 12 weeks resulted in significant decreases in levels of plasma C-reactive protein ( $P < 0.0012$ ), insulin ( $P < 0.005$ ), total cholesterol ( $P < 0.001$ ) and triglycerides ( $P < 0.0005$ ) compared to placebo in a double-blind, crossover RCT involving 45 overweight adults with three or more risk factors associated with metabolic syndrome. The decreases in total cholesterol and triglycerides, while statistically significant, was not of a magnitude considered clinically significant (Vulevic et al 2013).

### OTHER USES

#### Liver disease — hepatic encephalopathy

Lactulose has been used routinely as part of the treatment for hepatic encephalopathy, although the exact mechanism of its action is still undetermined.

Lactulose treatment results in normalising of the intestinal microflora, lowering faecal pH, decreasing colonic ammonia production and increasing nitrogen excretion (Ballongue et al 1997, Elkington et al 1969). A meta-analysis of prebiotics in the treatment of minimal hepatic encephalopathy found lactulose treatment (five studies) to be associated with significant improvement in the condition (Shukla et al 2011). Lactulose therapy has also recently found in RCTs to effectively prevent the development of hepatic encephalopathy in patients with liver cirrhosis (Sharma et al 2012, Wen et al 2013).

### Pancreatitis

Some studies have found that synbiotic supplementation was more beneficial than prebiotics alone for improved systemic inflammatory response in patients with acute pancreatitis (Olah et al 2005).

### DOSAGE RANGE

Lactulose, FOS and GOS have all demonstrated dose-dependent responses in terms of altering the GIT microbiota, with larger doses inducing greater beneficial changes in the ecosystem. However, prebiotics are known to induce gastrointestinal side effects, such as abdominal pain, bloating, borborygmi and excessive flatulence when used in high doses; these symptoms tend to diminish over time or with dose reduction. Hence, the initial dose should be small and increased gradually dependent on gastrointestinal tolerance. Therapeutic dosage ranges are as follows: GOS: 2.5–20 g/day; FOS: 4–40 g/day; lactulose: 3–40 g/day.

### TOXICITY

Overall, prebiotics have a good profile but their consumption can result in some adverse gastrointestinal side effects. (See [Adverse reactions](#), below.)

### ADVERSE REACTIONS

There are many reports of transient gastrointestinal side effects of prebiotic treatment; symptoms such as abdominal pain, bloating, diarrhoea and increased flatulence are commonly reported. The severity of the symptoms is dose-dependent.

A potentially more troubling aspect of prebiotic prescription is their possible enhancement of bacterial translocation, although the research results have been mixed, with some research finding a protective effect and other research finding the opposite, and others no effect. Studies in rats have shown that both inulin and FOS supplementation not only increased intestinal lactobacilli and bifidobacteria colonisation, but also enhanced translocation of *Salmonella enterica* serovar *enteritidis* and the caecal contents also contained *Salmonella*, although concurrent calcium intake was noted to resolve this problem (Bovee-Oudenhoven et al 2003, Ten Bruggencate et al 2004). On the other hand, reduced bacterial translocation to the liver has been reported in rats with dextran sulfate sodium-induced colitis when fed FOS (Osman et al 2006) and feeding mice a

combination of FOS and inulin was found to protect against *Klebsiella pneumoniae* translocation (Silva et al 2009). In piglets, the addition of GOS or polydextrose to their diet had no impact on rates of bacterial translocation (Monaco et al 2011). In a human study of 72 elective surgery patients, synbiotic feeding (FOS in combination with four strains of probiotic bacteria) did not result in increased bacterial translocation (Anderson et al 2004).

A published case study has described an instance of anaphylaxis attributed to inulin found in vegetables and processed foods. This was later confirmed with skinprick testing and blinded food provocation testing (Gay-Crosier et al 2000). This allergy appears to be extremely rare considering the widespread consumption of FOS-containing foods. There is also one report describing an allergic reaction to lactulose ingestion in a child with severe milk allergy, presumably due to contamination of trace amounts of cow's milk protein in the preparation used (Maiello et al 2011).

### SIGNIFICANT INTERACTIONS

Controlled studies are not available and at present there are no known drug interactions with prebiotics.

### CONTRAINDICATIONS AND PRECAUTIONS

Prebiotics/synbiotics are contraindicated in those people who are hypersensitive to any component of the prebiotics/synbiotics-containing product. People with IBS who may have increased gas production should avoid high intakes of prebiotics (Serra et al 2001); low doses of GOS have, however, been found to decrease gas-related symptoms in IBS patients (Silk et al 2009). People with lactose intolerance should use lactulose with caution, as its use may cause more gastrointestinal adverse events than in lactose digesters (Teuri et al 1999). On the other hand, long-term ingestion of lactulose in lactose maldigesters has been found to increase their tolerance to lactose (Szilagyi et al 2001). Patients with fructose intolerance may also be more sensitive to the gastrointestinal adverse effects of FOS (Shepherd et al 2008).

One research group has found FOS intake to promote bacterial translocation and increase mucosal irritation in an animal model of *Salmonella* infection (Bovee-Oudenhoven et al 2003, Ten Bruggencate et al 2005). Hence, FOS supplementation may be contraindicated in patients with *Salmonella* enteritis.

### PREGNANCY USE

Prebiotics found in the food chain (FOS, inulin and GOS) are considered safe to consume in pregnancy. Lactulose in laxative doses (10–20+ g in a single dose) carries a category B classification (Prather 2004).

### Practice points/Patient counselling

- Prebiotics can be obtained from foods such as artichoke, Jerusalem artichokes, asparagus, bananas, chicory root, garlic, leek, onions and wheat, although not necessarily in clinically relevant amounts.
- Prebiotics may be combined with probiotics to produce synbiotics that will enable the two components to work together in synergy.
- Although prebiotics may improve the long-term bowel flora, prebiotic supplementation has many other benefits not associated with improvement in the ecosystem of the GIT.
- There is some evidence that prebiotics support both the development and the maintenance of a healthy immune system.
- Prebiotics have been used in the management of diarrhoea, constipation, other gastrointestinal disorders, bone health, allergic disease and food sensitivity.
- Continuous intake of prebiotics is required in order to maintain their health benefits.
- Some individuals may experience greater gastrointestinal discomfort with use, although some symptoms may subside over time and dose reduction can improve tolerance.

### PATIENTS' FAQs

#### What will this supplement do for me?

Studies have shown that prebiotics are beneficial in the treatment of digestive disorders such as diarrhoea, constipation and some IBDs, such as ulcerative colitis, and also other conditions, such as IBS, food allergies and eczema. There is some evidence that prebiotics may be useful for bone health.

#### When will it start to work?

Usually prebiotics can exert beneficial effects for digestive disorders such as constipation and diarrhoea within 1–2 weeks, although continuous use for several weeks/months may produce long-term benefits and be necessary in the treatment of other disorders.

#### Are there any safety issues?

Generally, prebiotics have a good safety profile; however, high-dose supplementation can cause a number of gastrointestinal adverse effects, such as bloating, distension and increased flatulence. These effects are most often noted at the beginning of prebiotic therapy and are generally dose-related. Hence, in some patients it is advisable to commence prebiotic supplementation at a low dose and slowly increase to achieve the optimal dose over several weeks.

## Probiotics

**HISTORICAL NOTE** There is a long history of consuming fermented foods and beverages containing microorganisms to improve health. The term ‘probiotic’ is derived from Greek and means ‘for life’. As far back as 1907, Metchnikoff, the Nobel laureate, popularised the idea that fermented milk products could beneficially alter the microflora of the gastrointestinal tract (GIT). He believed that many diseases, and even ageing itself, were caused by putrefaction of protein in the bowel by intestinal bacteria. Lactic acid-producing bacteria were thought to be able to inhibit the growth of putrefactive bacteria in the intestines and, thus, yoghurt consumption was recommended to correct this ‘auto-intoxication’ and improve the composition of the microflora (Metchnikoff 1907). The term ‘probiotics’ was first coined in 1965 and has since been applied to those live microorganisms that are able to promote health when consumed in sufficient quantities (FAO/WHO 2001). This definition includes fermented foods, as well as specific supplements containing freeze-dried bacteria. Although it has taken more than a century for scientists to investigate their health benefits, there are now several thousand studies published on probiotics, the majority published since 2000.

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Prior to birth, the GIT of the neonate is generally considered completely sterile, although new research findings suggest that there may be some degree of transfer from the mother’s microbiota in utero. During delivery, the newborn is inoculated with microorganisms from the birth canal (ideally) and the mother’s faecal flora, as well as from organisms in the environment (Matamoros et al 2013). Subsequently, growth of normal gut flora is influenced by factors such as composition of the maternal GIT microbiota, diet (breast milk vs formula), degree of hygiene, use of antibiotics or other medication, the environment and possibly genetic aspects. These microorganisms confer many health benefits by preventing the colonisation of the GIT with pathogenic microorganisms and by carrying out a number of biochemical functions, such as deconjugation and dehydroxylation of bile acids, the conversion of bilirubin to urobilinogen, generation of short-chain fatty acids (SCFA) and the metabolism of cholesterol to coprostanol (Bengmark 1998, Hill 1997). Additionally the microbiota modulates immune function, enhances GIT motility and gut barrier function, induces mucin production, improves digestion and nutrient absorption, metabolises xenobiotics (e.g. phyto-oestrogens), and produces vitamins K, B<sub>1</sub>, B<sub>2</sub>,

B<sub>6</sub> and B<sub>12</sub> (Fotiadis et al 2008, Hawrelak & Myers 2004, Isolauri 2012).

The gastrointestinal microbiota is reasonably resilient to change and remains fairly constant in adults, although research has shown that components such as pre- and probiotics can beneficially modulate the gut microflora, while antibiotics, chemotherapy, stress and a Western diet can negatively impact the ecosystem (Hawrelak & Myers 2004). It has been estimated that the intestines are host to 10<sup>14</sup> microbes representing over 1000 different species (Rajilic-Stojanovic et al 2007), which includes yeasts, mostly *Candida albicans* (<0.1% of the microbiota) (Vandenplas et al 2007).

Probiotics can be obtained from the consumption of fermented foods as well as supplements. It is important to note, however, that probiotic organisms require certain characteristics to enable them to exert maximum therapeutic effects. These qualities are summarised in Table 1.

Out of these characteristics, there are some that are considered most important for a probiotic to have therapeutic effects. These are: (1) gastric acid and bile salt stability; (2) an ability to adhere to the intestinal mucosa; and (3) an ability to colonise the intestinal tract (Dunne et al 2001). Some commercially available probiotic supplements and yoghurts contain strains that do not exhibit these vital characteristics. If a probiotic strain does not exhibit these

TABLE 1 THE DESIRABLE CHARACTERISTICS OF EFFECTIVE PROBIOTIC STRAINS

Characteristics	Functional benefit
Gastric acid and bile salt stability	Survival through stomach and small intestine
Adherence to intestinal mucosa	Believed to be essential for immune cell modulation and competitive inhibition of pathogens
Colonisation of intestinal tract	Multiplication in the intestines suggests that daily ingestion may not be needed; immune cell modulation
Human origin	Human origin should translate to the ability to survive conditions in the human gastrointestinal tract, as well as the possibility of species-specific health effects
Safety in food and documented clinical safety	Adverse effects absent or minimal; accurate identification (genus, species, strain)
Production of antimicrobial compounds	Normalisation of gastrointestinal tract flora; suppressed growth of pathogens
Antagonism against pathogenic organisms	Prevention of adhesion and toxin production by pathogens
Clinically documented and validated health effects	Clinicians can be confident of therapeutic effects; dose-response data for minimum effective dosage in different formulations are known
Increased shelf-life and stability during processing	All of the above properties should be maintained during storage and processing

Adapted from [Mattila-Sandholm & Salminen \(1998\)](#).

characteristics, then it will be less effective than strains that do.

Recently, the concept that probiotics should be viable/live has been re-evaluated. Studies have shown that bacterial DNA sequences may have similar effects as the live bacteria in some situations, and therefore colonisation of the intestinal tract may not be a prerequisite for the action of probiotics ([Jijon et al 2004](#), [Rachmilewitz et al 2002](#)). In addition, the mucosal immune system may not require direct contact with probiotics for beneficial effects as other routes of administration (such as the parenteral route) are also effective ([Rachmilewitz et al 2004](#), [Sheil et al 2004](#)). However, there are significant species and strain differences between the probiotic microorganisms, and therefore, they do not all share the same characteristics.

At present, there are numerous uses of probiotics, and reports of their beneficial effects cover a wide range of diseases and conditions.

#### **Clinical note — Probiotics and synbiotics**

Prebiotics are components that modify the environment of the GIT to selectively favour proliferation of the beneficial intestinal microflora, lactobacilli and bifidobacteria ([Gibson & Roberfroid 1995](#)). Prebiotics include oligo-fructose (fructooligosaccharides), inulin, lactulose and galactooligosaccharides. (See *Prebiotics monograph*.) Synbiotics contain both pre- and probiotics.

## **CHEMICAL COMPONENTS**

There are many different microorganisms currently used as probiotics in supplement and functional food form. [Table 2](#) provides examples of commonly used probiotic species.

### **Common probiotic microorganisms**

To better understand how bacteria are named and classified, the following discussion may be helpful. Genus is the first name of a bacterium (e.g. *Lactobacillus*). It is somewhat general and refers to a grouping of organisms based on similarity of qualities, such as physical characteristics, metabolic needs and metabolic end products. Species is a bacterium's second name (e.g. *acidophilus*). It is a much more narrow classification based on shared common characteristics that distinguish them from other species. Strain is an even more specific classification that divides members of the same species into subgroups based on several properties that a bacterial strain has that are distinct from other members of that species (e.g. strain LA5) ([McKane & Kandel 1986](#)).

## **FOOD SOURCES**

Traditional fermented foods, such as sauerkraut ([Dedicatoria et al 1981](#)), kim chi ([Cheigh et al 1994](#)), ogi ([Oyewole 1997](#)) and kefir ([Garrote et al 2001](#)), are rich sources of probiotic organisms. The most commonly consumed probiotic food in Australia and New Zealand is yoghurt. As research has suggested that the main yoghurt-producing bacteria (*Lactobacillus delbrueckii* ssp. *bulgaricus* and *Streptococcus thermophilus*) have limited therapeutic potential,

**TABLE 2 SOME ORGANISMS THAT ARE CURRENTLY USED AS PROBIOTICS (LISTED BY GENUS AND SPECIES) (GOLDIN 1998, MACFARLANE & CUMMINGS 1999, MATTILA-SANDHOLM & SALMINEN 1998)**

<i>Lactobacillus</i> spp.	<i>Bifidobacterium</i> spp.	<i>Bacillus</i> spp.	<i>Streptococcus</i> spp.	<i>Enterococcus</i> spp.	<i>Saccharomyces</i> spp.
<i>acidophilus</i>	<i>breve</i>	<i>coagulans</i>	<i>thermophilus</i>	<i>faecium</i>	<i>cerevisiae</i>
<i>plantarum</i>	<i>infantis</i>				
<i>rhamnosus</i>	<i>longum</i>				
<i>paracasei</i>	<i>bifidum</i>				
<i>fermentum</i>	<i>thermophilum</i>				
<i>reuteri</i>	<i>adolescentis</i>				
<i>johnsonii</i>	<i>animalis</i>				
<i>brevis</i>	<i>lactis</i>				
<i>casei</i>					
<i>lactis</i>					
<i>delbrueckii</i>					
<i>gasseri</i>					

### Strain selectivity of action

Within each species of bacteria there is a multitude of strains. Some probiotic strains are resilient and strong, with a demonstrated capacity to survive passage through the upper GIT and inhibit pathogenic bacteria, whereas others are weak and cannot even survive transit through the stomach. It is vital to note that, just because one strain of bacteria in a given species has a proven action or characteristic, it does not always mean that another strain will too, even if they are closely related. Strains of bacteria within the same species can have significantly different actions, properties and characteristics, as these are all essentially strain-specific qualities (Guarner et al 2011, Marteau 2011). For example, *Lactobacillus plantarum* strain 299v has been shown to effectively reduce irritable bowel syndrome (IBS) symptoms (Ducrotte et al 2012), whereas administration of *L. plantarum* strain MF1298 may actually worsen IBS symptoms (Ligaarden et al 2010). Thus, to achieve the desired therapeutic result, it is imperative to prescribe the precise probiotic strains that have demonstrated therapeutic and clinical efficacy in the condition in question. Additionally, strains that work in one condition will not necessarily be as effective in other conditions. For example, *Lactobacillus rhamnosus* GG (LGG) appears to be effective in the prevention of antibiotic-associated side effects (Arvola et al 1999) but not of any demonstrable benefit in urinary tract infections (Kontiohari et al 2001). When reviewing the Clinical Use section below, it is important to take note of the strains that were used in the summarised trials, not just the species.

human GIT-derived probiotic strains are now commonly added to yoghurt in an attempt to increase its therapeutic potential (e.g. strains of *Lactobacillus acidophilus* and *Bifidobacterium* spp.) (Molin 2001).

### DEFICIENCY SIGNS AND SYMPTOMS

Clear deficiency signs are difficult to establish because the symptoms may vary enormously. Local signs and symptoms of disruption of the intestinal microflora leading to an imbalance (intestinal dysbiosis) include bloating, flatulence, abdominal pain, diarrhoea and/or constipation and fungal overgrowth (such as *Candida*). An imbalance in the gastrointestinal microflora can be caused by the use of antibiotics, GIT infections, stress and dietary factors (Hawrelak & Myers 2004). Administration of probiotics is often used as a means of restoring this microflora imbalance (Bengmark 1998, Hedin et al 2007, Hoveyda et al 2009, Kajander et al 2008, McFarland 2006, 2007, McFarland & Dublin 2008).

### MAIN ACTIONS

The exact mechanisms by which probiotics accomplish their myriad of beneficial actions have become clearer over the past decade and we now know of several mechanisms that explain many of their favourable effects.

#### Immune modulation

A growing body of evidence indicates that some probiotic strains are capable of modulating the immune system at both the systemic and the mucosal level, affecting many cell types (e.g. epithelial cells, dendritic cells, natural killer cells). This immune response may take the form of increased secretion of immunoglobulin A (IgA) via interaction with mesenteric lymph nodes (Link-Amster et al 1994,

Walker 2008), elevated numbers of natural killer cells or enhanced phagocytic activity of macrophages (Schiffirin et al 1997). Recent research has demonstrated that dendritic cells in the lamina propria can extend their appendices between epithelial cells, and, via Toll-like receptors on their surface, sample probiotic-bacterial molecular patterns. This interaction leads to the maturation of the dendritic cells and to the release of cytokines, which orchestrate the conversion of naïve T-helper cells (Th0) into a mature, balanced response of T-helper cells (Th1, Th2 and Th3/Tr1) (Walker 2008).

### Anti-inflammatory activity

Probiotic strains have been shown to have anti-inflammatory effects via a number of different mechanisms. They can secrete metabolites with anti-inflammatory properties (anti-tumour necrosis factor- $\alpha$  [TNF- $\alpha$ ] effects) (Ménard et al 2004), they can interact with Toll-like receptors (Rachmilewitz et al 2004), downregulate the transcription of a number of genes encoding proinflammatory effectors (Tien et al 2006) and upregulate the production of anti-inflammatory cytokines (Imaoka et al 2008).

### GIT transit time modification

Some probiotic strains can modify GIT transit. Two strains of bifidobacteria have been found to significantly speed colonic transit time (Meance et al 2001, Waller et al 2011), while a strain of propionibacteria has been shown to slow descending colon transit (Bougle et al 1999). The mechanisms by which probiotics alter GIT transit time have not yet been fully elucidated; however, it is postulated that a bacterial metabolite may impact sigmoid tone and alter colonic motility (Marteau et al 2002).

### Induction of oral tolerance

The GIT microflora has been shown to play a crucial role in generating an adequate population of Th2 cells that are capable of oral tolerance induction (Sudo et al 1997). In the presence of intestinal dysbiosis, some probiotic strains can also help induce oral tolerance and help protect against the development of food allergies (Prioult et al 2003).

### Decrease visceral hypersensitivity

Animal research has suggested that some probiotic strains are capable of decreasing visceral hypersensitivity, believed to be one of the main contributing factors in IBS and other functional gastrointestinal disorders (Ait-Belgnaoui et al 2006, Johnson et al 2011, McKernan et al 2010). The exact mechanisms are unknown, but another lactobacilli strain has been shown to decrease visceral hypersensitivity by inducing cannabinoid and opioid receptor expression in the colonic epithelium (Rousseaux et al 2007).

### Competition for gastrointestinal adhesion sites

Many pathogenic organisms must associate with the GIT epithelium in order to colonise effectively.

However some strains of bifidobacteria and lactobacilli can adhere to the epithelium and act as 'colonisation barriers' by preventing pathogens from adhering to the mucosa (Fuller & Gibson 1997). This effect has been demonstrated with LGG and *L. plantarum* 299v. Both of these organisms have shown the ability to inhibit attachment of *Escherichia coli* to human colon cells (Mack et al 1999).

### Antagonism against potentially pathogenic microorganisms and viruses

One of the mechanisms by which probiotics exert their beneficial effects is via inducing changes to the GIT microflora; specifically by inhibiting the growth of potentially pathogenic organisms. Some probiotic strains are capable of producing inhibitory substances such as bacteriocins, lactic acid and toxic oxygen metabolites. Of the toxic oxygen metabolites, hydrogen peroxide is of major importance as it exerts a bactericidal effect on many pathogens (Kaur et al 2002). The ability to produce bacteriocins, hydrogen peroxide and other antimicrobial compounds is strain-dependent. Probiotics have demonstrated in vitro inhibitory activity against a range of potentially pathogenic microorganisms, such as *Helicobacter pylori*, *Clostridium difficile*, *Escherichia coli*, *Candida albicans*, *Salmonella enterica*, *Shigella sonnei* and *Vibrio cholerae* (Hasslof et al 2010, Naaber et al 2004, Sgouras et al 2004, Spinler et al 2008). Some probiotic strains (LGG and *Bifidobacterium lactis* Bb12) can also bind to viruses, such as rotaviruses, helping to prevent mucosa-associated viral infections (Salminen et al 2010). Several probiotic strains have also demonstrated the ability to bind or remove toxins, such as aflatoxins and cyanotoxins (Salminen et al 2010), as well as inhibit the effects of bacterial toxins, such as *Clostridium difficile* toxins A and B (Castagliuolo et al 1999). Specific strains have also been found to reduce the expression of virulence factors via inhibition of pathogen gene encoding (Corr et al 2009).

### Selective gastrointestinal antimicrobial activity

Ingestion of selected probiotic strains has been found to significantly increase gastrointestinal populations of beneficial bacteria (i.e. lactobacilli or bifidobacteria), while simultaneously decreasing populations of less health-promoting genera (Ahmed et al 2007, Benno et al 1996, Mohan et al 2006).

### Production of beneficial compounds

The production of SCFAs as metabolic byproducts is a characteristic which almost all probiotic strains share. These SCFAs help create a healthier colonic milieu by decreasing the luminal pH and some (e.g. butyrate) are used as energy sources by colonocytes (D'Argenio & Mazzacca 1999, Ng et al 2009). Other probiotic strains can help restore normal small intestinal architecture and upregulate intestinal brush border enzyme expression via the luminal release of polyamines (Buts et al 1986, 1994, Guillot et al 1995). These strains will have clinical utility in

situations of small intestinal damage and decreased brush border enzyme activity, such as coeliac disease, Crohn's disease, or after small intestinal infections.

### Strengthen the intestinal barrier

A number of probiotic strains have been found to increase mucin production in the gut via increases in mucin gene expression, which provides a protective coating between the lumen and intestinal epithelial cells (Caballero-Franco et al 2007, Mack et al 2003). Probiotics are also capable of directly strengthening the intestinal barrier. A strain of *Lactobacillus plantarum* (WCSF1) has been found to decrease paracellular intestinal permeability by increasing the relocation of occludin and zonulin into the tight junction between duodenal epithelial cells (Ahrne & Hagslatt 2011). Other strains appear to enhance barrier function via the preservation of enterocyte cytoskeleton architecture and enhancement of tight junctional protein structures (Ng et al 2009). Such strains should prove useful in the treatment and prevention of intestinal permeability.

### Chemopreventive effects

Select probiotics may have anticancer properties. Different strains of *Lactobacillus acidophilus* and bifidobacteria have been studied to investigate their antimutagenic activity against chemical mutagens (Lankaputhra & Shah 1998).

Antimutagenic activity against chemical mutagens and promutagens has been demonstrated for different strains of *Lactobacillus acidophilus*, bifidobacteria and the organic acids usually produced by these probiotics, with live cells producing the most positive results (Lankaputhra & Shah 1998). Some probiotics also reduce faecal enzymes implicated in cancer initiation, while others produce butyric acid, which affects the turnover of colonocytes and neutralises the activity of dietary carcinogens, such as nitrosamines. Additionally, enhancing host immunity and qualitative and quantitative changes to the intestinal microflora and physicochemical conditions are important contributing factors (Hirayama & Rafter 1999).

### OTHER ACTIONS

Several clinical studies have investigated lipid-lowering activity of probiotics (see section on **Clinical Use**, below).

### CLINICAL USE

#### Restoring GIT microflora after antibiotic use

Antibiotic use frequently results in significant perturbations in the GIT microflora and gastrointestinal adverse events, such as diarrhoea (Rafii et al 2008). It was once believed that taking probiotics concurrently with antibiotics would be a waste of time and money as the antibiotic would be likely to destroy all the administered probiotic bacteria. However, research conducted over the past 20 years clearly shows that concurrent administration of specific

#### How to choose an effective probiotic supplement

Firstly, one needs to know not only the genera and species details of the organisms contained in the supplement, but also the strain details. Ideally, this should be detailed on the label, but if this is not clear, contact the manufacturer for further information. Secondly, the strains contained in the supplement will ideally display the desirable characteristics highlighted in **Table 1**. Thirdly, the right strain(s) with the desired action should be chosen for the clinical scenario at hand. Fourthly, there should be adequate amounts of viable organisms contained in the supplement at the time of consumption — for most strains this is currently considered to be  $\geq 10^9$  colony-forming units of each organism per dose, but will vary depending on indication (see **Dosage Range** section below for more details).

probiotic strains alongside antibiotics is effective and significantly decreases the incidence of antibiotic-related side effects. **Table 3** highlights the research examining the impact of probiotics on antibiotic-related gastrointestinal adverse events, primarily antibiotic-associated diarrhoea. As can be seen, the probiotic strains with the highest level of substantiating evidence are *L. rhamnosus* GG and *Saccharomyces cerevisiae* var. *boulardii* Biocodex, but a number of other strains have also demonstrated efficacy.

#### Abdominal pain (functional)

A meta-analysis of trials evaluating LGG in the treatment of functional abdominal pain in children found LGG effective. LGG supplementation was associated with a significantly higher rate of treatment responders (defined as no pain or a decrease in pain intensity) in the overall population of children with abdominal pain-related functional gastrointestinal disorders (three trials;  $n = 290$ ; relative risk [RR] 1.31, 95% confidence interval [CI] 1.08–1.59) and in the IBS subgroup (three randomised controlled trials;  $n = 167$ ; RR 1.70, 95% CI 1.27–2.27, number needed to treat 4, 95% CI 3–8). There was also a significant decrease in the perception of pain intensity in children with functional abdominal pain (Horvath et al 2011).

#### Atopic eczema

The intestinal microflora plays a major protective role against the development of allergy because it reduces antigen transport through the intestinal mucosa and helps induce oral tolerance (Tanaka & Ishikawa 2004). Consequently, probiotics may have a protective role in the prevention and/or management of atopic dermatitis and eczema because of their proposed actions (Rosenfeldt et al 2004).

A number of clinical trials have investigated probiotic therapy to prevent atopic eczema development, and some have evaluated the efficacy of probiotic therapy in the treatment of atopic eczema.

TABLE 3 IMPACT OF PROBIOTICS ON ANTIBIOTIC-RELATED GASTROINTESTINAL ADVERSE EVENTS (comments in italics)		
Trial methodology	Strain(s) utilised	Results and comments
Meta-analysis 16 studies <i>n</i> = 3432 paediatric subjects	Various	In the per protocol analysis, the incidence of antibiotic-associated diarrhoea (AAD) in the probiotic group was 9% compared to 18% in the control group (2874 participants; relative risk [RR] 0.52; 95% confidence interval [CI] 0.38–0.72). An extreme-plausible intention to treat (ITT) analysis, where 60% of the drop-outs in the probiotic group was assumed to have AAD compared to only 20% of drop-outs in the control group, revealed no significant benefit to probiotic therapy (RR 0.81; 95% CI 0.63–1.04) (Johnston et al 2011). <i>The considerable bias against probiotic therapy built into the ITT analysis made the chance of a positive outcome very remote. Additionally, meta-analyses that combine the results of studies utilising different probiotic strains (such as this one) are actively discouraged as they are fundamentally flawed and fail to provide clinically relevant conclusions. Each strain is a unique therapeutic agent and should be evaluated as such. Meta-analyses such as this can only provide proof of concept data</i>
Meta-analysis 63 studies <i>n</i> = 11,811 subjects of all ages	Various	Probiotic administration was associated with a significant reduction in risk of AAD (RR = 0.58; 95% CI 0.50–0.68; <i>P</i> < 0.001) (Hempel et al 2012). <i>The same criticism of combining results on different probiotic strains is valid for this meta-analysis as well</i>
Meta-analysis two studies <i>n</i> = 307 paediatric subjects	<i>Lactobacillus rhamnosus</i> GG	70% reduced risk of developing AAD in children (95% CI 0.15–0.6; <i>P</i> = 0.00003) (Szajewska et al 2010). <i>This meta-analysis combines the data on a single probiotic strain, providing valuable clinically relevant information, demonstrating that this strain is effective in the prevention of AAD in paediatric populations being administered antibiotics</i>
Meta-analysis five studies <i>n</i> = 1076 subjects of all ages	<i>Saccharomyces cerevisiae</i> var. <i>boulardii</i> Biocodex	Supplementation reduced the risk of AAD from 17.2% in controls to 6.7% (RR = 0.43; 95% CI 0.23–0.78) (Szajewska & Mrukowicz 2005)
R, DB, PC <i>n</i> = 162 adult subjects receiving antibiotic treatment for <i>Helicobacter pylori</i> infection	<i>Lactobacillus acidophilus</i> strains CUL-60 and CUL-21, <i>Bifidobacterium lactis</i> CUL-34 and <i>Bifidobacterium bifidum</i> CUL-20 (Lab4)	Coadministration of the probiotic combination with antibiotics prevented the increase in faecal <i>Candida albicans</i> populations immediately following antibiotic therapy ( <i>P</i> = 0.049) (Plummer et al 2005)
R, DB, PC <i>n</i> = 239	<i>Lactobacillus plantarum</i> 299v	31% reduced risk of developing loose or watery stools (95% CI 0.52–0.92; <i>P</i> = 0.012); 49% reduced risk of experiencing nausea (95% CI 0.30–0.85; <i>P</i> = 0.0097) (Lonnermark et al 2010)
R, DB, PC <i>n</i> = 40 paediatric subjects	<i>Lactobacillus reuteri</i> MM53	Reduced incidence of a number of gastrointestinal symptoms relative to placebo in triple therapy-treated children — epigastric pain (15% vs 45%; <i>P</i> < 0.04), abdominal distension (0% vs 25%; <i>P</i> < 0.04), disorders of defecation (15% vs 45%; <i>P</i> < 0.04) and halitosis (5% vs 35%; <i>P</i> < 0.04) (Lionetti et al 2006)
R, DB, PC <i>n</i> = 87 subjects	<i>Lactobacillus rhamnosus</i> GG, <i>Lactobacillus acidophilus</i> LA5 and <i>Bifidobacterium lactis</i> Bb12	79% reduced risk of developing AAD ( <i>P</i> = 0.035) (Wenus et al 2008)

R, randomised; DB, double-blind; PC, placebo-controlled.

TABLE 4 ROLE OF *LACTOBACILLUS RHAMNOSUS* GG (LGG) IN THE PREVENTION OF ATOPIC ECZEMA

Trial design	Intervention details	Results
R, DB, PC <i>n</i> = 159 pregnant women with an atopic family history	$1 \times 10^{10}$ CFU/day LGG for 2–4 weeks before expected delivery. After delivery, breastfeeding mothers could take the capsules; otherwise infants received the agent directly for the following 6 months	There was a 49% reduced risk of eczema development at 2 years of age ( $P = 0.008$ ), 43% reduced risk of eczema at 4 years of age ( $P < 0.05$ ) and a 36% reduced risk at 7 years of age (Kalliomaki et al 2001, 2003, 2007)
R, DB, PC <i>n</i> = 105 pregnant women with an atopic family history	$1 \times 10^{10}$ CFU/day LGG for 4–6 weeks before expected delivery. After delivery, exclusively breastfeeding mothers took the LGG directly for the initial 3 months and it was administered directly to the infant for the following 3 months. Formula-fed infants received LGG directly for 6 months	The risk of atopic dermatitis in children on LGG was not decreased relative to placebo (relative risk [RR] = 0.96; confidence interval [CI] 0.38–2.33) (Kopp et al 2008)
R, DB, PC <i>n</i> = 250 pregnant women with an atopic family history	LGG $1.8 \times 10^{10}$ CFU/day from 36 weeks' gestation until delivery only	Prenatal LGG treatment was not associated with reduced risk of eczema (34% probiotic, 39% placebo; RR 0.88; 95% CI 0.63–1.22) or immunoglobulin E-associated eczema (18% probiotic, 19% placebo; RR 0.94; 95% CI 0.53–1.68) (Boyle et al 2011)

R, randomised; DB, double-blind; PC, placebo-controlled; CFU, colony-forming unit.

### Prevention of atopic eczema

The initial research detailing the efficacy of probiotics in the prevention of atopic eczema utilised the probiotic strain LGG (Kalliomaki et al 2001). Other studies assessing this same strain have since been published, with conflicting results (Boyle et al 2011, Kopp et al 2008). Table 4 provides details on these trials. As can be seen, the studies by Kalliomaki et al and Kopp et al had similar protocols, but contrasting results. The small differences in protocol are unlikely to explain the differences. The trial by Boyle et al only gave LGG to the mother from week 36 until delivery. Lack of apparent efficacy in this study might suggest that LGG needs to be given to the infant (either directly or via breast milk) for efficacy to be seen. More research is needed, however, to clearly define the role of LGG in the prevention of atopic eczema development.

A number of other probiotic strains have been evaluated for their effectiveness in the prevention of atopic eczema, with conflicting results. Pelucchi et al (2012) performed a meta-analysis of randomised controlled trials to investigate whether probiotic use during pregnancy and early life decreases the incidence of atopic eczema and IgE-associated atopic eczema in infants and young children. Eighteen publications based on 14 studies were included in the analysis. Meta-analysis demonstrated that probiotic use decreased the incidence of atopic dermatitis (RR = 0.79; 95% CI 0.71–0.88). The corresponding RR of IgE-associated atopic dermatitis was 0.80 (95% CI 0.66–0.96) (Pelucchi et al 2012). While the evidence on the whole supports

the use of probiotics to decrease the incidence of atopic dermatitis in infancy and early childhood, some strains were not effective.

In a randomised, double-blind, placebo-controlled trial, Taylor et al (2007) administered *Lactobacillus acidophilus* strain LAVRI-A1 ( $3 \times 10^9$  colony-forming units [CFU]/day) to infants at high risk of allergic disease for the first 6 months of life. At both 6 and 12 months, the incidence of atopic dermatitis was similar in both the probiotic and the placebo group. The proportion of children with a positive skin prick test and atopic eczema was significantly higher in the probiotic group ( $P = 0.045$ ) at 12 months, as was the rate of allergen sensitisation ( $P = 0.030$ ). Hence, this strain was not effective in decreasing the incidence of atopic dermatitis development and may have actually increased allergen sensitisation, despite promising preliminary in vitro results (Taylor et al 2007).

Abrahamsson et al (2007) conducted a double-blind, randomised, placebo-controlled trial investigating the role of *Lactobacillus reuteri* strain ProGaia (MM53) in the prevention of atopic dermatitis development ( $n = 232$ ). The mothers received *L. reuteri* ProGaia ( $1 \times 10^8$  CFU) daily from gestational week 36 until delivery. Their babies then continued with the same product from birth until 12 months of age. The incidence of eczema was found to be similar in both groups at 2 years of age. However, infants in the probiotic group did have less IgE-associated eczema (8 vs 20%;  $P = 0.02$ ) and, in infants with allergic mothers, less skin prick test reactivity (14 vs 31%;  $P = 0.02$ ) (Abrahamsson et al 2007).

Wickens et al (2008) performed a randomised, double-blind, placebo-controlled trial to assess the impact of two different probiotic strains on the development of atopic eczema. Pregnant women with an atopic family history were randomised to take *Lactobacillus rhamnosus* HN001, *Bifidobacterium animalis* subsp. *lactis* strain HN019 or placebo daily from 35 weeks' gestation until 6 months if breastfeeding, and their infants were randomised to receive the same treatment from birth to 2 years ( $n = 474$ ). Infants in the *L. rhamnosus* HN001 group had a 49% reduced risk of eczema development at 2 years of age (95% CI 0.30–0.85;  $P = 0.01$ ). On the other hand, there was no reduced risk of eczema development in infants receiving *Bifidobacterium animalis* subsp. *lactis* strain HN019 (Wickens et al 2008).

In another randomised, placebo-controlled, double-blind trial, the efficacy of *Lactobacillus paracasei* F-19 was evaluated. In this trial, the probiotic was administered to the infant ( $n = 179$ ) directly at the time of weaning (mixed into food). Infants consumed the probiotic agent ( $1 \times 10^8$  CFU/day) from 4 to 13 months of age. Probiotic supplementation resulted in a significantly reduced cumulative incidence of eczema at 13 months of age (11 vs 22%;  $P < 0.05$ ) and an improved Th1/Th2 ratio (West et al 2009).

In a further double-blind trial, women ( $n = 415$ ) were randomised to receive either placebo or a probiotic milk (containing LGG, *Lactobacillus acidophilus* La5 and *Bifidobacterium lactis* Bb12) from 36 weeks' gestation to 3 months postnatally during breastfeeding. At 2 years old, the odds ratio (OR) for the cumulative incidence of atopic eczema was 0.51 in the probiotic group compared with the placebo (95% CI 0.30–0.87;  $P = 0.013$ ). There were no significant effects on rates of asthma or atopic sensitisation (Dotterud et al 2010).

### Treatment of atopic eczema

To determine whether probiotics are efficacious in treating atopic eczema, Michail et al (2008) performed a meta-analysis of randomised controlled trials. Eleven studies were located and data from 10 trials were available to pool and analyse ( $n = 678$ ). There was an overall statistically significant difference favouring probiotics compared with placebo in reducing the Scoring of Atopic Dermatitis Severity Index score (mean change from baseline,  $-3.01$ ; 95% CI  $-5.36$  to  $-0.66$ ;  $P = 0.01$ ). Children with moderately severe disease appeared more likely to benefit. There was also a trend for greater improvement in IgE-sensitised patients ( $P = 0.07$ ) (Michail et al 2008).

A randomised, double-blind study of 56 young children (aged 6–18 months) with moderate or severe atopic eczema found that treatment with *L. fermentum* VRI-003 PCC ( $1 \times 10^9$  twice daily) produced a significant reduction in the Severity Scoring of Atopic Dermatitis (SCORAD) index (Weston et al 2005). At week 16, 92% of children receiving probiotics had a SCORAD index that was

significantly better than baseline compared with the placebo group ( $n = 17$ , 63%;  $P = 0.01$ ). Another randomised double-blind study has found that supplementation of infant formula with viable, but not heat-inactivated, LGG may have benefits for the management of atopic eczema and cow's milk allergy, particularly in terms of acceleration of improvement (Kirjavainen et al 2003).

According to two other placebo-controlled studies, it appears that people with greater allergic responses may be better suited to treatment and experience superior effects. Rosenfeldt et al (2003) found that treatment with two *Lactobacillus* strains (lyophilised *L. rhamnosus* 19070-2 and *L. reuteri* DSM 122460) given in combination for 6 weeks to children aged 1–13 years with atopic dermatitis resulted in 56% experiencing improvement. Interestingly, the total SCORAD score did not change significantly. Allergic patients with a positive skin prick test response and increased IgE levels experienced a more pronounced response to treatment.

Similarly, a randomised, controlled trial by Sistik et al (2006) found that a combination of two probiotic strains (*Lactobacillus rhamnosus* HN001 and *Bifidobacterium lactis* HN019) given to children with established atopic eczema effectively reduced the SCORAD index among the food-sensitised children, but not in other children. Children in this study received  $2 \times 10^{10}$  CFU/g of probiotics or placebo daily as a powder mixed with food or water.

### Gastrointestinal infections

Probiotics have a role in the management of various gastrointestinal infections, such as bacterial and viral-induced diarrhoea, *Helicobacter pylori*, traveller's diarrhoea (TD), recurrent *Clostridium difficile*-associated disease (CDAD) and pancreatitis.

### Diarrhoea

Various probiotic strains have been subjected to clinical trials to evaluate their efficacy in diarrhoea of different origins.

### Viral gastroenteritis — prevention

In a randomised, double-blind, placebo-controlled trial, infants admitted to a chronic medical hospital (average duration of stay 80 days) ingested formula that was supplemented with either placebo or a combination probiotic. The probiotic contained *Bifidobacterium lactis* Bb12 ( $1.9 \times 10^8$  CFU/g powdered formula) and the TH-4 strain of *Streptococcus thermophilus* ( $0.14 \times 10^8$  CFU/g powdered formula). Probiotic supplementation was found to significantly reduce diarrhoea incidence (7 vs 31%;  $P = 0.035$ ) and rotavirus shedding (10 vs 39%;  $P = 0.025$ ) (Saavedra et al 1994).

Another randomised, controlled trial found that the administration of LGG to hospitalised children reduced the risk of rotavirus gastroenteritis by 87% ( $P = 0.02$ ) (Szajewska et al 2001).

## Treatment

A meta-analysis of eight randomised controlled trials ( $n = 988$ ) by Szajewska et al (2007) found that supplementation of LGG significantly reduced duration of rotavirus diarrhoea by 2.1 days in children ( $P = 0.006$ ) and the risk of diarrhoea lasting  $>7$  days was reduced by 75% ( $P = 0.01$ ). The authors did caution, however, that the heterogeneity and methodological considerations of the studies limited the strength of the conclusions (Szajewska et al 2007).

In order to determine the dose-dependent effect of LGG on faecal rotavirus shedding, Fang et al (2009) conducted an open-label randomised study where 23 children with rotavirus gastroenteritis were treated for 3 days with a daily dose of LGG: 0 CFU/day (control group,  $n = 6$ );  $2 \times 10^8$  CFU/day (low-dose group,  $n = 9$ ); or  $6 \times 10^8$  CFU/day (high-dose group,  $n = 8$ ). The high-dose LGG group was the only group who experienced a significant reduction of rotavirus levels in stool samples (86% after 3 days).

A randomised, placebo-controlled trial comparing the efficacy of two different doses of *Lactobacillus reuteri* MM53 ( $1 \times 10^{10}$  CFU/day or  $1 \times 10^7$  CFU/day) with placebo in children with rotavirus-associated diarrhoea ( $n = 66$ ) found that probiotic treatment reduced the duration of viral gastroenteritis-induced diarrhoea from 2.5 days in the placebo group to 1.9 days in the low-dose group and 1.5 days in the high-dose group ( $P = 0.01$ ). By the second day of treatment watery diarrhoea persisted in 80% of the placebo, 70% of the low-dose group and 48% of the large-dose group ( $P = 0.04$ , large dosage vs. placebo) (Shornikova et al 1997).

Another double-blind, randomised, placebo-controlled study evaluated the efficacy of the multistrain probiotic preparation (VSL#3) in the treatment of rotavirus diarrhoea in children. Two hundred and thirty children were enrolled in the trial. By day 2, a lower mean stool frequency and improved stool consistency were noted in the VSL#3 group (both  $P \leq 0.05$ ). On day 4 of treatment, 89% of VSL#3-treated children were recovered vs 40% of controls ( $P < 0.001$ ) (Dubey et al 2008).

## Bacterial gastroenteritis — traveller's diarrhoea

TD is the most common health problem in those visiting developing countries, affecting between 20% and 50% of tourists. Although it is usually short-lived and self-limiting, TD represents a considerable socioeconomic burden for both the traveller and the host country. The most common enteropathogen is *Escherichia coli*, but a number of other microorganisms are also implicated (Ardley & Wright 2010). Recent research has highlighted the causative role of TD in the development of postinfectious IBS (Stermer et al 2006). Thus agents capable of preventing the development of TD are much needed.

Clinical trials with probiotics have thus far produced mixed results. In an attempt to clarify the role

of probiotics in the prevention of TD, McFarland (2007) conducted a systematic review and meta-analysis on the area. Combining the data from 12 randomised, controlled trials indicated that probiotics significantly prevent the development of TD, with a pooled RR of 0.85 (95% CI 0.79–0.91;  $P < 0.001$ ). While the data for probiotics as a whole were positive, a number of preparations were found to be ineffective: *Lactobacillus fermentum* VRI-003 (Katelaris & Salam 1995), Lactinex (unspecified strains of *Lactobacillus acidophilus* and *Lactobacillus helveticus* in combination) (de Dios Pozo-Olano et al 1978) and an unspecified strain of *Lactobacillus acidophilus* (Antibiophilus-Kapsein) (Kollaritsch et al 1989). Only strains with proven efficacy in TD should be utilised clinically (see below).

In a randomised, double-blind, placebo-controlled trial by Black et al (1989), the combination of *Lactobacillus acidophilus* La5 and *Bifidobacterium lactis* Bb12 was evaluated for the prevention of TD. Ninety-five Danish travellers touring Egypt took part in the trial and consumed either placebo or a probiotic preparation containing  $1.8 \times 10^{10}$  CFU/day of a combination of *Lactobacillus acidophilus* La5, *Bifidobacterium lactis* Bb12, *Lactobacillus delbrueckii* ssp. *bulgaricus* and *Streptococcus thermophilus* starting 2 days prior to travel. The first two strains constituted 90% of the mixture. The number of tourists developing diarrhoea was significantly reduced in the probiotic group — from 71% in controls to 43% ( $P = 0.019$ ). This equated to a protection rate of 39.4% (Black et al 1989).

A large, randomised, placebo-controlled, double-blind study of the efficacy of LGG in preventing TD involved 820 people on holiday to Turkey to two destinations. The group was randomly assigned either LGG ( $2 \times 10^9$  CFU/day) or placebo in identical sachets. On the return flight, each participant completed a questionnaire indicating the incidence of diarrhoea and related symptoms during the trip. Of the original group, 756 (92%) subjects completed the study. The overall incidence of diarrhoea was 43.8% (331 cases), and the total incidence of diarrhoea in the LGG group was 41.0% compared with 46.5% in the placebo group, indicating an overall protection of 11.8%. Protection rates varied between two different destinations, with the maximum protection rate reported as 39.5% and no side effects reported (Oksanen et al 1990).

In another randomised, placebo-controlled trial investigating the efficacy of LGG ( $2 \times 10^9$  CFU/day) in the prophylaxis of TD, 245 subjects travelling from Finland to developing nations were enrolled. The risk of TD development for subjects taking LGG was reduced by 47% compared to the placebo-treated controls ( $P = 0.05$ ) (Hilton et al 1997).

Utilising a randomised, placebo-controlled, double-blind trial design, Kollaritsch et al (1989) investigated the efficacy of two different doses of *Saccharomyces cerevisiae* var. *boulardii* strain Biocodex (250 mg/day and 500 mg/day) in the prevention of

TD. Four hundred and six Austrian subjects traveling to tropical locales were enrolled. The rate of TD in the placebo group was 42.6%, versus 33.6% in the low-dose group and 31.8% in the high-dose group. This equates to a 21% reduction in incidence in the 250 mg/day group ( $P < 0.007$ ) and 25% reduction with 500 mg/day ( $P < 0.002$ ) compared to placebo (Kollaritsch et al 1989).

In another placebo-controlled double-blind study, two doses (250 and 1000 mg) of *Saccharomyces cerevisiae* var. *boulardii* strain Biocodex were administered prophylactically to 3000 Austrian travellers. A significant reduction in the incidence of diarrhoea was observed, with success depending directly on the rigorous use of the preparation. A tendency was noted for *S. cerevisiae* var. *boulardii* Biocodex to have a regional effect, which was particularly marked in North Africa and in Turkey. The effect was also dose-dependent, with participants taking the higher dose of probiotics experiencing the lowest incidence of TD (29%); little difference was observed between low-dose supplementation (34%) and placebo (39%). Treatment was considered very safe (Kollaritsch et al 1993).

#### *Clostridium difficile*-associated diarrhoea

*Clostridium difficile* is a common cause of diarrhoea associated with treatment with antimicrobial and/or antibiotic medication and can potentially progress to colitis, pseudomembranous colitis, toxic megacolon and death. In spite of antimicrobial therapy, recurrence is common, and increasingly, probiotic supplementation has been investigated as a potential treatment for CDAD.

A meta-analysis by McFarland (2006) assessed six blinded randomised controlled trials ( $n = 354$  patients) that used a mixture of probiotics in the management of CDAD. The results showed that only *S. cerevisiae* var. *boulardii* supplementation resulted in a significant reduction in recurrence. These findings are in contrast to an earlier meta-analysis by Dendukuri et al (2005), where a role for probiotic use in CDAD was not supported in all the studies; the authors of this meta-analysis reported methodological flaws in some of the studies, although some benefit of probiotic therapy was seen in patient subgroups, particularly those characterised by severe CDAD and high use of vancomycin. Individual strains that have demonstrated efficacy in randomised, controlled trials for the prevention or treatment of CDAD include *S. cerevisiae* var. *boulardii* Biocodex (McFarland et al 1994, Surawicz et al 2000) and *Lactobacillus plantarum* 299v (Klarin et al 2008).

#### Vancomycin-resistant enterococci

Over the past 15–20 years, there has been a rapid increase in the prevalence of vancomycin-resistant enterococci (VRE). This has been associated with the widespread use of broad-spectrum antibiotics. VRE can be involved in the pathogenesis of persistent, hospital-acquired infections that often have

poor outcomes. Additionally, they have the capacity to transfer their antibiotic resistance factors to other organisms. Non-antibiotic control measures of VRE are much needed. This randomised, double-blind, placebo-controlled trial was performed to assess the efficacy of LGG in the eradication of VRE. Twenty-seven VRE-positive hospital inpatients were randomly allocated to consume either a yoghurt containing LGG (100 g daily for 4 weeks) or an equivalent amount of pasteurised yoghurt. All subjects who received LGG yoghurt were cleared of VRE, compared to only 8% of controls ( $P < 0.001$ ) (Manley et al 2007).

#### Pancreatitis

Probiotic therapy has been investigated in pancreatitis because of the increased risk of bacterial infections. Some animal studies have shown that the use of *L. plantarum* 299v (Mangiante et al 2001) and *S. cerevisiae* var. *boulardii* (Akyol et al 2003) reduced bacterial translocation. Human studies have investigated the use of single probiotic agents such as live *L. plantarum* 299v given to 22 patients compared with an inactivated form given to 23 patients; the probiotic-supplemented group had reduced rates of infection and abscess formation (Olah et al 2002).

However, these findings are in contrast to those of Besselink et al (2008), who used a novel preparation consisting of six different strains from six different species of lactic acid bacteria — *Lactobacillus acidophilus*, *L. casei*, *L. salivarius*, *Lactococcus lactis*, *Bifidobacterium bifidum* and *B. lactis* — in patients with severe acute pancreatitis. Use of this probiotic preparation was associated with significantly increased risk of bowel ischaemia (see section on Adverse Reactions, below). Thus not all probiotic preparations have a role for use as an adjunct treatment in pancreatitis.

#### Chemotherapy-induced diarrhoea

In an open-label trial, subjects ( $n = 150$ ) undergoing 5-fluorouracil-based chemotherapy for colorectal cancer were randomly assigned to receive supplementation with LGG ( $1-2 \times 10^{10}$  CFU/day). LGG supplementation was associated with a 41% reduced frequency of severe diarrhoea ( $P = 0.027$ ), an 83% reduction in abdominal discomfort scores ( $P = 0.025$ ) and 55% decreased frequency in bowel toxicity-induced dose reductions ( $P = 0.0008$ ) compared to untreated controls (Osterlund et al 2007).

#### AIDS-related diarrhoea

In a small double-blind, placebo-controlled study, 24 women with AIDS/HIV, aged 18–44 years, who were not being treated with antiretrovirals and had moderate diarrhoea, were given either a yoghurt fermented with *Lactobacillus delbrueckii* ssp. *bulgaricus* and *Streptococcus thermophilus* (the typical yoghurt-making bacteria), supplemented with the probiotic strains *Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14 or an unsupplemented yoghurt for 15 days. Women receiving the supplemented probiotic

yoghurt experienced less diarrhoea, flatulence and nausea compared to those receiving the unsupplemented yoghurt. All probiotic-treated subjects were free of diarrhoea after 15 days' treatment vs 9% of controls. Additionally, there was an increase in CD4 counts observed in probiotic-treated subjects compared to a decrease in controls ( $P < 0.02$ ) (Anukam et al 2008).

In an open-label trial, 17 HIV-positive patients with chronic diarrhoea were given *Saccharomyces cerevisiae* var. *boulardii* Biocodex strain (3 g/day) for 15 days. The mean number of stools per day decreased from 9.0 on enrolment to 2.1 on day 15. Patients gained a mean of 3.6 kg during the trial (McFarland & Bernasconi 1993, Saint-Marc et al 1991).

Trois et al (2008) investigated the effect of probiotics on the immune response in a randomised, double-blind, controlled trial of two groups of children (2–12 years) infected with HIV. The study of 77 children administered either a formula containing unspecified strains of *Bifidobacterium bifidum* and *Streptococcus thermophilus* —  $2.5 \times 10^{10}$  CFU/day (NAN2 probiotico Nestlé) — or a standard formula on a daily basis for 2 months. At the end of the study, there was an increase in CD4 cell count in the probiotic group (+118 cells/mm vs -42 cells/mm in controls;  $P = 0.049$ ), suggesting that this probiotic combination has immunostimulatory properties.

### Constipation

Constipation affects a significant proportion of the population. Probiotics have long been touted as useful for the treatment of constipation and recent randomised controlled trials have demonstrated efficacy for some probiotic strains.

In a randomised, controlled trial, Yang et al (2008) evaluated the effect of consuming a fermented milk containing *Bifidobacterium animalis* DN-173010 ( $1.25 \times 10^{10}$  CFU/day) on stool parameters in constipated women ( $n = 135$ ). Compared to controls, stool frequency was significantly increased in the bifidobacteria group after 1 week (3.5 movements/week vs 2.5;  $P < 0.01$ ) and after 2 weeks' consumption (4.17 vs 2.6;  $P < 0.01$ ). Defecation condition and stool consistency also significantly improved after 1 and 2 weeks (all  $P < 0.01$ ) of bifidobacteria consumption (Yang et al 2008).

Another randomised, double-blind, placebo-controlled trial compared the efficacy of placebo to a probiotic drink containing *Lactobacillus casei* Shirota ( $6.5 \times 10^9$  CFU/day) in constipated subjects ( $n = 70$ ). After a 4-week treatment period, there was a significant decrease in the occurrence of moderate and severe constipation ( $P < 0.001$ ) and in occurrence of hard stools ( $P < 0.001$ ) in the probiotic group. There was also an increase in defecation frequency ( $P = 0.004$ ) and improvement in stool consistency ( $P < 0.001$ ). General wellbeing was also significantly improved in the probiotic group ( $P = 0.008$ ) (Koebnick et al 2003).

### Immune enhancement/infection prevention

The potential role of probiotics in the enhancement of immune function has been under investigation over the past few decades. The process started with in vitro and animal research, followed by studies evaluating the effects of probiotic administration on immune cell function in human subjects. More recently, well-conducted human trials with hard outcomes have been published.

In a systematic review, Vouloumanou et al (2009) assessed the data from randomised controlled trials (14 trials) that had investigated the role of probiotics for the prevention and treatment of respiratory tract infections (RTIs). Ten of the 14 trials did not find that the probiotic agents trialled reduced the incidence of RTIs compared to placebo; the remaining four trials found the incidence of RTIs to be significantly lower in probiotic-treated patients. A significant reduction in the severity of RTI symptoms associated with probiotic treatment was found in five of six randomised controlled trials that provided relevant data. In the remaining randomised controlled trial, no difference was noted. Three randomised controlled trials reported a significant decrease in duration of RTI symptoms associated with probiotic therapy, whereas nine did not (Vouloumanou et al 2009). The data suggest that some, but not all, probiotic preparations have the capacity to enhance immune function and decrease risk and duration of RTIs.

A number of probiotic strains have demonstrated the capacity to reduce the incidence of infections and/or shorten their duration. The results of these trials are detailed in Table 5.

### Infantile colic

In a randomised, open-label trial, colicky breastfed infants ( $n = 90$ ; aged 21–90 days) were supplemented with either simethicone (active control) or *Lactobacillus reuteri* MM53 ( $1 \times 10^8$  CFU/day) for 4 weeks. Significant reductions in daily crying time were noted by day 7 in the MM53 group compared to the simethicone group ( $P = 0.005$ ). This improvement continued until day 28, when median crying time was reduced to 51 min/day in the MM53 group vs 145 min/day in controls ( $P < 0.001$ ). On day 28, 95% of patients were responders in the probiotic group versus 7% in the simethicone group (Savino et al 2007).

### Irritable bowel syndrome

Although the aetiology of IBS is still unknown, there is growing evidence that there is a persistent, mild inflammatory state with changes in mucosal function or structure and an associated imbalance of intestinal flora (Camilleri 2006). Dysbiosis has long been theorised to play a role in the pathophysiology of IBS and the first trial conducted investigating the efficacy of probiotics in IBS was published in 1955 (Rafsky & Rafsky 1955). Many trials have been conducted since this time.

TABLE 5 PROBIOTICS IN THE PREVENTION OF INFECTIONS		
Trial methodology	Strain(s) utilised	Results
R, DB, PC <i>n</i> = 201 infants 4–10 months old	<i>Bifidobacterium lactis</i> Bb12	Over a 3-month period, there was a reduction in fever episodes by 34% ( $P < 0.001$ ), diarrhoea episodes by 58% ( $P < 0.001$ ) and duration of diarrhoea episodes by 37% ( $P < 0.001$ ) (Weizman et al 2005)
R, DB, PC <i>n</i> = 326 children 3–5 years of age	<i>Lactobacillus acidophilus</i> NCFM	Over a 6-month period, fever incidence was reduced by 53% ( $P = 0.0085$ ) and coughing incidence by 41% ( $P = 0.027$ ); use of antibiotics reduced by 68% ( $P = 0.0002$ ); 32% reduction in days absent from child care ( $P = 0.002$ ) (Leyer et al 2009)
R, DB, PC <i>n</i> = 326 children 3–5 years of age	<i>Lactobacillus acidophilus</i> NCFM and <i>Bifidobacterium lactis</i> Bi07	Over a 6-month period, fever incidence was reduced by 73% ( $P = 0.0009$ ), coughing incidence by 62% ( $P = 0.005$ ) and rhinorrhoea incidence by 59% ( $P = 0.03$ ); use of antibiotics reduced by 84% ( $P < 0.0001$ ); 28% reduction in days absent from child care ( $P < 0.001$ ) (Leyer et al 2009)
R, DB, PC <i>n</i> = 215 infants aged 6–12 months	<i>Lactobacillus fermentum</i> CECT5716	Over a 6-month period, there was a 46% reduced incidence of gastrointestinal infections ( $P = 0.032$ ), a 26% reduction in respiratory tract infections ( $P = 0.022$ ) and a 30% reduction in the total number of infections ( $P = 0.003$ ); the incidence of recurrent respiratory tract infections was reduced by 72% (Maldonado et al 2012)
R, DB, PC, CO <i>n</i> = 20 elite, male distance runners	<i>Lactobacillus fermentum</i> VRI-003	Over a 4-month winter period, distance runners taking the probiotic reported less than half the number of days of respiratory symptoms (30 vs 72; $P = 0.00006$ ) compared with placebo; illness severity was also decreased ( $P = 0.06$ ) (Cox et al 2010).
R, DB, PC <i>n</i> = 201 infants 4–10 months old	<i>Lactobacillus reuteri</i> MM53	Over a 3-month period, fever episodes were reduced by 73% ( $P < 0.001$ ), diarrhoea episodes by 94% ( $P < 0.001$ ), duration of diarrhoea by 75% ( $P < 0.001$ ) and child care absences by 67% ( $P = 0.015$ ) in infants (Weizman et al 2005)
R, DB, PC <i>n</i> = 262 healthy adults	<i>Lactobacillus reuteri</i> MM53	Over the 80-day trial period, there was a 58% reduction in number of subjects reporting sick days in the MM53 group compared to placebo ( $P < 0.01$ ); amongst shift workers, 33% of those in the placebo group reported sick over the study period vs none in the MM53 group ( $P < 0.005$ ) (Tubelius et al 2005)
R, DB, PC <i>n</i> = 571 children aged 1–6 years	<i>Lactobacillus rhamnosus</i> GG (LGG)	Over the 7-month winter period, there were 16% fewer days absent from day care in children in the LGG group ( $P = 0.03$ ) and a 19% reduction in antibiotic use for respiratory tract infections ( $P = 0.03$ ) (Hatakka et al 2001)
R, DB, PC <i>n</i> = 281 day-care- aged children	<i>Lactobacillus rhamnosus</i> GG	Over the 3-month intervention period, there was a 34% reduced risk of upper respiratory tract infections in toddlers in the LGG group, a 43% reduced risk of respiratory tract infections lasting longer than 3 days and significantly fewer number of days with respiratory tract symptoms (all $P < 0.001$ ). There was a trend for reduced number of days with gastrointestinal symptoms ( $P = 0.06$ ) (Hojsak et al 2009)
R, DB, PC <i>n</i> = 81 infants < 2 months old	<i>Lactobacillus rhamnosus</i> GG and <i>Bifidobacterium lactis</i> Bb12	Over the 10-month period, there was a 56% reduced risk of otitis media in infants ( $P = 0.014$ ), a 48% reduced risk of antibiotic prescription ( $P = 0.015$ ) and a 49% reduced risk of recurrent respiratory tract infection ( $P = 0.022$ ) (Rautava et al 2009)

R, randomised; DB, double-blind; PC, placebo-controlled; CO, crossover.

Moayyedi et al (2010) performed a systematic review and meta-analysis of randomised controlled trials that investigated the efficacy of probiotics in the treatment of IBS. Nineteen randomised controlled trials were included ( $n = 1650$ ) in the review. Combining the data found probiotics to be significantly better than placebo in relieving IBS symptoms (relative risk of IBS not improving = 0.71;

95% CI 0.57–0.88) with a number needed to treat of four (95% CI 3–12.5). The authors concluded that probiotics appear to be efficacious in the treatment of IBS, but the magnitude of benefit and the most effective strains are uncertain (Moayyedi et al 2010).

A 2008 meta-analysis concluded that the use of probiotics can result in improved symptom relief in

patients with IBS (McFarland & Dublin 2008). Twenty randomised controlled clinical trials ( $n = 1404$ ) were reviewed, and either single or multiple probiotics were used for varying time periods ranging from 2 to 24 weeks (median = 4 weeks). Probiotic use was associated with improvement in global IBS symptoms compared to placebo (pooled relative risk [RR<sub>pooled</sub>] 0.77, 95% CI 0.62–0.94). Probiotic use was also associated with less abdominal pain compared to placebo (RR<sub>pooled</sub> 0.78 [0.69–0.88], 95% CI 0.45–0.81). There were insufficient data, however, to draw conclusions about the most effective probiotic strains or the assessment of individual IBS symptoms.

Similarly, a systematic review and meta-analysis by Hoveyda et al (2009) reported that probiotic therapy for several weeks may result in modest improvement in the overall symptoms of IBS. A total of 14 randomised placebo-controlled trials of varying length (from 4 weeks to 6 months; although the majority lasted 8 weeks or less) were included in the analyses. The probiotic therapy varied in the strains utilised as well as the dose and strength; in addition, some studies used a single agent and others used combinations of multiple strains. It is important to note, however, that not all clinical studies have produced positive results. A large randomised, parallel-group, double-blind study by Drouault-Holowacz et al (2008) investigated the effects of four strains of lactic acid (LA) bacteria ( $1 \times 10^{10}$  CFU *Bifidobacterium longum* LA 101 [29%], *Lactobacillus acidophilus* LA 102 [29%], *Lactococcus lactis* LA 103 [29%] and *Streptococcus thermophilus* LA 104 [13%]) on symptoms of IBS in 100 patients over a 4-week period. The probiotic combination was not significantly superior to the placebo in relieving symptoms of IBS, although symptomatic improvement was noted in some patient subgroups. Studies utilising LGG (in isolation) (O'Sullivan & O'Morain 2000), *Lactobacillus salivarius* UCC4331 (O'Mahony et al 2005a, 2005b) and *Lactobacillus acidophilus* NCFM (Newcomer et al 1983) also failed to demonstrate positive results. Probiotic preparations that have shown efficacy in the treatment of IBS are detailed in Table 6.

### Inflammatory bowel disease

Probiotics are also being used as adjunctive therapy for Crohn's disease and ulcerative colitis (Goh & O'Morain 2003, Guslandi 2003a, 2003b, Kanauchi et al 2003, Karthik 2003, Marteau et al 2003, Rutgeerts 2003). Overall, present research indicates a limited role for probiotics in Crohn's disease; the results for ulcerative colitis are more promising, and there does seem to be a beneficial effect in pouchitis.

### Crohn's disease

Only a limited number of studies have indicated a role for probiotics in the remission of Crohn's disease. In an open-label study, Guslandi et al (2000) compared *Saccharomyces cerevisiae* var. *boulardii* Biocodex plus mesalazine with mesalazine alone and found that adjunctive probiotic treatment resulted in fewer relapses (6% vs 38%;  $P = 0.04$ ).

Supplementation with VSL#3 has also been evaluated. VSL#3 contains a high concentration of eight strains of lactic acid bacteria — *Bifidobacterium breve*, *B. longum*, *B. infantis*, *Lactobacillus acidophilus*, *L. plantarum*, *L. casei*, *L. bulgaricus* and *Streptococcus thermophilus*. A study of 40 patients randomised to 3 months of rifaximin followed by 9 months of VSL#3 or to 12 months of mesalazine also reported relapse prevention with probiotic therapy (Campieri et al 2000).

Other studies, including randomised, double-blind placebo-controlled trials, have suggested that LGG and *Lactobacillus johnsonii* La1 have no role to play in maintaining Crohn's disease in remission (Hedin et al 2007). Similarly, studies that have administered probiotics for the treatment of active Crohn's disease have also provided mixed results, mainly because of concurrent use of medications during the intervention period (e.g. prednisolone use or metronidazole) (Gupta et al 2000).

A Cochrane systematic review by Rolfe et al (2006) did not advocate a role for probiotics in Crohn's disease based on the available evidence, suggesting that, because all studies enrolled small numbers of patients, they may have lacked statistical power to show differences should they exist. Seven randomised controlled trials were identified that had utilised a variety of probiotics, such as LGG, *Escherichia coli* Nissle 1917 and *Saccharomyces cerevisiae* var. *boulardii*; most of the studies had a relatively small number of participants with different treatment protocols, probiotic strains and outcome measures, making it difficult for comparisons to be made.

Similar conclusions were reached in a recent systematic review of probiotics in Crohn's disease, where the authors stated there was no evidence from randomised controlled trials to support the use of probiotic therapy in Crohn's disease (Jonkers et al 2012).

Given the promising preliminary research on *Saccharomyces cerevisiae* var. *boulardii* Biocodex in Crohn's disease, the strain was evaluated using a more rigorous randomised, double-blind, placebo-controlled trial design. One hundred and sixty-five subjects with Crohn's disease that was currently in remission after treatment with steroids or salicylates were randomly allocated to receive either placebo or probiotic (1 g/day) for 12 months. Over the 12 months, the relapse rates were 47.5% in the probiotic group and 53.2% in the placebo group (a non-significant difference). The median time to relapse did not differ significantly between patients given probiotics (40.7 weeks) vs placebo (39.0 weeks). There were also no significant differences between groups in mean Crohn's disease activity index scores or erythrocyte sedimentation rates or in median levels of C-reactive protein. A post hoc analysis did reveal, however, that non-smokers given *S. cerevisiae* var. *boulardii* Biocodex were less likely to experience a relapse of Crohn's disease than non-smokers given placebo (OR 0.22, 95% CI 0.07–0.70;  $P = 0.01$ ) (Bourreille et al 2013). The latter result requires confirmation in future research to ensure it was not

TABLE 6 PROBIOTICS IN THE TREATMENT OF IRRITABLE BOWEL SYNDROME (IBS)		
Trial methodology	Strain(s) utilised	Results
R, DB, PC <i>n</i> = 34 female subjects with C-IBS	<i>Bifidobacterium animalis</i> strain DN-173 010	After a 4-week treatment period, there was a significant reduction in abdominal distension ( <i>P</i> = 0.02), an acceleration of gut transit time ( <i>P</i> = 0.049) and a reduction in overall IBS symptom severity ( <i>P</i> = 0.032). There were also reductions in abdominal pain/discomfort ( <i>P</i> = 0.044), bloating ( <i>P</i> = 0.059) and flatulence scores ( <i>P</i> = 0.092) (Agrawal et al 2009)
R, DB, PC <i>n</i> = 362 female subjects with IBS	<i>Bifidobacterium infantis</i> 35624	After a 4-week treatment phase, there were significant reductions in abdominal pain/discomfort ( <i>P</i> = 0.023), bloating/distension ( <i>P</i> = 0.046), feeling of incomplete evacuation ( <i>P</i> < 0.04), sense of straining at stool ( <i>P</i> < 0.02), passage of gas ( <i>P</i> < 0.04) and composite IBS symptom scores ( <i>P</i> = 0.013) compared to controls. There was also a significant improvement in bowel habit satisfaction ( <i>P</i> < 0.02) (Whorwell et al 2006)
R, DB, PC <i>n</i> = 52 subjects with IBS	<i>Lactobacillus acidophilus</i> strains CUL-60 and CUL-21, <i>Bifidobacterium lactis</i> CUL-34, and <i>Bifidobacterium bifidum</i> CUL-20 (Lab4)	After an 8-week treatment period, there were significant reductions in composite IBS symptom scores ( <i>P</i> = 0.0217) and improvements in quality-of-life scores ( <i>P</i> = 0.0068) compared to controls (Williams et al 2008)
R, DB, PC <i>n</i> = 48 subjects with IBS and bloating	VSL#3	After either a 4- or an 8-week treatment phase, there was a significant reduction in flatulence scores ( <i>P</i> = 0.011). There were no significant changes in other IBS symptoms or bowel function, although colonic transit time was retarded in the VSL#3 group (Kim et al 2005)
R, DB, PC <i>n</i> = 214 subjects with IBS	<i>Lactobacillus plantarum</i> 299V	After a 4-week treatment phase, the frequency and severity of abdominal pain, bloating and feeling of incomplete evacuation scores were significantly reduced in the 299V group compared to controls (all <i>P</i> < 0.05). Stool frequency was significantly reduced in the 299V group ( <i>P</i> < 0.05), and 78% of subjects in the 299V group scored the symptomatic effect as excellent or good vs 8% of controls ( <i>P</i> < 0.01) (Ducrotte et al 2012)

R, randomised; DB, double-blind; PC, placebo-controlled; CO, crossover; C-IBS, constipation-predominant irritable bowel syndrome.

a random finding, but in the meantime a trial of this probiotic strain would be warranted in non-smoking Crohn's disease patients.

### Ulcerative colitis

A Cochrane review conducted in 2011 found four randomised controlled trials (*n* = 587) that evaluated probiotics for the maintenance of remission in ulcerative colitis. Combining the data from the three trials comparing probiotics to mesalazine found no significant difference in recurrence rates between the two treatments: 40.1% of subjects in the probiotics group and 34.1% in the mesalazine group relapsed over the treatment period. The final trial included a small placebo controlled trial (*n* = 32), and found no statistically significant difference in efficacy — 75% of probiotic patients relapsed at 1 year compared to 92% of placebo patients. The authors concluded that there is currently insufficient evidence to draw conclusions about the efficacy of probiotics for maintenance of remission in ulcerative colitis (Naidoo et al 2011).

A recent meta-analysis of randomised, controlled trials assessed the impact of probiotics on remission induction and maintenance in ulcerative colitis. Thirteen randomised controlled trials were included in the analysis. Seven reports evaluated remission rates (*n* = 399). When combined, the adjunct use of probiotics alongside standard care did not significantly alter remission rates. There was, however, marked heterogeneity in the results. Eight reports assessed the recurrence rate (*n* = 709). Compared to the placebo group, the use of probiotics was found to significantly reduce the ulcerative colitis recurrence rate (recurrence rate: 0.69, 95% CI 0.47–1.01; *P* = 0.05). Heterogeneity was again observed. The results suggest that using probiotics provides no additional benefit in inducing remission of ulcerative colitis, but probiotics auxiliary therapy is much better than non-probiotics therapy for maintenance of remission (Sang et al 2010). The significant heterogeneity observed in this study, which should have precluded the conduction of a meta-analysis, was most likely caused by the all-too-common error

TABLE 7 PROBIOTICS IN THE TREATMENT OF ULCERATIVE COLITIS (UC) — INDUCTION OF REMISSION

Trial methodology	Strain(s) utilised	Results
R, DB, C <i>n</i> = 116 patients with active UC	<i>Escherichia coli</i> Nissle 1917	Over a 12-month treatment period, <i>Escherichia coli</i> Nissle 1917 supplementation, in conjunction with standard inflammatory bowel disease therapy (corticosteroids), was equivalent to mesalazine in terms of remission rate ( $P = 0.05$ ) and time to remission ( $P = 0.009$ ). The duration of remission was also equivalent ( $P = 0.017$ ) (Rembacken et al 1999)
R, DB, PC <i>n</i> = 90 patients with moderately active distal UC	<i>Escherichia coli</i> Nissle 1917	Intrarectal administration (via enema) of three different doses of <i>E. coli</i> Nissle 1917 (40, 20, or 10 mL) daily for 2 weeks did not significantly impact rates of remission in intention to treat analysis. There were a large number of protocol violations, however, and a per protocol analysis demonstrated a significant dose-dependent effect ( $P = 0.0446$ ). Remission rates in the 40 mL group were 53%, 44% in the 20 mL group and 27% in the 10 mL group, compared to 18% in the placebo group (Matthes et al 2010)
R, DB, PC <i>n</i> = 147 subjects with mild to moderate active UC	VSL#3	At 6 weeks, 33% of VSL#3-treated subjects achieved >50% in the UC disease activity index versus 10% of controls ( $P = 0.001$ ). At week 12, 43% of subjects in the VSL#3 group were in remission vs 16% of controls ( $P < 0.001$ ) (Sood et al 2009)
R, DB, PC <i>n</i> = 29 children with active UC	VSL#3	In conjunction with standard UC therapy (steroids and mesalamine), remission was achieved in 93% of VSL#3-treated children vs 36% of controls ( $P < 0.001$ ). Twenty-one per cent of VSL#3-treated subjects relapsed within 1 year versus 73% of controls ( $P = 0.014$ ) (Miele et al 2009)
R, DB, PC <i>n</i> = 144 subjects with mild to moderate relapsing UC	VSL#3	In conjunction with standard UC therapy (stable doses of 5-aminosalicylic acid and/or immunosuppressants), the number of subjects experiencing a decrease in UC disease activity index scores of 50% or more was higher in the VSL#3 group than in the placebo group ( $P = 0.031$ ). Rectal bleeding also improved significantly more in the VSL#3 group than controls ( $P = 0.036$ ). Rates of remission were higher in the VSL#3 group, but not significantly so (43.6% vs 31.5%; $P = 0.132$ ) (Miele et al 2009)

R, randomised; DB, double-blind; PC, placebo-controlled.

of combining research conducted on different probiotic strains or variations in study designs. Each strain must be viewed as a separate therapeutic agent.

Probiotic preparations that have shown efficacy in the treatment of ulcerative colitis are detailed in Tables 7 and 8.

### Pouchitis

Probiotics have also been used in patients with relapsing or chronic pouchitis (Kailasapathy & Chin 2000). While studies have produced inconsistent results, overall there appears to be some evidence to support the therapeutic use of probiotics in postoperative pouchitis (Penner et al 2005) and the general view is that VSL#3 treatment can be effective in controlling this condition.

Studies by Gionchetti et al (2000, 2003) assessed the use of VSL#3 in both primary prevention of pouchitis and maintenance therapy for chronic relapsing pouchitis, demonstrating some success. In their randomised, controlled, double-blind study, 40 patients with relapsing pouchitis in remission received a 6 g daily dose of VSL#3 or a placebo for 9 months. Probiotic treatment resulted

in a significantly reduced incidence of pouchitis (Gionchetti et al 2000), but when VSL#3 treatment was ceased, all patients relapsed 3 months later. In a subsequent randomised controlled study to investigate VSL#3 treatment for primary prophylaxis of pouchitis in 40 patients, Gionchetti et al (2003) reported that treatment with VSL#3 resulted in fewer relapses.

In another randomised, double-blind, controlled trial, Mimura et al (2004) also utilised VSL#3 in 36 patients with more severe recurrent pouchitis over a 1-year follow-up period and reported good results regarding maintenance of remission and improved quality of life in the patients.

A combination of probiotics also has been reported to result in beneficial effects; lactobacilli and bifidobacteria in fermented milk were administered to patients who had pouchitis after ulcerative colitis surgery, resulting in some resolution of disease activity (Laake et al 2005).

In contrast, in an uncontrolled study of 31 patients who were treated with antibiotics and were in remission, Shen et al (2005) found little benefit with VSL#3 administered for 8 months.

TABLE 8 PROBIOTICS IN THE TREATMENT OF ULCERATIVE COLITIS (UC) — MAINTENANCE OF REMISSION		
Trial methodology	Strain(s) utilised	Results
R, DB, C <i>n</i> = 327 UC patients in remission	<i>Escherichia coli</i> Nissle 1917	Over the 12-month trial period, <i>E. coli</i> Nissle 1917 treatment was found to be equally effective as mesalazine in preventing relapse (36.4% relapse vs 33.9%; <i>P</i> = 0.003) (Kruis et al 2004)
R, DB, C <i>n</i> = 120 UC patients in remission	<i>Escherichia coli</i> Nissle 1917	Over a 12-week period, relapse rates were 11.3% under mesalazine and 16.0% under <i>E. coli</i> Nissle 1917 (not significantly different). The mean relapse-free time was 103 ± 4 days for mesalazine and 106 ± 5 days for <i>E. coli</i> Nissle 1917 (not significantly different) (Kruis et al 1997)
R, OL <i>n</i> = 187 UC patients in remission	<i>Lactobacillus rhamnosus</i> GG	Subjects were randomised to receive either <i>Lactobacillus rhamnosus</i> GG (LGG) alone or in combination with mesalazine, or mesalazine alone. Over the 12-month trial period, there was no difference in relapse rates between the three groups. LGG supplementation was equally effective as mesalazine in maintaining clinical remission, but significantly more effective than mesalazine in prolonging the relapse-free time ( <i>P</i> < 0.05) (Zocco et al 2006)
OL <i>n</i> = 34 UC patients in remission aged 11–18 years	<i>Escherichia coli</i> Nissle 1917	Over the 12-month treatment period, the relapse rate was 25% in probiotic-treated subjects vs 30% in the mesalazine group (Henker et al 2008)
OL <i>n</i> = 20 UC patients in remission	VSL#3	After 12 months, 15 of the 20 participants remained in remission, which compares favourably to rates of remission observed during long-term mesalazine therapy (Venturi et al 1999)

R, randomised; DB, double-blind; C, controlled; OL, open-label.

An open-label trial evaluated the efficacy of LGG in preventing pouchitis. Subjects with ulcerative colitis who had undergone an ileal pouch–anal anastomosis (*n* = 117) took part in the trial. LGG supplementation (1–2 × 10<sup>10</sup> CFU/day) significantly delayed first onset of pouchitis compared to no-treatment controls (cumulative risk at 3 years: 7 vs 29%; *P* = 0.011) (Gosselink et al 2005).

### Probiotics and diverticular disease

It has been suggested that altered bacterial flora is one of the causes of diverticular inflammation (White 2006). Consequently, some investigators have evaluated the role of probiotics in diverticular disease. In an open-label study, 15 patients with diverticular disease were treated with an antimicrobial and charcoal for the first symptomatic episode after enrolment and the second episode was treated with the same therapy, followed by *Escherichia coli* Nissle 1917 for 6 weeks. This second treatment resulted in a longer symptom-free duration of a mean of 14 months compared to a mean of 2.4 months in the control group (Fric & Zavoral 2003).

Various studies have attempted to restore the altered microflora using probiotics, but most of these studies have been limited in their design and methods (Sheth & Floch 2009). However, results from these studies appear to be mostly positive, and randomised placebo-controlled studies are needed in order to make recommendations.

### Alcohol-induced liver disease

In a prospective, randomised, clinical study, 66 men with advanced alcohol-induced liver disease received either *Bifidobacterium bifidum* (unspecified strain) and *Lactobacillus plantarum* 8PA3 or standard therapy (no probiotics) for 5 days. At the end of the study, patients who had received the probiotic therapy had significantly increased numbers of both bifidobacteria (7.9 vs 6.81 log 10<sup>9</sup> CFU/g) and lactobacilli (4.2 vs 3.2 log 10<sup>9</sup> CFU/g) compared to the standard therapy group; likewise, the former group had a significant improvement in hepatic enzyme levels (Kirpich et al 2008).

### Non-alcoholic fatty liver disease (NAFLD)

NAFLD comprises a spectrum of diseases ranging from simple steatosis to non-alcoholic steatohepatitis, fibrosis and cirrhosis. Probiotics have been proposed as a treatment option because of their modulating effect on the gut flora that could influence the gut–liver axis and there are now considerable data from animal models in support of this idea. A Cochrane systematic review conducted in 2007 found no human randomised controlled trials that evaluated probiotics in the treatment of NAFLD. The authors concluded that the lack of randomised controlled trials makes it impossible to support or refute the use of probiotics in NAFLD (Lirussi et al 2007).

In a randomised, double-blind, placebo-controlled trial, supplementation of obese children (*n* = 20; mean age 10.7 years) with persisting hypertransaminasaemia and ultrasonographic changes

suggestive of NAFLD with LGG ( $1.2 \times 10^{10}$  CFU/day) for 8 weeks resulted in a decrease in alanine aminotransferase concentration ( $P = 0.03$ ) and in antipeptidoglycan-polysaccharide antibody levels ( $P = 0.03$ ). Alanine aminotransferase levels normalised in 80% of LGG-treated subjects (Vajro et al 2011).

### Hepatic encephalopathy

To date, there are only a few reports about the role of probiotics in hepatic encephalopathy; in addition to the conventional management with antibiotics and lactulose, probiotics may confer favourable changes in intestinal microflora in patients with hepatic encephalopathy.

A recent randomised, controlled, single tertiary centre study with open allocation by Bajaj et al (2008) investigated the effects of a probiotic yoghurt on minimal hepatic encephalopathy (MHE), a pre-clinical stage prior to full-blown hepatic encephalopathy. The probiotics *Streptococcus thermophilus*, *L. bulgaricus*, *L. acidophilus*, bifidobacteria and *L. casei* (unspecified strains) were administered in the form of a commercial yoghurt to a group of non-alcoholic MHE cirrhotic patients for 60 days; the study demonstrated a significant rate of MHE reversal (71% vs 0% in controls;  $P = 0.003$ ).

### Colon cancer

A number of factors may be involved in colon cancer risk, and it has been suggested that the colonic microbiota may be involved in the aetiology of colorectal cancer. A lower incidence of colon cancer has been associated with the consumption of lactobacilli or bifidobacteria. The exact mechanisms have not been fully elucidated (Fotiadis et al 2008), but may have to do with probiotic-induced reductions in colonic expression of  $\beta$ -glucuronidase, nitroreductase and azoreductase (Marotta et al 2003).

A randomised, controlled trial evaluated the efficacy of *Lactobacillus casei* Shirota in the prevention of colorectal cancer in patients ( $n = 398$ ) who had had at least two colorectal tumours removed. Daily consumption of the probiotic over a 4-year period resulted in a significant reduction in the occurrence of colorectal tumours with moderate or severe atypia compared to the dietary instruction only group ( $P < 0.05$ ) (Ishikawa et al 2005).

### High cholesterol

Some probiotics may have cholesterol-lowering effects due to several mechanisms, including enzymatic deconjugation of bile acids and metabolic

#### Clinical note — The hygiene hypothesis

The intestinal tract is the largest immune organ of the body. It produces more antibodies than any other part of the body and contains 80% of all antibody-producing cells. The intestinal mucosa functions as a barrier against infections, but it also provides communication between the different mucosal surfaces of the body (Ouwehand et al 2002).

At birth, the GIT is sterile. Normal gut flora develops gradually over time and is influenced by factors such as composition of the maternal gut microbiota, diet, degree of hygiene, use of antibiotics or other medications, the environment and possibly genetic aspects. Studies in germ-free mice have shown that, without these bacteria, the systemic immune system will not function normally (Vanderhoof & Young 2002).

In the absence of microbes, a mammal develops fewer Peyer's patches (part of the gut-associated lymphoid tissue) and less than 10% of the number of IgA-producing B cells compared with normal. However, on exposure to a normal microflora, previously germ-free animals develop their immune system very much like other animals. This indicates that the intestinal microflora is instrumental in the proper development of the immune system (Ouwehand et al 2002) and has led to the emergence of the 'hygiene theory of immune disorders'.

More specifically, the hygiene hypothesis suggests that improved hygienic conditions and

vaccinations, which reduce early-life exposure to microbes, are associated with a heightened risk of allergic disease and other immune disorders. This is because reduced exposure may result in reduced stimulation of the immune system. As a result, lymphocytes that would normally differentiate to become Th1-type differentiate to Th2-type cells and produce inflammatory cytokines in the allergic response in much greater quantities. As such, very early stimulation of the immune system is important in dampening the Th2 dominance and reducing the development of IgE-mediated food reactions as well as other allergic reactions. In a closely observed cohort of 329 Finnish children, it was shown that the earlier an acute respiratory infection occurred, the greater the protective effect was against atopic eczema (Vanderhoof & Young 2003).

The obvious solution for increasing microbial exposure without increasing the health risk is the use of prebiotics and probiotics. Supplementation with probiotics has been shown to both reduce the risk and treat the symptoms of childhood eczema (see *Atopic Eczema*, above).

Modulating the intestinal microflora with probiotics and prebiotics may be an effective and safe therapy for the natural development of a balanced immune defence in infants and children. In adults and the elderly, prebiotics and probiotics may be used to improve the general functioning of the immune system.

utilisation of cholesterol (Brashears et al 1998, Liong & Shah 2005).

According to a meta-analysis of six studies of a probiotic dairy product containing *Enterococcus faecium*, treatment with the fermented yoghurt product produced a 4% decrease in total cholesterol and a 5% decrease in low-density lipoprotein cholesterol (Agerholm-Larsen et al 2000).

Since then, mixed findings have been reported regarding the use of encapsulated probiotics; a hypocholesterolaemic effect was not observed in some studies (Greany et al 2008, Hatakka et al 2008, Larsen et al 2006, Lewis & Burmeister 2005, Simons et al 2006), but Hlivak et al (2005) provided a daily dose of  $10^9$  CFU of probiotic bacteria and noted a hypocholesterolaemic effect. It is possible that lipid-lowering activity induced by probiotics is dependent on whether patients have high cholesterol levels ( $>6.0$  mmol/L) (Agerback et al 1995, Bertolami et al 1999, Hlivak et al 2005, Xiao et al 2003) or lower to normal cholesterol levels ( $<5.4$  mmol/L) (de Roos et al 1999, Greany et al 2004), although further randomised trials are required to confirm this observation. It is also possible that some probiotic strains have the capacity to lower serum cholesterol levels while others do not.

Most recently, two randomised, placebo-controlled studies failed to detect a significant lipid-lowering activity for different strains of probiotics. Greany et al (2008) conducted a randomised, single-blinded, placebo-controlled, parallel-arm study of 33 normocholesterolaemic women and 22 men aged 18–36 years. Subjects in the intervention group were treated for 3 months with probiotic capsules (three capsules daily) containing a total of  $10^9$  CFU *Lactobacillus acidophilus* strain DDS-1 and *Bifidobacterium longum* strain UABL-14 and 10–15 mg fructooligosaccharide. These probiotic strains had no effect on plasma lipid concentrations (Greany et al 2008).

Likewise, Hatakka et al (2008) conducted a double-blind, randomised, placebo-controlled, two-period crossover study to investigate the effects of taking on a daily basis two probiotic capsules containing viable *Lactobacillus rhamnosus* LC705 and *Propionibacterium freudenreichii* ssp. *shermanii* JS ( $2 \times 10^{10}$  CFU of each strain) on serum cholesterol and triglyceride levels: the study of 38 mildly or moderately hypercholesterolaemic men aged 24–55 years found that probiotic treatment over 4 weeks did not have any effect on serum lipids.

### Mastitis

Mastitis is an inflammatory condition of the breast that may, or may not, be associated with infection. It is a common reason for premature cessation of breastfeeding (Academy of Breastfeeding Medicine 2008). Recent research has found some probiotic strains to be of benefit in the treatment of mastitis and the prophylaxis of recurrent mastitis.

In a randomised, double-blind, placebo-controlled trial, 352 women with lactational mastitis were

allocated into one of three groups: antibiotics, *Lactobacillus fermentum* CECT5716 or *L. salivarius* CECT (both at  $1.0 \times 10^9$  CFU/day). After 3 weeks' treatment, both probiotic strains were found to be superior to antibiotics in decreasing levels of pathogenic bacteria in breast milk, increasing lactobacilli counts in breast milk and decreasing breast pain scores (all  $P < 0.001$ ). They also significantly reduced the rate of recurrence compared to antibiotics: 10.5% in the *L. fermentum* CECT5716 group and 7.1% in the *L. salivarius* CECT5713 group versus 30.7% in the antibiotic group (both  $P < 0.001$ ) (Arroyo et al 2010).

In another randomised, placebo-controlled trial, women ( $n = 20$ ) with antibiotic-resistant mastitis were allocated to receive either placebo or a probiotic preparation (*Lactobacillus salivarius* CECT5713 and *L. gasseri* CECT5714;  $2.0 \times 10^{10}$  CFU/day) for 14 days. All mastitis signs were eliminated by day 14 in the probiotic group, whereas mastitis persisted in all women in the control group. There was also an ~100-fold decrease in milk staphylococcal counts in probiotic group (Jimenez et al 2008).

### Postpartum obesity

Another novel area of research is using probiotics to prevent postpartum obesity. Ilmonen et al investigated the use of a probiotic combination product (containing LGG and *Bifidobacterium lactis* Bb12) in the prophylaxis of postpartum obesity. In the first trimester of pregnancy, 256 women were randomly assigned to receive no dietary counselling or nutritional counselling (low-fat and high-fibre diet) plus probiotics (LGG and Bb12;  $2.0 \times 10^{10}$  CFU/day) or counselling plus placebo. Interventions lasted until the end of exclusive breastfeeding for up to 6 months. At 6 months postpartum, the risk of central adiposity (defined as waist circumference 80 cm or more) was lowered in women in the diet/probiotics group compared with the control/placebo group (OR 0.30, 95% CI 0.11–0.85;  $P = 0.023$  adjusted for baseline body mass index), while the diet/placebo group did not differ from the controls (OR 1.00, 95% CI 0.38–2.68;  $P = 0.994$ ). The number needed to treat with diet/probiotics to prevent one woman from developing a waist circumference of 80 cm or more was four (Ilmonen et al 2011). At 12 months postpartum, central obesity occurred in 25% of diet/probiotic subjects versus 43% in the diet/placebo group. The proportion of body fat was also 3.5% lower in the diet/probiotic group ( $P = 0.018$ ) (Laitinen et al 2009).

### Urogenital infections

Probiotics are widely used in the treatment and prevention of urogenital infections. They can be administered both orally and locally, with several trials supporting their use. There are additional criteria needed for probiotic strains to be efficacious in urogenital applications. Strains must demonstrate the capacity to adhere to uroepithelial and vaginal cells, colonise the vagina, inhibit urogenital pathogen

growth and/or attachment and ideally should produce hydrogen peroxide. Strains that will be administered orally must have sufficient tolerance to gastric acid and bile salts and the capacity to colonise the vagina after oral intake (Reid & Bruce 2001). Probiotic strains that do not exhibit these characteristics are unlikely to be therapeutic for urogenital applications.

The mechanisms by which some *Lactobacillus* strains reduce bacterial vaginosis, vaginal candidiasis and urinary tract infections appear to involve a combination of antiadhesion factors, byproducts such as hydrogen peroxide, bacteriocins and lactic acid, and destruction of urogenital pathogen biofilms, as well as immune modulation or modification of vaginal epithelial cell cytokine production (Kohler et al 2012, Korshunov et al 1999, McMillan et al 2011, Wagner & Johnson 2012).

### Bacterial vaginosis

Bacterial vaginosis is the most prevalent vaginal infection worldwide and is characterised by an altered vaginal ecosystem — specifically depletion of the indigenous lactobacilli. Administration of exogenous lactobacilli strains has thus been an area of research interest (Martinez et al 2009a).

A Cochrane systematic review conducted in 2009 included four randomised controlled trials that examined probiotic agents in the treatment of bacterial vaginosis. Analysis suggested that probiotics were effective in enhancing microbiological cure rates, with the oral metronidazole/probiotic (*Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14) regimen (OR 0.09; 95% CI 0.03–0.26) and the probiotic (unspecified strain of *Lactobacillus acidophilus*)/oestriol preparation (OR 0.02; 95% CI 0.00–0.47) showing effectiveness. The authors cautioned, however, that larger well-designed trials were needed before any firm conclusions could be made (Senok et al 2009). Research on specific strains that have demonstrated efficacy is highlighted below.

A randomised, controlled, open-label trial evaluated the efficacy of a probiotic combination (*Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14;  $2 \times 10^9$  CFU/day) in women with bacterial vaginosis. Women received either metronidazole gel or the probiotic preparation. Both preparations were applied intravaginally for 5 days. Application of probiotics resulted in a 90% cure rate by day 30. Follow-up at day 6, 15 and 30 showed cure of bacterial vaginosis in significantly more probiotic-treated subjects (16, 17 and 18/20, respectively) compared to metronidazole gel treatment (9, 9 and 11/20, respectively;  $P = 0.016$  at day 6,  $P = 0.002$  at day 15 and  $P = 0.056$  at day 30) (Anukam et al 2006).

In a randomised, double-blind, placebo-controlled trial, 64 women diagnosed with bacterial vaginosis were randomly assigned to receive a single dose of tinidazole supplemented with either two placebo capsules or two capsules containing *Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14 ( $2 \times$

$10^9$  CFU/day) taken orally every morning for the following 4 weeks. At the end of the trial, subjects in the probiotic group had a higher rate of bacterial vaginosis cure (88% vs 50%;  $P = 0.001$ ). Vaginal flora normalised in 75% of probiotic-treated subjects compared to only 34% of controls ( $P = 0.011$ ) (Martinez et al 2009a).

A more recent randomised, double-blind, placebo-controlled trial evaluated the efficacy of probiotics in isolation on bacterial vaginosis. Women diagnosed with bacterial vaginosis ( $n = 544$ ) were randomly assigned to receive either oral placebo or probiotic therapy (*Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14;  $\sim 1 \times 10^9$  CFU/day) for 6 weeks. Restitution of a balanced vaginal ecosystem was reported in 27% of subjects in the placebo group compared to 62% in the probiotic group ( $P < 0.001$ ). After an additional 6 weeks of follow-up, a normal vaginal ecosystem was still present in more than half (51%) of subjects in the probiotic group, but only in around one-fifth (21%) of subjects who were taking placebo ( $P < 0.001$ ) (Vujic et al 2013).

A randomised, double-blind, placebo-controlled trial investigating the potential role of probiotics in the prevention and cure of bacterial vaginosis in women with HIV ( $n = 65$ ) found 6 months' daily treatment with a probiotic preparation (*Lactobacillus rhamnosus* GR-1 and *Lactobacillus reuteri* RC-14;  $2 \times 10^9$  CFU/day) to be ineffective in enhancing bacterial vaginosis cure rates in this population. Nor was there a difference in recurrence rates of bacterial vaginosis between the probiotics and the placebo groups. There was, however, a trend for a higher prevalence of normal vaginal flora in the probiotic group (53% normalised vs 25%;  $P = 0.08$ ) (Hummel et al 2010).

The strains to use in the prevention and treatment of bacterial vaginosis appear to be *Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14.

### Urinary tract infections

Grin et al (2013) performed this systematic review and meta-analysis to review the data on the potential effectiveness of lactobacilli in the prevention of recurrent urinary tract infections in women. Five randomised, controlled trials were included in the analysis. Combining the data from all the trials (294 patients) found no preventive effect of lactobacilli supplementation (RR = 0.85, 95% CI 0.58–1.25;  $P = 0.41$ ). However, a sensitivity analysis was performed, excluding studies using ineffective strains and studies testing for safety only. Data from 127 patients in two trials were included. A statistically significant decrease in recurrent urinary tract infections was found in patients given lactobacilli, denoted by the pooled risk ratio of 0.51 (95% CI 0.26–0.99;  $P = 0.05$ ) (Grin et al 2013).

A significant reduction in urinary tract infection recurrence rate was reported in a randomised, double-blind study involving 55 premenopausal women (Reid 2001). The study investigated the effectiveness of treatment for 1 year with a weekly

suppository containing either 0.5 g *L. rhamnosus* GR-1 and *L. fermentum* B-54 or a *Lactobacillus* growth factor (skim milk). Treatment resulted in the urinary tract infection rate decreasing by 73% and 79%, respectively, with no adverse effects reported.

A recent, randomised, double-blind, non-inferiority trial compared the efficacy of 12 months of prophylaxis with antibiotics (trimethoprim-sulfamethoxazole; 480 mg/day) or oral probiotics ( $2 \times 10^9$  CFU/day of *Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14) in the prevention of urinary tract infections in postmenopausal women with recurrent cystitis ( $n = 252$ ). The number of symptomatic urinary tract infections over the 12-month treatment period was 2.9 in the antibiotic group and 3.3 in the lactobacilli group — a between-treatment difference of 0.4 episodes (95% CI  $-0.4$  to  $1.5$ ) or 13.8%. In the year preceding the trial, the subjects experienced a mean of 6.9 urinary tract infections. The percentage of patients with at least one urinary tract infection at 12 months was 69.3% in the trimethoprim-sulfamethoxazole group and 79.1% in the lactobacilli group. The median times to first recurrence were 6 and 3 months, respectively. After 12 months of trimethoprim-sulfamethoxazole prophylaxis, all urinary *E. coli* isolates of asymptomatic women were resistant to trimethoprim-sulfamethoxazole and trimethoprim. Probiotic use, however, was not associated with increased antibiotic resistance. The authors stated that this lactobacilli combination may be an acceptable alternative for the prevention of urinary tract infections, especially in women who dislike taking antibiotics (Beerepoot et al 2012). While probiotic therapy appeared slightly less effective than antibiotic prophylaxis in postmenopausal women with recurrent urinary tract infections, their use does not damage the GIT ecosystem, nor create antibiotic-resistant organisms, and for these reasons, some have argued that this probiotic combination has a role to play in the prevention of recurrent urinary tract infections (Trautner & Gupta 2012).

The probiotic combination of *Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14 appears to have the greatest evidence supporting its use in the prevention of urinary tract infections.

### Vaginal candidiasis

Lactobacilli can impair the growth of *Candida albicans* via the production of lactic acid, which creates a low-pH environment, resulting in suppressed fungal growth. Cocultures of specific lactobacilli strains with *C. albicans* revealed that *C. albicans* cells lost metabolic activity and eventually died. Transcriptome analyses showed increased expression of stress-related genes and lower expression of genes involved in antifungal resistance (Kohler et al 2012).

A systematic review examining the role of lactobacilli probiotics in the treatment and prevention of vulvovaginal candidiasis (and other urogenital infections) was conducted by Abad and Safdar in

2009. Only four studies were found that evaluated lactobacilli supplementation in vulvovaginal candidiasis — two assessed preventive effects and two treatment effects. Only one prospective crossover trial found a significant benefit of probiotic therapy for the prevention of vulvovaginal candidiasis (RR 0.39; 95% CI 0.17–0.70). The authors concluded that there were insufficient data to make definitive conclusions at this point in time (Abad & Safdar 2009).

Some probiotic preparations have been shown to be ineffective in the treatment of vulvovaginal candidiasis — Lactobac (unspecified strains of *Lactobacillus rhamnosus* and *Bifidobacterium longum*) and Femilac (unspecified strains of *L. rhamnosus*, *L. delbrueckii* ssp. *bulgarius*, *L. acidophilus* and *Streptococcus thermophilus*) (Pirootta et al 2004). Probiotic preparations that have shown efficacy in the treatment of vulvovaginal candidiasis are detailed in Table 9, although it should be highlighted that most of these trials were small in size.

### OTHER USES

Probiotics may have many potentially important clinical applications, and current areas of active research include mostly animal studies investigating a range of diseases, including control or prevention of cancer (Fotiadis et al 2008) and prevention or treatment of graft-versus-host disease in transplant recipients (Gerbitz et al 2004).

### DOSAGE RANGE

Probiotic doses are usually standardised in terms of the amount of living bacteria per unit of volume. Each living bacterium is referred to as a colony-forming unit or CFU.

The minimum concentration of probiotic bacteria needed to achieve therapeutic effects appears to be somewhat strain-dependent, in that, for some strains (e.g. *L. reuteri* MM53),  $10^7$  bacteria is a sufficient quantity to produce beneficial effects (Shornikova et al 1997), while for other strains,  $10^9$  viable bacteria is needed (e.g. *L. rhamnosus* GG) (Saxelin 1996). This situation, unfortunately, makes it hard to give firm dosage recommendations, as the minimum effective dosage appears to differ by strain. Thus it is best practice to ensure that supplements contain bacteria in concentrations  $>10^9$  bacteria/dose, unless research has demonstrated that the specific strain contained in the supplement is effective in smaller amounts.

If a product contains multiple strains, then each strain should be present at levels of  $\geq 10^9$  to ensure effectiveness. The viable bacteria are typically mixed in a suitable matrix, which may contain maltodextrin, cellulose, and small amounts of prebiotics, such as fructooligosaccharides and inulin.

Supplements are best taken with meals to enhance bacterial survival.

A serving of yoghurt containing fewer than  $10^8$  viable bacteria is unlikely to have any therapeutic activity beyond acting as a nutritional source.

TABLE 9 PROBIOTICS IN THE TREATMENT OF VULVOVAGINAL CANDIDIASIS (VC)

Trial methodology	Strain(s) utilised	Results
R, DB, PC <i>n</i> = 27 women with a history of recurrent VC	<i>Lactobacillus acidophilus</i> NAS as a vaginal suppository in isolation or with <i>L. acidophilus</i> NAS strain; <i>Bifidobacterium bifidum</i> Malyoth strain, and <i>Lactobacillus bulgaricus</i> LB-51 strain taken orally	In women who used the <i>L. acidophilus</i> NAS vaginal suppository, the incidence of recurrent VC was significantly reduced compared to controls ( <i>P</i> = 0.005). Subjects who took both the suppository and the oral probiotic supplement also had a significant reduction in the number of infections compared to controls ( <i>P</i> = 0.011). There was, however, no extra benefit seen from taking the oral probiotic preparation (Metts et al 2003)
R, DB, PC <i>n</i> = 55 women with VC	<i>Lactobacillus rhamnosus</i> GR-1 and <i>Lactobacillus reuteri</i> RC-14	After a single dose of fluconazole and 4 weeks' oral treatment with either probiotic or placebo, subjects in the probiotic group had reduced <i>Candida</i> colonisation (10% vs 39%; <i>P</i> = 0.014) and decreased vaginal discharge (10% vs 35%; <i>P</i> = 0.03) (Martinez et al 2009b)
R, PC, CO <i>n</i> = 33 women with a history of recurrent VC	<i>Lactobacillus acidophilus</i> LA5	The mean number of infections per 6 months decreased while in the probiotic phase compared to control phase of trial (0.38 vs 2.54; <i>P</i> = 0.001). The incidence of <i>Candida</i> colonisation also decreased during probiotic treatment (0.84 vs 3.23 per 6 months; <i>P</i> = 0.001) (Hilton et al 1992)
OL <i>n</i> = 28 women with a history of recurrent VC	<i>Lactobacillus rhamnosus</i> GG (LGG)	Twice-daily intravaginal application of LGG resulted in decreased symptoms of vulvovaginal candidiasis, as well as less erythema and discharge; 4/5 women who were positive for <i>Candida</i> at baseline had negative cultures at the end of 7 days (Hilton et al 1995)

R, randomised; DB, double-blind; PC, placebo-controlled; CO, crossover; OL, open-label.

### Practice points/Patient counselling

- Some probiotics may improve the long-term bowel flora; however, the benefits of probiotics extends well beyond this role.
- Studies have shown that probiotics are beneficial in the treatment of digestive disorders such as diarrhoea and some inflammatory bowel diseases and also other conditions, such as urogenital infections, antibiotic-induced and TD, IBS, ulcerative colitis, food allergies, eczema and the prevention and treatment of paediatric atopic dermatitis.
- It is vital to note that, just because one strain of bacteria in a given species has a proven action or characteristic, it does not mean that another strain will too, even if they are closely related. Strains within the same species can have

significantly different actions, properties and characteristics, as these are all essentially strain-specific qualities.

- Probiotics can be administered orally or intravaginally. They can also be taken as yoghurt or other cultured dairy products. It should be noted that only products containing actual probiotic strains will be beneficial. The so-called starter cultures (strains of *Lactobacillus delbrueckii* ssp. *bulgaricus* and *Streptococcus thermophilus*) have limited beneficial effects.
- For traveller's diarrhoea prevention, it is recommended that the probiotic dose be started some days before travelling to ensure that the beneficial bacteria have colonised the gut; the dosage may vary depending on the probiotic strain.

P

### ADVERSE REACTIONS

Probiotics are generally regarded as safe. However, probiotic therapy should be used with caution in the immunocompromised, as they may be at increased risk of adverse reactions. Infections, sepsis and meningitis have been reported in adult cases when administered lactobacilli (Land et al 2005, Mackay et al 1999, Rautio et al 1999). Cases of young children and infants have also been reported

(Borriello et al 2003). Opportunistic pathogenicity is, however, considered low (Shanahan 2012).

There have been a number of cases of fungaemia reported in the literature from the oral administration of *Saccharomyces cerevisiae* var. *boulardii* (aka *S. boulardii*). These have occurred almost exclusively in immunocompromised or critically ill individuals, in particular those with intravascular catheters. Thus administration of strains of *S. cerevisiae* var.

*boulardii* may best be limited to immunocompetent individuals — i.e. those with well-functioning immune systems (Enache-Angoulvant & Hennequin 2005, Lherm et al 2002, Riquelme et al 2003). Additionally, in hospitalised patients with a central venous catheter, supplementation with a strain of *S. cerevisiae* var. *boulardii* should be avoided to prevent inadvertent catheter contamination (Venugopalan et al 2010).

There is also concern in critically ill patients because impaired intestinal barrier function could result in infection as a result of bacterial translocation (Land et al 2005, Munoz et al 2005). Recently, there has been one report citing increased mortality in patients with severe acute pancreatitis who were administered a novel multispecies probiotic (Besselink et al 2008).

## SIGNIFICANT INTERACTIONS

### Antibiotics

Concomitant administration of some strains of probiotics reduces gastrointestinal and genitourinary side effects according to clinical studies — combination can be safely used together and a beneficial interaction is likely.

### CONTRAINDICATIONS AND PRECAUTIONS

Specific strains of probiotics are appropriate for different disorders. Probiotics are contraindicated in those people who are hypersensitive to any component of the probiotics-containing product. Strains of *Saccharomyces cerevisiae* var. *boulardii* may best be avoided in immunocompromised individuals

### PREGNANCY USE

Likely to be safe in pregnancy; however, it is best practice to utilise strains that have demonstrated excellent safety profiles in clinical trials conducted on pregnant women.

### PATIENTS' FAQs

#### What can probiotics do for me?

Studies have shown that probiotics are beneficial in the treatment of digestive disorders such as diarrhoea and some inflammatory bowel diseases and also other conditions not directly connected with the digestive tract, such as vaginal thrush and recurrent cystitis, antibiotic-induced and TD, IBS, food allergies and eczema.

#### When will they start to work?

Usually, probiotics can exert beneficial effects in digestive disorders within days, although continuous use for several weeks/months may produce long-term benefits and be necessary in the treatment of other disorders.

#### Are there any safety issues?

Generally, probiotics have a good safety profile; however, supplements should be used under supervision in the immunocompromised.

## Psyllium

**HISTORICAL NOTE** Psyllium has a long history of use in both conventional and traditional medical systems and has been listed in various pharmacopoeias around the world.

### OTHER NAMES

Psyllium seed, Blonde *Plantaginis ovatae* semen — ripe seeds of *Plantago ovata* (*P. isphagula*).

*Plantago ovata* semen refers to the unprocessed seed.

White or blond psyllium, also known as Indian plantago.

Psyllium seed husk, Blonde *Plantaginis ovatae* testa — referring to the epidermis layers of *Plantago ovata* (*P. isphagula*)

Psyllium seed, Black *Psyllii semen* — referring to the dried ripe seed of *Plantago psyllium* (*P. afra*, *P. arenaria* and *P. indica*)

Black, French or Spanish psyllium comes from *P. psyllium* (syn. *P. afra*) and *P. arenaria* (*P. indica*).

### BOTANICAL NAME/FAMILY

*Plantago ovata*, *P. psyllium*, *P. arenaria* (family Plantago)

## PLANT PART USED

Seed coat and seed

## CHEMICAL COMPONENTS

*Plantago ovata* seed husk generally consists of 67–71% fibre; constituents includes 10–30% mucilage (arabinoxylans), iridoid glycosides ( $\approx$  aucubin), trace monoterpene alkaloids, sugars, protein, sterols, triterpenes, fatty acids and tannins. Phytosterol and beta-sitosterol (Nakamura et al 2005). The seeds contain a 20:80 ratio of soluble to insoluble fibre, and the husks a 70:30 ratio (Lopez et al 2009).

## MAIN ACTIONS

### Bulking agent

Psyllium husk is commonly used throughout the world as a bulking agent in the treatment of both constipation and diarrhoea. A component of psyllium husk is incompletely fermented, forming a mucilaginous gel which provides lubrication, increases moisture content and facilitates propulsion of the colon contents (Marlett et al 2000).

Psyllium promotes stools that are more frequent and softened, and reduces pain on defecation. Psyllium has been shown to be more beneficial in maintaining regularity than bran (Singh 2007).

### Promotes satiety

A placebo-controlled study of a *P. ovata* preparation administered in water found a significant difference in satiety 1 hour after consumption (Turnbull & Thomas 1995). Increased satiety was apparent up to 6 hours after consumption. A recent animal study showed that among its proposed range of action psyllium had the potential to attenuate weight gain (Wang et al 2007).

### Lipid lowering

Psyllium husk effectively reduces lipid levels by altering cholesterol metabolism, increasing hepatic cholesterol catabolism and increasing faecal bile acid excretion (Romero et al 2002). *Psyllium* sequesters bile salts during passage through the intestinal lumen as well as physically disrupts the intraluminal formation of micelles, thereby reducing the absorption of cholesterol and reabsorption of bile salts. As a result, bound bile acids are moved to the terminal ileum and colon, thereby interrupting the enterohepatic circulation so that more cholesterol is converted into newly produced bile acids (Rodriguez-Moran et al 1998). It is postulated that this increased hepatic conversion of cholesterol into bile acids results in increased LDL uptake by the liver, leading to decreased levels of serum LDL cholesterol and total cholesterol (Theuwissen & Mensink 2008). Reduced cholesterol biosynthesis results in an upregulation of LDL receptors and enhanced uptake of LDL cholesterol (Shrestha et al 2007). Both the unfermented and viscous components of psyllium are considered responsible for the observed lipid-

lowering effects (Marlett & Fischer 2003, Dikeman & Fahey 2006).

### Slows glucose absorption

Animal and human models have demonstrated that psyllium modulates the glycaemic response through various mechanisms. Psyllium supplementation delays gastric emptying, small bowel motility and reduces intestinal mixing, thereby slowing and reducing glucose absorption across the intestinal lumen of the small intestine (Dikeman & Fahey 2006). Psyllium has induced an upregulation of GLUT-4 receptors in skeletal muscle cell membranes in vitro (Song et al 2000), and has been shown to improve glycaemic response by modulating postprandial glucose concentrations and insulin requirements (Anderson et al 1999, Frati-Munari et al 1989, Sierra et al 2001). Wang et al demonstrated in vivo that psyllium enhances insulin sensitivity, reduces weight gain and modulates GLP-1 secretion (Wang et al 2007).

### Metabolic syndrome

Psyllium husk administration may beneficially alter many of the abnormalities observed in metabolic syndrome through the actions detailed above, but recent animal research also suggests a capacity to upregulate hepatic AMP-activated protein kinase phosphorylation, reduce secretion of tumour-necrosis factor- $\alpha$  (TNF- $\alpha$ ), increase production of adiponectin, and enhance expression of its receptors in visceral adipose tissue (Galisteo et al 2010).

### Colonic anti-inflammatory effects

In a rat model of ulcerative colitis, administration of psyllium seeds resulted in increased concentrations of short-chain fatty acids (particularly butyrate) in the colonic lumen, ameliorated the development of colonic inflammation, and decreased colonocyte production of pro-inflammatory mediators leukotriene B<sub>4</sub> and tumour-necrosis factor- $\alpha$  (Rodriguez-Cabezas et al 2003).

### Promotes apoptosis of colorectal cancer cells

The fermentation products of psyllium husks (representative of what occurs in the colon after ingestion) were found to induce apoptosis in primary colorectal tumour cells and metastatic cell lines (Caco-2, HCT116, LoVo, HT-29 and SW480). Apoptosis was caspase-dependent and both intrinsic and extrinsic pathways were involved (Sohn et al 2012).

## CLINICAL USE

Psyllium is used mainly for its mucilage content, which comes from the seed coat (husk).

### Bulking agent

Psyllium is commonly used as a bulking agent to treat constipation or diarrhoea and to regulate stool consistency in people with a colostomy or ileostomy. As a bowel regulator, psyllium husk absorbs

water in the colon to increase faecal bulk, which stimulates peristaltic activity. Alternatively, psyllium can be used to promote normal stool formation in people with diarrhoea by decreasing the frequency of fluid stools. Commission E approves the use of black psyllium seed and blond psyllium seed for chronic constipation and when a soft stool is desirable, such as in patients with haemorrhoids, anal fissures or postrectal surgery (Blumenthal et al 2000).

The symptoms associated with constipation-induced haemorrhoids may also be reduced through administration of psyllium. A reduction of pain and length of hospital stay following open haemorrhoidectomy were achieved through supplementation of laxomucil (3.26 g psyllium) (Kecmanovic et al 2004). A subsequent study further identified a reduction of postsurgical tenesmus rate (Kecmanovic et al 2006).

### Weight loss aid

Psyllium is used to increase the subjective feeling of satiety before and between meals in an attempt to reduce total caloric intake. One study comparing *Plantago ovata* preparation (20 g granules with 200 mL water) to water or a placebo preparation found a significant difference in fullness 1 hour after consumption (Turnbull & Thomas 1995). Other studies have confirmed a suppressant effect on hunger and increased satiety that remains apparent up to 6 hours after consumption. Psyllium also significantly delays gastric emptying from the third hour after a meal (Bergmann et al 1992, Delargy et al 1997).

### Metabolic syndrome

Psyllium husks also appear able to beneficially alter a number of metabolic syndrome abnormalities. In a randomized, double-blind, placebo-controlled trial, Sola et al administered psyllium husks (14 g/day) or placebo to hypercholesterolaemic patients ( $n = 254$ ) for 8 weeks. Relative to placebo, administration of psyllium husks reduced plasma LDL cholesterol by 6% ( $P < 0.0002$ ), total cholesterol by 6% ( $P < 0.0001$ ), triglycerides by 22% ( $P = 0.0004$ ), apolipoprotein B-100 by 7% ( $P < 0.0001$ ), oxidised LDL by 7% ( $P = 0.0003$ ), insulin by 4.7 pmol/L ( $P = 0.02$ ) and systolic blood pressure by 4.0 mmHg (95% CI 1.2–6.7;  $P < 0.05$ ) (Sola et al 2010).

### Hyperlipidaemia

Psyllium is also used as a cholesterol-lowering agent, usually as an adjunct to a low-fat diet (Reid et al 2002). Soluble fibres, such as psyllium husk, increase the cholesterol-lowering effect of a low-fat diet in people with elevated cholesterol (Anderson et al 2000). A meta-analysis of 21 controlled clinical trials ( $n = 1697$ ) testing psyllium dosages ranging between 3.0 and 20.4 g daily confirmed that psyllium produced a time- and dose-dependent serum cholesterol-lowering effect in patients with mild-to-moderate hypercholesterolaemia (Wei et al 2009). Reductions

in serum cholesterol occurred more quickly than changes in LDL cholesterol with psyllium supplementation.

Similar results were obtained in two previously published meta-analyses. Davidson et al (1996) evaluated data from eight studies and found that psyllium (10.2 g/day) lowered serum total cholesterol by 4%, LDL cholesterol by 7% and the ratio of apolipoprotein (apo) B to apo A-I by 6% relative to placebo. This was achieved together with a low-fat diet over 8 weeks. It has also been used with some success in the paediatric population and is easy to incorporate into various foods (Davidson et al 1996). Olson et al (1997), using the data from 404 subjects with mild-to-moderate hypercholesterolaemia, concomitantly consuming a high-fat diet supplemented with psyllium in the form of cereal, found psyllium to be beneficial in lowering both LDL and total cholesterol; however, HDL concentrations were unaffected (Olson et al 1997).

### Studies with statin drugs

A 12-week blinded, placebo-controlled study comprising 68 patients demonstrated that supplementation of dietary psyllium 15 g (Metamucil) daily in patients taking 10 mg of simvastatin was as effective in lowering cholesterol as 20 mg of simvastatin alone (Moreyra et al 2005). However, a 4-week open-label, randomised, parallel study of 36 subjects demonstrated that 10 g of psyllium daily added to 20 mg of lovastatin provided an additive effect in cholesterol-lowering than lovastatin alone, although the difference was not statistically significant (Agrawal et al 2007). The duration of the supplementation may offer some insight into conflicting outcomes. In a 12-week study involving 100 subjects with hyperlipidaemia randomised to receive either a combination of ispaggol powder (Naturolax) 5.6 g twice daily and atorvastatin 10 mg once daily or atorvastatin 10 mg daily alone, significant reduction in LDL cholesterol was achieved at the end of week 8; there was, however, no difference between treatment groups. However, at the end of week 12, the combination of ispaggol and atorvastatin produced significantly greater reduction in LDL when compared to atorvastatin alone (Jayaram et al 2007).

### Colorectal cancer

A 2002 case-control study ( $n = 424$ ) found the consumption of psyllium husks to be inversely proportional to the risk of colorectal cancer (OR = 0.17, 95% CI 0.03–0.81;  $P = 0.01$ ). The effect was even stronger in constipated individuals (OR = 0.08, 95% CI 0.01–0.38;  $P = 0.001$ ) (Juarraz et al 2002). This was followed by another epidemiological study in 2009 correlating the rate of mortality from colorectal cancer in a number of Spanish provinces to the consumption of psyllium husks in these same areas. The highest quintile intake of psyllium husks was found to be inversely correlated with mortality from colorectal cancer (RR = 0.746, 95% CI 0.416–0.908;  $P = 0.042$ ) (Lopez et al 2009).

## Diabetes

Fibre products, such as psyllium, have been used as an aid to metabolic control in patients with diabetes (Pittler & Ernst 2004, Sierra et al 2002). Epidemiological and clinical data suggest a role for both soluble and insoluble fibre products in the management of hyperglycaemia. It appears that soluble fibre has a dose-dependent effect on serum glucose levels and the insulin response to a meal, improves glycaemic control in type 2 diabetes and can reduce the amount of medication required (Pastors et al 1991).

The adjunct use of 5.1 g psyllium twice daily for 8 weeks with a traditional diet for 34 men with type 2 diabetes and mild-to-moderate hypercholesterolaemia was well tolerated and shown to improve glycaemic and lipid levels as compared to placebo (Anderson et al 1999). One clinical study using 14 g/day of psyllium (Plantaben, ALTANA Pharma, Mexico) showed a significant 12.2% reduction in glucose absorption, as well as a significant reduction in total cholesterol and LDL cholesterol, and also uric acid (Sierra et al 2002). Another study identified that a higher dose (20 g/day in divided doses) may produce better results, and it significantly lowers both basal and postprandial hyperglycaemia (Fрати-Munari et al 1989). In an 8-week double-blind, placebo-controlled study of 49 subjects, psyllium (5.1 g twice daily) was evaluated as an adjunct to the use of diet and pharmaceutical hypoglycaemic therapy in patients with type 2 diabetes. Fasting blood glucose and glycosylated haemoglobin were significantly reduced following psyllium administration and improved gastric tolerance to metformin was identified in the psyllium group. The authors concluded psyllium to be safe, well tolerated and improved glycaemic control in patients with type 2 diabetes (Ziai et al 2005). Psyllium significantly improved the breakfast postprandial glycaemic, insulinaemic and free fatty acid response in 45 patients with type 2 diabetes mellitus participating in a randomised, crossover intervention trial of a low-glycaemic-load breakfast meal containing soluble psyllium fibre 6.6 g for 3 weeks duration (Clark et al 2006).

## Irritable bowel syndrome (IBS)

In a systematic review examining the effects of fibre supplementation in IBS, Bijkerk et al identified 17 randomised, controlled trials including a total of 1363 IBS patients. Nine studies investigated soluble fibre supplementation (eight of these studies utilised psyllium husks) and eight insoluble fibres. A meta-analysis was performed looking at the effects of fibre (as a whole), and soluble fibre and insoluble fibre specifically on global IBS symptoms, abdominal pain and constipation. Fibre (as a whole) was found to significantly improve global IBS symptoms (RR = 1.33, 95% CI 1.19–1.50) and IBS-related constipation (RR = 1.56, 95% CI 1.21–2.02). However, fibre supplementation was found to significantly worsen abdominal pain (RR = 0.78, 95% CI

0.64–0.95). When soluble fibre was examined in isolation, it was found to induce a greater reduction in global IBS symptoms (RR = 1.55, 95% CI 1.35–1.78) and to improve constipation in constipation-predominant IBS subjects (RR = 1.60, 95% CI 1.06–2.42). Conversely, insoluble fibre supplementation was found to have no significant impact upon global IBS symptoms, although it did improve constipation (RR = 1.54, 95% CI 1.10–2.14) (Bijkerk et al 2004).

The superiority of soluble fibre over insoluble was further confirmed in a 12-week randomised, double-blind, placebo-controlled trial ( $n = 275$ ) comparing psyllium husks (10 g/day), wheat bran (10 g/day) and placebo in IBS patients. The proportion of subjects describing their IBS symptoms as 'adequately relieved' was significantly greater in the psyllium group than the bran or placebo groups in the first 2 months of treatment, but not the third. At the end of the 12-week treatment period, total IBS symptom severity was significantly reduced only in the psyllium group. However, abdominal pain scores and quality of life scores were not (Bijkerk et al 2009).

Black and blond psyllium seed is approved for use by Commission E in IBS and recommended when a soft stool is desired (Blumenthal et al 2000).

## Ulcerative Colitis

A limited number of studies have examined the role of psyllium in the treatment of ulcerative colitis (UC).

A randomised, open-label trial in 1999 ( $n = 105$ ) compared the efficacy of psyllium seeds (10 g bid) to mesalamine and the combination of mesalamine and psyllium seeds over a 12-month period. Over the trial period, there was no significant difference in remission rates between the three groups — 60% of subjects in the psyllium seed group remained in remission, versus 65% in the mesalamine group and 70% in the combination group. Faecal butyrate concentrations increased significantly in the psyllium seed treated groups ( $P = 0.018$ ) (Fernandez-Banares et al 1999).

A randomised controlled trial of 120 patients with ulcerative colitis demonstrated that patients receiving treatment with a synbiotic therapy of *Bifidobacterium longum* ( $2 \times 10^9$  colony-forming units per day; unspecified strain) and psyllium (8 g daily) reported greater 'quality-of-life' changes than those treated with the probiotic strain or psyllium alone, as well as significant decreases in C-reactive protein levels (Fujimori et al 2009).

## Hypertension

Participants in a randomised controlled trial of 41 hypertensive patients increased their intake of dietary protein and psyllium (additional 12 g/day) for 8 weeks. A net reduction in 24-hour systolic blood pressure of 5.9 mmHg was demonstrated (Burke et al 2001). In a 6-month, randomised, open-label clinical trial involving 141 hypertensive and

overweight patients, treatment with psyllium powder as compared to guar gum appeared to significantly reduce systolic and diastolic blood pressures (Cicero et al 2007).

### OTHER USES

In the confectionery industry psyllium is used as a thickening agent in ice cream and frozen desserts.

### DOSAGE RANGE

#### General recommendations

- Blond psyllium seed: 12–40 g of whole seeds or equivalent taken in divided doses daily.
- Black psyllium seed: 10–30 g of whole or ground seeds or equivalent taken in divided doses daily.
- Seeds should be presoaked in 100–150 mL of warm water for several hours before ingestion. Each dose should be followed by another full glass of water.
- Powdered blond psyllium seed husk: 4–5 g taken up to four times daily. Stir desired dose into 150 mL of water and drink immediately. Follow each dose with  $\frac{1}{2}$ –1 glass of water.

#### According to clinical studies

- Weight loss: *Plantago ovata* preparation (20 g granules with 200 mL water).
- Constipation: 7–11 g daily in divided doses with water.
- Hyperlipidaemia: 7–20 g daily in divided doses with water.
- Hyperglycaemia: 10–15 g daily in divided doses with water.
- Diabetes: 14–20 g daily in divided doses.
- Metabolic syndrome: 14 g daily in divided doses with water.
- Diarrhoea: 7–30 g in divided doses for 7 days with water.
- Haemorrhoids: 7 g daily for 6 weeks with water.
- Children 6–12 years: 3–8 g in divided doses.

### SIGNIFICANT INTERACTIONS

#### Calcium

Animal studies suggest that soluble fibre from sources of purified psyllium negatively impact calcium balance by decreasing the bioavailability of calcium from the diet (Luccia & Kunkel 2002) — psyllium and other soluble fibre supplements should be taken at least 1 hour before or after calcium.

#### Lithium

Soluble fibre may decrease the bioavailability of lithium (EMEA 2003) — take psyllium at least 1 hour before or after lithium.

#### Levodopa

Animal research suggests that concomitant administration of psyllium husks with levodopa results in an improvement in the levodopa kinetic profile with

higher final concentrations and a longer plasma half-life (Diez et al 2008).

#### Coumarin derivatives

Soluble fibre may decrease the bioavailability of coumarin derivatives (EMEA 2003) — take psyllium at least 1 hour before or after coumarin derivatives.

#### Vitamin B<sub>12</sub>

Soluble fibre may decrease the bioavailability of vitamin B<sub>12</sub> (EMEA 2003) — take psyllium at least 1 hour before or after vitamin B<sub>12</sub>.

#### Cardiac glycosides

Soluble fibre may decrease the bioavailability of cardiac glycosides (EMEA 2003) — take psyllium at least 1 hour before or after cardiac glycosides.

#### Hypoglycaemic agents

Additive hypoglycaemic effects are theoretically possible — drug dose may need modification and the outcome can be favourable under professional supervision.

#### Anticonvulsant medication

Absorption concomitantly administered with psyllium may be delayed (EMEA 2007) — product taken 1 hour to half an hour before or after the medicinal product.

#### Thyroid hormones

Medication dose may need to be adjusted — seek medical supervision (EMEA 2007).

#### Lipid lowering agents

Concurrent use of psyllium with lipid-lowering drugs may lead to a reduction in drug dose and further lipid-lowering effects — beneficial interaction.

#### Other vitamins and minerals

Given the known capacity of psyllium husks to decrease the absorption of calcium, it would be prudent to avoid coadministration of psyllium husks with any vitamin or mineral supplement. Ensure administration is at least 1 hour before or after nutritional supplementation.

### ADVERSE REACTIONS

Allergy is possible, although rare and is characterised by tightness in the chest, wheezing and urticaria. According to a study of healthcare workers, daily exposure to laxatives containing *Plantago ovata* causes sensitisation to *Plantago ovata* seed in approximately 14% of people (Bernedo et al 2008). Psyllium should not be consumed dry, as it may cause oesophageal obstruction. In practice, it is not unusual for people to experience flatulence, bloating and mild abdominal discomfort when they start to use psyllium; however, these symptoms can reduce with long-term use. It is also worth noting that patients can experience a worsening in their

constipation if they consume psyllium husks without a concomitant increase in water intake.

A rare adverse effect noted in the literature is intestinal obstruction. A handful of cases of intestinal obstruction have been reported in the medical literature over the past 80 years secondary to the ingestion of psyllium, typically in individuals with a very low fluid intake (Fisher 1938, Souter 1965). Hence, all individuals should be strongly advised to significantly increase their fluid intake upon commencement of psyllium therapy.

### **?** CONTRAINDICATIONS AND PRECAUTIONS

Although psyllium is considered a safe substance, it should not be used by people with partial or complete bowel obstruction, colonic impaction or stenosis of the gastrointestinal tract.

According to Commission E, blond psyllium seed is contraindicated if there is difficulty regulating diabetes mellitus.

### **P** PREGNANCY USE

May be used during pregnancy and lactation.

### **Practice points/Patient counselling**

- Psyllium seed husk contains a water-soluble fibre that forms a mucilaginous gel on contact with aqueous fluids and is degraded by human intestinal flora.
- It is most commonly used to treat constipation or diarrhoea and to regulate stool consistency.
- It is also used to promote satiety and weight loss, and as an aid to metabolic control in diabetes and metabolic syndrome, as well as hyperlipidaemia when combined with a low-fat diet.
- The seeds and husks should be presoaked in warm water before ingestion. Each dose should be followed by at least a full glass of water and patients should be instructed to ensure their water intake is adequate while taking psyllium husks. Ingesting it dry may cause oesophageal obstruction.
- Although generally safe, it should not be used by people with partial or complete bowel obstruction, colonic impaction or stenosis of the gastrointestinal tract.

### **!** PATIENTS' FAQs

#### *What will this herb do for me?*

Psyllium is a bulking agent that can regulate stool consistency, increase satiety, improve metabolic control in diabetes and reduce cholesterol when combined with a low-fat diet.

#### *When will it start to work?*

As a bulking agent, it will start to have an effect within several hours. It will improve satiety within 30–60 minutes and has a mild cholesterol-lowering effect after 8 weeks of use.

#### *Are there any safety issues?*

Although generally safe, it should not be ingested dry or used by people with partial or complete bowel obstruction, colonic impaction or stenosis of the gastrointestinal tract.

## Pygeum

**HISTORICAL NOTE** *Pygeum africanum* is a large, evergreen tree native to Africa. Its bark has been used medicinally for thousands of years by traditional African healers to treat bladder disorders, kidney disease, prostate disorders and malaria, as well as male baldness, and to enhance sexual functioning. Since the late 1960s, the extract has been used in clinical practice in Europe; however, because of overharvesting, the plant is now considered an endangered species and efforts are under way to protect it.

### Clinical note — Popular to the point of extinction?

For the past 35 years, pygeum has been used in Europe for the treatment of benign prostatic hyperplasia (BPH) and other disorders. The bark is entirely wild-collected, mainly from Cameroon, Madagascar, Equatorial Guinea and Kenya, and exported principally to Europe for production into commercial medicinal extracts (Stewart 2003). Since 1995, it has been considered an endangered species, so attempts at cultivation are under way to protect the plant from extinction. Prior to 1966, when it was discovered to have significant medicinal effects, *P. africana* was a relatively common, but never abundant, species. The reasons for its demise include economic, social and ecological factors. Currently, wildcrafting is no longer commercially viable in Cameroon, and harvest has ceased in both Uganda and Kenya.

### COMMON NAME

Pygeum

### OTHER NAMES

African plum tree, African prune tree, *Pygeum africanum*, alumty, iluo, kirah, Natal tree, Pignil, Pronitol, Tanaden

### BOTANICAL NAME/FAMILY

*Prunus africana* (Hook. f.) KalRm (family Rosaceae)

### PLANT PART USED

Bark

### CHEMICAL COMPONENTS

Phytosterols (beta-sitosterol, beta-sitostenone), pentacyclic triterpenes (oleanolic and ursolic acids) and ferulic esters (*n*-docosanol and *n*-tetracosanol) (Stewart 2003), atraric acid (AA) and *N*-butylbenzene

sulfonamide (NBBS) (Daniela & Baniahmad 2011, Papaioannou et al 2010).

### MAIN ACTIONS

Pygeum has demonstrated several different pharmacological effects according to in vitro and in vivo data. The majority of initial studies conducted on *P. africanum* were investigating its role in the symptomatic relief of BPH. More recent research is seeking to elucidate pygeum's pharmacological capacity in the modulation and restoration of bladder function, androgen receptor modification and attenuating prostatic cancer cell line replication.

#### Hormonal effects

In vivo studies have shown that orally administered pygeum extract has a significant effect on dihydrotestosterone (DHT)-induced prostatic enlargement (Choo et al 2000, Yoshimura et al 2003). Pretreatment with pygeum extract counteracted the effect of DHT-induced prostate enlargement (Choo et al 2000), and the more recent study found that oral administration of pygeum extract suppressed the effects of DHT on micturition (Yoshimura et al 2003) and effectively suppressed prostatic growth when coadministered with DHT; however, it did not reverse established prostatic growth when administered after DHT. A comparative study found that pygeum exerted only a weak inhibition of 5- $\alpha$  reductase compared to that of finasteride (Rhodes et al 1993). Phyto-oestrogens isolated in pygeum can exert a dose-dependent oestrogenic or antioestrogenic effect, according to other in vivo tests (Mathe et al 1995), and may also contribute to its effects in the prostate.

#### Antiandrogenic

Recent in vitro investigations have confirmed the antiandrogenic activity of pygeum. When compared to *Serenoa repens* and *Cucurbita pepo*, pygeum exhibited the highest androgen antagonistic activity (Schleich et al 2006). AA and NBBS, isolated from pygeum, has been shown to selectively competitively inhibit transactivation-mediated ligand-activated human androgen receptor, inhibiting the expression of endogenous prostate-specific antigen. Its effects have proved more potent than currently used clinical antiandrogens such as flutamide and do not display the molecular mechanisms of current antiandrogens associated with resistance. Therefore not only might AA and NBBS be useful novel antiandrogens, but they may also increase the effectiveness of current treatments (Daniela & Baniahmad 2011, Papaioannou et al 2010, Quiles et al 2010).

#### Anti-inflammatory

Phytosterols (beta-sitosterol, beta-sitostenone) reportedly inhibit the production of prostaglandins in the prostate, which suppresses the inflammatory symptoms associated with BPH and chronic prostatitis. The pentacyclic triterpenes (oleanolic and ursolic acids) are believed to inhibit the activity of gluco-

sytransferase, an enzyme involved in the inflammation process (Stewart 2003).

Studies with pygeum extract confirm that it decreases production of leukotrienes and other 5-lipoxygenase metabolites (Cristoni et al 2000).

#### Bladder effects

Pygeum protects the bladder from contractile dysfunction induced by ischaemia and reperfusion according to in vivo animal studies (Chen et al 1999). Pretreatment with pygeum prior to induced partial outlet obstruction in animal models prevents the development of contractile dysfunction, possibly by protecting the bladder from ischaemic injury (Levin et al 2005). Administration of pygeum was found to reverse already ischaemic compromised bladder function in a dose-dependent manner (Levin et al 2002).

#### Inhibition of fibroblast proliferation and apoptosis

Pygeum is a potent inhibitor of prostatic growth factor-mediated fibroblast proliferation, as demonstrated in animal models (Szolnoki et al 2001, Yablonsky et al 1997). A dose-dependent inhibition of fibroblastic growth was exerted in human stromal cells treated with pygeum extract (Boulbes et al 2006).

Further study comparing cell lines harvested from prostatic tissue with or without BPH and treated with pygeum extract demonstrated apoptosis via alpha-smooth-muscle actin, found in greater amounts in those with BPH. Transforming growth factor-beta<sub>1</sub> and fibroblast growth factor 2 were both downregulated. Smooth-muscle tissue was unaffected (Quiles et al 2010).

#### Chemopreventive

Recent investigations have focused primarily upon *P. africanum* regulation of cancer cell growth in vitro and in vivo. Treatment with pygeum extract exhibited a significant and dose-dependent inhibition of human prostate cancer cell lines and BPH-derived epithelial cells. Pygeum also exerted a potent antimutagenic action in this study (Santa Maria Margalef et al 2003). Pygeum-treated mice displayed a significant reduction in prostate cancer incidence (35%) in comparison to the casein-fed mice (62.5%) (Shenouda et al 2007).

#### OTHER ACTIONS

Ferulic esters (*n*-docosanol and *n*-tetracosanol) reportedly lower blood levels of cholesterol, from which testosterone is produced (Stewart 2003).

New metabolomics studies may soon shed further light on the action of pygeum on the prostate. Cornu et al (2012) compared the urine of 15 newly diagnosed men with BPH pre- and posttreatment with pygeum. The result was the identification of three novel compounds that were increased and one that was reduced in the urine samples treated with pygeum only.

## CLINICAL USE

The most commonly investigated form of *P. africanum* is Tanenan (DEBAT Pharmaceuticals, France), which is a lipophilic extract standardised to contain 13% total plant sterols. One capsule of Tadenan contains 50 mg of standardised extract.

### Benign prostatic hyperplasia

Clinical trials since the late 1970s have been encouraging, most reporting improvement in BPH symptoms.

A Cochrane systematic review analysed the results of 18 clinical trials that involved a total of 1562 participants (Wilt et al 2002). Seventeen studies were double-blinded, and the mean treatment duration was  $61 \pm 21$  days (range 30–122 days). Most studies used a standardised extract of *P. africanum* in doses ranging from 75 to 200 mg/day.

The overall summary effect size indicated a large and statistically significant improvement with *P. africanum*. More specifically, active treatment increased peak urine flow by 23% and reduced residual urine volume by 24%, and doctors were twice as likely to report that their patients were experiencing an overall improvement in symptoms when pygeum was being used. The authors report that these findings are similar to other widely used treatment options and that treatment was well tolerated.

An observational study (TRIUMPH trial) in six European countries including 2559 newly-presented BPH patients compared treatment with either *P. africanum*, *Serenoa repens*, finasteride or alpha-blocker drugs (tamsulosin etc.) to untreated men (watchful waiters). Follow-up was at 1 year, with significant improvement (IPSS change  $>4$ ) seen in all categories for the treatments: *P. africanum* 43.3%, *S. repens* 42.7%, finasteride 57% and alpha-blockers 68%, when compared to watchful waiters (Hutchison et al 2007).

### IN COMBINATION

In 2013, a randomised, double-blind placebo-controlled trial was published which investigated the effects of a combination supplement ProstateEZE Max — *Cucurbita pepo* seed oil (160 mg), *Epilobium parviflorum* extract (equivalent to 500 mg dry herb), lycopene (2.1 mg), *Prunus africana* (equivalent to 15 g dry stem, standardised to  $\beta$ -sitosterol) and *S. repens* (equivalent to 660 mg dry leaf) on 57 patients with newly medically diagnosed BPH. At the end of 3 months, active treatment resulted in a symptom reduction in the median score (IPSS) of 36% compared to placebo 8% ( $P < 0.05$ ). Daytime frequency of urination was reduced by 15.5% compared to no significant reduction in placebo group ( $P < 0.03$ ) and nighttime frequency was reduced by 39.3% compared to placebo 7% ( $P < 0.004$ ) (Coulson et al 2013).

## OTHER USES

### Fertility disorders

Pygeum extract was used experimentally in the treatment of 22 men with reduced fertility and

diminished prostatic secretion and proved to have a beneficial effect (Lucchetta et al 1984). Treatment was administered every day over 2 months and was most effective in men who did not have prostatitis.

## DOSAGE RANGE

According to clinical studies:

- BPH: 50–100 mg of extract twice daily standardised to 12–13% total sterols.

## ADVERSE REACTIONS

Pygeum is well tolerated, with side effects similar to placebo (Wilt et al 2002). Mild gastrointestinal discomfort has been reported.

## SIGNIFICANT INTERACTIONS

None known.

### CONTRAINDICATIONS AND PRECAUTIONS

People with known allergies should avoid use.

### PREGNANCY USE

Safety not scientifically established; however, it is not used for any indication that would cause a pregnant woman to use it.

### Practice points/Patient counselling

- Pygeum is a popular treatment in Europe for BPH.
- A systematic review of 18 clinical studies found that it has significant effects in BPH, such as increasing peak urine, reducing residual urine volume and producing an overall improvement in symptoms.
- Several different mechanisms of action have been identified using animal models, which would explain its effectiveness in BPH.
- According to clinical studies, the dose used is 50–100 mg of standardised extract twice daily for BPH and the treatment is well tolerated.
- Overharvesting has meant the tree is now considered endangered and efforts are being made to protect it from extinction.

### PATIENTS' FAQs

#### What will this herb do for me?

Standardised pygeum extract is an effective treatment in benign prostate enlargement or inflammation and improves several symptoms.

#### When will it start to work?

Some men will notice an improvement in symptoms after 4 weeks; however, others will require a long-term treatment.

### Are there any safety issues?

It is a well-tolerated treatment but should not be used by people with a known allergy to the plant. If symptoms worsen, seek professional advice.

## Quercetin

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Quercetin is a flavanol belonging to a group of polyphenolic substances known as flavonoids or bioflavonoids, the first of which were identified in 1936 by Albert Szent-Györgyi, who was awarded the Nobel Prize for his discovery of vitamin C (Challem 1998).

Quercetin is regarded generally to exhibit poor solubility and instability, making it the target of research involving the use of several modified forms, e.g. liposomes, nanoparticles or micelles, which appear to provide higher solubility and bioavailability (Cai et al 2013).

Studies on the absorption, bioavailability and metabolism of quercetin after oral intake in humans to date therefore have produced contradictory results (Graefe et al 1999). It is thought that quercetin is extensively metabolised in the gut and liver after absorption, and occurs in the blood stream mainly as conjugated metabolites (Meng et al 2013). In human trials, supplementation increased plasma quercetin concentrations in a dose-dependent manner — 178% (50 mg), 359% (100 mg) and 570% (150 mg) — and maximum plasma concentrations

were reached 6 hours after intake of a 150 mg dose. There was also a significant interindividual variability in plasma quercetin concentrations (36–57%) (Egert et al 2008, Jin et al 2010). The main determinant of absorption of quercetin conjugates is the nature of the sugar moiety. Glucose-bound glycosides (quercetin glucosides) are effectively absorbed from the small intestine because the cells possess glucoside-hydrolysing activity and their glucose transport system is capable of participating in glucoside absorption, whereas quercetin glycosides are subject to deglycosidation by enterobacteria before absorption in the large intestine (Murota & Terao 2003).

After absorption, quercetin is transported to the liver via the portal circulation, where it undergoes significant first-pass metabolism. Peak plasma levels of quercetin occur from 0.7 to 9 hours following ingestion, and the elimination half-life of quercetin is approximately 23–28 hours (Hollman et al 1997, PDRHealth 2005). Due to its long half-life, repeated consumption of quercetin-containing foods should cause accumulation of quercetin in the body. Excretion is likely to be via the biliary system (Erlund 2004).

**Clinical note — Improving quercetin bioavailability**

Human studies have also been undertaken to find combinations which improve quercetin bioavailability, with quercetin from quercetin-enriched cereal bars significantly more bioavailable than from quercetin powder-filled hard capsules (Egert et al 2012), and a threefold increase in bioavailability when ingested via onions compared to apples (Hollman et al 1997) and twofold increase with black tea (deVries et al 1998). Ingestion of quercetin with onion powder results in faster absorption and higher plasma levels compared to apple peel powder (Lee & Mitchell 2012). Other factors that may improve bioavailability include gender (especially females taking oral contraceptives), gastrointestinal flora (Duda-Chodak 2012, Erlund 2004) and concurrent intake of dietary fat (Guo et al 2013) or bromelain and papain (Shoskes et al 1999).

**CHEMICAL COMPONENTS**

Quercetin, also known as meletin and sophretin, is known chemically as 2-(3,4-dihydroxyphenyl)-3,5,7-trihydroxy-<sup>4</sup>H-1-benzopyran-4-one and 3,3',4',5,7-penthydroxyflavone. It is typically found in plants as a glycone or carbohydrate conjugate but does not in itself possess a carbohydrate moiety in its structure. Quercetin glycone conjugates include rutin (quercetin-3-rutinoside) and quercitrin (thujin, quercetin-3-L-rhamnoside or 3-rhamnosylquercetin) (Erlund et al 2000, PDRHealth 2005).

**FOOD SOURCES**

Food sources include apples, berries (blackcurrants, lingonberries and bilberries), beans, black tea, broccoli, grapes, green tea, onions and red wine (Duda-Chodak 2012, Somerset & Johannot 2008).

Herbal medicines such as St John's wort, *Ginkgo biloba*, *Vaccinium macrocarpon* (cranberry) and *Oenothera biennis* (evening primrose) also contain quercetin and this may help to explain part of their therapeutic benefits.

**MAIN ACTIONS****Antioxidant/pro-oxidant**

Quercetin is a phenolic antioxidant shown to inhibit lipid peroxidation, protecting the lens of the eye (Cornish et al 2002) and renal tubular epithelial cells from oxidant-induced injury (Pietruck et al 2003). The antioxidant activity may be the result of free radical scavenging, metal chelation, enzyme inhibition or the induction of protective enzymes (Erlund 2004). When compared to curcumin, quercetin exhibits higher reduction potential at three different pH settings, with a total antioxidant capacity 3.5-fold higher than curcumin (Zhang et al 2011).

While some studies demonstrate that quercetin treatment at low concentrations or for short periods

may exert an antioxidant effect, other trials suggest that higher concentrations (>0.5% in rats fed a 1.0% Met-supplemented diet) or treatment which lasts longer than 6 weeks may produce a pro-oxidant effect (Ferraresi et al 2005, Meng et al 2013, Robaszkiewicz et al 2007). These effects may be due to induction of oxidative stress due to formation of reactive oxygen species in the extracellular medium (Robaszkiewicz et al 2007) or increasing oxidant activity due to a reduction in glutathione (GSH) levels (Ferraresi et al 2005). The paradox is that, in the process of offering protection, quercetin depletes GSH levels and is converted into potentially toxic products (thiol-reactive quercetin metabolites) (Boots et al 2007). In the absence of GSH, potentially harmful oxidation products such as orthoquinone may be produced when quercetin exerts its antioxidant activity. Therefore, adequate GSH levels should be maintained when quercetin is supplemented (Boots et al 2003).

In human trials, while daily supplementation of quercetin (50, 100 and 150 mg/day) for 2 weeks dose-dependently increased plasma quercetin concentrations, it did not appear to affect antioxidant status, oxidised low-density lipoprotein (LDL), inflammation or metabolism (Egert et al 2008). Research also suggests that the effects of antioxidant supplementation reducing oxidative stress can only be expected in people with enhanced oxidative stress or inflammation (Boots et al 2011), potentially explaining the negative outcome of many clinical studies (Egert et al 2008, Shanely et al 2010), where antioxidants were supplied to healthy subjects.

**Anti-inflammatory**

In animal and in vitro studies, quercetin inhibits inflammation by modulating neutrophil function, prostanoid synthesis, cytokine production and inducible nitric oxide synthase (iNOS) expression via the inhibition of the neutrophil factor (NF)-kappa-B pathway (Busse et al 1984, Comalada et al 2005, Morikawa et al 2003). In vitro studies on human adipocytes and grape powder extract, containing both quercetin and *trans*-resveratrol (*trans*-RSV), have demonstrated that quercetin is equally as or more effective than *trans*-RSV in attenuating tumour necrosis factor-alpha (TNF- $\alpha$ )-mediated inflammation and insulin resistance (Chuang et al 2010).

While quercetin supplementation has been shown to decrease circulating markers of inflammation in mice (Stewart et al 2008), these effects have not been consistently replicated in humans (Egert et al 2008, McAnulty et al 2008, Pfeuffer et al 2013). Further clinical trials are required to clarify these findings.

**Antiviral**

Quercetin causes a dose-dependent reduction in the infectivity and intracellular replication of herpes simplex virus-1, poliovirus type 1, parainfluenza virus type 3 and respiratory syncytial virus in vitro

(Kaul et al 1985); however, pretreatment with quercetin does not appear to provide any additional benefit. In vitro and in vivo evidence also suggests that quercetin has the ability to block the replication of rhinovirus, responsible for producing the common cold (Ganesan et al 2012). Animal studies have also suggested that the antioxidant effects of quercetin may protect the lungs from the deleterious effects of oxygen-derived free radicals released during influenza infection (Kumar et al 2005).

### Immunomodulation

Results from animal and in vitro studies have produced contradictory findings, suggesting both an induction and an inhibition of Th1 cytokines (Muthian & Bright 2004, Nair et al 2002).

According to in vitro research, quercetin induces Th1-derived cytokines (promoting cellular immunity) and inhibits Th2-derived cytokines, which exert negative effects on cellular immunity (Nair et al 2002). An excess of Th2 cytokines has also been implicated in allergic tendencies, and this provides a theoretical basis for the use of quercetin as an antiallergic substance. Conversely, animal studies have demonstrated that quercetin is able to inhibit Th1 differentiation and signalling of interleukin (IL)-12 (Muthian & Bright 2004) and appears to exert an effect on Th1-mediated immune responses through suppression of both interferon-gamma and IL-2 cytokine production (Yu et al 2008). As a result, a possibility exists that quercetin actually exerts an immunomodulatory effect on these cells.

### Antiallergy

Quercetin is structurally similar to the antiallergic drug disodium cromoglycate (available as Intal or Cromex in Australia) and has been proposed as a useful treatment for mast cell-derived allergic inflammatory diseases, including contact dermatitis and photosensitivity, especially in formulations that have enhanced oral absorption (Min et al 2007, Weng et al 2012). Antiasthmatic activity similar to cromolyn sodium and dexamethasone has been demonstrated in guinea pigs (Moon et al 2008) and a greater effect on inhibiting IL-8 and TNF release from LAD2 mast cells stimulated by substance P for quercetin than cromolyn in vitro (Weng et al 2012).

In vitro and animal studies demonstrate that quercetin stabilises mast cells, neutrophils and basophils inhibiting antigen as well as mitogen-induced histamine release (Blackburn et al 1987, Busse et al 1984, Middleton & Drzewiecki 1982, Middleton et al 1981, Ogasawara et al 1996, Pearce et al 1984). Inhibition of inflammatory enzymes, prostaglandins and leukotrienes and modulation of Th2 excess may further contribute to the antiallergic effects. Pretreatment with quercetin does not appear to produce any additional benefits.

### Antihypertensive

Chronic treatment with quercetin lowers blood pressure and restores endothelial dysfunction in

animal models of hypertension (Garcia-Saura et al 2005, Sanchez et al 2006). This effect may be in part due to modulation of renal function, including increased urinary and sodium output (Mackraj et al 2008). Several small clinical trials have confirmed a moderate blood pressure-lowering activity (Edwards et al 2007, Egert et al 2009).

### Cardioprotective

During inflammation, circulating conjugates of quercetin pass through the endothelium to reach vascular smooth-muscle cells, where they exert their biological effects and are then deconjugated (Mochizuki et al 2004). The cardioprotective effects of quercetin may be related to its vasorelaxant (Ke Chen & Pace-Asciak 1996, Roghani et al 2004), anti-inflammatory and antioxidant properties and inhibition of vascular smooth-muscle cell proliferation and migration (Alcocer et al 2002, Moon et al 2003), as demonstrated in animal and in vitro models.

Animal experiments indicate that doses of quercetin equivalent to one to two glasses of red wine (approximately 2 mg) exert a cardioprotective effect following ischaemia-reperfusion by improving the function of mitochondria, which plays a critical role in myocardial recovery (Brookes et al 2002), and may also prevent the development of atherosclerosis through several indirect mechanisms (Auger et al 2005).

In humans, quercetin inhibits platelet aggregation and signalling and thrombus formation at a dose of 150 or 300 mg quercetin-4'-O-beta-D-glucoside (Hubbard et al 2004). One small crossover randomised controlled trial (RCT) involving 12 healthy men testing the acute effects of oral administration of 200 mg quercetin, (-)-epicatechin or epigallocatechin gallate on nitric oxide, endothelin-1 and oxidative stress found that quercetin augmented nitric oxide status and reduced endothelin-1 concentrations, thereby having the potential to improve endothelial function (Loke et al 2008).

### Antiatherogenic

Adhesion of circulating monocytes to vascular endothelial cells is a critical step in both inflammation and atherosclerosis. Experimental studies have indicated that both quercetin and its metabolites can inhibit the expression of key molecules involved in monocyte recruitment during the early stages of atherosclerosis (Tribolo et al 2008), suggesting a theoretical basis for the use of quercetin in preventing this condition. Further human trials are required to examine this effect.

### Neuroprotective

Quercetin protects neuronal cells from oxidative stress-induced neurotoxicity (Heo & Lee 2004) and inflammatory-related neuronal injury (Chen et al 2005). In vitro studies have found that quercetin protects against elevated reactive oxygen species induced by  $H_2O_2^-$  and changes in plasma

membrane integrity and nuclear morphology as a result of increased oxidative stress (Jazvinščak Jembrek et al 2012). At lower doses (5 and 10 microM), it has been proposed as a treatment worthy of further investigation for Alzheimer's disease and other oxidative stress-related neurodegenerative diseases; however, at higher doses (20 and 40 microM) it may be neurotoxic (Ansari et al 2008). A key consideration remains the bioavailability of oral quercetin. A comprehensive review of the neuroprotective effects of quercetin concluded that, although quercetin and quercetin-containing plants exhibit potential as therapeutic modalities in neuropathology, the data collectively highlight the need to elucidate issues such as low bioavailability in plasma and in the brain (Dajas 2012). Whether quercetin needs to actually cross the blood-brain barrier to a large extent to exert benefits remains to be seen, as accumulating research suggests that peripheral reductions in inflammation can have potent reciprocal effects in the central nervous system (Kang et al 2011).

### Mood and cognitive enhancement

Anxiolytic effects have been demonstrated in stress-affected mice (Kumar & Goyal 2008) and both anxiolytic and cognitive-enhancing effects have been shown in rats following both oral and intranasal-administered quercetin treatment (Priprem et al 2008).

### Gastroprotective

Quercetin treatment (100 mg/kg/day by intragastric gavage) inhibits hyperproliferation of gastric mucosal cells in rats treated with chronic oral ethanol (Liu et al 2008). It has been suggested that the gastroprotective effect of quercetin in animal models may be due to its antiperoxidative, antioxidant and antihistamine effects, resulting in a significant reduction in the number of mast cells and size of gastric erosions (Kahraman et al 2003). More recent studies demonstrate the inhibition of gastric tumour promotion by inducing cell cycle arrest and promoting apoptotic cell death, while exposure of gastric cancer cells AGS and MKN28 to quercetin results in pronounced proapoptotic effects through mitochondrial pathway activation (Wang et al 2011).

### Hepatoprotective

In vitro and animal studies have demonstrated the hepatoprotective effects of quercetin. It protects the liver from oxidative damage and may reduce biliary obstruction (Alia et al 2006, Peres et al 2000). In experimental models, quercetin protects human hepatocytes from ethanol-induced oxidative stress (Yao et al 2007) and reduces liver fibrosis in rats by enhancing antioxidant enzyme activity (Amalia et al 2007). Pretreatment of rats with quercetin (10 mg/kg) reduced the mortality rate for paracetamol (1 g/kg) from 100% to 30% and prevented liver damage at sublethal doses (640 mg/kg) (Janbaz et al 2004).

### Chemoprotective

In the 1970s, quercetin was considered to be carcinogenic after demonstrating mutagenicity in the Ames test; however, subsequent long-term studies have refuted this and demonstrated an anticarcinogenic effect in laboratory animals (Erlund 2004). Epidemiological and experimental studies have demonstrated potential benefits for melanoma (Thangasamy et al 2007), colon, lung (Murakami et al 2008), breast (Lin et al 2008), gastric (Ekström et al 2011), prostate (Wang et al 2012) and liver cancer (Mu et al 2007).

In vitro and preliminary animal and human data indicate that quercetin inhibits tumour growth and induces apoptosis. The anticarcinogenic effects may be due to its antioxidant properties, protection against DNA damage, inhibition of angiogenesis, effects on gene expression, effects on cell cycle regulation, phyto-oestrogen-like activity, interaction with type II oestrogen-binding sites and tyrosine kinase inhibition (Duraj et al 2005, Erlund 2004, Igura et al 2001, Lamson & Brignall 2000, Lee et al 2003, 2006, Tan et al 2003, van der Woude et al 2005, Wilms et al 2005, Zhang et al 2008). Quercetin is also believed to block the activation of pro-carcinogens by modulating the expression of cytochrome P450 (Scalbert et al 2005). Moreover, a natural inhibitor of catechol-O-methyl transferase, quercetin has been shown to inhibit epigallocatechin gallate (EGCG) methylation, leading to enhanced antiproliferative activity of EGCG in prostate cancer cells. Quercetin and EGCG synergistically inhibit cell proliferation, cause cell cycle arrest and induce apoptosis in prostate cancer-3 cells (Wang et al 2012).

Quercetin may also protect against nicotine-induced cellular and DNA damage in rats (Muthukumar et al 2008a, 2008b) and radioprotective effects have also been reported (Devipriya et al 2008). In vivo and in vitro evidence also suggests that quercetin increases tumour radiosensitivity and inhibits ataxia telangiectasia-mutated activation in the DNA damage response pathways, thus enhancing the effectiveness of radiotherapy (Lin et al 2012).

### Antidiabetic effects

Oral administration of quercetin (10 mg/kg body weight) to diabetic rats restores vascular function, and this is thought to be due to enhancement in the bioavailability of endothelium-derived nitric oxide as well as a reduction in blood glucose levels and oxidative stress (Machha et al 2007). Diabetic rats receiving quercetin (15 mg/kg/day) for 4 weeks also experienced a decrease in blood glucose and an increase in plasma insulin, calcium and magnesium (Kanter et al 2007). A similar trial investigated the hypoglycaemic, hypolipidaemic and antioxidant effects of dietary quercetin in an animal model of type 2 diabetes over a 4-week period (Jeong et al 2012). A reduction of plasma glucose levels, triglycerides and total cholesterol, as well as an increase in

high-density lipoprotein (HDL) cholesterol, were observed in the low (0.04% of diet) and high (0.08% of diet) quercetin groups when compared to the control group.

### Preventing bone loss

Quercetin is claimed to play an important role in preventing bone loss by affecting osteoclastogenesis and regulating many systemic and local factors, including hormones and cytokines (Son et al 2006), providing a theoretical basis for its use in the prevention of postmenopausal bone loss. In vitro studies reveal that bone resorption is mediated by oestrogen receptor proteins via inhibition of nuclear factor kappa beta (RANK) protein and/or the activation of caspases (Rassi et al 2005, Wattel et al 2003). However, in vitro studies also suggest that quercetin inhibits the metabolism of not only osteoclasts (bone resorption cells) but also osteoblasts (bone-forming cells) in a dose-dependent manner, and therefore further research is required to elucidate whether quercetin increases or decreases bone mass (Notoyo et al 2004).

### Sperm quality

An injected form of high-dose quercetin (270 mg/kg body weight/day over 14 days) resulted in improved sperm motility, viability and concentration and increased the weight of the testes, epididymis and ductus deferens in a rat model (Taepongsorat et al 2008). Oral administration of quercetin and onions to mice has also been shown to reduce the male reproductive toxicity (sperm abnormalities) induced by diesel exhaust particles (Izawa et al 2008). Although quercetin has the ability to attenuate the negative effects of heavy metals and maintain membrane integrity, one review (Ranawat et al 2013) concluded that overall there are conflicting biological effects of quercetin, and thus more research is required.

### OTHER ACTIONS

Quercetin has been shown to reduce oxalate-induced urinary crystal formation and increase catalase and superoxide dismutase activities in rats (Park et al 2005).

### CLINICAL USE

Quercetin is mainly consumed as part of the food chain as it is present in many fruits and vegetables. It is also an ingredient in some nutritional supplements.

#### Allergies

Quercetin is used in the treatment of acute and chronic allergic symptoms, such as hayfever and chronic rhinitis. The anti-inflammatory activity of quercetin and its ability to block allergic mediators provide a rationale for its use in these indications. Quercetin stabilises mast cells, neutrophils and basophils and inhibits histamine release (Blackburn et al 1987, Busse et al 1984, Middleton & Drzewiecki

1982, Middleton et al 1981, Ogasawara et al 1996, Pearce et al 1984). It acts as an inhibitor of mast cell secretion; reduces the release of tryptase, monocyte chemotactic protein-1 and IL-6 and downregulates histidine decarboxylase mRNA from several mast cell lines (Shaik et al 2006).

In a study of 123 patients sensitised to house dust mite and displaying nasal symptoms of mild to severe perennial allergic rhinitis, nasal scrapings were taken and histamine release measured as a percentage of the total content in the specimen (Otsuka et al 1995). Antigen exposure resulted in an increase in mast cells of the epithelial layer of the nasal mucosa, resulting in nasal hypersensitivity. Quercetin inhibited histamine release by 46–96% in a dose-dependent manner.

Further human trials are required to further explore the potential for quercetin to act as an antihistaminic agent in various allergic conditions.

### Upper respiratory tract infections (URTIs)

A clinical trial of 40 trained male cyclists receiving 1000 mg/day of quercetin or placebo for 2 weeks found that active treatment resulted in a significantly reduced incidence of URTIs during a 2-week postexercise period (quercetin = 1/20 vs placebo = 9/20;  $P = 0.004$ ), despite there being no significant differences in immune markers such as natural killer cells, phytohaemagglutinin-stimulated lymphocyte proliferation and salivary IgA output (Nieman et al 2007).

More recently, a double-blind RCT investigated the effect of two different doses of quercetin (500 mg/day and 1000 mg/day) on the incidence and severity of URTIs in a large community group ( $n = 1002$ ) of adults (aged 18–85 years). Overall, quercetin supplementation over the 12-week study period had no significant influence on URTI rates or symptomatology when compared to placebo. However, a reduction in number of URTI-related sick days and severity was observed in a subgroup of middle-aged and older subjects ingesting 1000 mg quercetin/day who rated themselves as physically fit (Heinz et al 2010).

### Asthma

Quercetin has also been used as an adjunct in the management of asthma, often in combination with vitamin C because of its antiallergic activity and ability to inhibit leukotriene synthesis (Formica & Regelson 1995). While preclinical studies have demonstrated antihistamine, antioxidant and anti-inflammatory activity, there has been a paucity of clinical trials investigating the potential of quercetin in the management of asthma.

### Preventing diabetic complications

As quercetin has been shown to inhibit aldose reductase, the first enzyme in the polyol pathway, a theoretical basis exists for its use in the prevention of long-term diabetic complications such as cataracts, nephropathy, retinopathy and neuropathy

(Chaudhry et al 1983). Quercetin may also provide beneficial effects in people with diabetes by decreasing oxidative stress and preserving pancreatic beta-cell integrity (Coskun et al 2005). In vivo evidence also reveals that quercetin attenuates the damage caused by diabetes by promoting a neuroprotective effect and reducing enteric glial loss in the duodenum (Lopes et al 2012).

Preliminary evidence suggests a possible antinociceptive activity of quercetin, probably through modulation of opioidergic mechanism, suggesting a potential for the treatment of diabetic neuropathic pain (Anjaneyulu & Chopra 2003). Topical application of quercetin, in combination with ascorbyl palmitate and vitamin D<sub>3</sub>, has been tested in a randomised, placebo-controlled, double-blind trial of 34 men and women (age 21–71 years) with diabetic neuropathy. The QR-333 preparation or placebo was applied three times daily for 4 weeks to each foot experiencing symptoms. QR-333 was well tolerated and reduced the severity of numbness, jolting pain and irritation from baseline values and improved quality-of-life scores (Valensi et al 2005).

The diabetic status of rats fed high-dose quercetin (1 g/kg) was found to be ameliorated by approximately 25%; however, the amounts used were considerably higher than those commonly used in humans (Shetty et al 2004) and these results cannot be applied to oral doses in humans. Further research is required to confirm any potential benefits.

### Cataracts

In addition to the potential reduction in diabetic cataract formation afforded by the inhibition of aldose reductase (Chaudhry et al 1983, Ramana et al 2007), quercetin may reduce oxidative stress associated with the initiation of maturity-onset cataracts.

Cataracts may result from oxidative damage to the lens, which causes a disruption of the redox system, membrane damage, proteolysis, protein aggregation and a loss of lens transparency. Quercetin has been shown to inhibit oxidative damage to the lens and maintain lens transparency in vitro (Cornish et al 2002, Sanderson et al 1999). In rats with galactosaemic cataracts, quercetin improves lens transparency by maintaining the characteristic osmotic ion (calcium, sodium and potassium) equilibrium and protein levels of the lens (Ramana et al 2007). Further trials are warranted to confirm the effects of oral doses in humans.

### Preventing cardiovascular disease

The cardioprotective properties of quercetin, as demonstrated in human, animal and in vitro studies, provide a basis for investigating quercetin in the prevention of cardiovascular disease; however, current evidence is unclear as to whether benefits are clinically relevant.

A double-blind, placebo-controlled study investigating the effects of a quercetin-containing supplement on plasma quercetin status, risk factors for

heart disease and serum/platelet fatty acid levels was conducted on 27 healthy men and women with cholesterol levels of 4.0–7.2 mmol/L (Conquer et al 1998). The subjects consumed a quercetin-containing supplement (1 g quercetin/day) or rice flour placebo for 28 days. Quercetin intakes were approximately 50-fold greater than dietary intakes previously associated with lower coronary heart disease mortality in epidemiological studies. Plasma quercetin concentrations were approximately 23-fold greater in subjects consuming the quercetin capsules than in the placebo group. No effect was observed on the levels of omega-3 or omega-6 polyunsaturated fatty acids in serum or platelet phospholipids, nor did quercetin supplementation alter serum total, LDL or HDL cholesterol or triglyceride levels or other cardiovascular disease or thrombogenic risk factors, such as platelet thromboxane B<sub>2</sub> production, blood pressure or resting heart rate. This is in contrast to the findings of other trials (Hubbard et al 2004, Pfeuffer et al 2013), which demonstrated inhibition of platelet aggregation and signalling and thrombus formation at a dose of 150 or 300 mg quercetin-4'-O-beta-D-glucoside (Hubbard et al 2004); as well as decreased postprandial triacylglycerol concentrations.

### IN COMBINATION

Another clinical trial which involved a large group of community-dwelling adults ( $n = 1000$ ) who were randomised into one of three groups, and given placebo or a combination of quercetin (500 mg), vitamin C (125 mg) and niacin supplements (5 mg) or the same combination at double the dosage over a 12-week period also yielded non-significant results. A difference in serum total cholesterol was measured between Q-500 and placebo groups, and there was a small decrease in HDL cholesterol levels in the Q-1000 group. Change in inflammatory measures did not differ between groups, except for a slight decrease in IL-6 for the Q-1000 group (Knab et al 2011).

### Metabolic syndrome

One double-blind, randomised trial involving 200 healthy persons with dyslipidaemia evaluated the effects of regular consumption of quercetin (over 2 months) on blood lipids. Upon completion of therapy, the test group demonstrated a decrease in cholesterol, triglyceride and LDL values, with a parallel increase in HDL (Talirevic & Jelena 2012). Although quercetin was used in supplemental form, no doses are mentioned in this study.

### Hypertension

In a small randomised, double-blind, placebo-controlled, crossover study, 730 mg quercetin/day for 4 weeks resulted in reductions in mean systolic ( $-7 \pm 2$  mmHg), diastolic ( $-5 \pm 2$  mmHg) and arterial blood pressures ( $-5 \pm 2$  mmHg) ( $P < 0.01$ ) in patients with stage 1 hypertension. Significant effects were not demonstrated in prehypertensive subjects,

and indices of oxidative stress were not affected by quercetin (Edwards et al 2007). A more recent clinical trial revealed that quercetin supplementation (150 mg/day over 6 weeks) reduced systolic blood pressure by an average of 2.6 mmHg ( $P < 0.01$ ) (Egert et al 2009). The same double-blind, crossover RCT showed that quercetin supplementation reduced plasma oxidised LDL concentrations in overweight subjects with a high-cardiovascular disease risk phenotype. At this dose, no adverse effects were seen.

### Performance enhancing

Some evidence suggests that quercetin supplementation increases performance in humans (Dunke et al 2009); however, not all studies are positive. A meta-analysis which reviewed 11 studies involving 254 human subjects of differing fitness levels found that quercetin (median treatment duration of 14 days; median dosage of 1083 mg/day) provides a significant benefit in human endurance exercise capacity, but the effect is small, with greater effects observed in subjects with a lower fitness level (Kressler et al 2011). The proposed mechanisms for ergogenic effects of quercetin are the antagonism of adenosine receptors, and improved mitochondrial biogenesis (through peroxisome proliferator-activated receptor gamma coactivator 1-alpha), which in turn would increase oxidative capacity and subsequently endurance performance (Kressler et al 2011).

Interestingly, previously a placebo-controlled trial of 40 athletes found that 6 weeks of treatment with quercetin (1000 mg/day) did not protect against exercise-induced oxidative stress and inflammation (McAnulty et al 2008). Additionally, a recent small crossover study of soldiers found that oral quercetin (1000 mg/day) taken for 8.5 days had no effects on aerobically-demanding soldier performance compared to placebo (Casuso et al 2013, Sharp et al 2012).

Recent research using an animal model found that quercetin supplementation during exercise provided a disadvantage to exercise-induced muscle adaptations (Casuso et al 2013), a finding which should be investigated in humans to better understand the benefit:risk considerations in athletes.

### Chronic prostatitis

Thirty men with category IIIa or IIIb chronic pelvic pain syndrome received either placebo or quercetin 500 mg twice daily for 1 month. Sixty-seven per cent of the treated subjects had at least a 25% improvement in symptoms compared to 20% of the placebo group. In a follow-up, unblinded, open-label study, 17 additional men received the same dose of quercetin (combined with bromelain and papain to enhance absorption) for 1 month. The combination increased the response rate from 67% to 82% (Shoskes et al 1999). The anti-inflammatory, antioxidant and immunomodulating activities of quercetin may help to explain these results.

### Cancer

Early concerns that quercetin may be carcinogenic have not been supported by recent research. Quercetin is primarily found in fruit and vegetables, which have been shown to decrease the risk of certain human cancers when consumed regularly (Ekström et al 2011, Morrow et al 2001), thereby casting doubt on this proposition. In fact, the anti-carcinogenic effects of quercetin seen in laboratory animals suggest a possible preventive role (Erlund 2004), and in vitro and epidemiological studies have suggested potential benefits in the prevention of colon (Kim et al 2005, Park et al 2005), lung (Schwarz et al 2005), prostate (Yuan et al 2004) and breast cancer (Otake et al 2000).

### Sarcoidosis

Oral quercetin supplementation ( $4 \times 500$  mg over 24 hours) increased total plasma antioxidant capacity, and reduced markers of oxidative stress and inflammation according to a double-blind, placebo-controlled study of non-smoking, untreated sarcoidosis patients, matched for age and gender ( $n = 18$ ). The effects of quercetin supplementation appeared to be more pronounced when the levels of the oxidative stress and inflammation markers were higher at baseline (Boots et al 2011).

### Aphthous ulcers

One clinical trial involving 40 male patients found that daily (2–3 times) topical application of a quercetin-based cream may be useful in accelerating the healing process of minor aphthous ulcers (Hamdy & Ibrahim 2010).

### OTHER USES

Although the potential benefits of quercetin in allergic conditions have yet to be confirmed by large human trials, quercetin is often used to treat conditions such as hayfever and other respiratory allergies and histamine-related conditions based on demonstrated pharmacological properties. In practice, quercetin is also commonly used to stabilise the integrity of blood vessel walls and address conditions resulting from capillary fragility, and used in conjunction with vitamin C for the treatment of viral infections. It is sometimes considered as a means of reducing the toxic effects of exposure to heavy metals. In vivo research suggests that quercetin consumption may attenuate the toxicity of environmental cadmium by decreasing lipid peroxidation and restoring the activities of antioxidant enzymes such as glutathione peroxidase and superoxide dismutase (Bu et al 2011).

### DOSAGE RANGE

#### General dose range

- 200–1500 mg daily taken in divided doses (PDRHealth 2005, Spoerke & Rouse 2004).

### Specific doses

- Chronic prostatitis: 500 mg (combined with bromelain and papain to enhance absorption) twice daily (Shoskes et al 1999).
- Acute allergies: 2 g every 2 hours for 2 days (often used with vitamin C) in practice.
- Chronic allergies: 2 g daily used in practice.
- Asthma: as an adjunct to standard treatment 2 g daily used in practice.
- Sarcoidosis: 2000 mg/day oral quercetin.
- Cardiovascular disease prevention: 3 × 200 mL of black tea per day, or two medium-sized apples per day.
- Hypertension: 150 mg/day for 6 weeks.
- Aphthous ulcers: topical quercetin cream, three times a day.

### ADVERSE REACTIONS

Quercetin is generally well tolerated and appears to be associated with little toxicity when administered orally or intravenously (Lamson & Brignall 2000). Adverse effects are rare and include nausea, dyspnoea, headache and mild tingling of the extremities (PDRHealth 2005, Spoerke & Rouse 2004).

### SIGNIFICANT INTERACTIONS

Possible modulation of P-glycoprotein (Choi & Li 2005, Hsiu et al 2002, Limtrakul et al 2005) and inhibition of CYP1A1 (Schwarz et al 2005) and CYP1A2 (Chang et al 2006) activity should be considered when prescribing. According to a recent crossover RCT, 500 mg of oral quercetin significantly induces CYP3A4; therefore healthcare providers should carefully monitor the concurrent use of all drugs chiefly metabolised by CYP3A4 to avoid drug interactions (Duan et al 2012).

Note: Phase II metabolites of quercetin appear to inhibit human multidrug resistance-associated protein 1 (MRP1) and 2 (MRP2), which may prove beneficial in MRP-mediated multidrug resistance (van Zanden et al 2007). For instance, the combined effect of quercetin with hyperthermia in human myelogenous leukaemia cells may assist in the reversal of multidrug resistance (Shen et al 2008).

### Iron

Quercetin is a powerful iron chelator so should not be ingested at the same time as iron supplements or iron-rich foods to avoid reducing absorption (Vanhees et al 2011). Separate dose by 2 hours.

### Adriamycin

Quercetin has demonstrated to have a protective effect against Adriamycin-induced cardiotoxicity in mice. The effect is likely to be related to enhanced myocardial superoxide dismutase activity, decreased iNOS activity and inhibition of myocardial apoptosis (Pei et al 2007).

### Cisplatin

Quercetin pretreatment may sensitise human cervix carcinoma cells to cisplatin-induced apoptosis

(Jakubowicz-Gil et al 2005). Beneficial interaction is theoretically possible under professional supervision, but clinical significance is unknown.

### Cyclosporin

Animal studies demonstrate that coadministration of quercetin significantly decreases the oral bioavailability of cyclosporin (Hsiu et al 2002) — avoid concurrent use.

### Digoxin

An increase in drug bioavailability is theoretically possible and has been observed in an in vivo study. Although human studies at lower doses are not available, the narrow therapeutic range of digoxin and the serious nature of the interaction should not be underestimated. Avoid concurrent use.

### Diltiazem

Pretreatment of rabbits with quercetin resulted in an increased bioavailability of the calcium channel blocker diltiazem, which may be the result of inhibition of P-glycoprotein and CYP 3A4 (Choi & Li 2005). Caution — use under professional supervision; doses may need to be adjusted accordingly.

### Doxorubicin

A positive interaction has been observed. When combined with doxorubicin, quercetin potentiated antitumour effects, specifically in the highly invasive breast cancer. Moreover, in non-tumour cells, quercetin reduced doxorubicin cytotoxic side effects (Staedler et al 2011). Therefore, it theoretically may have benefits in reducing doxorubicin-mediated toxicity (Vaclavikova et al 2008); however, further investigation is required to confirm.

### Haloperidol

Tardive dyskinesia (rhythmical involuntary movements of the tongue, face, mouth or jaw, e.g. protrusion of tongue, puffing of cheeks, puckering of mouth and chewing movements) may result from long-term therapy with the traditional antipsychotic medication haloperidol and may be irreversible in some individuals. Oxidative stress and the products of lipid peroxidation have been implicated in the pathophysiology of tardive dyskinesia, and coadministration of quercetin (25–100 mg/kg) has been shown to dose-dependently reduce haloperidol-induced vacuous chewing movements and tongue protrusions in animal models (Naidu et al 2003). Beneficial interaction is theoretically possible under professional supervision.

### Paclitaxel

Pretreatment with quercetin may increase the bioavailability of paclitaxel according to animal studies (Choi et al 2004). Caution — use under professional supervision; doses may need to be adjusted accordingly.

### Paracetamol

According to animal data, pretreatment with quercetin may reduce the risk of mortality from paracetamol overdose (Janbaz et al 2004). However, effects in humans have not been studied —beneficial interaction theoretically possible.

### Pioglitazone

Quercetin may increase the bioavailability of pioglitazone (Actos) (Umathe et al 2008). Due to the potential for toxicity, careful monitoring of hepatic and cardiac function is required — caution.

### Quinolone antibiotics

In vitro, quercetin binds to the DNA gyrase site in bacteria and therefore may theoretically compete with quinolone antibiotics that also bind to this site (PDRHealth 2005) — caution.

### Saquinavir

Despite the inhibition of P-glycoprotein by quercetin, coadministration does not appear to alter plasma saquinavir concentrations. However, as there appears to be a substantial inter- and intrasubject variability in saquinavir intracellular concentrations, caution should be exerted until more is known (DiCenzo et al 2006).

### Stibamate

Concurrent use of quercetin with the antileishmanial drug stibamate appears to improve the efficacy of

the drug and reduce anaemia and parasitaemia associated with the condition (Sen et al 2005) — beneficial interaction theoretically possible.

#### Practice points/Patient counselling

- Quercetin is a flavanol belonging to a group of polyphenolic substances known as flavonoids or bioflavonoids and is found in many fruits and vegetables and some herbal medicines.
- According to experimental studies, it has antioxidant, anti-inflammatory, antiviral, mast cell stabilisation and inhibition, neuroprotective, gastroprotective, hepatoprotective and possibly cardioprotective actions.
- In practice, it is used for respiratory allergies such as hayfever, as an adjunct in asthma management, preventing diabetic complications such as cataracts and symptom relief in prostatitis; however, large controlled studies are not available to determine its effectiveness.
- Numerous drug interactions are possible, mainly due to CYP3A4 induction.
- Quercetin is generally well tolerated, although adverse effects may include nausea, dyspnoea, headache and mild tingling of the extremities.
- The daily intake of quercetin from food sources ranges from 5 to 40 mg but can reach up to 500 mg/day when consumption of fruits and vegetables is high, especially when the peel of the fruit is consumed (Harwood et al 2007).

#### CONTRAINDICATIONS AND PRECAUTIONS

Hypersensitivity to quercetin.

According to experimental studies, quercetin may possess some antithyroid properties, inhibiting thyroid cell growth in association with inhibition of insulin-modulated phosphatidylinositol 3-kinase-Akt kinase activity. While these findings are preliminary, quercetin should be used with caution in thyroid disease and therapy until more is understood about these effects in humans (Giuliani et al 2008).

#### PREGNANCY USE

Quercetin is widely available in the food chain and considered safe when consumed in dietary amounts (4–68 mg per day). The safety of higher oral doses is unclear, as some in vivo research indicates that quercetin crosses the placenta and accumulates in the fetus, and a relatively high intake of quercetin (302 mg/kg feed, which is comparable to supplemental intake of between 200 and 1800 mg/day) may have detrimental effects later in life (Vanhees et al 2011). However doses greater than this (333 mg/kg feed) did not exhibit teratogenic effects in other in vivo trials (Prater et al 2008).

#### PATIENTS' FAQs

##### What will this supplement do for me?

Quercetin has several pharmacological effects, may provide some symptom relief in allergic conditions and prostatitis and may be beneficial in the prevention of many chronic diseases, such as diabetes, osteoarthritis, neurodegeneration, cancer (as an adjunct) and cardiovascular disease; however, further research is required to clarify its effectiveness.

##### When will it start to work?

This will depend on the indication it is being used to treat.

##### Are there any safety issues?

Although it is generally well tolerated, numerous drug interactions are possible, so seek professional advice if taking other medication.

## Raspberry leaf

**HISTORICAL NOTE** Although the fruits of the raspberry are used as a luxury food source and in dietary drinks, midwives have used raspberry leaves since ancient times to prepare the uterus for childbirth. Raspberry has also been used as an antidiarrhoeal agent and an astringent to treat inflammations of the mucous membranes of the mouth and throat.

### COMMON NAME

Red raspberry

### OTHER NAMES

Framboise, *Rubi idaei folium*, rubus

### BOTANICAL NAME/FAMILY

*Rubus idaeus* (synonym: *Rubus strigosus*) (family Rosaceae [roses])

### PLANT PART USED

Leaf

### CHEMICAL COMPONENTS

Raspberry leaves have a tannin content of between 13% and 15%, as well as phenolic compounds like the flavonoids rutin and quercetin, volatile oils, organic acids and vitamin C.

### MAIN ACTIONS

Raspberry leaf contains a number of active constituents and their therapeutic actions have been reviewed (Patel et al 2004). Currently, evidence of activity comes from in vitro and in vivo studies.

#### Uterine effects

Raspberry leaf has demonstrated a variable effect on uterine muscle tone, as it contains a smooth-muscle stimulant, an anticholinesterase and an antispasmodic. The results of animal studies indicate that raspberry can either reduce or initiate uterine contractions (Bamford et al 1970). It appears to inhibit uterine contractions in samples from pregnant test animals, but has no effect in non-pregnant ones. Samples from human pregnant uteri respond with contraction effects; however, no effect was seen on non-pregnant uteri samples. Overall, it appeared

that raspberry leaf extract promoted more regular contractions that generally became less frequent (Newell et al 1996). A more recent preliminary study produced similar results with fractions of raspberry leaf extract, both stimulating and relaxing uterine muscle in pregnant rats (Briggs & Briggs 1997). There is evidence of at least two components of raspberry leaf extract that exhibit relaxant activity in an in vitro guinea pig ileum preparation (Rojas-Vera et al 2002). Results imply a regulatory action on contractions.

### Antidiarrhoeal

In addition to the high tannin content of the leaves which may exert an antidiarrhoeal action, raspberry cordial and juice, made from the fruits, were found to significantly reduce the growth of several species of gut bacteria, including *Salmonella*, *Shigella* and *Escherichia coli*. However, no antimicrobial activity was detected in the leaf extract or tea (Ryan et al 2001).

### Anti-inflammatory

Raspberry leaf exhibits anti-inflammatory activity because of its high tannin content, which has been found to inhibit cyclooxygenase (Duke 2003). When applied topically to mucous membranes, tannins have a local anti-inflammatory effect, produce capillary vasoconstriction and decrease vascular permeability (Halvorsen et al 2001).

### Astringent

The high tannin content of the leaf is responsible for the astringent activity.

### Antioxidant

The polyphenols in raspberry leaf demonstrate cytotoxic effects through antioxidant action in in vitro studies (Durgo et al 2012).

## OTHER ACTIONS

The phenolic content of raspberry leaves may provide antioxidant protection against oxidative stress that can induce neuronal damage. Raspberry ketone, which is an aromatic compound with similar structure to capsaicin and synephrine, has been shown in vivo to prevent and improve obesity and fatty liver though increasing noradrenaline-induced lipolysis in white adipocytes (Morimoto et al 2005).

## CLINICAL USE

The therapeutic effects of raspberry have not been significantly investigated under clinical trial conditions, so most evidence is derived from traditional, in vitro and animal studies.

### Uterine tonic

Raspberry leaf is commonly used as a 'partus preparator' to prepare the uterus for delivery and to

facilitate labour, as well as for treating morning sickness, dysmenorrhoea, leucorrhoea and menorrhagia (McFarlin et al 1999). A study of 588 pregnant women of 36–38 weeks' gestation who were attending a public tertiary maternity hospital in Melbourne, Australia were surveyed to measure the prevalence of herbal medicine use in pregnancy. Thirty-six per cent of women took at least one herbal supplement during the current pregnancy, their most common supplement being raspberry leaf (14%).

In vitro studies using pregnant rat and human uteri preparations suggest that raspberry may increase the regularity and decrease the frequency of uterine contractions (Bamford et al 1970), although a recent trial suggests that this varies depending on the herbal preparation used and pregnancy status (Jing et al 2010). In a double-blind trial of 192 low-risk nulliparous women, raspberry leaf (2 × 1.2 g/day), consumed from 32 weeks' gestation until labour, was associated with a lower rate of interventions with no adverse effects for mother or baby (Simpson et al 2001). Raspberry leaf did not shorten the first stage of labour; however, it did significantly reduce the second stage. A retrospective, observational study of 108 mothers also found that treatment with raspberry leaf was associated with a lower rate of medical intervention (Parsons et al 1999). This study further suggested that treatment may shorten labour, and reduce the incidence of pre- and post-term labour. Some pregnant women commenced use of raspberry leaf from 8 weeks' gestation; however, most chose to start it between 30 and 34 weeks' gestation.

A more recent finding from a survey of 600 Norwegian women after delivery in a regional hospital found 5.7% had taken raspberry leaf during their pregnancy. A significant association was found between the use of raspberry leaf and caesarean delivery (23.5% vs 9.1% among women with no use of herbal medicines). The authors conclude that this finding should be explored further where information about the reason for caesarean section and the amount, timing and duration of raspberry leaf intake are included (Nordeng et al 2011).

### Topical inflammatory conditions

The high tannin content of raspberry supports its traditional use as a topical treatment for inflammation of the mouth, throat, eye and skin, as well as to treat cuts and wounds.

### Diarrhoea

Once again, the high tannin content of raspberry supports its traditional use as an antidiarrhoeal agent.

### Dyspeptic complaints

Traditionally understood to act as a choleric, raspberry leaf is used to improve digestion and detoxifying processes, but controlled studies are not available to determine its effectiveness.

## OTHER USES

Raspberry leaf is commonly recommended for nausea and vomiting in pregnancy, but this advice is based more on anecdotal evidence than rigorous scientific evidence, highlighting a need for more research in this area.

Cold infusions of raspberry leaf have been used to treat diarrhoea, loose bowels and stomach complaints in children. Raspberry leaf has traditionally been incorporated into mouthwashes to treat inflammation of the mouth and throat, used as a diaphoretic for fever, as a choleric to improve digestion and detoxification, and as a food and flavouring agent.

In a small, uncontrolled, prospective pilot study of eight women, raspberry leaf in combination with 11 other botanical extracts was found to relieve menopausal symptoms (Smolinski et al 2005).

### *Practice points/Patient counselling*

- Raspberry leaves have been traditionally used to prepare the uterus for childbirth, with some modern research suggesting that they may be useful.
- When used in this way, raspberry leaf is often combined with other herbs and used during the last 6–8 weeks of pregnancy under close supervision.
- Raspberry leaves are high in tannins, which may make them useful as a mouthwash and to treat diarrhoea, although this has not been confirmed in clinical trials.
- As tannins may reduce the absorption of other substances, it is recommended to take raspberry leaf preparations separately from other medications. Raspberry leaf preparations can be considered safe and non-toxic.

## DOSAGE RANGE

### Internal use

- Infusion of dried leaf: 4–8 g taken up to three times daily.
- Liquid extract: (1:1): 4–8 mL three times daily.

### External use

- Topically, the tea can be used as a mouth or eye wash, or to clean wounds.

## TOXICITY

There is no evidence that raspberry leaf tea is toxic.

## ADVERSE REACTIONS

Owing to the tannin content of the herb, it may cause gastrointestinal discomfort.

## SIGNIFICANT INTERACTIONS

### Iron, calcium, magnesium

Due to its high tannin content, raspberry leaf may decrease absorption of iron, calcium and magnesium, as well as some drugs. As such, it is advised to separate the administration of these substances by at least 2 hours.

### CONTRAINDICATIONS AND PRECAUTIONS

The high tannin concentration within the herb means it should be avoided in constipation and used cautiously in active peptic ulcer and gastrointestinal conditions associated with inflammation.

### PREGNANCY USE

A systematic review of raspberry leaf and safety or efficacy during pregnancy, pharmacology and in vitro tests explaining mode of action or constituents looked at 12 original publications, some of which were 50 years old or older. Six of the studies were in vitro or animal experiments, five were clinical trials or other human studies and one proposed possible pharmacological actions. All the studies were small and only the latest animal study (Johnson et al 2009) indicated any potential for increased risk (Holst et al 2009). There is no evidence of harmful effects on the fetus, despite consumption by a large number of women. Clinical studies suggest that it is safe to use after the first trimester, although it is prudent to ensure close professional supervision.

### PATIENTS' FAQs

#### *What will this herb do for me?*

Raspberry leaf preparations have been used since ancient times to prepare the uterus for birth in an attempt to facilitate a complication-free labour. It is also used to treat diarrhoea and dyspeptic complaints, and incorporated into a mouthwash to reduce inflammation of the mouth and throat.

#### *When will it start to work?*

Currently, there is insufficient research to answer this question. However, it is used in increasing doses during the last few weeks of pregnancy. Symptomatic relief of diarrhoea and inflammation of the oral cavity is likely to occur within the first few doses.

#### *Are there any safety issues?*

Considering that raspberry leaf has uterine activity, it is recommended that pregnant women wanting to use it do so under the careful supervision of an experienced healthcare professional.

## Red clover

**HISTORICAL NOTE** Red clover has been used for a long time as an animal fodder as well as a human medicine. Traditionally, it is considered as an alternative remedy with blood-cleansing properties useful in the treatment of skin diseases such as psoriasis, eczema and rashes. A strong infusion was used to ease whooping cough and other spasmodic coughs due to measles, bronchitis and laryngitis. It was recommended for 'ulcers of every kind, and deep, ragged-edged, and otherwise badly conditioned burns. It possesses a peculiar soothing property, proves an efficient detergent, and promotes a healthful granulation'. Combined with other herbs, red clover was recommended for syphilis, scrofula, chronic rheumatism, glandular and various skin afflictions (Felter & Lloyd 1983). Interestingly, red clover was not traditionally used for the treatment of menopausal symptoms.

### OTHER NAMES

Cow clover, meadow clover, purple clover, trefoil

### BOTANICAL NAME/FAMILY

*Trifolium pratense* L. (family Fabaceae)

### PLANT PARTS USED

Flower head or leaf

### CHEMICAL COMPONENTS

#### Flower head

Flavanoids, including formononetin; flavonols, including isorhamnetin and quercetin glucosides; phenolic acids, including salicylic and *p*-coumaric acids; volatile oils and other constituents, including sitosterol, starch, fatty acids (British Herbal Medicine Association Scientific Committee 1983).

#### Leaf

Isoflavones, including biochanin A, daidzein, formononetin and genistein; caffeic acid derivatives; and coumestrol (trace) (Clifton-Bligh et al 2001, He et al 1996).

In the plant, the isoflavones are attached to a sugar molecule, usually glucose. The chemical term for any compound attached to a sugar is glycoside. The free isoflavone form is known as an aglycone. The active aglycone is liberated in the gut. Isoflavones are readily absorbed from the gut; they circulate freely in the blood and are excreted in the urine; 50% of ingested isoflavones are eliminated within 12 hours (Joannou et al 1995).

The aglycone forms of the four main oestrogenic isoflavones are genistein, daidzein, biochanin and formononetin.

#### Bioavailability

The isoflavone content of the marketed red clover products is highly variable and this has been shown to significantly affect the metabolism of red clover isoflavones by altering their absorption and excretion rates (S Wang et al 2008). New research testing the bioavailability of three isoflavones from a commercial red clover dietary supplement (Meno-Stabil) found a relatively high bioavailability of irilone, compared to the main isoflavone metabolites expected in plasma, daidzein and genistein, even after a single dose (Maul & Kulling 2010).

## MAIN ACTIONS

### Oestrogenic activity

The pharmacological investigation of red clover has mainly centred around the activity of the isoflavone constituents, especially their oestrogenic activity (Miksicek 1994). Red clover products contain primarily formononetin and biochanin A. The isoflavones have varying levels of subtle oestrogenic activity, with biochanin A having the strongest effect. Red clover isoflavones have been shown to have an affinity for oestrogen alpha- and beta-receptors and may act as both agonists and antagonists, depending on the level of endogenous oestrogens (Nelson et al 2006, Yatkin & Diaglioglu 2011, Zava et al 1998). The isoflavones in red clover (and soy extracts) act as selective oestrogen receptor modulators as well as selective oestrogen enzyme modulators. The higher affinity of isoflavones to oestrogen beta-receptors compared to oestrogen alpha-receptors has been used to explain why red clover extracts treat menopausal disorders, reduce risk of breast cancer and have protective effects on osteoporosis and the cardiovascular system (Beck et al 2005). Animal studies show that red clover extract, standardised to contain 15% isoflavones, produced a dose-dependent increase in uterine weight and differentiated vaginal cells, but did not stimulate cell proliferation in mammary glands in an ovariectomised rat model. The extract did not produce any antioestrogenic or additive oestrogenic effects when combined with 17-beta-oestradiol (Burdette et al 2002). Another animal study showed that formononetin had antioxidant and oestrogenic effects and, further, the oestrogenic effect was not dosage-related (Mu et al 2009). Supplementing isoflavones, either daidzein (at 100 mg/kg) or red clover extract (at 6.68 mg/kg), in menopausal rabbits also showed significant improvements in bone density, tissue integrity and vaginal blood flow, with minimal effect on uterine weight (Adaikan et al 2009). Animal studies have also demonstrated that red clover stimulates oestrogen receptors in the endometrium without increasing cell proliferation (Alves et al 2008).

### Antioxidant activity

The isoflavones in red clover display antioxidant activity at concentrations well within the range found in the plasma of subjects consuming soy products, even though they undergo extensive metabolism in the intestine and the liver (Rufer & Kulling 2006).

### Opioid activity

A new understanding of a potential mechanism of action for red clover has been identified which involves interaction with opiate receptors. Red clover extract has high binding affinity for the mu-opiate receptor and also affinity at the delta-opiate receptor. Given the essential role of the

### Clinical note — Phyto-oestrogens and isoflavones

Phyto-oestrogens are plant-based compounds that are structurally similar to oestradiol. The term phyto-oestrogen encompasses isoflavone compounds, such as genistein and daidzein, found predominantly in soy and red clover, and the lignans, such as matairesinol and secoisolariciresinol, found in many fruits, cereals and in linseed. Phyto-oestrogens have been investigated for their potential to reduce the risk of hormone-dependent diseases such as breast and prostate cancers and osteoporosis. The metabolism of isoflavones and lignans is complex and involves gut microbial processes. Isoflavones are present predominantly as glucosides; however, their bioavailability requires initial hydrolysis of the sugar moiety by intestinal beta-glucosidases. After absorption, phyto-oestrogens are re-conjugated predominantly to glucuronic acid and, to a lesser degree, to sulfuric acid. There is further metabolism of isoflavones (to equol and O-desmethylangolensin) and lignans (to enterodiol and enterolactone) by gut bacteria. In humans, even those on controlled diets, there is large inter-individual variation in the metabolism of isoflavones and lignans, particularly in the production of the gut bacterial metabolite equol (from daidzein). Dietary factors and gut microflora directly influence the absorption and metabolism of phyto-oestrogens and are likely to influence the clinical benefits of supplementation with phyto-oestrogens (Rowland et al 2003).

opioid system in regulating temperature, mood and hormonal levels, this newly identified activity provides further rationale for its investigation as a treatment for relieving menopausal symptoms (Nissan et al 2007).

### Reducing cancer risk

As red clover has various antiangiogenic active compounds with different modes of action, it may be useful as a chemoprotective agent against carcinogenesis; however, the evidence is still not definitive (Adlercreutz et al 1995, Clarke et al 1996, Ingram et al 1997, Pagliaici et al 1994). Biochanin A isolated from red clover has been shown to be antimutagenic, as well as protective against chemically induced DNA damage in vitro (Chan et al 2003, Kole et al 2011) and inhibitory on melanogenesis in vitro and in vivo (Lin et al 2011). Genistein has been shown to inhibit cell proliferation and in vitro angiogenesis (Fotsis et al 1995) and the antiangiogenic effect of genistein and daidzein has been confirmed in an in vivo study using hen's eggs (Krenn & Paper 2009). Formononetin has been found in breast cancer cell models, both in vitro and in vivo, to cause cell cycle arrest by inactivating some insulin-like growth factor pathways and decreasing protein expression, indicating its potential use in the

prevention of breast cancer carcinogenesis (Chen et al 2011).

An animal study has found that red clover isoflavones significantly increase oestrogen beta-receptor and E-cadherin expression, but decrease transforming growth factor beta-1. These proteins are markers of oestrogen-induced proliferation, preservation of cell phenotype and reduction of the potential for neoplastic and metastatic transformation. These results suggest that red clover isoflavones may be useful in the treatment of prostatic hyperplasia and reduce the risk of neoplastic transformation (Slater et al 2002). A study has reported that red clover-derived isoflavones significantly reduced non-malignant prostatic growth in mice by acting as antiandrogenic agents rather than weak oestrogenic substances (Jarred et al 2003). The metabolites of the red clover isoflavone, biochanin, are thought to contribute to its chemopreventive effects.

Biochanin A, daidzein and genistein have demonstrated antiproliferative activity in vitro (Hempstock et al 1998). In an in vitro study, red clover isoflavones were tested for their potential in transactivating aryl hydrocarbon receptor (AhR), which is known to affect the cell cycle and drive cells to apoptosis. Selective AhR modulators have previously been implicated in cancer therapy and prevention, particularly for hormone-dependent cancers. It was found that the isoflavones biochanin A and formononetin were potent AhR agonists in vitro — 10 times more potent compared to the indole compounds (Medjakovic & Jungbauer 2008). Red clover isoflavones (50 mg total isoflavones), however, were found not to be antiproliferative in a double-blind, randomised study of 30 perimenopausal women (Hale et al 2001).

## CLINICAL USE

Considerable research has been carried out on the constituents of red clover; however, very few investigations have concentrated specifically on the flower heads and the traditional uses.

### Relief of menopausal symptoms

Numerous clinical studies have been conducted using red clover extracts or isoflavones, which are found in red clover in varying concentrations. Many isoflavone studies do not report whether these constituents were derived from red clover or other sources, making interpretation of the data difficult. Additionally, inferences about red clover based on soy isoflavone studies may not be valid because the two substances differ in their balance of individual isoflavones.

#### Red clover extract studies

The general consensus from systematic reviews and meta-analyses is that there is a lack of evidence to support the use of monopreparations containing *Trifolium pratense* isoflavones as a means of significantly reducing hot-flush frequency, severity or other menopausal symptoms (Booth et al 2006, Cheema

et al 2007, Coon et al 2007, Low Dog 2005, Nelson et al 2006). A Cochrane review also supported this conclusion (Lethaby et al 2007).

The most recent meta-analysis evaluated data from five randomised clinical trials of monopreparations containing *T. pratense* isoflavones (40–82 mg daily) and concluded that active treatment resulted in a marginally significant effect, reducing frequency of hot flushes in menopausal women, although the size of this effect may not be considered clinically relevant (Coon et al 2007). In 2007, Lethaby et al also reported in their systematic review that, of the five trials with data suitable for pooling that assessed daily frequency of hot flushes, there was no significant difference overall in the frequency of hot flushes between Promensil (a red clover extract) and placebo. Furthermore, a systematic review by Low Dog (2005) stated that the largest study showed minimal to no effect in reducing menopausal symptoms.

Three recent placebo-controlled studies again demonstrated that red clover had no significant effect in reducing menopausal symptoms. In each of these studies improvements in vasomotor symptoms were observed from baseline in both red clover and placebo groups; however, there were no significant differences between groups. In a randomised, triple-blind, placebo-controlled clinical trial, 55 menopausal women were randomly allocated to receive either placebo or 45 mg of red clover isoflavones for 8 weeks. Before the treatment and at the end of the study, a menopause-specific quality of life questionnaire was completed in both groups; however, the differences between two groups were not significant for total quality of life, nor for its domains (Ehsanpour et al 2012). A prospective, randomised, double-blind, placebo-controlled study in which 120 postmenopausal women received either 40 mg red clover or placebo over a 12-month trial period did not show significant improvement in menopausal symptoms or sexual satisfaction in women in the red clover group compared with placebo (del Giorno et al 2010).

A four-arm, randomised, double-blind clinical trial of standardised black cohosh, red clover, placebo and oestrogen/progesterone found that neither black cohosh nor red clover reduced the number of vasomotor symptoms compared with placebo, but that both herbal extracts were safe during daily administration for 12 months (Geller et al 2009). In a discussion paper about this study it was suggested that particular aspects of methodology may have led to these negative results, such as a large proportion of non-Caucasian participants (perhaps women with genomic differences from those women historically included in menopausal studies), long trial period and rigorous authentication of the herbal preparations could have led to marked differences in clinical outcomes from earlier trials. The authors of this discussion paper conclude that, because of these factors, further studies could be of value to determine if there are specific populations that may find such interventions of clinical

value. They suggest, for example, that studies with different primary and secondary clinical outcomes, or studies determining if earlier trials used herbal products that may have contained different active compounds, may result in clinical outcomes different from those reported (Shulman et al 2011).

In a study to test whether phyto-oestrogens had any impact on cognition in menopausal women, 66 women with 35 or more weekly hot flushes were enrolled in a randomised, double-blind, placebo-controlled study and received red clover (120 mg) or black cohosh (128 mg) or 0.625 mg conjugated equine oestrogens plus 2.5 mg medroxyprogesterone acetate or placebo. Participants completed measures of verbal memory (primary outcome) and other cognitive measures (secondary outcomes) before and during 12 months of treatment. Neither of the herbal treatments was found to have an impact on any cognitive measures (Maki et al 2009).

### Isoflavone studies

Several reviews have evaluated the clinical evidence relating to isoflavone treatment in the relief of menopausal hot flushes, finding conflicting and ambiguous results. Some of this confusion may arise from the fact that a variety of isoflavone sources have been tested, often without discriminating between the identities of individual isoflavones or the different concentrations contained in the tested intervention product. As such, volunteers may be receiving greatly different doses or ranges of specific isoflavones from the different test products, but researchers have not taken this into account when evaluating and comparing results.

A review by Williamson-Hughes et al (2006) highlights this issue and the importance of clearly defining the chemical composition of isoflavone treatments in research reports. The authors evaluated results from 11 studies that tested similar total isoflavone doses. Five of the 11 studies ( $n = 177$ ) reported a statistically significant decrease in hot-flush symptoms. Later evaluation revealed that the test products used in these studies provided more than 15 mg genistein (calculated as aglycone equivalents) per treatment. Of the remaining six studies ( $n = 201$ ), five failed to find a significant decrease in hot-flush symptoms. Participants in these studies received less than 15 mg genistein per treatment. Thus, the reduction in hot flushes was related to genistein content and not total isoflavone content of the treatments.

To demonstrate this point, a 12-month, prospective, randomised, double-blind, placebo-controlled study showed that the phyto-oestrogen genistein (54 mg/day) from red clover reduced the number and severity of hot flushes in postmenopausal women, with no adverse effect on the endometrium (D'Anna et al 2007). Similarly, another prospective randomised, double-blind, placebo-controlled trial ( $n = 109$ ) demonstrated that 40 mg mixed aglyconic isoflavones from red clover produced superior results over placebo in the treatment of vasomotor and

menopausal symptoms, with a concomitant decrease in depression and anxiety symptoms (Lipovac et al 2012).

Red clover-derived isoflavones have been shown to be effective in reducing depressive and anxiety symptoms among postmenopausal women. A randomised placebo control study evaluated the effect of isoflavones derived from red clover extracts (MF11RCE) on anxiety and depressive symptoms in 109 postmenopausal women. Participants were given 80 mg red clover isoflavones or placebo for a 90-day period; then, after a washout period of 7 days, medication was crossed over and taken for 90 days more. Anxiety and depressive symptoms were measured at baseline, 90 and 187 days with the Hospital Anxiety and Depression Scale and Zung's Self-rating Depression Scale. After adjustment for the placebo response the red clover isoflavone extract was shown to cause a significant decrease on both scales by an average 21.7% in comparison to baseline (Lipovac et al 2010).

### IN COMBINATION

A nutritional supplement containing isoflavones from kudzu and red clover, along with other targeted nutrients, produced a 46% decrease in hot-flush frequency, and quality of life, as assessed by the standardised Greene Questionnaire, showed similar improvement in a small pilot study of 25 menopausal women suffering from severe hot flushes and night sweats (Lukaczer et al 2005). A modest improvement in the ratio of total cholesterol to high-density lipoprotein (HDL) cholesterol was also observed and a statistical improvement in a proposed marker of breast cancer risk (the ratio of 2-hydroxyestrone to 16 alpha-hydroxyestrone) was also demonstrated. While promising, the role of red clover in achieving these results remains unknown.

### Other potential benefits in menopause

A randomised controlled trial using a standardised extract of red clover found that red clover exerts a moderate effect on testosterone levels in postmenopausal women, while oestradiol levels remained unchanged (Imhof et al 2006). The significance of this finding for clinical practice remains unknown.

There is some evidence from animal studies that oestrogen deprivation reduces the pain threshold and administration of phyto-oestrogens may reverse this. A methanol extract of isoflavones from red clover was administered orally (500 mg/kg of body weight) to ovariectomised and normal (controls) rats for 90 and 180 days. The pain threshold levels in ovariectomised rats treated with isoflavones extract were found to be similar to those of the control animals (Vishali et al 2011).

### Cardiovascular effects

#### Lipid lowering

The isoflavones in red clover regulate genes involved in lipid metabolism and antioxidant (Pakalapati et al 2009). Red clover isoflavones have anti-inflammatory effects and activate peroxisome

proliferator-activated receptor- $\alpha$ , which leads to an improved blood lipid profile (Mueller et al 2010).

A 2006 systematic review of randomised controlled trials, which included peri- and postmenopausal women, concluded that red clover extracts reduce levels of triglycerides and increase HDL cholesterol (Geller & Studee 2006). A randomised, placebo-controlled, crossover study of 60 postmenopausal women found that red clover isoflavones (80 mg/day) significantly decreased total cholesterol, low-density lipoprotein (LDL) cholesterol and lipoprotein A levels in women with body mass index (BMI) > 25 kg/m<sup>2</sup>, but not women with lower BMI (Chedraui et al 2008).

In a prospective open randomised controlled clinical trial, 40 healthy postmenopausal women were given one capsule daily of either placebo or 40 mg of red clover-derived isoflavones (containing 23 mg biochanin A, 1 mg daidzein, 15 mg formononetin and 1 mg genistein). All participants had total blood cholesterol, LDL and HDL cholesterol and triglycerides tested at baseline and at 4-month intervals over the following 12 months. Total serum cholesterol, LDL cholesterol and triglyceride levels significantly decreased and HDL cholesterol levels significantly increased in the group receiving phyto-oestrogens (Terzic et al 2009).

Despite these positive results, a 2013 Cochrane review found no evidence of cholesterol-lowering effects of isoflavones (red clover- or soy-derived) in people with hypercholesterolaemia. Five randomised trials ( $n = 208$ ) with interventions ranging from 3 to 6 months were analysed. There was a slight significant effect of isoflavones on triglycerides compared with placebo, but no statistically significant effects on total cholesterol, LDLs or HDLs. None of the trials found serious adverse events. The authors suggest their results be interpreted cautiously due to the low number of participants in the trials (Qin et al 2013).

### Blood pressure

Clinical studies have not consistently shown red clover isoflavones to significantly reduce blood pressure (Atkinson et al 2004b, Teede et al 2003); however, there is evidence that red clover isoflavones reduce arterial stiffness and total vascular resistance (Fugh-Berman & Kronenberg 2001, Nestel et al 1999, Teede et al 2003). A reduction in blood pressure and improved endothelial function were reported for red clover isoflavones (approximately 50 mg/day) in a small randomised, double-blind, crossover trial ( $n = 16$ ) involving postmenopausal women with type 2 diabetes (Howes et al 2003).

Given the lack of serious safety concerns, red clover supplementation might be beneficial for postmenopausal women to reduce cardiovascular risk.

### Antiatherogenic

In vitro studies on cultured human endothelial cells have shown that phyto-oestrogens contained in red

clover extracts act as anti-inflammatory and antiatherogenic agents by reducing the expression of the leucocyte adhesion molecules (Simoncini et al 2008).

### Reducing cancer risk

Much of the research in this area has focused on isoflavones generally derived from soy products rather than red clover sources. As such, it is uncertain whether the results from these studies can be extrapolated to red clover extracts. For more information about the association between soy isoflavones and cancer risk, refer to the soy monograph.

### Prostate cancer

In vitro models have confirmed that transforming growth factor 1 (TGF-1) increases dehydroepiandrosterone metabolism to androgens and prostate-specific antigen (PSA) in prostate tissue. Red clover isoflavones inhibit TGF-induced androgenicity and are therefore protective of prostate tissue (Liu et al 2011). Investigation of the mechanism involved in the apoptosis effect of formononetin on human prostate cancer cells found it inactivated the extracellular signal-regulated kinase1/2 (ERK1/2) mitogen-activated protein kinase (MAPK) signalling pathway in a dose-dependent manner (Ye et al 2012). These studies suggest that further research on the use of red clover isoflavones in the prevention and treatment of prostate cancer is warranted.

A non-randomised, non-blinded trial of 38 men with clinically significant prostate cancer found that 160 mg/day red clover-derived dietary isoflavones, containing a mixture of genistein, daidzein, formononetin and biochanin A, significantly increased apoptosis compared with matched controls ( $P = 0.0018$ ). There were no significant differences between pre- and posttreatment serum levels of PSA, testosterone or biochemical factors or Gleason score in the treated patients ( $P > 0.05$ ). The study was performed in men undergoing radical prostatectomy; however, it indicates that the isoflavones may halt the progression of prostate cancer by inducing apoptosis in low-to-moderate-grade tumours (Gleason grade 1–3) (Jarred et al 2002).

### Breast cancer

An antioestrogenic effect on breast tissue is particularly important in women at high risk, or with a history, of breast cancer. A 2010 systematic review and meta-analysis assessing the effects of isoflavone-rich foods or supplements on mammographic density, a biomarker of breast cancer risk, looked at eight randomised controlled trials ( $n = 1287$  women) comparing isoflavones with placebo for between 6 months and 3 years. The meta-analysis suggested no overall effect of dietary isoflavones on breast density in all women combined or postmenopausal women; however, there was a modest increase in mammographic density in premenopausal women. The authors concluded that isoflavone intake does not

alter breast density in postmenopausal women, but may cause a small increase in breast density in premenopausal women and that larger, long-term trials are required to determine if these small effects are clinically relevant (Hooper et al 2010).

Overexposure of oestrogen is a major contributing factor in the development of breast cancer, and cytochrome P450 (CYP) 19 enzyme, or aromatase, catalyses the reaction converting androgen to oestrogen. Biochanin A, isolated from red clover, has been shown to inhibit CYP19 activity and gene expression (Y Wang et al 2008). In vitro studies have shown that genistein slightly increases breast cancer cell migration and invasion, but in the presence of oestradiol its effect is antioestrogenic (Mannella et al 2012). In another in vitro study, isoflavones were added to 11 human cancer cell lines and one human fibroblast cell line, and their effects on cell proliferation, apoptosis induction and cell cycle were measured. It was found that high isoflavone concentrations did not promote the growth of these human cancer cells in vitro. Furthermore, oestrogen receptor-positive MCF-7 breast cancer cells grown under pre- and postmenopausal conditions showed decreased rather than increased cell proliferation (Reiter et al 2011). Another in vitro study found that formononetin inhibits the proliferation of oestrogen receptor-positive, but not oestrogen receptor-negative, breast cancer cells (Chen & Sun 2012).

A large prospective study (the HEAL study;  $n = 1183$ ) conducted surveys of women with breast cancer within 12 months of diagnosis and again at 30 and 40 months after diagnosis, in particular seeking information about quality of life and levels of fatigue. At 30 months after diagnosis, 39.5% of women were using phyto-oestrogenic supplements, but only 38 women were taking supplements of red clover. In this small sample only three symptoms — weight gain, night sweats, and difficulty concentrating — were less common than in women not consuming any phyto-oestrogens (Ma et al 2011).

A 2006 systematic review of complementary and alternative therapeutic approaches, including the use of red clover, in patients with early breast cancer drew the conclusion that available data on complementary and alternative medicine modalities in the treatment of early-stage breast cancer did not support their application (Gerber et al 2006). However more recent in vitro research on isoflavones from red clover suggests that further investigation for their use in treating oestrogen receptor-positive breast cancer may be warranted.

### Benign prostatic hypertrophy

Isoflavone-containing food and supplements are widely used in patients with benign prostatic hypertrophy (BPH). An in vivo study using mice showed that red clover-derived isoflavones have a significant effect on prostatic growth, and are capable of reducing the tendency to enlarged non-malignant prostate, by acting as antiandrogenic agents rather than

weak oestrogenic substances (Jarred et al 2003). An ex vivo study investigating the effect on contractility of rat prostatic smooth muscle concluded that, as well as having antiproliferative effects, red clover isoflavones cause inhibition of prostatic smooth-muscle contractions; however, such high concentrations were required that this may be of limited clinical use (Brandli et al 2010).

A case series ( $n = 29$ ) presented at the Endocrine Society's 82nd Annual Meeting in 2000 suggested that 3 months of treatment with one or two tablets of Trinovin (standardised to 40 mg red clover isoflavones per tablet) significantly decreased nocturia frequency, the International Prostate Symptom Score, increased urinary flow rates and quality-of-life score. PSA values and prostate size did not alter from baseline (Ulbricht & Basch 2005). A small clinical trial involving 20 men aged over 65 years with elevated PSA levels and negative prostate biopsy findings showed that oral administration of a red clover isoflavone extract (60 mg/day) significantly decreased total PSA levels by >30%. During the 1-year treatment period, active treatment was well tolerated and caused no side effects, and significantly increased liver transaminases (an indication of improved liver function) were observed (Engelhardt & Riedl 2008).

### Osteoporosis prevention

Pharmaceutical hormone replacement therapy (HRT) is sometimes used to prevent loss of bone following menopause; however, a growing number of users are concerned about the increased risk of breast cancer associated with long-term HRT. As such, phyto-oestrogens have been used as an alternative to prevent osteoporosis. Most research has focused on soy isoflavones, although there is some evidence that red clover-derived isoflavones may also be of benefit.

Animal studies have demonstrated that red clover isoflavones are effective in reducing bone loss, probably by reducing bone turnover via inhibition of bone resorption (Kawakita et al 2009, Occhiuto et al 2007). However, human studies show variable results. In a trial by Atkinson et al (2004a), loss of lumbar spine bone mineral content and bone mineral density was significantly reduced in women taking red clover-derived isoflavones (43.5 mg/day) compared to placebo in a double-blind, placebo-controlled, randomised trial in 205 women over 12 months. Bone formation markers were also significantly increased; however, no improvement in hip bone mineral content or bone mineral density was noted. A double-blind study of 46 postmenopausal women investigated the effects of a red clover isoflavone preparation (Rimostil) containing genistein, daidzein, formononetin and biochanin A after a single-blind placebo phase and followed by a single-blind washout phase. Patients were randomly assigned to receive 28.5 mg, 57 mg or 85.5 mg phyto-oestrogens daily for a 6-month period. After the test period, the bone mineral density of the

proximal radius and ulna rose significantly — by 4.1% with a dose of 57 mg/day and by 3.0% with a dose of 85.5 mg/day isoflavones. The response with 28.5 mg/day isoflavones was not significant (Clifton-Bligh et al 2001).

No significant difference in bone turnover markers was apparent after 12 weeks of treatment with Promensil and Rimostil in a double-blind, placebo-controlled, randomised clinical trial in 252 menopausal women aged between 45 and 60 years (Schult et al 2004).

## OTHER USES

Several human and animal studies have attributed hypolipidaemic, hypoglycaemic or antiatherosclerotic effects to red clover extract or isoflavones. A recent *in vivo* study, however, showed that red clover extract, biochanin A and formononetin had no hypoglycaemic effect in diabetic mice (Qiu et al 2012). A recent small randomised controlled trial ( $n = 43$ ) compared the effects of transdermal oestrogen with Promensil (40 mg or 80 mg/day) on plasma glucose, insulin sensitivity, plasma testosterone, oestradiol and sex hormone-binding globulin (SHBG) over a 12-week period. In contrast to prior studies on red clover-based phyto-oestrogens, this study found that red clover was associated with a significant decrease in insulin sensitivity, but had no effect on SHBG, oestradiol or testosterone levels in healthy non-diabetic postmenopausal women (Lee et al 2012).

*In vitro* research suggests that red clover isoflavones have a protective effect on dopaminergic neurons through inhibition of the generation of proinflammatory factors (Chen et al 2008) and exert a neuroprotective effect in human cortical neurons, possibly due to antioxidant and oestrogenic actions (Occhiuto et al 2008, 2009).

An animal study to investigate the effects of red clover isoflavones on skin ageing, the histology of the skin, skin thickness and the amount of total collagen, with a red clover extract standardised to contain 11% isoflavones, concluded that red clover isoflavones are effective in reducing skin ageing induced by oestrogen deprivation (Circosta et al 2006). A combination of red clover isoflavones from various *Trifolium* species, including *T. pratense*, demonstrated wound-healing properties in animal models (Renda et al 2013).

## TRADITIONAL USES

Red clover flower heads are traditionally used for indications not related to the potential hormonal activity of the herb. The alterative or blood-cleansing action is used in skin eruptions and as part of treatment for cancer. A poultice of red clover flowers can be used to soothe the local inflammations such as acne, burns or ulcers.

The British Herbal Pharmacopoeia lists red clover as a dermatological agent, mild antispasmodic

and expectorant (British Herbal Medicine Association Scientific Committee 1983). The specific indications are for eczema and psoriasis. Red clover is said to combine well with yellow dock for the treatment of chronic skin disease.

## DOSAGE RANGE

- 4 g as infusion or extract.
- Liquid extract (1:1) in 25% alcohol: 1.5–3.0 mL/day.
- Concentrated isoflavone extract containing 40–80 mg total isoflavones is recommended, based on the daily intake of phyto-oestrogens in a traditional Japanese diet.

Note: The isoflavone content of the marketed red clover products is highly variable and this alone may significantly affect absorption rates.

## According to clinical reports

- Menopausal symptoms: 40–82 mg daily of red clover-derived isoflavones.
- Lipid lowering: 40–86 mg daily of red clover-derived isoflavones.
- Osteoporosis prevention: 44–86 mg daily of red clover-derived isoflavones.
- BPH symptom relief: 40–80 mg daily of red clover-derived isoflavones.

## Practice points/Patient counselling

- Red clover flower heads are traditionally considered a dermatological agent, mild antispasmodic and expectorant and specifically used for eczema and psoriasis. In practice, red clover is often combined with yellow dock for the treatment of chronic skin disease.
- In recent years, red clover isoflavones have been studied and shown to have an affinity for oestrogen alpha- and beta-receptors and may act as both agonists and antagonists, depending on the level of endogenous oestrogens.
- Evidence that red clover-derived isoflavones reduce hot-flush frequency in menopause is unconvincing.
- Preliminary evidence suggests a possible preventive role in osteoporosis; however, further research is required.
- Concentrated isoflavone extracts from red clover are used in cardiovascular disease as there is weak evidence that it may reduce arterial stiffness, increase HDL cholesterol and decrease triglycerides.
- Evidence from animal studies and case series suggests a potential role in BPH, but further research is required.
- There is weak evidence that red clover isoflavone extracts may reduce the risk of hormone-sensitive cancers and that they may be beneficial in the treatment of prostate cancer.

## ADVERSE REACTIONS

The oestrogenic potency of the isoflavones has been well documented. Overgrazing cattle or sheep on red clover can be detrimental to their fertility. In 'clover disease', ewes are made permanently infertile by clover consumption. In animals with clover disease, the uterine response to oestrogen is reduced, as is the surge in luteinising hormone. Clover disease has not been observed with normal therapeutic doses in humans. None of the trials has reported adverse effects. An isoflavone preparation from soy bean, and red clover extracts containing genistein, daidzein, biochanin A and formononetin, did not modify the endometrial architecture in 25 post-menopausal women taking the preparation for 1 year (Aguilar et al 2002).

## SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

## Anticoagulant agents

The byproduct, dicoumarol (produced by microorganisms in poorly dried sweet clover), has

established anticoagulant effects. Therefore, only red clover extracts made from poorly dried raw materials may pose an interaction risk. Observe patients taking red clover and anticoagulants concurrently.

## Oestrogens

Theoretically, if taken in large quantities, phyto-oestrogens may compete with synthetic oestrogens for receptor binding, but the clinical significance of this remains unknown. One review concluded that up to 2 mg of red clover-derived isoflavones per kg should be considered a safe dose for most patient groups (Barnes 2003).

### PREGNANCY USE

Scientific evidence for the use of red clover during pregnancy has not been established, so safety is unknown.

### PATIENTS' FAQs

#### *What will this herb do for me?*

Red clover is traditionally used for skin disorders. In recent years, concentrated red clover isoflavone extracts have been promoted for use in the treatment of menopausal symptoms, although clinical studies are inconsistent and generally unresponsive.

#### *When will it start to work?*

Red clover tea or extract for skin diseases requires long-term use. Improvement may occur within several weeks, with the condition continuing to improve with long-term use. Improvement in menopausal symptoms from the use of concentrated isoflavone extracts may take 2–3 months, although results are inconsistent.

#### *Are there any safety issues?*

Short- or long-term use of red clover tea or flower head extract is not thought to be associated with any adverse reactions and its use is considered safe. Concentrated red clover isoflavone extracts may have subtle oestrogenic activity and little is known about drug interactions or long-term use. As a result, they should not be used by people with oestrogen-sensitive tumours or conditions that may be aggravated by increased oestrogen levels, such as endometriosis, unless under professional supervision. People with breast cancer should only use red clover extracts under professional supervision.

### CONTRAINDICATIONS AND PRECAUTIONS

There are no known contraindications for the flower head extracts. Concentrated isoflavone extracts should only be used by people with oestrogen-sensitive cancers under professional supervision because of the possible proliferative effects. Additionally, people with conditions that may be aggravated by increased oestrogen levels, such as endometriosis or uterine fibroids, should use this herb under professional supervision only. Importantly, no randomised controlled trials have addressed the long-term safety of phyto-oestrogens in patients after a diagnosis of breast cancer (Boekhout et al 2006).

Red clover isoflavones are well tolerated in healthy women, according to a 3-year study of 400 women. Supplements containing red clover isoflavones did not adversely affect breast density, skeletal strength or cardiovascular status. In post-menopausal women, endometrial status was not adversely affected. The adverse event profile was similar between red clover isoflavones and placebo and endocrine status did not differ (Powles et al 2008).

There are some concerns whether isoflavones exert oestrogen-like effects in men by lowering bioavailable testosterone. A recent meta-analysis evaluated the effects of soy protein or isoflavones from red clover on testosterone, SHBG, free testosterone and free androgen index in men. Fifteen placebo-controlled trials and 32 reports were assessed and no significant effects were detected (Hamilton-Reeves et al 2010).

## Red yeast rice

**HISTORICAL NOTE** Red yeast rice (RYR), also known as red Koji or 'Hongqu', is a dietary staple in many Asian countries, including China and Japan, and has been used as a food, medicine and seasoning for more than a thousand years. Li Shizhen, the great pharmacologist of the Ming Dynasty (1368–1644), reported that 'Hongqu' promotes digestion and blood circulation, and can strengthen the spleen and dry the stomach' (Ma et al 2000). RYR, which is produced by fermenting steamed, non-glutinous rice with *Monascus* species of food fungus, is widely used in making pickled tofu, for brewing rice wine and as a preservative for meat and fish, thereby giving many dishes such as Peking duck their characteristic red colour. In recent years, several commercial versions of RYR have been made available and it has been included by the Chinese Ministry of Health into food additive standards to increase the colour and delicacy of meat, fish and soybean products.

In 1979, Professor Akira Endo, working in Japan on fungicides, found that *Monascus purpureus* on rice contained a compound that he called 'monacolin K', which was identified as a new hypocholesterolaemic agent that specifically inhibits HMG-CoA reductase (Endo 1980). It is now known as lovastatin. This discovery led to the development of a new class of lipid-lowering drugs, called statins.

Due to concerns about the quality and safety of RYR, it is no longer a listable ingredient for use in over-the-counter products in Australia ([www.tga.gov.au/archive/committees-cmec-resolutions-34.htm](http://www.tga.gov.au/archive/committees-cmec-resolutions-34.htm)).

**COMMON NAME**

Red yeast rice (RYR)

**OTHER NAMES**

Chinese red yeast rice, red Koji, Hongqu, Hon-Chi, Beni-koji. Zhi Tai is the dried, powdered form, while Xuezhikang is a standardised ethanolic extract.

**BOTANICAL NAME/FAMILY**

RYR is produced by fermenting cooked rice with various *Monascus* species, most commonly *M. pilous* and *M. purpureus*.

**CHEMICAL COMPONENTS**

RYR is a food and medicine with a range of potentially active and synergistic constituents whose amounts vary widely depending on preparation.

While it is assumed that the main active constituents are the monacolins, particularly monacolin K or lovastatin, there are a number of other potentially active constituents, including 13 kinds of natural statins, anti-inflammatory pigments ankaflavin and monascin; amino acids, gamma-aminobutyric acid, unsaturated fatty acids, plant sterols, isoflavones and isoflavone glycosides, tannins, alkaloids and other phytochemicals and trace elements that may act synergistically to produce clinical effects (Feng et al 2012, Lee & Pan 2012).

**Quality concerns**

The monacolin content of traditionally produced RYR has been found to vary widely (Huang et al 2006, Li et al 2004). This may be due to variations in *Monascus* species or growing and storage conditions, as monacolin levels are influenced by exposure to light and heat (Li et al 2005). RYR, as both a food and supplement, may also contain a toxic fermentation by-product, citrinin, a mycotoxin. Citrinin is a hepatonephrotoxin, which causes functional and structural damage through alterations in liver and kidney metabolism (Nigovic et al 2013). Levels of citrinin vary based on preparation method (Childress et al 2013).

A 2010 study tested 12 commercially available 600 mg RYR products, with the amount of monacolins ranging from 0.31 to 11.15 mg per capsule (Gordon et al 2010); many failed to contain the anticipated or effective quantities. The study also found four of the 12 products had levels of citrinin many times higher than allowed in Japan and Europe (Gordon et al 2010).

Interestingly, other constituents of RYR have been identified which may be protective against the cytotoxicity of citrinin, such as deferricoprogen, which has strong antiapoptotic properties in human embryonic kidney cells (Hsu et al 2012b). Improved production (Suh et al 2007) and testing methods are being developed which should help standardise the monacolin content and minimise the citrinin content in RYR products in the future (Lee et al 2006, Nigovic et al 2013, Wu et al 2011) and allay quality and safety concerns.

**MAIN ACTIONS**

RYR has many different actions with potential benefits on human health. As a consequence, Feng et al (2012) suggest that Xuezhikang (a RYR product standardised to 2.5–3.2 mg of monacolin K/capsule) should be considered a natural ‘polypill’ as it seems to assist in so many areas — in cardiovascular disease, such as improving lipid profile management and inhibiting atherosclerosis, liver protection, anti-cancer, antidiabetic, neural and kidney protection (Feng et al 2012).

**Cholesterol lowering**

RYR has significant lipid-lowering activity which is due to multiple mechanisms. One of the most studied is its inhibition of HMG-CoA reductase, which is the rate-limiting enzyme in cholesterol biosynthesis. Inhibition of the enzyme causes a decrease in endogenous cholesterol production, which leads to upregulation of low-density lipoprotein (LDL) receptors, increasing the rate of removal of LDL from plasma. RYR contains natural statin components that inhibit HMG-CoA reductase in a dose-dependent manner and hence reduce cholesterol synthesis in human hepatic cells (Feng et al 2012, Man et al 2002).

RYR has also been found to reduce serum total cholesterol and triglycerides in rabbits and quails with experimental hyperlipidaemia and suppress atherosclerosis induced by atherogenic diets (Li et al 1997, Wei et al 2003). Investigation with an animal model suggests the antiatherogenic effects are superior to the isolated chemical, lovastatin (Wei et al 2003).

As well as reducing cholesterol, RYR may have positive effects on endothelial function by reducing homocysteine-stimulated endothelial adhesiveness, as well as downregulating intracellular reactive oxygen species formation (Lin et al 2008). RYR extract (Xuezhikang) significantly enhanced the proliferation and adhesion capacity of endothelial progenitor cells derived from the peripheral blood of patients with stable coronary artery disease, to the same extent as atorvastatin (Kong et al 2008).

**Anti-inflammatory**

Studies suggest that, in addition to lowering cholesterol, the statin drugs may have potent vascular anti-inflammatory actions that produce reductions in vascular plaque adherence and migration to sites of inflammation in atherosclerosis. This has led to the suggestion that low-dose statins may be used for long-term treatment of cardiovascular disease in susceptible individuals (Liao 2004).

In a randomised controlled trial (RCT) involving 36 patients with cardiovascular disease, 1200 mg/day of an RYR extract (Xuezhikang) was found to significantly reduce C-reactive protein (CRP) and other inflammatory markers and prolong exercise tolerance and time, in addition to significantly reducing total cholesterol, LDL cholesterol and triglycerides (Li et al 2007). Other studies support

Xuezhikang's CRP-lowering actions (Kao et al 2006, Li et al 2007), as well as the attenuation of additional inflammatory mediators such as tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-6 (IL-6) and fibrinogen (Feng et al 2012).

Treatment with Xuezhikang improves preprandial and postprandial endothelial function after 6 weeks of use in patients with coronary heart disease (CHD) (Liu et al 2003, Zhao et al 2004). These findings have led to the suggestion that the inclusion of RYR in Asian diets may contribute to the median CRP level of Asians being only one-tenth that of Westerners (Kao et al 2006).

Hsu et al (2012b) suggest that monascin is one of the key components responsible for the anti-inflammatory mechanism.

### Anticancer

In vitro studies indicate that RYR and some of its individual constituents exert anticancer activity. The effect is not simply attributed to the lovastatin content but also to other monacolins, pigments or the combined matrix effects of multiple constituents which may affect intracellular signalling pathways differently from lovastatin (Hong et al 2008a, 2008b). This suggestion is supported by an in vitro study using prostate cancer cells, which found that RYR had a more potent inhibitory action on cell growth compared to isolated lovastatin (Hong et al 2008b).

Hsu et al (2012a) proposed that monascus-fermented metabolites may be developed into a topical application to prevent or cure oral carcinogenesis. This is a novel therapeutic approach focusing on tumour growth attenuation to improve patient survival and quality of life. Their results suggest that functional secondary metabolites of monascus, including monacolin K, citrinin, ankaflavin and monascin, have shown anti-inflammatory, antioxidative and antitumour activities (Hsu & Pan 2012). Additionally, a new derivative, monapurpyridine A, which has been isolated from RYR, shows moderate cytotoxicity against breast cancer cells (MCF-7) in vitro (Hsu et al 2012a).

### Osteogenesis

Just as statins demonstrate an ability to stimulate bone formation, similarly, RYR preparations have also been shown to produce strong bone anabolic effects, both in vitro and in vivo (Gutierrez et al 2006, Wong & Rabie 2008). As a result, RYR may provide a dietary intervention to stimulate bone formation and prevent osteoporosis (Mundy 2006). In vitro studies suggest that RYR extract may increase osteogenic effect by stimulating cell proliferation and alkaline phosphatase activity in osteoblastic cells (Cho et al 2010).

### Antidiabetic

In vivo research with RYR and its ankaflavin component demonstrate several different mechanisms of action with potential benefits in diabetes.

Oral administration of RYR (Hon-Chi) decreased plasma glucose in a dose-dependent manner and delayed the development of insulin resistance in rats fed a fructose-rich diet. Oral administration of Hon-Chi (150 mg/kg) three times daily improved insulin sensitivity in streptozotocin-induced diabetic rats (Su et al 2007).

RYR attenuated the elevation of plasma glucose induced by an intravenous glucose challenge test in normal rats and reversed hyperphagia in streptozotocin-diabetic rats (Chang et al 2006). Further rat studies suggest that the plasma glucose-lowering action of RYR is due to release of acetylcholine and subsequent stimulation of muscarinic M<sub>3</sub> receptors in pancreatic cells that affect insulin release (Chen & Liu 2006), as well as decreasing hepatic gluconeogenesis to lower plasma glucose in diabetic rats lacking insulin (Chang et al 2006). The ankaflavin component attenuated insulin resistance in high-fat diet-induced mice by increased glucose uptake by adipocytes through peroxisome proliferator-activated receptor-gamma activation of insulin receptors and p-Akt (Hsu et al 2013).

### Hepatoprotective

Used in combination with conventional therapies, Xuezhikang can positively affect patients with fatty liver, relieving clinical syndromes and improving liver function (Feng et al 2012), as it can reverse aminotransferase abnormalities and inhibit hepatic expression of TNF- $\alpha$ . The high levels of selenium and flavonoids in Xuezhikang may also be important due to their antioxidant actions (Feng et al 2012). RYR was also effective against obesity-related inflammation, insulin resistance and non-alcoholic fatty liver disease in mice (Fujimoto et al 2012).

### CLINICAL USE

RYR and its various preparations are gaining a reputation as a natural polypill due to its wide range of biologically active constituents with multiple mechanisms of action, such as lipid lowering, anti-inflammatory, antioxidant, atherosclerotic prevention and effects on blood glucose regulation and endothelial activity. Recent research in China indicates significant decreases in cardiovascular events and mortality amongst people with established cardiovascular disease, lending weight to this description.

### Hyperlipidaemia, reducing coronary events and mortality

RYR preparations induce a significant reduction in serum total cholesterol levels, triglyceride levels and LDL cholesterol levels and an increase in high-density lipoprotein (HDL) cholesterol levels compared to placebo, according to a meta-analysis of 93 RCTs involving 9625 participants. The three RYR preparations tested were Cholestin, Xuezhikang and Zhibituo. These studies found that the lipid modification effects of RYR were comparable to standard statin medications and RYR treatment is

generally safe and well tolerated. When compared with non-statin lipid-lowering agents, RYR preparations are superior to nicotinate and fish oils, but equal to or less effective than fenofibrate and gemfibrozil (Liu et al 2006). Three more recent placebo-controlled studies with RYR have shown a significant reduction in total cholesterol by up to 23.7% as well as a significant reduction in LDL cholesterol (Yang & Mousa 2012).

The large China Coronary Secondary Prevention Study (CCSP), a multicentre, placebo-controlled trial involving 4870 Chinese patients with a history of myocardial infarction (MI), found that 4.5 years of supplementation with Xuezhikang 600 mg twice daily (standardised to 2.5–3.2 mg of monacolin K/capsule) significantly reduced total cholesterol (11.3%) and LDL cholesterol (21.2%), respectively, compared with only 2.3% and 2.3% in the placebo group ( $P < 0.0001$ ). Triglyceride levels fell 12.1% with active treatment compared with 3.1% for placebo ( $P = 0.0031$ ) and there was a significant increase in HDL cholesterol by 4.0% compared with baseline ( $P = 0.0043$ ) (Lu et al 2008). A daily dose of Xuezhikang 1200 mg naturally contains 10–13 mg of lovastatin, together with other bioactive natural compounds displaying different mechanisms of action.

### All-cause mortality and CHD mortality

A systematic review of 22 RCTs of Xuezhikang in patients with CHD, complicated by dyslipidaemia, concluded that there were significant benefits with regard to all-cause mortality, CHD mortality, MI and revascularisation as compared with placebo. Placebo was based on conventional treatment for CHD. Active treatment with RYR lowered total cholesterol, triglyceride and LDL cholesterol compared with placebo or inositol nicotinate. It raised HDL cholesterol compared to placebo or no intervention and was found to be safe (Shang et al 2012).

Supplementation with Xuezhikang 600 mg twice daily (standardised to 2.5–3.2 mg of monacolin K/capsule) over 4.5 years significantly decreased the recurrence of coronary events and the occurrence of new cardiovascular events and deaths in the CCSP study, involving 4870 Chinese patients with a history of MI (Lu et al 2008). Besides a significant lipid-lowering effect on total cholesterol, triglyceride and LDL cholesterol, this study found a relative risk reduction of 45% and an absolute risk reduction of 4.7% for coronary events, along with a 33% reduction in total mortality in those taking the RYR extract. Interestingly, a marked 45% reduction of cancer-related deaths was also observed in the treatment group (Lu et al 2008). The participants in this study had experienced an acute MI between 28 days and 5 years before entering the study and were aged between 18 and 75 years. Patients maintained a stable diet and lifestyle during the test period and all medical treatments for hypertension or CHD or complications of CHD were

continued throughout the study and only lipid-lowering medication was prohibited.

A subgroup analysis of the 1530 elderly (>65 years) hypertensive patients in the CCSP study found that treatment with Xuezhikang significantly decreased the risk of a coronary event by 38.2% ( $P = 0.0009$ ), risk of non-fatal MI by 53.4% ( $P = 0.0042$ ) and risk of death due to CHD by 29.2% ( $P = 0.0503$ ) compared with placebo (Li et al 2009). Furthermore, the risk for all-cause death was 36.3% lower in the active treatment group compared to placebo ( $P = 0.0030$ ). Beyond the effects on CVD, the total events from cancer were 49.2% less with RYR treatment compared to controls ( $P = 0.0395$ ). Interestingly, when these results are compared to studies utilising statin therapy in a Western population, treatment with Xuezhikang produced a greater reduction in mortality from all-cause and coronary events. This RCT compared placebo ( $n = 758$ ) to active treatment ( $n = 772$ ) and found no significant changes to blood pressure with treatment, indicating that other mechanisms were at work. At baseline, the two groups were well matched for age, body mass index, blood lipids, fasting blood glucose and blood pressure, prevalence of smoking or diabetes and use of antihypertensive medications and aspirin. The incidence of adverse effects was comparable between the groups.

Another subgroup analysis of the 591 diabetic patients in the CCSP study found even more dramatic results with a 50.8% reduction for CHD events ( $P < 0.001$ ) and 63.8% reduction in risk of non-fatal MI ( $P < 0.05$ ) (Zhao et al 2007). Additionally, the risk of CHD death reduced by 44.1% ( $P < 0.05$ ) for patients taking RYR compared to the placebo group. The beneficial effect on reducing mortality was observed after the first year of treatment and overall, the risk for all-cause mortality was 44.1% lower in the active treatment group compared to placebo ( $P < 0.01$ ). Once again, the incidence of side effects was comparable between the groups.

### OTHER USES

It has been suggested that, in addition to reducing cholesterol, it is possible that monacolins could prevent stroke and reduce the development of peripheral vascular disease. This class of molecules has antithrombotic and anti-inflammatory effects, which may offer protection against atherosclerotic plaque growth as well as being used for the treatment of hypertension, osteoporotic fractures, ventricular arrhythmia and immune response (Manzoni & Rollini 2002).

### DOSAGE RANGE

RYR is a dietary staple in many Asian countries, with typical consumption ranging from 14 to 55 g/person/day. The average dose of RYR products is 2.4 g/day depending on the product used.

### Supplemental forms

Xuezhikang 300 mg capsules, also known as lipasacor, is standardised to 2.5–3.2 mg of monacolin K/capsule. Doses range from 600 to 2400 mg per day (Lu et al 2008, Shang et al 2012).

### ADVERSE REACTIONS

The American College of Cardiology Task Force on integrating complementary medicine into cardiovascular medicine suggested that RYR should be ‘treated as an HMG-CoA reductase inhibitor, with all the possible side effects, drug interactions, and precautions associated with this class of drugs’ (Vogel et al 2005). While this approach simplifies the issue, consideration should be made for the fact that RYR contains multiple active components and is not just a natural source of low-dose statin-like compounds. RCTs indicate that it is well tolerated and not associated with serious adverse effects.

A meta-analysis of 77 controlled trials reported that there were no serious adverse events and non-serious adverse effects were limited to dizziness, low appetite, nausea, stomach ache, abdominal distension and diarrhoea, with a small proportion of participants having increased serum blood urea nitrogen and alanine aminotransferase levels (Liu et al 2006). More recently, an RCT of elderly (>65 years) Chinese patients with previous MI and hypertension found that the most common side effects were gastrointestinal discomfort, allergic reactions, myalgias, oedema, psychoneurological symptoms and erectile dysfunction, although the incidence of side effects was comparable to placebo (Li et al 2009). Another RCT of diabetic Chinese patients with previous MI confirmed that the incidence of side effects was similar to placebo. When side effects were reported, they were limited to gastrointestinal disorders, oedema and a case of mental-neurological symptoms (Zhao et al 2007).

A number of cases of statin-like muscle damage have been reported in patients taking RYR (Smith & Olive 2003, Vercelli et al 2006), and animal studies have demonstrated a dose-dependent reduction in coenzyme Q10 (CoQ10) levels with high levels of RYR (Yang et al 2005). Also, in a randomised, double-blind placebo-controlled trial of 62 patients with known statin-associated myalgias, RYR (3600 mg/day, 13 mg monacolins, 6 mg monacolin K for 24 weeks) was better tolerated than statins (Becker et al 2009).

### SIGNIFICANT INTERACTIONS

#### Statin drugs

RYR products contain low doses of natural statins and, as such, a pharmacodynamic interaction is possible with other statin medications with increased lipid-lowering effects — observe.

#### Cyclosporin and P450 inhibitors

Monacolins are metabolised by the cytochrome P450 system and therefore cyclosporin and other

P450 inhibitors have the potential to increase the risk of rhabdomyolysis (Prasad et al 2002). This is a theoretical concern only — clinical significance unclear.

### Coenzyme Q10

Similar to statin medications, RYR may reduce endogenous production of CoQ10 — a 3-month trial of CoQ10 supplementation may be worth considering with long-term use of RYR in people complaining of fatigue.

### CONTRAINDICATIONS AND PRECAUTIONS

Patients with statin-induced muscle damage should be cautioned if using RYR (Becker et al 2009, Vercelli et al 2006).

### PREGNANCY USE

Avoid use during pregnancy. The major ingredient in RYR is monacolin K, which is also known as mevinolin or lovastatin and has statin-like activity. Statins are potential teratogens based on theoretical considerations and, in small case studies, central nervous system and limb defects have been reported in newborns exposed to statins in utero (Childress et al 2013, <http://www.drugs.com/npp/red-yeast.html>).

### Practice points/Patient counselling

- RYR is a complex whole-food substance that has a long traditional use as a food and medicine and is still a common feature of Asian diets.
- RYR has been found to naturally contain monacolins (statins) together with a variety of other bioactive constituents. It has demonstrated beneficial effects on blood lipids, atherosclerosis, blood glucose regulation and endothelial function, free radical scavenging and bone mineral density.
- Meta-analyses confirm that RYR preparations (Cholestin, Xuezhikang and Zhibituo) significantly reduce total and LDL cholesterol and triglycerides and increase HDL cholesterol.
- Significant reductions in coronary events, total mortality and cancer-related deaths have been observed in a large, randomised, placebo-controlled study of elderly Chinese patients with a previous MI, using Xuezhikang long-term.
- There are quality concerns regarding RYR products, with variable amounts of both the active monacolins and potential toxic byproducts and therefore standardisation and quality control of RYR supplements are imperative.
- RYR products should be stored away from heat and light and not used in pregnancy.

## ! PATIENTS' FAQs

### What will this supplement do for me?

RYR will effectively lower total cholesterol levels and reduce the risk of atherosclerosis. It may also have beneficial effects for people with diabetes, osteoporosis, inflammatory disease and cancer.

### When will it start to work?

Lipid-lowering effects will take 6–8 weeks to become fully established.

### Are there any safety issues?

RYR may have rare adverse effects similar to the statin medications, such as unexplained muscle pain and weakness and, depending on the preparation of the supplement and ultimate quality, can lead to kidney damage. In general, it is well tolerated.

## Rhodiola

**HISTORICAL NOTE** Rhodiola is a popular herb in the traditional medicine of Eastern Europe, Asia and Scandinavia where it has been used to stimulate the nervous system, enhance physical and mental performance and improve resistance to high-altitude sickness (van Diermen et al 2009). It grows in high-altitude Arctic regions of Europe and Asia (Goel et al 2006) and is reported to have been used by the Vikings to enhance physical strength and endurance (Darbinyan et al 2007). It is also mentioned by Dioscorides as early as the 1st century AD. Rhodiola has been categorised as an ‘adaptogen’ in traditional systems due to its ability to increase resistance to a variety of chemical, biological and physical stressors, and is noted for its antidepressant, anticancer and cardioprotective properties (Kelly 2001). It has a reputation for improving depression, enhancing work performance, eliminating fatigue and treating symptoms of debility following intense physical and psychological stress (Perfumi & Mattioli 2007).

### OTHER NAMES

Arctic root, golden root, Hongjingtian, king’s crown, Lignum rhodium, rose root, rosenroot, orpin rose, Russian rhodiola, Siberian golden root

### BOTANICAL NAME/FAMILY

*Rhodiola rosea* (family Crassulaceae)

A number of rhodiola species can be identified in the scientific literature and may possess varying pharmacological activities, chemical constituents and efficacy in clinical application (Kucinskaite et al 2007, Li & Zhang 2008). These include: the Indian herb *Rhodiola imbricata* (Goel et al 2006) and the Tibetan herb *Rhodiola sacra* (Shih et al 2008), *Rhodiola quadrifida* (Skopnska-Rozewska et al 2008), *Rhodiola sachalinensis* (Wu et al 2008), *Rhodiola crenulata* (Song et al 2008) and *Rhodiola dumulosa* (Liu et al 2008).

The characteristic feature of *R. rosea* is the presence of cinnamic alcohol glucosides and relatively high content of phenylpropanoids rosavin, whereas salidroside is common to most other *Rhodiola* species. In particular, *R. rosea* extracts contain a substantial concentration of proanthocyanidins, including (-)-epigallocatechin and its 3-O-gallate esters (Yousef et al 2006).

### PLANT PART USED

Root

### CHEMICAL COMPONENTS

Salidroside (aka rhodiolosides A–F, monoterpene glycosides), and their aglycones; rhodiolol A, rosiridol and sachalinol A (Ali et al 2008, Li HB et al 2008, Li W et al 2008, Ma et al 2006, Yu et al 2008); rosavins (rasavin, rosin, rosarin; phenylpropanoids) (Kucinskaite et al 2007); gossypetin-7-O-L-

rhamnopyranoside, rhodioflavonoside, gallic acid, trans-p-hydroxycinnamic acid and p-tyrosol (Ming et al 2005); cinnamic alcohol, cinnamaldehyde and cinnamic acid (Panossian et al 2008); hydroquinone (Wang et al 2007).

Most commercial preparations are standardised to specific levels of marker compounds rosavin, salidroside or both. The balance of rosavins to salidrosides is usually 3:1.

### MAIN ACTIONS

#### Adaptogenic (modulates stress response)

Prolonged exposure to stressful life events and depression may contribute to significant behavioural, endocrinological and neurobiological changes in both humans and animals. Animal studies have suggested that chronic administration of rhodiola extract (standardised to 3% rosavin and 1% salidroside; 10, 15 and 20 mg/kg by gavage) results in potent inhibition of the behavioural and physiological changes induced by chronic exposure to mild stressors in a manner comparable to those of fluoxetine (oral 10 mg/kg) (Mattioli et al 2009). Other studies suggest an ability to selectively attenuate stress-induced anorexia (Mattioli & Perfumi 2007). In experimental studies, extracts of rhodiola appear to increase stress resistance and contribute to a longer lifespan. The extract induces translocation of the DAF-16 transcription factor from the cytoplasm into the nucleus, suggesting a reprogramming of transcriptional activities favouring the synthesis of proteins involved in stress resistance and longevity (Wiegant et al 2009).

Single-dose studies of rhodiola extract (standardised to 3% rosavin and 1% salidroside; 10, 15 and 20 mg/kg) have demonstrated antidepressant,

adaptogenic, anxiolytic and stimulating effects in mice (Perfumi & Mattioli 2007). In addition, rhodiola has been reported to prevent catecholamine release and subsequent cyclic AMP elevation in the myocardium, and the depletion of adrenal catecholamines induced by acute stress in vivo (Maslova et al 1994). According to Panossian and Wagner (2005), the beneficial effects of multidose administration of adaptogens, such as rhodiola, are mainly associated with the hypothalamic–pituitary–adrenal (HPA) axis, while single-dose applications are more useful in situations that require a rapid response to tension or to a stressful situation via the sympatho-adrenal system (SAS). Rhodiola exerts a stimulating effect within 30 minutes of administration that continues for approximately 4–6 hours. This activity appears to be due to salidroside and rosavin (Panossian & Wagner 2005).

### Improved physical performance

While earlier animal studies seemed promising (Abidov et al 2003, Azizov & Seifulla 1998), rhodiola has produced mixed results when attempting to demonstrate an ergogenic effect during exercise in humans (Walker & Robergs 2006). Rhodiola is purported to enhance physical performance, possibly by improving adenosine triphosphate (ATP) turnover; however, several small-scale human trials have produced inconsistent results.

### Improved mental performance

It has been suggested that rhodiola extract promotes the release of monoamine neurotransmitters in the ascending pathways of the brainstem, thus activating the cerebral cortex and limbic system. As a result, cognitive function, attention, memory and learning may be enhanced (Panossian & Wagner 2005). Animal experiments have demonstrated improvements in learning and retention after 24 hours following a single dose (0.10 mL/rat) and long-term memory after 10 days treatment at the same dose. Higher (1.0 mL) and lower (0.02 mL) doses did not appear to be effective (Petkov et al 1986).

### Anticholinesterase

Spectral methods (NMR, UV and MS) have identified a strong anticholinesterase activity for hydroquinone, a component of rhodiola (Wang et al 2007).

### Antidepressant

Rhodiola is one of the more promising herbal medicines for the treatment of monopolar depression (Kelly 2001, Kucinskaite et al 2004, Sarris 2007). It appears to influence the levels and activity of monoamine neurotransmitters such as serotonin, noradrenalin and dopamine (Stancheva & Mosharrof 1987).

Extracts of rhodiola exhibit potent anti-depressant activity by inhibiting monoamine oxidase (MAO)-A in vitro which may partly explain its effects (van Diermen et al 2009). It increases serotonin levels

and significantly increases serotonin receptor 1A according to research with a nicotine withdrawal model (Mannucci et al 2012). It is suspected that rhodiola also facilitates neurotransmitter transport within the brain (Stancheva & Mosharrof 1987). Other studies indicate that antidepressant effects are likely to be due to salidroside on stress-activated protein kinases (SAPK), which play a key role in HPA axis overactivity by inhibiting the sensitivity of glucocorticoid receptors to cortisol (Darbinyan et al 2007).

### Immunomodulation

While studies using rhodiola alone for immune modulation could not be located, several polyherbal preparations containing rhodiola have been tested producing good results. In a placebo-controlled trial, a combined preparation known as Admax (Nulab Inc), containing *Rhodiola rosea* in combination with *Eleutherococcus senticosus*, *Schisandra chinensis* and *Leuzea carthamoides* (270 mg/day) was given to 28 patients with stage III–IV epithelial ovarian cancer receiving a one-off dose of cisplatin (75 mg/m<sup>2</sup>) and cyclophosphamide (600 mg/m<sup>2</sup>). Subjects received treatment or placebo for 4 weeks. In patients who took Admax, the mean numbers of four T-cell subclasses (CD3, CD4, CD5 and CD8) and the mean amounts of IgG and IgM were increased, suggesting attenuation of the suppressed immunity experienced by ovarian cancer patients undertaking chemotherapy (Kormosh et al 2006). Additionally, a double-blind, placebo-controlled, randomised trial of Chisan (a standardised combination of *Rhodiola rosea*, *Schisandra chinensis* and *Eleutherococcus senticosus*) was carried out on 60 patients receiving cephazoline, bromhexine and theophylline for acute non-specific pneumonia. The addition of Chisan twice daily for 10–15 days in the treatment group resulted in a 2-day reduction in the mean time required to bring about recovery from the acute phase and improved quality-of-life (QOL) scores during convalescence (Nariman et al 2005).

### Antibacterial

The methanolic extract of rhodiola root has been shown to inhibit the activity of *Staphylococcus aureus* in Microbial Sensitivity Tests. The active compounds were identified as gossypetin-7-O-L-rhamnopyranoside and rhodioflavonoside at concentrations of 50 microgram/mL and 100 microgram/mL, respectively (Ming et al 2005).

### Cardioprotective

Rhodiola extract has been shown to exert cardioprotective effects in vivo. More specifically, rhodiola extract demonstrates protection against reperfusion injury after ischaemia, antiarrhythmic activity and increases serum levels of beta-endorphin and leu-enkephalin in myocardial tissue. The effects appear to be dependent on the occupancy of opioid receptors by endogenous opioid peptides (Maslov & Lishmanov 2007).

Salidroside isolated from *rhodiola* provided a protective effect on epirubicin-induced early left ventricular regional systolic dysfunction in patients with breast cancer according to a randomised placebo-controlled study (Zhang et al 2012). Participants received salidroside (600 mg/day) or placebo starting 1 week before chemotherapy and were investigated by means of echocardiography and strain rate (SR) imaging. Additionally, a significant increase in plasma concentrations of reactive oxygen species was found in the placebo group, but levels remained unchanged with salidroside, indicating an antioxidant mechanism.

Combination preparations, such as tonizid (containing *Rhodiola rosea* in combination with *Aralia mandshurica*, *Panax ginseng* and *Eleutherococcus senticosus*), have also demonstrated cardioprotective and antifibrillatory properties during acute cardiac ischaemia/reperfusion and postinfarction cardiac fibrosis (Arbuzov et al 2006, Lishmanov et al 2008).

### Improved cardiac function

Oral administration of a *Rhodiola rosea* ethanolic extract (75 mg/kg) for 21 days increased the cardiac output of streptozocin-induced diabetic rats showing heart failure without modifying the diabetic parameters (Cheng et al 2012). Mean arterial pressures in STZ-diabetic rats were significantly increased after treatment with *rhodiola*. The effect was abolished after administration of an antagonist of PPAR $\delta$ .

Previously, oral administration of *R. rosea* extract (3.5 mg/kg) was shown to improve heart contractility and coronary flow parameters, thought to be due to an increase in the level of endogenous opioid peptides (Lishmanov et al 1997). The anti-arrhythmic effect of *rhodiola* extract is a result of activation of both central and peripheral opioid receptors (Maimeskulova & Maslov 2000) and stimulation of kappa-opioid receptor (Maimeskulova et al 1997).

## OTHER ACTIONS

### Antioxidant

*Rhodiola* extract reduces oxidative stress in vitro (Battistelli et al 2005) and increases endogenous antioxidant production in vivo. *Rhodiola* was able to significantly protect human erythrocytes from glutathione (GSH) depletion, glyceraldehyde-3-phosphate dehydrogenase (GAPDH) inactivation and haemolysis induced by the oxidant hypochlorous acid (HOCl), in a dose-dependent manner (De Sanctis et al 2004). In animal studies, *rhodiola* extract (200 mg/kg/day for 12 weeks) increased the levels of reduced glutathione and the activity of glutathione reductase, glutathione S-transferase, glutathione peroxidase, catalase and superoxide dismutase in the liver (Kim et al 2006). In human trials, a trend towards decreased lipid peroxidation has been observed following 7-day treatment with *Rhodiola rosea* (Wing et al 2003). Additionally, a placebo-controlled study utilising salidroside isolated from *rhodiola* acted via an antioxidant mechanism

to provide a cardioprotective effect on epirubicin-induced early left ventricular regional systolic dysfunction (Zhang et al 2012).

### Antidiabetic

*Rhodiola* extract (200 mg/kg/day for 12 weeks) significantly decreases blood glucose and lipid peroxidation in vivo. It also increases levels of reduced glutathione and the activity of glutathione reductase, glutathione S-transferase, glutathione peroxidase, catalase and superoxide dismutase in the liver (Kim et al 2006). Further in vivo studies have revealed that water-soluble *rhodiola* extract inhibits alpha-glucosidase and pancreatic alpha-amylase (Apostolidis et al 2006). Ethanolic extracts also inhibit alpha-amylase, alpha-glucosidase and also angiotensin-converting enzyme (ACE) (Kwon et al 2006). The effect appears to be dependent on the phenolic content and profile (Apostolidis et al 2006, Kwon et al 2006). In experimental studies, salidroside, one of the major active components of *rhodiola*, has a dose-dependent effect on glucose transport activation and insulin sensitivity via AMP-activated protein kinase (AMPK) activation (Li HB et al 2008) and may inhibit lipid peroxidation (Zhang & Liu 2005).

### Anti-inflammatory

Salidroside demonstrates significant anti-inflammatory activity (Li et al 2013).

### Neuroprotective

Salidroside, an isolated component of *rhodiola*, has demonstrated a dose-dependent neuroprotective effect in animal models (Bocharov et al 2008). Salidroside has protective effects against oxidative stress-induced cell apoptosis (Zhang et al 2007), inhibits intracellular reactive oxygen species (ROS) production and restores mitochondrial membrane potential (Yu et al 2008) and decreases intracellular free calcium concentration (Zhang et al 2004). As a result, salidroside may warrant further investigation for preventing and treating cerebral ischaemic and neurodegenerative diseases (Yu et al 2008).

### Cytoprotective

Salidroside, extracted from *R. rosea*, may protect PC12 cells against glutamate excitotoxic damage through suppressing the excessive entry of calcium and the release of the calcium stores (Cao et al 2006).

### Hepatoprotective

Hepatoprotective effects have been demonstrated in rats with experimental toxic hepatitis: normalising the activity of aspartate aminotransferase (AST) and alkaline phosphatase (ALP); reducing the activity of alanine aminotransferase (ALT) and glutathione-S-transferase; and normalising the content of medium-molecular-weight peptides, urea and bilirubin in plasma (Iaremi & Grigor'eva 2002). *Rhodiola* extract has also been shown to reduce the liver

dysfunction associated with adriamycin (an anthracycline antibiotic) in mice without affecting the drug's antitumour activity (Udintsev et al 1992).

### Anticancer effects (antitumagenic, cytostatic, antiproliferative, antimetastatic)

Rhodiola extract demonstrates anticancer activity according to test tube and animal studies, which is due to a combination of mechanisms. The main constituent attracting attention for its anticancer activity is salidroside, which has been studied in a variety of models. However, it is not the only active constituent with anticancer activity; for example, gossypetin-7-O-L-rhamnopyranoside and rhodioflavonoid have cytotoxic activity against prostate cancer cell lines (Ming et al 2005a).

*R. rosea* extracts reduce experimentally-induced mutations, most likely due to increased efficiency of intracellular DNA repair mechanisms (Salikhova et al 1997). The cytostatic and antiproliferative effects of rhodiola extract have been demonstrated in experimental models. Rhodiola has been shown to inhibit the division of HL-60 cells leading to induction of apoptosis and necrosis, and to a marked reduction in their survival. After treatment with the extract, no chromosome aberrations or micronuclei were observed (Majewska et al 2006). Antiproliferative and antimetastatic effects have been noted in animal models of Pliss lymphosarcoma (Udintsev & Shakhov 1991b).

In a small human trial, oral administration of rhodiola extract to 12 patients with superficial bladder carcinoma (T1G1-2) resulted in improvements in urothelial tissue integration, parameters of leucocyte integrins and T-cell immunity. A non-significant reduction in the average frequency of relapse was also noted (Bocharova et al 1995).

### Salidroside

Salidroside inhibits the growth of various human cancer cell lines in concentration- and time-dependent manners, and the sensitivity to salidroside is different for different cancer cell lines (Hu et al 2010a).

Hu et al (2010a) report that salidroside causes G1-phase or G2-phase arrest in different cancer cell lines, a decrease of CDK4, cyclin D1, cyclin B1 and Cdc2, and upregulation of the levels of p27(Kip1) and p21(Cip1). Taken together, salidroside appears to inhibit the growth of cancer cells by modulating CDK4-cyclin D1 pathway for G1-phase arrest and/or modulating the Cdc2-cyclin B1 pathway for G2-phase arrest.

The salidroside constituent from *Rhodiola rosea* has cytotoxic effects on human breast cancer MDA-MB-231 cells (oestrogen receptor negative) and human breast cancer MCF-7 cells (oestrogen receptor positive) by inducing cell-cycle arrest and apoptosis (Hu et al 2010b).

A study by Liu et al (2012) showed that both *R. rosea* extracts and salidroside could decrease the growth of bladder cancer cell lines with minimal

effect on non-malignant bladder epithelial cells TEU-2 via inhibition of the mTOR pathway and induction of autophagy (Liu et al 2012).

### Effect on cytochromes and p-glycoprotein

In vitro tests reveal that *R. rosea* extract inhibits CYP 3A4 and p-glycoprotein (Hellum et al 2010). These effects have not been investigated in clinical studies so the significance of the findings are unknown.

An in vivo study showed that *R. rosea* extract did not affect the metabolism of warfarin or theophylline, therefore it is unlikely to significantly affect CYP 1A2 or CYP 2C9 (Panossian et al 2009). Recently, an in vivo test showed that *R. rosea* significantly alters the pharmacokinetic properties of losartan after concurrent oral administration to rabbits, increasing the maximum plasma concentration ( $C_{max}$ ), the area under the curve (AUC) and the apparent total body clearance (CL/F) (Spanakis et al 2013). Losartan is metabolised by CYP2C9 and 3A4. Based on negative results for activity on CYP2C9, it is likely that the interaction is mainly due to inhibition of CYP3A4. Clinical tests are now warranted to further investigate this drug interaction.

### CLINICAL USE

Both *Rhodiola rosea* liquid extract and solid dose forms have been investigated in clinical studies. Some recent clinical research has been conducted with the *R. rosea* rhizome product known as SHR-5 which is standardised to provide a minimum 3% rosavins and 0.8% salidroside, because the naturally occurring ratio of these compounds in *R. rosea* root is approximately 3:1.

Unfortunately, conclusions about the body of evidence are difficult to make as studies use a wide range of doses, so are not easy to compare. As with all pharmacologically active treatments, a dose-response is likely to occur. Results from several studies investigating mental and physical performance effects suggest the dose response is not linear but instead a bell-shaped curve whereby very low and high doses are less effective than moderate doses. Further investigation is required to confirm the clinical effects and discover the optimal dosage range for use in various indications.

The variation in chemical makeup for the test extracts may be another factor contributing to the inconsistent findings observed. The stimulating and adaptogenic properties of *R. rosea* are attributed specifically to p-tyrosol, salidroside, rosavins, and additional phenolic compounds, while the high content in organic acids and flavonoids contributes to the strong antioxidant properties of the plant (Ming et al 2005b).

### Adaptogen

*Rhodiola rosea* was first investigated in human studies in the 1960s as a possible adaptogenic agent. Based on positive results in these early studies, it was

recommended as a stimulant for fatigue in 1969 by the Pharmacological Committee of the Ministry of Health of the USSR and it remains a very popular adaptogen in Russia today (Panossian et al 2010). It is also very popular in Sweden where it is a recognised herbal medicinal product by authorities. *Rhodiola rosea* is used by healthy people during periods of high mental stress or physical exertion. The adaptogenic activity of *R. rosea* has been demonstrated in numerous preclinical trials and attributed primarily due to its ability to influence levels and activity of biogenic monoamines such as serotonin, dopamine and noradrenaline in the central nervous system (Kelly 2001).

The European Food Safety Authority (EFSA) allows rhodiola treatment to carry the functional claim 'contributes to optimal mental and cognitive activity'.

The human clinical trials conducted to date tend to focus on mental stress and fatigue, response to physical stress, physical fatigue or ergogenic activity.

### Mental stress and fatigue

In the 1960s, two non-randomised, placebo-controlled studies were conducted which demonstrated that a single dose of rhodiola liquid extract or salidroside (2.5 mg) improved mental performance for at least 4 hours and reduced the number of errors in Anfimov's correction test (Panossian et al 2010). In the study by Zatova, doses of 5–10 drops were found to be the most effective, reducing the number of errors by an average of 46%. At a dose of 5 drops, the rhodiola extract led to a reduction in the number of errors in 88% of the subjects tested, but to an increase in the remaining 12%. This was in comparison to placebo, which produced a reduction in the number of errors in 35% of the subjects, an increase in 58% and no change in the remaining 7% (Panossian & Wagner 2005).

A 28-day course of SHR-5 extract (576 mg/day) demonstrated a significant improvement in fatigue scores (Pines burnout scale) and a significant improvement in mental performance, particularly the ability to concentrate according to a randomised, double-blind study of 60 people aged between 20 and 55 years with fatigue syndrome (Olsson et al 2008). Treatment also decreased cortisol response to awakening stress.

A randomised, double-blind, placebo-controlled study involving 161 cadets aged 19–21 years found that single doses of SHR-5 extract produced a highly significant antifatigue effect using the antifatigue index (AFI). Both the standard (9 mg/day salidroside) and high dose (13.5 mg/day salidroside) treatment regimens were significantly superior to placebo, but were as effective as each other (Shevtsov et al 2003).

The same extract (SHR-5) was also used in a double-blind, randomised, placebo-controlled trial of 40 foreign students during a stressful examination period. A repeated low-dose regimen (100 mg/day)

was administered for 20 days resulting in significant improvements in hand-eye co-ordination ( $P < 0.01$ ), self-reported mental fatigue ( $P < 0.01$ ) and general wellbeing. There were no significant differences for speed or accuracy of mental performance between the groups or physical performance (Spasov et al 2000).

A randomised, double blind, crossover study of 56 young, healthy doctors tested a dose of 170 mg of SHR-5 extract. Placebo or active treatment was taken for 2 weeks with a 2-week washout period between crossing over to the alternative treatment (Darbinyan et al 2000). Authors reported that two weeks of active treatment in the first period improved performance by approximately 20% ( $P < 0.01$ ). It was effective at relieving mental fatigue symptoms and improving concentration and speed of audio-visual perception. When active treatment was taken by the alternative group in the second 2-week treatment term, no significant changes were found. It is possible that after 6 weeks of night duty, the test dose used was insufficient to have a significant effect, whereas it was sufficient after only 2 weeks of night duty. While these results are promising, the study did not use a validated fatigue scale.

### IN COMBINATION

During a 12-week study, the efficacy and safety of rhodiola extract given in combination with vitamins and minerals (Vigodana) was tested in 120 adults (83 women and 37 men aged 50–89 years) with physical and cognitive deficiencies (Fintelmann & Gruenwald 2007). Two different dosage regimens were chosen: 2 capsules orally in the morning after breakfast, or 1 capsule after breakfast and 1 after lunch. A significant improvement in physical and cognitive performance was observed in both groups ( $P < 0.001$ ), but it was more pronounced in the group taking both capsules after breakfast. No adverse events occurred during the course of the study (Fintelmann & Gruenwald 2007). While the results of this study are promising, this was not a placebo-controlled clinical trial of stand-alone rhodiola treatment.

Results of four double-blind studies with rhodiola extract (SHR-5) are promising but not decisive, as some studies indicate significant antifatigue effects, whereas others are inconclusive or show no changes in aspects of mental performance.

### Physical fatigue and enhanced physical performance

Randomised clinical trials involving both trained and untrained people have been published with wide ranging test doses.

A double-blind, placebo-controlled study demonstrated beneficial effects with acute but not with chronic dosing of rhodiola. A single dose of rhodiola extract (200 mg standardised to 3% rosavin and 1% salidroside) significantly increased time to exhaustion ( $16.8 \pm 0.7$  min to  $17.2 \pm 0.8$  min;  $P <$

0.05),  $VO_{2peak}$  and  $VCO_{2peak}$  compared to placebo, and also tended to increase pulmonary ventilation ( $P = 0.07$ ) ( $124.8 \pm 7.7$  L/min versus  $115.9 \pm 7.7$  L/min). Prior administration of the same dose daily for 4 weeks did not alter any of the variables measured (De Bock et al 2004).

Treatment with a higher dose (340 mg/day) of *Rhodiola rosea* extract containing 30 mg active RR (including rosavin) for 30 days before and 6 days after exhausting physical exercise significantly reduced C-reactive protein levels when tested 5 hours and 5 days after exercise when compared to controls (Abidov et al 2004). The double-blind study of 36 untrained people also found blood CK levels decreased after 5 days only in the active treatment group and not in controls. These results suggest active treatment reduced inflammation and protected muscle tissue from damage during exercise.

A significant decrease in reported level of fatigue and tiredness was demonstrated after 1 week of treatment with SHR-5 (280 mg/day) according to another double blind, placebo-controlled study (Schutgens et al 2009).

In contrast, two studies found no significant effect on various aspects of physical performance; however, one study used a very high dose (1500 mg/day) and the other a very low dose (100 mg/day), making conclusions difficult to draw (Walker et al 2007, Spasov et al 2000).

Walker et al (2007) conducted a placebo-controlled trial of 12 resistance-trained men, aged 19–39 years that completed an incremental forearm wrist flexion exercise to fatigue, after ingesting very high dose rhodiola (1500 mg/day) or placebo for 4 days (Walker et al 2007). At this dose there were no significant differences between groups for time to exhaustion or recovery. Negative results were also obtained by Spasov et al (2000) in another double-blind, randomised, placebo-controlled trial. This study involved 40 foreign students during a stressful examination period and found that treatment with low dose SHR-5 extract (100 mg/day) for 20 days did not produce any significant changes in physical performance as measured by work capacity using a stationary bicycle and pulse rate immediately after the ergometric test. It did, however, produce a significant improvement in hand-eye coordination ( $P < 0.01$ ) (Spasov et al 2000).

#### IN COMBINATION

Two double-blind RCTs using a formula containing *R. rosea* and *Cordyceps sinensis* failed to observe any significant changes to various aspects of physical performance.

Earnest et al (2004) found that competitive amateur cyclists given 14 days of treatment with a commercial herbal product, taken as 6 capsules daily for 4 days then 3 capsules daily for 11 days (3 capsules = *Rhodiola rosea* 300 mg; *Cordyceps sinensis* 1000 mg and assorted nutrients), produced no significant change for oxygen consumption ( $VO_2$ ), time to exhaustion, peak power output

or peak heart rate compared to placebo (Earnest et al 2004). Similarly, a double-blind, RCT of the same combination of herbs (*Rhodiola rosea* 300 mg and *Cordyceps sinensis* 1000 mg per 3 capsules) failed to demonstrate significant effects on muscle tissue oxygen saturation,  $VO_{2max}$ , ventilatory threshold or time to exhaustion (Colson et al 2005). The dose used was 6 capsules daily for 6 days and 3 capsules daily for 7 days.

#### Depression

Several studies with experimental models have shown that rhodiola exhibits significant antidepressant activity and in vitro tests provide plausible mechanisms of action (Panossian & Wagner 2005, Perfumi & Mattioli 2007). In one study, rhodiola exhibited a stronger antidepressant effect than either imipramine (30 mg/kg) or *Hypericum perforatum* (20 mg/kg). Rhodioloside and tyrosol were identified as active principles (Panossian et al 2008). Despite this encouraging preliminary evidence, clinical investigation has only just begun and produced inconsistent results.

In a double-blind RCT conducted over 6 weeks, 89 participants aged 18–70 years were selected according to Diagnostic and Statistical Manual of Mental Disorders (DSM)-IV diagnostic criteria for mild-to-moderate depression (Darbinyan et al 2007). The severity of the depression was determined by scores gained in the Beck Depression Inventory (BDI) and Hamilton Rating Scale for Depression (HAM-D) questionnaires. Patients with initial HAM-D scores between 21 and 31 were randomised to receive either *Rhodiola rosea* extract SHR-5 (340 mg/day) or SHR-5 (680 mg/day) or placebo. At the end of the 6-week trial, participants in both treatment groups experienced significant improvements ( $P < 0.0001$ ) in overall depression, insomnia, emotional instability and somatisation compared to the placebo group. The high-dose group also experienced improvements in self-esteem. There was a dose-dependent effect for the BDI but not for the HAM-D and no serious side effects were reported in any of the groups (Darbinyan et al 2007).

In contrast, a 28-day course of SHR-5 extract (576 mg/day) demonstrated no significant effect on the Montgomery-Asberg Depression Rating Scale (MADRS) in a randomised, double-blind study of 60 people aged between 20 and 55 years with fatigue syndrome (Olsson et al 2008). Whether this means a longer treatment period is required to see effects (as per Darbinyan et al) or that the treatment is ineffective requires further investigation.

#### Generalised anxiety disorder (GAD)

In a small pilot study, 10 participants aged 34–55 years were selected according to DSM-IV diagnostic criteria for generalised anxiety disorder (GAD). Participants received rhodiola extract (340 mg/day) for 10 weeks after which time there was a significant decrease in mean Hamilton Anxiety Rating Scale (HAM-A) scores. Only mild-to-moderate adverse

effects were noted, most commonly dizziness and dry mouth, and no drug interaction was observed in the three patients taking benzodiazepines (Bys-tritsky et al 2008). Larger well-designed trials should be conducted to confirm these effects.

## OTHER USES

### Reward deficiency syndrome (RDS)

Reward deficiency syndrome (RDS), associated with low dopamine 2 (D<sub>2</sub>) receptors, may increase craving behaviour, causing the individual to seek out substances that increase the release of dopamine. Researchers in this area have suggested that the addition of rhodiola, a known catechol-O-methyl-transferase (COMT) inhibitor, may be a useful adjunct to the treatment of this condition. It is thought that during recovery or rehabilitation from alcohol or other psychoactive drugs (dopamine releasers), decreasing COMT activity should result in 'enhanced synaptic dopamine, thereby proliferating D<sub>2</sub> receptors while reducing stress, increasing wellbeing, reducing craving behaviour and preventing relapse' (Blum et al 2007).

### Opioid addiction

Results from two studies with experimental mouse models indicate that *Rhodiola rosea* L. extract significantly and dose-dependently attenuates both the development and the expression of morphine dependence after chronic or acute administration and reduced opioid craving and vulnerability to relapse (Mattioli & Perfumi 2011a, Mattioli et al 2012). Based on these preliminary results, *R. rosea* extract has potential as a treatment for opioid addiction and should be investigated further.

### Nicotine withdrawal

In an experimental model of nicotine dependence, *Rhodiola rosea* extract abolished both affective and somatic signs induced by nicotine withdrawal in a dose-dependent fashion, during both nicotine exposure and nicotine cessation (Mattioli & Perfumi 2011b). Positive results were also obtained in another study which found *R. rosea* or isolated salidroside significantly reduced the rewarding properties of nicotine at all doses tested and prevented relapse to nicotine through both priming and stress-induced influences (Titomanlio et al 2013). Currently, no human studies have been published to determine whether the effects are clinically significant.

### Cardiovascular disease prevention

In animal studies, rhodiola extract has demonstrated cardioprotective, antiarrhythmic and antioxidant effects (Lishmanov et al 1997, Maimeskulova & Maslov 2000, Maslov & Lishmanov 2007, Wing et al 2003). Whether these effects are clinically relevant in human populations at risk of cardiovascular disease remains to be tested.

## Diabetes

In animal studies, rhodiola extract (200 mg/kg/day for 12 weeks) significantly decreased blood glucose and lipid peroxidation. It also increased the levels of reduced glutathione and the activities of glutathione reductase, glutathione S-transferase, glutathione peroxidase, catalase and superoxide dismutase in the liver. As increased oxidative stress has been shown to play an important role in the pathogenesis and long-term complications of diabetes mellitus, rhodiola shows potential as a useful treatment in diabetes with multiple mechanisms of relevance (Kim et al 2006).

### Practice points/Patient counselling

- Rhodiola may have beneficial effects on physical and mental performance and fatigue; pre-clinical trials are supportive; however, results from clinical trials have been inconsistent. This may relate to incorrect dosage and/or variations in herbal test substances.
- Rhodiola has antidepressant activity according to preclinical studies and improves mood, reduces irritability, insomnia and emotional instability according to a placebo-controlled study of people with depression. However, it had no antidepressant effect in a study of people with fatigue syndrome.
- It may also be a useful treatment in generalised anxiety disorder, according to a small clinical study.
- Rhodiola is safe and well tolerated, but it has the potential to interact with some medications.
- Preliminary research also shows it has potential in opioid dependency, nicotine withdrawal, diabetes, cardioprotection, improves heart function in heart failure and kills various cancer cells.

## DOSAGE RANGE

- Fluid extract (1:2): 20–40 mL/wk (Australian manufacturer recommendations).
- In clinical trials, extracts are often standardised to 3% rosavin and 1% salidroside (Perfumi & Mattioli 2007).

### Doses used in clinical trials

Mental fatigue: 100–576 mg/day

Physical fatigue and performance: 200 mg/day–1500 mg/day

- Positive results on various aspects of mental performance have been seen for the dose range 100–576 mg daily.
- For physical fatigue and performance, the most effective dose range appears to be 200 mg–340 mg daily with no significant results seen for doses of 600 mg or higher.

- Depression and anxiety: rhodiola extract 340 mg/day (equiv 1500 mg dried root) (Bystritsky et al 2008, Darbinyan et al 2007).

Note: One study suggested improved results from taking rhodiola after breakfast rather than in divided doses after breakfast and lunch (Fintelmann & Gruenewald 2007). This may be due to diurnal variations in HPA and adrenal function.

## ADVERSE REACTIONS

Serious adverse events have not been reported to this herbal medicine and side effects tend to be uncommon and mild and can include allergy, insomnia, irritability, fatigue and unpleasant sensations at high doses. An increase in irritability and insomnia has been reported within several days in some individuals taking high doses (1500 mg–2000 mg, standardised to 2% rosavin) (Iovieno et al 2011).

A review of 11 clinical studies involving 446 volunteers identified only 2 adverse events among those taking active rhodiola treatment — one was mild headache and another severe headache when taking a dose of 200 mg daily for 4 weeks. Similarly, headaches were reported in the placebo groups, so it is not considered serious (Ishaque et al 2012).

## SIGNIFICANT INTERACTIONS

As controlled human studies are not available, interactions are currently speculative and based on evidence of pharmacological activity, test tube and animal studies.

### Adriamycin

Rhodiola extract has been shown to reduce the liver dysfunction (suggested by a sharp increase in blood transaminase levels) associated with Adriamycin in vivo without affecting the drug's antitumour effects (Udintsev et al 1992). Theoretically, a beneficial interaction is possible under clinical supervision.

### Cyclophosphamide

*Rhodiola rosea* root extract synergises the antitumour activity of cyclophosphamide and decreases its hepatotoxicity in an experimental rodent model (Udintsev & Schakhov 1991a).

Whether the effects are clinically relevant remains to be tested.

### Antidepressants

In vitro tests suggest an inhibition of MAO-A by rhodiola extracts (van Diermen et al 2009), a theoretical interaction exists with MAOI antidepressants. The clinical significance of this and whether other antidepressants may be affected is as yet unclear. Observe.

### P-glycoprotein substrates

In vitro tests reveal that *R. rosea* extract inhibits P-gp — clinical significance is unknown (Hellum et al 2010).

## Cytochrome 3A4 substrates

In vitro tests reveal that *R. rosea* extract inhibits CYP 3A4; this has also been suggested in vivo — clinical significance is unknown (Hellum et al 2010).

Until further tests have been conducted, caution is advised when concurrently using medicines chiefly metabolised by CYP3A4 as the interaction could result in raised drug serum levels.

### Losartan

*R. rosea* significantly alters the pharmacokinetic properties of losartan after concurrent oral administration to rabbits (Spanakis et al 2013). The results indicate that rhodiola is likely to inhibit CYP3A4, resulting in increased drug serum levels. Avoid — until further research is available to determine the seriousness of the interaction.

## CONTRAINDICATIONS AND PRECAUTIONS

While the administration of rhodiola may be beneficial in monopolar depression, use is not recommended for bipolar states.

Theoretically, the possibility of the herb exerting MAO-inhibiting effects may require consumers to adhere to dietary restriction of tyramine-rich foods (e.g. some cheeses, pickled foods, chocolates, meats, beer, wine etc), as the interaction of tyramine with MAOIs can result in a significant elevation in blood pressure.

## PREGNANCY USE

Safety in pregnancy and lactation has not been established.

## PATIENTS' FAQs

### What will this herb do for me?

Rhodiola may be of assistance in the treatment of stress-related conditions, in particular depression, mental and/or physical and fatigue and also generalised anxiety disorder. It may also be of benefit in depression.

### When will it start to work?

Rhodiola exerts a stimulating effect within 30 minutes of administration that continues for approximately 4–6 hours.

In mild-to-moderate depression, the benefits of *Rhodiola rosea* extract SHR-5 (340 mg/day) or SHR-5 (680 mg/day) were noted at the end of a 6-week trial.

### Are there any safety issues?

It is generally considered very safe and well tolerated with side effects being rare and mild. People taking MAOI antidepressants or drugs chiefly metabolised by cytochrome 3A4 should be closely monitored until more is known about the mechanism of action of this herb and its drug interactions. Safety in pregnancy and lactation has not been established.

## Rosehip

R

**HISTORICAL NOTE** Rosehips are fruits of the dog rose or wild briar rose that appear as orange-red oval berries and have been used traditionally to treat a range of conditions, including diarrhoea, bladder infections and diabetes. In foods and manufacturing, rosehips are used for tea, jam, jellies and soup, and as a natural source of vitamin C. Rosehips are one of the richest plant sources of vitamin C and rosehip syrup was used in Britain during World War II to help prevent scurvy when citrus supplies were limited. Rosehips are also fed to pet animals such as horses, chinchillas and guinea pigs to enhance their health.

### COMMON NAME

Dog rose or wild briar rose

### BOTANICAL NAME/FAMILY

*Rosa canina* / Rosaceae

### PLANT PARTS USED

Berries/fruit of the rose plant

### CHEMICAL COMPONENTS

Rosehip is a rich source of vitamins C, A, B<sub>3</sub>, D and E, along with folate, flavonoids, carotenoids (including beta-carotene and lycopene and lutein), beta-sitosterol, fructose, malic acid, tannins, magnesium, zinc, copper and numerous other phytochemicals, including recently characterised galactolipids (Böhm et al 2003, Christensen 2009, Machmudah

et al 2008, Rein et al 2004). These nutrients can be depleted or destroyed during processing and drying and the content of phytochemicals has been shown to be sensitive to maturity of the fruits as well as drying time, drying air temperature and moisture content (Erenturk et al 2005, Pirone et al 2007, Strålsjö et al 2003, Türkben et al 2010).

## MAIN ACTIONS

### Antioxidant

Rosehip is rich in polyphenolic compounds such as proanthocyanidins and flavonoids such as quercetin and catechin (Türkben et al 2010). The antioxidant activity of rosehip is attributed to its high phenolic and flavonoid content (Wenzig et al 2008) and when rosehip extract containing these phenolics is deprived of vitamin C it still shows considerable antioxidant activity (Daels-Rakotoarison et al 2002). This activity includes protective effects against oxidative stress, enhanced activity of antioxidant enzymes such as superoxide dismutase and catalase and protective effects on gap junction intercellular communication (Yoo et al 2008).

### Anti-inflammatory

Rosehip has been found to have anti-inflammatory and antinociceptive activities in several in vivo experimental models (Deliorman Orhan et al 2007). The anti-inflammatory power of rosehip is reported to be similar to that of indomethacin, although its mode of action is different (Lattanzio et al 2011). The lipophilic constituents have particularly high anti-inflammatory activity, including actions on arachidonic acid metabolism and inhibition of both cyclooxygenase (COX)-1 and COX-2 (Wenzig et al 2008). A recent series of studies involving horses, dogs and double-blind, placebo-controlled, randomised controlled trials in humans found that rosehip seeds make an important contribution to rosehip's anti-inflammatory properties (Marstrand et al 2013).

Much of the anti-inflammatory action of rosehip has been attributed to high quantities of galactolipids, a class of compounds widely found in the plant kingdom as an important part of cell membranes and recently shown to possess antitumour-promoting and anti-inflammatory activity in both in vitro and in vivo studies (Christensen 2009). Rosehip and its constituent galactolipids have been found to inhibit the production of inflammatory mediators and confer chondroprotective effects in vitro (Schwager et al 2011). A particular galactolipid named GOPO has been shown to be the active principle responsible for the observed in vitro inhibition of chemotaxis and chemiluminescence of human peripheral blood leucocytes without any toxicity to the cells (Kharazmi 2008, Kharazmi & Winther 1999, Larsen et al 2003, Winther et al 1999). GOPO is suggested to play an important role in reducing inflammation, serum C-reactive protein and creatinine levels (Kharazmi & Winther 1999, Rossnagel & Willich

2001) and improving pain and joint movement in osteoarthritis patients (Rein et al 2004, Warholm et al 2003).

Unlike conventional non-steroidal anti-inflammatory drugs (NSAIDs), rosehip does not cause gastric ulceration, inhibit platelets or influence the coagulation cascade or fibrinolysis (Winther 2000). It has therefore been suggested that the anti-inflammatory properties of rosehip allow it to replace or supplement conventional anti-inflammatory drugs in patients who may be at increased risk from the gastrointestinal or cardiovascular side effects of NSAIDs (Cohen 2012, Kharazmi 2008).

## OTHER ACTIONS

### Antidiabetic

Antidiabetic, lipid-lowering and antiobesogenic activity

Rosehip's traditional use as a treatment for diabetes is supported by reports of hypoglycaemic effects in diabetic rats (Orhan et al 2009), as well as reduction of blood glucose levels after glucose loading in mice, without affecting food intake, weight gain or accumulation of visceral fat (Ninomiya et al 2007). While rosehip has been found to produce modest cholesterol-lowering effects in humans (Rein et al 2004), further confirmation is required in large human clinical trials (Chrubasik et al 2008b).

## CLINICAL USES

Standardised patented rosehip powder is the only preparation that has been studied in clinical trials, although some laboratory studies have used other extracts. The standardised extract has been available for more than a decade in Scandinavia as a herbal remedy (Winther 2008) and is sold under the trade names LitoZin and LitoMove in Europe and i-flex throughout the rest of the world, and is available in Australia and New Zealand under the name Rose-Hip Vital. Since the patenting of standardised rosehip powder, there have been a number of clinical trials exploring the efficacy of this preparation in conditions such as osteoarthritis, rheumatoid arthritis and inflammatory bowel disease, with all studies being supported by the manufacturer Hyben Vital.

### Osteoarthritis

Clinical research into rosehip includes open-label and randomised controlled trials with durations of 6 months or less (Christensen et al 2013, Rein et al 2004, Warholm et al 2003, Winther & Thamsborg 2005), along with a number of corresponding systematic reviews and meta-analyses (Cohen 2012). These studies have consistently found rosehip to be extremely safe, with occasional mild allergic reactions or gastrointestinal complaints but no serious adverse effects (Chrubasik et al 2009) and rosehip is included in the Arthritis Australia Complementary Therapies Information Sheet as a therapy

with moderate evidence of osteoarthritis (*Arthritis Australia 2011*). Reviews of controlled trials suggest that rosehip has a moderate effect in patients with osteoarthritis (*Chrubasik et al 2006, Rosznagel et al 2007*). Similarly, a meta-analysis of three randomised controlled trials involving 287 osteoarthritis patients reported that treatment for 3 months with patented rosehip powder consistently reduced pain scores and that patients allocated to rosehip powder were twice as likely to respond to rosehip (as indicated by a reduction in Western Ontario and McMaster Universities Arthritis Index [WOMAC] pain) compared to placebo (effect size of 0.37, 95% confidence interval 0.13–0.60) (*Christensen et al 2008*). A more recent meta-analysis indirectly compared the pain-reducing effect of glucosamine hydrochloride and standardised rosehip powder for osteoarthritis. This analysis, which was based on three studies on glucosamine hydrochloride involving a total of 933 patients and the three rosehip studies described above involving 287 patients, concluded that rosehip is more efficacious than glucosamine hydrochloride in reducing pain in osteoarthritis patients (*Christensen 2009*). These results are supported by a more recent 8-week randomised controlled trial involving 46 patients that found that 4500 mg/day of rosehip showed better efficacy than 1500 mg/day of glucosamine sulfate in terms of total WOMAC score reduction, and functional disability reduction at the end of the eighth week, with less evidence and severity of adverse reactions (*Christensen et al 2013*).

### Rheumatoid arthritis

A 6-month, double-blind, placebo-controlled trial involving 89 patients with rheumatoid arthritis found that, compared to placebo, 5 g/day of standardised rosehip powder significantly improved scores on the Health Assessment Questionnaire Disability Index (HAQ-DI) along with various other patient- and doctor-reported scales, as well as significantly reducing erythrocyte sedimentation rate levels (*Willich et al 2010*). While these results appear promising, they are modest and larger studies with greater statistical power are needed to confirm these results.

A more recent and much smaller open, case-control study of 20 female patients with rheumatoid arthritis and 10 female controls found no significant effects on clinical symptoms, level of C-reactive protein or laboratory measures of antioxidant enzyme activity after 4 weeks' treatment with 10.5 g/day of rosehip powder (*Kirkeskov et al 2011*). The lack of significant improvements in this study may be due to a lack of effect or a slow onset of action, modest effect size, small sample size and lack of statistical power (*Cohen 2012*).

### Back pain

A 1-year surveillance of 152 patients found that rosehip provided significant pain relief for patients with acute exacerbations of chronic back pain (*Chrubasik et al 2008b*).

### DOSAGE

Dosage depends on the formulation and the indication. A commencement dose of around 5 g/day for 3–4 weeks followed by a maintenance dose of 2.5 g/day is recommended for treating osteoarthritis or chronic inflammation with the standardised extract. Rosehip should be taken with meals to enhance the absorption of its lipid elements.

### TOXICITY

Modern clinical studies and widespread traditional use have not raised any significant safety concerns.

### ADVERSE REACTIONS

Rosehip is considered safe and there are no documented interactions of major significance.

### SIGNIFICANT INTERACTIONS

There are no documented interactions of significance, although some mild gastrointestinal side effects are reported.

#### PREGNANCY USE

There is little published on the use of rosehip in pregnancy. Rosehip tea has been traditionally recommended during pregnancy and there are no reports of ill effects.

#### *Practice points/Patient counselling*

- Rosehip is traditionally taken as a high-vitamin-C tea. A standardised rosehip extract has recently been shown to be an effective anti-inflammatory agent against osteoarthritis and rheumatoid arthritis.

#### PATIENTS' FAQs

##### *What will this herb do for me?*

Rosehip can serve as a source of vitamin C and an anti-inflammatory agent that may help to relieve the pain and disability of osteoarthritis and rheumatoid arthritis and the use of rosehip may reduce the need for anti-inflammatory drugs.

##### *When will it start to work?*

Rosehip may take 2–4 weeks to provide effective arthritis relief.

##### *Are there any safety issues?*

The growing evidence base for rosehip suggests that this traditional herbal remedy has a high safety profile.

## Rosemary

**HISTORICAL NOTE** Rosemary is an evergreen perennial shrub that is native to Europe (Dias et al 2000) and is grown in many parts of the world (Bakirel et al 2008). Since ancient times, rosemary has been used as a tonic and stimulant. The ancient Greeks used rosemary for stimulating the brain and strengthening memory function (Pengelly et al 2012). Furthermore, scholars wore garlands of rosemary during examinations in order to improve their memory and concentration (Blumenthal et al 2000). Nicolaus Copernicus (1473–1543) was noted to use rosemary, as well as nettle, clivers and pumpkin, for renal ailments (Popowska-Drojecka et al 2011). Rosemary was used in traditional Turkish folk medicine for the treatment of hyperglycaemia (Bakirel et al 2008). Folk medicine described the healing properties of rosemary as well as its use as a microbicide and for the treatment of gastrointestinal disturbances (Dias et al 2000). Some cemeteries have planted rosemary bushes, possibly as a sign to always remember those who have been buried there. It is widely used as a food spice and as an antioxidant to preserve foods.

**COMMON NAME**

Rosemary

**OTHER NAMES**

Compass plant, compass weed, garden rosemary, old man, polar plant, *Rosmarini folium*

**BOTANICAL NAME/FAMILY**

*Rosmarinus officinalis* (family Labiatae or Lamiaceae)

**PLANT PART USED**

Fresh or dried leaf

**CHEMICAL COMPONENTS**

Chemical components include phenolic acids and diterpenoid bitter substances, including rosmarinic acid (Nolkemper et al 2006, Tu et al 2013), carnosic acid and carnosol (Aruoma et al 1992, Bicchi et al 2000, Romo Vaquero et al 2013, Wei & Ho 2006), luteolin 3-glucuronide (Nolkemper et al 2006), triterpenoid acids, flavonoids, tannins and volatile oils (0.5–2.5%) that consist of 1,8-cineole (Kabouche et al 2005, Wang et al 2012), 2-ethyl-4,5-dimethylphenol gamma-terpinene (Kabouche et al 2005), pinene (Blumenthal et al 2000, Wang et al 2012), terpineol, camphor, camphene, borneol and bornyl acetate (Blumenthal et al 2000). Rosemary has also been found to contain high amounts of salicylates (Swain et al 1985).

**MAIN ACTIONS**

Preclinical research has been conducted with rosemary essential oil, leaves and other preparations. There has also been research with individual constituents such as rosmarinic acid, carnosol and carnosic acid.

**Antioxidant**

Rosemary has strong antioxidant activity and is widely used to preserve food and cosmetics (Etter 2004). The antioxidant activity of rosemary is due to a variety of compounds, most notably the phenolic abietane diterpenes and phenolic acids such as rosmarinic acid. These antioxidant effects may contribute to membrane stabilisation and the reduction of free radical production, which may assist with the electron donor ability of the rosemary diterpenes in protecting membranes against oxidative damage (Pérez-Fons et al 2010). Rosemary leaf extract has been shown to enhance superoxide dismutase activity (Kim et al 1995) and to have an effect stronger than vitamin E in scavenging oxygen radicals (Zhao et al 1989). The antioxidant activity of rosemary extract was measured by Trolox equivalent antioxidant capacity (TEAC) (Cheung & Tai 2007). The test is based on the reduction of the 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) (ABTS) radical cation by antioxidants. Cell-free ABTS OH radical scavenging assay showed that 1/10 and 1/5 dilutions of the rosemary extract had substantial antioxidant activity. In the cell culture studies, rosemary extract at 1/2000 and 1/1000 concentrations

significantly inhibited nitric oxide (NO) production by the lipopolysaccharide-activated RAW 264.7 cells in a dose-dependent manner. NO in the culture supernatant was also significantly reduced in the LPS-activated cells.

It is suggested that carnosol and carnosic acid account for over 90% of its antioxidant properties (Aruoma et al 1992, 1996). Carnosic acid has been shown to have a photoprotective action on human dermal fibroblasts exposed to ultraviolet A light in vitro (Offord et al 2002) and rosemary extract inhibits oxidative alterations to skin surface lipids, both in vitro and in vivo (Calabrese et al 2000), as well as enhancing cell-mediated immunity in rats under oxidative stress (Babu et al 1999). Rosmarinic acid has also been investigated for its antioxidant activities and plays an important role in the antioxidant capacities of the extracts containing very similar diterpene concentrations (Jordán et al 2012). In this study, extracts with a lower rosmarinic acid concentration (50:50) exhibited a poorer antioxidant capacity and antioxidant activity was further improved by the presence of carnosol as the major diterpene content.

Antioxidant activity has also been investigated in a model of macular degeneration (Organisciak et al 2013). Sprague-Dawley rats were administered with intraperitoneal rosemary test solution 1 hour before the start of light exposure tests. Rosemary powder extract (34 mg/kg) alone and when combined with zinc (1.3 mg/kg) effectively decreased the extent of retinal light damage. Rosemary (17 mg/kg) plus zinc (1.3 mg/kg) treatment reduced the expression of oxidative stress protein markers and enhanced visual cell survival, as shown by improved photoreceptor cell morphology and by decreased retinal DNA degradation.

**Antibacterial**

Both rosemary essential oil and rosemary extract exhibit antibacterial properties against a range of organisms, with both preparations being more effective against Gram-positive bacteria.

Rosemary extract demonstrates in vitro antibacterial activity against a variety of bacteria (Del Campo et al 2000, Erdogru 2002, Ouattara et al 1997), including *Helicobacter pylori* (Mahady et al 2005), *Staphylococcus aureus* (Oluwatuyi et al 2004), *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* (Kabouche et al 2005). The in vitro inhibitory activity of the rosemary methanolic extracts was found to be more effective against the Gram-positive than the Gram-negative food-borne pathogens assayed. A higher concentration of carnosol in relation to carnosic acid was found to improve the degree of the antibacterial activities of the rosemary extracts against *Listeria monocytogenes* and *Staphylococcus aureus* strains (Jordán et al 2012).

Rosemary essential oil and three of its main constituents, 1,8-cineole (27.23%),  $\alpha$ -pinene (19.43%) and  $\beta$ -pinene (6.71%), were evaluated for their in vitro antibacterial activities (Wang et al 2012). Five

microorganisms consisting of three Gram-positive bacteria (*Bacillus subtilis*, *Staphylococcus aureus*, *S. epidermidis*) and two Gram-negative bacteria (*Escherichia coli* and *Pseudomonas aeruginosa*) were tested. Gram-positive bacteria were more sensitive than Gram-negative bacteria to rosemary essential oil,  $\alpha$ -pinene and  $\beta$ -pinene. Rosemary essential oil showed greater activity than its components.

### Antiulcerogenic activity

Rosemary has potential antiulcer activity. Rosemary extract demonstrated in vitro antibacterial activity against *Helicobacter pylori* (Mahady et al 2005). Dias and colleagues (2000) investigated the antiulcerogenic activity of the crude hydroalcoholic extract (CHE) of rosemary in an experimental rat model. The extract was made from the dried aerial parts of rosemary that were processed to produce a CHE. In the ethanol-induced ulcer model, doses of 100 and 200 mg/kg CHE demonstrated no antiulcerogenic activity, whereas doses of 500 and 1000 mg/kg CHE inhibited the ulcerative lesion index in 70% and 74.6%, respectively. In the indomethacin-induced ulcer model, CHE (1000 mg/kg) inhibited the ulcerative lesion index by 44%. The antiulcerogenic activity of the CHE was also maintained in the ethanol-induced ulcer model, with previous administration of indomethacin, inhibiting the ulcerative lesion index by 70%. The results of this study suggest that the CHE of rosemary has active substances that increase the mucosal non-protein sulfhydryl group content (Dias et al 2000).

### Antifungal activity

Topical application of rosemary essential oil preparations exerts antifungal activity (Ouraini et al 2005, Steinmetz et al 1988, Suleimanova et al 1995) and inhibits the growth and aflatoxin production of *Aspergillus* spp. at concentrations between 0.2% and 1% (Tantaoui-Elaraki & Beraoud 1994).

### Antiviral

The carnosol constituent found in rosemary demonstrates anti-HIV activity (Aruoma et al 1996) and carnosic acid also demonstrates an inhibitory effect on HIV-1 protease in cell-free assays (Paris et al 1993). Rosemary extract has some antiviral activity against herpes simplex virus (HSV) (Vijayan et al 2004).

### Herpes simplex virus

Rosemary and other herbs of the Lamiaceae family were examined for their antiviral activity against HSV. The in vitro testing was on plaque formation of HSV-1 and HSV-2 and an aciclovir-resistant strain of HSV-1. When rosemary extract was added during the adsorption period of viruses to host cells, the number of plaque-forming units was reduced by 36% for HSV-1 and 77% for HSV-2. Pretreatment of host cells with rosemary extracts prior to infection led to a 24% reduction for HSV-1. Pretreatment of HSV-1 and HSV-2 with rosemary extract

prior to infection caused a significant decline in the amount of plaque. The results of this study indicate that rosemary extract affected HSV before adsorption but had no effect on intracellular virus replication. Rosemary extract exerted its antiviral effect on free HSV and this offers a potential use for topical therapeutic application against recurrent herpes infections (Nolkemper et al 2006).

### Anti-inflammatory

Several different rosemary preparations have demonstrated anti-inflammatory activity using various models.

In vitro studies have found that rosemary extracts inhibited inflammatory-induced peroxynitrite radical and nitrite production (Chan et al 1995, Choi et al 2002) and that carnosol suppresses NO production (Lo et al 2002). Rosmarinic acid has been found to increase the production of prostaglandin E<sub>2</sub>, reduce the production of leukotriene B<sub>4</sub> in human polymorphonuclear leucocytes and inhibit the complement system (al-Sereiti et al 1999). The anti-inflammatory and analgesic activity of rosemary essential oil has been confirmed in vivo using several different animal models (Lucarini et al 2013, Takaki et al 2008).

In cell culture studies, rosemary extract at a 1/500 dilution significantly reduced interleukin-1 $\beta$  (IL-1 $\beta$ ) ( $P < 0.01$ ) and cyclooxygenase-2 ( $P < 0.05$ ) mRNA expression and non-significantly reduced tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) and inducible NO synthase mRNA expression in lipopolysaccharide-activated cells. Treatment with 1/1000 dilution of rosemary extract had no effect (Cheung & Tai 2007).

### Acne

*Propionibacterium acnes* is a key pathogen involved in the progression of acne inflammation. Tsai et al (2013) investigated the inhibitory effect of rosemary extract on *P. acnes*-induced inflammation (TNF- $\alpha$ , IL-8, and IL-1 $\beta$ ) in vitro and in vivo. Treatment with ethanolic rosemary extract significantly suppressed *P. acnes*-induced IL-8, IL-1 $\beta$  and TNF- $\alpha$  production. In addition, ethanolic rosemary extract suppressed the gene expression of IL-8, IL-1 $\beta$  and TNF- $\alpha$  in *P. acnes*-stimulated THP-1 cells. When individual constituents of rosemary were measured, rosmarinic acid significantly reduced the IL-8 production, but had no effect on the IL-1 $\beta$  level. Carnosol and carnosic acid significantly inhibited IL-1 $\beta$  levels at the concentration of 2.5 microM, but significantly increased IL-8 secretion at higher concentrations (10 microM). A mouse model was used to examine the in vivo anti-inflammatory effect of rosemary. Co-injection of ethanolic rosemary extract (1 mg/10 microL) attenuated the granulomatous response to *P. acnes* as compared to co-injection with an equal amount of vehicle, indicating a positive result.

### Antispasmodic

Rosemary is widely acknowledged to be a carminative and is used internally as an antispasmodic for

mild cramp-like gastrointestinal and biliary upsets, as well as for tension headache, renal colic and dysmenorrhoea (Blumenthal *et al* 2000). It is also used to relax bronchial smooth muscle in the treatment of asthma (al-Sereiti *et al* 1999). Antispasmodic activity has been confirmed in a study with isolated guinea pig ileum which tested the effects of different concentrations of an aqueous ethanolic extract of rosemary (Ventura-Martinez *et al* 2011). A significant dose-dependent activity was observed, which was mediated via calcium channels and muscarinic receptors but not nicotinic receptors, prostaglandins or NO.

### Hepatoprotective

The hepatoprotective properties of rosemary extract are attributed to its antioxidant properties and improving detoxification systems dependent on glutathione S-transferase (Sotelo-Felix *et al* 2002). Rosemary extract has been shown to reduce thioacetamide-induced cirrhosis (Galisteo *et al* 2000) and azathioprine-induced toxicity in rats (Amin & Hamza 2005), as well as partially prevent carbon tetrachloride-induced liver damage in both rats (Sotelo-Felix *et al* 2002) and mice (Fahim *et al* 1999, Sotelo-Felix *et al* 2002). A water extract of rosemary (200 mg/kg body weight) was investigated for hepatoprotective properties in streptozotocin-induced diabetic rats for 21 days (Ramadan *et al* 2013). The fresh leaves of rosemary (5 g) were soaked in 50 mL of boiled water with 1 hour of stirring at room temperature. The supernatant was decanted and the residue was macerated for two more days with distilled water. The pooled supernatants were combined and filtered. The treatment group starting with elevated liver function enzymes (aspartate aminotransferase, alanine transaminase and alkaline phosphatase) experienced significantly restored levels, returning to near normal.

There was also a significant increase in total protein and albumin compared to the diabetic rats. The authors note that the hepatoprotective effects of rosemary could be due to the presence of the phenolic and flavonoid compounds and their antioxidant effects. Another thing to note in this study was that serum insulin and C-peptide levels decreased in diabetic animals, whereas rosemary water extract treatment brought about a marked increase in their serum levels in streptozotocin-induced diabetic rats. The water extract also lowered the glucose content to near normal.

### Hypoglycaemic effects and activity in insulin resistance

Rosemary leaf extract significantly reduces blood glucose levels *in vivo*, according to a dose-response study utilising both normoglycaemic and alloxan-induced diabetic test animals (Bakirel *et al* 2008). Significant glucose-lowering effects were seen when using doses of 100 and 200 mg/kg in normoglycaemic rabbits whereas no significant effect was seen at the lower dose of 50 mg/kg. Two hours after

treatment, the 100 mg/kg test dose reduced blood glucose levels by 14.5%, which was short-lived, whereas the higher dose of 200 mg/kg reduced the level by 20.4%, and this remained significant after 6 hours. None of these doses affected insulin levels in the normoglycaemic rabbits.

When the three different rosemary extract doses were tested in hyperglycaemic rabbits, the 50 mg/kg and 100 mg/kg treatments showed a significant effect, with blood glucose levels dropping by 12.4% and 19.9% respectively compared to placebo at 6 hours after glucose administration. At 200 mg/kg a comparatively more potent reduction was observed with the blood glucose levels 30.8% and 35.6%, respectively from that of control after 2 and 6 hours of glucose administration. Of note, the highest treatment dose produced an effect similar in magnitude to glibenclamide at 6 hours post glucose loading.

Further acute dose testing conducted with alloxan-diabetic animals showed significant effects for 200 mg/kg after 6 hours producing a blood glucose decrease of 28.3%, which was similar to glibenclamide, together with a significant increase in insulin levels. The maximal percentages of increase in insulin levels that occurred after 6 hours with rosemary extract or glibenclamide administration were 60.3% and 75.8% in diabetic rabbits, respectively.

A subacute study was then conducted which found the highest dose (200 mg/kg) produced the greatest reduction in blood glucose on the 8th day of treatment (29.5% drop), and this was greater than glibenclamide (18.2%). Interestingly, daily administration of the extract at 200 mg/kg dose to alloxan-diabetic rabbits induced a significant increase in the insulin level on the 5th day when compared with diabetic control rabbits. The magnitude of the increase of insulin after administration of the extract of 200 mg/kg (77.8%) was much closer to that of glibenclamide (75.6%). The doses of 100 mg/kg and 200 mg/kg showed a marked increase on insulin level in alloxan-diabetic rabbits (60.5% and 78.7%, respectively) on day 8. In addition, a significant elevation in serum superoxide dismutase was observed on the 5th day in alloxan-diabetic rabbits given glibenclamide and rosemary (200 mg/kg), which showed 22.1% and 24.4% increase, respectively. A more pronounced activity (25%) was recorded at the later stage for rosemary (200 mg/kg). Inhibition of lipid peroxidation was also observed.

*In vivo* research conducted by Ibarra *et al* (2011) showed that rosemary extract (standardised to 20% carnosic acid; 500 mg/kg body weight per day) given to test animals on a high-fat diet resulted in 72% ( $P < 0.01$ ) less increase in plasma glucose levels and a rise in total cholesterol and a significant 12-fold increase ( $P < 0.01$ ) in total faecal content compared with mice on a high-fat diet and not receiving rosemary extract. These results suggest that the reduction of weight gain induced by rosemary extract was mediated, at least partially, through a limitation of lipid absorption. More research is

required to understand this mechanism of action and its possible applications. Rosmarinic acid shows potential in reducing cardiovascular risk-associated insulin resistance and metabolic syndrome. Rosmarinic acid supplementation (oral dosage of 10 mg/kg/day) to fructose-fed rats significantly improved insulin sensitivity, reduced lipid levels and oxidative damage, and the expression of p22phox subunit of nicotinamide adenine dinucleotide phosphate reduced oxidase and prevented cardiac hypertrophy. Blood pressure was also lowered by rosmarinic acid through a decrease in endothelin-1 and angiotensin-converting enzyme activity and increase in NO levels (Karthik et al 2011).

Harach et al (2010) investigated the effects of rosemary leaf extract (20 or 200 mg/kg body weight) on the prevention of weight gain and associated metabolic disorders in mice fed a high-fat diet. The final weight gain of the mice treated with 200 mg/kg body weight of rosemary extract was significantly reduced by 64% when compared with the control group. The reduction of weight gain was associated with a significant reduction of body fat mass gain (-57%). Treatment with 200 mg/kg body weight of rosemary extract also increased lipid excretion in the faeces.

Carnosic acid and derived diterpenes abundant in rosemary extracts have been found to exert anti-obesity effects (Romo Vaquero et al 2013), with carnosic acid inhibiting adipogenesis in vivo (Wang et al 2011). Carnosic acid added to test animal chow significantly inhibited the gain of body weight after 3 weeks ( $P < 0.01$ ). A magnetic resonance imaging (MRI) analysis revealed the areas of the abdomen ( $P < 0.01$ ), abdominal cavity ( $P < 0.05$ ) and visceral fat regions ( $P < 0.05$ ) in mice fed the carnosic acid diet to be significantly smaller than those in the control mice. A significant reduction of the levels of serum triglycerides, cholesterol and alanine aminotransferase in mice of the carnosic acid group was also observed in comparison to controls. Active treatment also led to a significant decrease in the weight of liver mass in comparison to the controls (Wang et al 2011).

### Neuroprotective effects

Carnosic acid and carnosol, which are major components of rosemary, have been found to markedly enhance synthesis of nerve growth factor in vitro (Kosaka & Yokoi 2003). Carnosic acid exhibits neuroprotective effects in vitro via its antioxidant activity and induction of antioxidant enzyme expression by means of activation of nuclear factor erythroid 2-related factor 2 transcription pathway. This neuroprotective effect is considered to be beneficial in the prevention of chronic neurodegenerative diseases (Kayashima & Matsubara 2012). For the development of carnosic acid as a protective agent against neurodegenerative diseases, penetration into the brain is an essential requirement. To examine this aspect, Satoh and colleagues (2008) administered carnosic acid orally to mice (3 mg per 25 g mouse)

and measured the level of carnosic acid (catechol form) in serum and brain parenchyma by high-performance liquid chromatography. Within 1 hour, carnosic acid reached significant levels in the brain, suggesting that carnosic acid was able to penetrate the blood-brain barrier. In another section of the study, mice were allowed free access to food containing 0.03% carnosic acid for a week. Their brains were then removed and measured for reduced glutathione (GSH) and glutathione disulfide (GSSG) levels. Carnosic acid increased both total GSH + GSSG and the ratio of GSH/GSSG. More research is required on this potential pathway in neuroprotection.

A study investigated the protective mechanism of carnosic acid on ischaemia-reperfusion and hypoxia-induced neuronal cell injury. The results showed that carnosic acid reduced 52% of the infarct volume from brains under ischaemia-reperfusion in vivo and protected the PC12 cells from hypoxic injury in vitro. Carnosic acid at a concentration of 1.0 microM enhanced cell viability, scavenged reactive oxygen species, increased superoxide dismutase activity, prevented lactic dehydrogenase release and attenuated  $Ca^{2+}$  release, lipid peroxidation and prostaglandin  $E_2$  production in hypoxic PC12 cells (Hou et al 2012).

### Chemoprotection and antimutagenic effects

Evidence from animal and cell culture studies demonstrates the anticancer potential of rosemary extract, carnosol, carnosic acid, ursolic acid and rosmarinic acid against several types of cancers (Ngo et al 2011). The effects appear to be dose-related and not tissue- or species-specific. For example, rosemary has been shown to suppress the development of tumours in several organs, including the colon, breast, liver and stomach, as well as melanoma and leukaemia cells, and is most likely to be due to the modulation of different molecular target.

In vivo studies suggest that rosemary extract may reduce the effects of carcinogenic or toxic agents on many cell lines, including rat mammary gland (Amagase et al 1996, Singletary et al 1996), mouse liver and stomach (Singletary & Rokusek 1997), bone marrow (Fahim et al 1999) and skin (Huang et al 1994).

An in vitro study on human bronchial cells found that rosemary extract and its constituents, carnosol and carnosic acid, may have chemoprotective activity by decreasing carcinogen activation via inhibition of the enzyme cytochrome P450 (CYP1A1) and increasing carcinogen detoxification by induction of phase II enzymes (Offord et al 1995). Carnosol has been found to also restrict the invasive ability of mouse melanoma cells in vitro by reducing matrix metalloproteinase-9 expression and activity (Huang et al 2005).

Cigarette smoking is causally associated with a large number of human cancers and rosemary may reduce the risk of cigarette-induced lung cancer (Alexandrov et al 2006). Benzo(a)pyrene (BP) is a

highly carcinogenic polycyclic aromatic hydrocarbon present in emission exhausts, charbroiled food, and in small quantities of cigarette smoke. It is metabolically activated into BP-7,8-diol-9,10-epoxide (BPDE), which reacts with DNA predominantly at the N<sup>2</sup> position of guanine to produce primarily N<sup>2</sup>-guanine lesions. More research is suggested in this novel use of rosemary. The BPDE-dG adduct is exclusively concentrated in bronchial cells and has been implicated in the initiation of human lung cancer. The modified cigarette filter containing rosemary extract decreased BPDE-dG adduct level by >70% due to the cigarette smoke oxygen-generated radicals in MCF-7 cells. A 30% decrease in the hydroxyl radical was also observed.

**Cheung and Tai (2007)** investigated the antiproliferative properties of rosemary on several human cancer cell lines. Rosemary extract induced differential antiproliferative activity on the breast and leukaemia cell lines tested, with HL60 being the most susceptible, and MCF7 the most resistant. IC50 was estimated at 1/700, 1/500, 1/400 and 1/150 for the HL60, MDA-MB-468, K562 and MCF7 cells, respectively. In addition, a 1/1000 dilution of rosemary extract induced  $9.5 \pm 2.2\%$  of HL60 cell differentiation along granulocyte lineage with  $P < 0.01$  compared to the untreated control at  $2.8 \pm 0.8\%$ .

### Increases oestrogen metabolism

Feeding female mice a 2% rosemary diet enhanced the liver microsomal metabolism of endogenous oestrogens (**Zhu et al 1998**), thereby reducing oestrogen levels.

### Antiobesity

Carnosic acid and derived diterpenes abundant in rosemary extracts have been found to exert anti-obesity effects (**Romo Vaquero et al 2013**), with carnosic acid inhibiting adipogenesis in vivo (**Wang et al 2011**).

Ob/ob mice were fed a chow diet supplemented with or without carnosic acid for 5 weeks. Carnosic acid significantly inhibited the gain of body weight after 3 weeks of treatment ( $P < 0.01$ ). An MRI analysis revealed the areas of the abdomen ( $P < 0.01$ ), abdominal cavity ( $P < 0.05$ ) and visceral fat regions ( $P < 0.05$ ) in mice fed the carnosic acid diet to be significantly smaller than those in the control mice. A significant reduction of the levels of serum triglycerides, cholesterol and alanine aminotransferase in mice of the carnosic acid group was observed in comparison to the mice of the non-carnosic acid group. In addition, the mice of the carnosic acid group showed a significant improvement in the non-fasting glucose levels and glucose tolerance 30 and 120 minutes after glucose loading. Mice of the carnosic acid group had a significant decrease in the weight of liver mass in comparison to the controls (**Wang et al 2011**). **Ibarra et al (2011)** investigated the effect of rosemary extract (standardised to 20% carnosic acid) in mice. Mice were given a low-fat

diet, a high-fat diet or a high-fat diet supplemented with 500 mg rosemary extract/kg body weight per day. Mice in the high-fat diet plus rosemary group experienced 72% ( $P < 0.01$ ) less increase in plasma glucose levels and 68% ( $P < 0.001$ ) less rise in total cholesterol and a significant 12-fold increase ( $P < 0.01$ ) in total faecal content compared with high-fat-diet mice. In vitro studies found rosemary extract (100 mcg/mL) inhibited pancreatic lipase activity and extracts at 30 and 100 mcg/mL activated peroxisome proliferator-activated receptor- $\gamma$ . **Harach et al (2010)** investigated the effects of rosemary leaf extract (20 or 200 mg/kg body weight) on the prevention of weight gain and associated metabolic disorders in mice fed a high-fat diet. The final weight gain of the mice treated with 200 mg/kg body weight of rosemary extract was significantly reduced by 64% when compared with the control group. The reduction of weight gain was associated with a significant reduction of body fat mass gain (-57%). Treatment with 200 mg/kg body weight of rosemary extract also increased lipid excretion in the faeces. Rosemary extract was able to inhibit pancreatic lipase activity in vitro. The results of this study suggest that the reduction of weight gain induced by rosemary extract was mediated, at least partially, through a limitation of lipid absorption. More research is required on this action.

### OTHER ACTIONS

Rosemary demonstrates significant antithrombotic activity in vitro and in vivo, possibly through a direct inhibitory effect on platelets (**Yamamoto et al 2005**).

Rosemary essential oil and its constituent monoterpenes, such as borneol, inhibit bone resorption in the rat (**Muhlbauer et al 2003**). Aqueous and ethanol extracts of rosemary have been found to produce significant antinociceptive activity and diminish morphine withdrawal syndrome in rats (**Hosseinzadeh & Nourbakhsh 2003**).

When used topically, rosemary essential oil is said to stimulate the skin and increase blood circulation (**Blumenthal et al 2000**).

Powdered rosemary leaves are said to be effective as a natural flea and tick repellent and rosemary essential oil has been found to be ovicidal and repellent towards mosquito (**Prajapati et al 2005**).

### CLINICAL USE

#### Increased mental concentration

Several clinical trials of different designs have been conducted demonstrating that inhalation of rosemary oil affects various aspects of brain function generally, leading to improved memory and increased alertness with greater relaxation. Less research has been conducted with orally ingested rosemary extract.

In 2002, a small case series of 10 subjects found that rosemary essential oil had positive effects on mood concentration and memory (**Svoboda et al**

**Clinical note — Carnosol investigation in cancer**

The constituent carnosol found in rosemary has been the subject of extensive preclinical research as a potential treatment in various cancers, including prostate, breast, skin, leukaemia and colon cancer, with promising results (Johnson 2011). Multiple mechanisms of action have been discovered for carnosol which are associated with inflammation and cancer, such as antiangiogenic activity (Kayashima & Matsubara 2012) and effects on NF- $\kappa$ B, apoptotic-related proteins, phosphatidylinositol-3-kinase/Akt, androgen and oestrogen receptors, as well as molecular targets (Johnson 2011). When administered to test animals, it displays selective toxicity against tumour cells and is well tolerated.

2002). A 2003 randomised controlled trial of 140 subjects found that a 5-minute inhalation of rosemary essential oil placed on diffuser pads in an aroma stream produced a significant enhancement of performance for overall quality of memory and secondary memory factors, but also produced an impairment of speed of memory compared with controls (Moss et al 2003). Further support comes from an observational study in 40 adults where a 3-minute exposure to rosemary essential oil was seen to decrease frontal alpha and beta power, suggesting increased alertness. Subjects felt more relaxed and alert, had lower anxiety scores and were faster, but not more accurate, at completing mathematical computations (Diego et al 1998). Sayorwan et al (2013) examined the effects of rosemary oil inhalation on the nervous system in 10 males and 10 females (age range 18–28 years). Brain electrical activity and autonomic nervous system parameters (blood pressure, heart rate, respiratory rate and skin temperature) were recorded as the indicators of the arousal level of the nervous system. After rosemary oil exposure, heart rate, blood pressure and respiratory rate had significantly increased ( $P < 0.010$ ). In contrast, skin temperature had decreased significantly. During the sessions of rosemary inhalation, the power of the alpha1 waves in the left and right anterior and right posterior regions was significantly decreased ( $P < 0.05$ ). The power changes in the alpha2 waves were also significantly decreased during rosemary inhalation, and was shown in all areas of the brain ( $P < 0.05$ ). In contrast, the power of the beta waves in the left and the right anterior brain regions was significantly increased. The participants felt fresher and became more active and less drowsy after exposure to the rosemary oil ( $P < 0.05$ ). A small case series of 10 subjects also found that rosemary essential oil had positive effects on mood concentration and memory (Svoboda et al 2002). Moss et al (2003) demonstrated significantly enhanced overall memory quality but impaired memory speed using rosemary essential oil placed on diffuser pads in an aroma stream placed in test cubicles and switched on for 5 minutes prior to

testing ( $n = 140$ , divided into three groups: lavender, rosemary and control).

**Orally ingested rosemary extract**

A double-blind crossover randomised controlled trial of 27 older adults (mean age 75 years) identified a biphasic dose-dependent effect in measures of speed of memory for acute oral rosemary treatment, with the lowest dose (750 mg) producing a statistically significant beneficial effect compared with placebo ( $P = 0.01$ ), whereas the highest dose (6000 mg) had a significant impairing effect ( $P < 0.01$ ). In regard to alertness, once again the lower dose of 750 mg produced a significant improvement ( $P = 0.01$ ) compared with placebo, whereas an opposite effect was found at 6000 mg, which was worse than placebo ( $P = 0.02$ ) (Pengelly et al 2012). This lower dose is more similar to levels found in culinary consumption. Less consistent were deleterious effects on other measures of cognitive performance. Further research using multiple doses of low concentrations may yield different effects and is worthy of greater exploration.

**Alopecia — in combination**

The traditional use of rosemary to stimulate hair growth is supported by a 7-month, randomised, double-blind study of 86 patients that found that rubbing oils (thyme, rosemary, lavender and cedarwood) into the scalp helped with alopecia for 44% of patients versus 15% of controls (Hay et al 1998).

While the role of rosemary as a stand-alone treatment in achieving these results is unclear, results from in vivo research indicate that topical rosemary leaf extract can improve hair regrowth, most likely by inhibition of dihydrotestosterone binding to androgen receptors (Murata et al 2013).

**Chemoprotective and adjunct in cancer therapy**

Rosemary was used topically to treat cancer in ancient Greece and South America. Although controlled trials are yet to be conducted, it has been suggested that rosemary may delay and inhibit tumour formation in women with breast cancer (Abascal & Yarnell 2001) and that it has potential as a preventive agent or as an adjunct in cancer therapy. An in vitro study in human breast cancer cells found that rosemary extract increased the intracellular accumulation of commonly-used chemotherapeutic agents, including doxorubicin and vinblastine via inhibition of P-glycoprotein, thereby overcoming multidrug resistance in tumour cells (Plouzek et al 1999). Clinical studies are required to determine whether the effect is significant.

**Potential use in drug withdrawal**

Solhi and colleagues (2013) investigated the efficacy of oral rosemary leaves in capsules as an adjunct therapy for alleviation of withdrawal syndrome in opium abuse ( $n = 81$ ). People either received rosemary treatment or acted as controls and all were treated with methadone. The treatment regimen

was 20 mg/day in the first week, then 15 mg/day in the second week, followed by 10 mg/day in the third week and 5 mg/day in the fourth week. The rosemary capsules were filled with 300 mg of dried powdered leaves and administered to the patients in the case group as 16 capsules/day for the first 3 days, 12 capsules/day for the following 4 days, and then 8 capsules for the next week in divided doses. Subjects in the active treatment group had significantly better duration of sleep on the third and seventh days compared to the control group ( $P < 0.001$  and  $P < 0.002$ , respectively) and experienced less severe withdrawal symptoms compared to those in the control group, particularly bone pain, perspiration and insomnia. The differences were statistically significant for the third and seventh days ( $P < 0.05$ ).

### OTHER USES

When applied topically, rosemary oil may stimulate the blood supply and act as supportive therapy for rheumatic conditions and circulatory problems (Blumenthal et al 2000). Topically, rosemary has also been used for wound healing, as an insect repellent and to treat toothache and eczema. Rosemary extract cream preparations have been shown to protect against sodium lauryl sulfate-induced irritant contact dermatitis (Fuchs et al 2005).

In a small, uncontrolled, prospective pilot study of eight women, rosemary in combination with 11 other botanical extracts was found to relieve menopausal symptoms (Smolinski et al 2005).

### Acne

Rosemary shows potential in the treatment of acne. In vitro and mouse model studies showed that rosemary significantly suppressed *Propionibacterium acnes*-induced IL-8, IL-1 $\beta$  and TNF- $\alpha$  production and granulomatous response to *P. acnes*, respectively (Tsai et al 2013). Further research is warranted to determine its potential role in clinical practice for acne management.

### Herpes simplex virus

In an in vitro study, rosemary extract exerted an antiviral effect on free HSV. This effect offers a potential use for topical therapeutic application of rosemary against recurrent herpes infections (Nolkemper et al 2006).

### Cardiovascular disease

Rosmarinic acid shows potential in reducing cardiovascular disease risk, insulin resistance and metabolic syndrome as significantly improved insulin sensitivity, reduced lipid levels and oxidative damage have been exhibited in a preclinical model. Blood pressure was also lowered by rosmarinic acid through a decrease in endothelin-1 and angiotensin-converting enzyme activity and increase in NO levels (Karthik et al 2011). Additionally, rosmarinic acid (25 micromol/L) and carnosic acid (25 micromol/L) inhibited low-density lipoprotein (LDL) oxidation

by 40.8% and 22.6%, respectively (Fuhrman et al 2000). Synergistic antioxidative effects with rosmarinic acid or carnosic acid (58.4% and 38.0%, respectively) were found against LDL oxidation when lycopene was added to LDL.

### Age-related macular degeneration

Age-related macular degeneration is a multifactorial disease with an increased risk of vision loss associated with oxidation and inflammation (Organisciak et al 2013). Rosemary extract may have benefits in delaying or slowing the progression of macular degeneration according to results from research conducted with animal models that tested rosemary extract administered as an intraperitoneal injection before light exposure, which showed protection against macular changes by enhancing visual cell survival.

### DOSAGE RANGE

- Infusion of dried leaf: 2–4 g three times daily.
- Fluid extract (45%): 1–4 mL three times daily.
- Topical preparations containing 6–10% essential oil can be applied directly to skin. Often a carrier oil, such as almond oil, is used as a vehicle for the essential oil.
- Bath additive: 10 drops essential oil added to bath.

### ADVERSE REACTIONS

Rosemary is generally recognised as safe for human consumption in quantities used as food. Consuming large amounts of rosemary may cause stomach and intestinal irritation, as well as seizures, owing to the high content of highly reactive monoterpene ketones, such as camphor (Burkhard et al 1999). Topically, rosemary is not considered to be highly allergenic; however, allergic contact dermatitis from rosemary has been reported (Fernandez et al 1997, Hjorth et al 1997, Inui & Katayama 2005), as has asthma from repeated occupational exposure (Lemiere et al 1996). Rosemary essential oil should be diluted before topical application to minimise irritation.

### SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

### Iron

Rosemary extracts are widely used as an antioxidant to preserve foods; however, the phenolic-rich extracts may reduce the uptake of dietary iron (Samman et al 2001). Separate doses by 2 hours.

### Anticoagulants

Increased bruising and bleeding theoretically possible — use caution.

### Drugs dependent on P-glycoprotein transport

Theoretically, increased drug uptake can occur with those drugs dependent on P-glycoprotein transport.

The clinical significance of this finding remains to be tested, although it has been suggested that this activity may be used to enhance the effects of chemotherapeutic agents (Plouzek et al 1999).

### CONTRAINDICATIONS AND PRECAUTIONS

None known.

### PREGNANCY USE

Rosemary has been shown to have an anti-implantation effect in rats, without interfering with normal fetal development postimplantation (Lemonica et al 1996). It is not recommended in pregnancy in doses higher than the usual dietary intake levels until safety is established or only under professional supervision.

### Practice points/Patient counselling

- Rosemary is widely used as a food seasoning and preservative.
- Rosemary extract exhibits antioxidant, antibacterial, anti-inflammatory, hepatoprotective, neuroprotective and chemoprotective activities in various in vitro and experimental models.
- Rosemary oil is widely used to assist in concentration and memory and to stimulate blood flow. There is some research that low doses of powdered rosemary leaf taken orally can improve memory speed in older adults.
- Traditionally, it has been used to as an antispasmodic agent to relieve stomach, gallbladder and menstrual cramps. Preclinical research confirms rosemary has significant antispasmodic activity.
- Rosemary is generally safe when the leaves are consumed in dietary amounts, although excessive intake may cause stomach irritation and seizures in susceptible people.

## S-Adenosyl-L-methionine (SAME)

**HISTORICAL NOTE** SAME was first discovered in Italy in 1952. About 20 years later, a stable salt was commercially manufactured and produced for injectable use. At first, it was investigated as a treatment for schizophrenia, for which it proved inappropriate; however, successful trials in depressed patients began in the 1970s and it was inadvertently found to improve symptoms of arthritis. Since then, numerous studies have been undertaken to examine the role of SAME in treating depression, osteoarthritis and liver pathology. To date, more than 75 clinical trials have been conducted using SAME as a therapeutic agent, involving over 23,000 people.

### BACKGROUND AND RELEVANT PHARMACOKINETICS

SAME is a naturally occurring molecule synthesised in the cytosol of every cell, with the liver being the major site of biosynthesis and degradation. SAME is derived from two acids: methionine (an amino acid) and adenosine triphosphate (ATP: a nucleic acid). Up to half the daily methionine is converted to SAME in the liver, where it is metabolised to S-adenosylhomocysteine (SAH) and then homocysteine. Being a central part of the one-carbon metabolism cycle, SAME is intrinsically linked with the other methyl donors such as betaine (choline), folate and B<sub>12</sub>. SAME also plays a role in the synthesis of choline, which plays a critical role in cell membrane structural integrity, cholinergic neurotransmission, cell signalling and lipid metabolism (Imbard *et al* 2013). SAME is the second most used cofactor in the cells after ATP, and is used by over 100 methyl transferases that act on DNA, RNA, proteins and for the synthesis of polyamides that stabilise DNA (Smith *et al* 2010).

SAME naturally exists as diastereoisomers and it is presently unclear whether both the R and the S forms are biologically active in humans. Evidence from a rat model suggests that they are equipotent (Dunne *et al* 1998). Oral doses achieve peak plasma concentrations within 3–5 hours after ingestion of an enteric-coated tablet (400–1000 mg). Enteric coating of SAME supplements is essential to ensure product stability and potency. Oral SAME has low systemic bioavailability due to first-pass effects and rapid metabolism. In vitro research by Wagner *et al* (2009) found that SAME absorption and the subsequent anti-inflammatory effects are enhanced by encapsulating SAME in liposomes derived from cholesterol. The half-life is reported to be 100 minutes, and excretion occurs via both urine and faeces (Najm *et al* 2004).

### MAIN ACTIONS

SAME is involved in myriad biochemical processes and metabolic pathways, chiefly as a methyl donor, where it is important for transmethylation reactions, including the synthesis of creatine, acetylcholine, carnitine, melatonin, glutathione (GSH), phospholipids, proteins, adrenaline, amino acids L-cysteine

and taurine and many small molecules, such as neurotransmitters, and for RNA and DNA methylation (Stabler *et al* 2009). SAME is closely linked with the metabolism of folate, vitamin B<sub>12</sub> and all sulfur-containing compounds.

This review only discusses those actions that have been confirmed clinically.

### Antidepressant activity

SAME supplementation produces a clinically significant antidepressant activity that has been demonstrated in numerous randomised controlled trials (RCTs).

The mode of antidepressant action is likely to involve several mechanisms. As a methyl donor, SAME plays a role in the metabolism and synthesis of various central nervous system neurotransmitters that play an integral part in synaptic transmission and behaviour, such as noradrenaline, dopamine and serotonin (Bottiglieri 1996, 2013, Stanger *et al* 2009). SAME improves tetrahydrobiopterin function, a cofactor required for the synthesis of monoamines (Felger & Lotrich 2013). Administration of oral SAME (800 mg daily) for 2 weeks significantly increased concentrations of 5-hydroxyindoleacetic acid in cerebrospinal fluid, a marker for increased serotonin in the brain (Bottiglieri 2013). Supplementation with SAME in depressed patients raises serotonin, dopamine and phosphatidylserine and improves neurotransmitter binding to receptor sites, resulting in increased activity (Pizzorno & Murray 2006). Evidence suggests that the dopaminergic activity is most prominent. One human study confirmed that 7 days of supplemental SAME (400 mg/day) decreased the exaggerated plasma noradrenaline levels found in depressed patients (Sherer *et al* 1986).

SAME is also involved in the formation of phosphatidylcholine, a major component of cell membranes and neurotransmission (Carney *et al* 1987). A recent review suggested that one mode of action in depression may be via the methylation of plasma phospholipids, altering the fluidity of the neuronal membrane and thereby modifying the response to monoamine neurotransmitters that traverse the membrane (Papakostas *et al* 2012). The results of studies on genetic, epigenetic and environmental

components of neuropsychiatric conditions such as depression, schizophrenia, bipolar disorder and autism point to the importance of the folate-methionine transsulfuration hub as a novel target pathway for treatment development (Ozbek et al 2008).

Additionally, SAME displays antioxidant, anti-inflammatory and neuroprotective activities which may all contribute to the antidepressant effect.

### Anti-inflammatory

A substantial body of evidence has identified clinically significant anti-inflammatory activity for SAME, with comparative trials showing it to be as effective as standard non-steroidal anti-inflammatory drugs (NSAIDs).

Although the mechanism of action remains unclear, it does not appear to be mediated by prostaglandins. SAME stimulates the synthesis of proteoglycans by articular chondrocytes and exerts a chondroprotective effect, according to in vitro research and tests with experimental animals (Barcelo et al 1987, Clayton 2007, Harmand et al 1987). In vitro studies using cultured rabbit synovial cells has found that SAME reduces tumour necrosis factor- $\alpha$  and fibronectin RNA expression (Gutierrez et al 1997). Clinical responses suggest a concomitant analgesic property. The mechanism for this was previously unknown; however Tsao et al (2012) noted that serotonin-induced pain hypersensitivity in mice is reduced by either SAME pretreatment or by the combined administration of SAME with selective antagonists for  $\beta_2$ - and  $\beta_3$ -adrenergic receptors, which have previously been shown to mediate pain signalling. This result highlights a potential analgesic mechanism.

### Hepatoprotective and restorative effects

SAME indirectly reduces oxidative stress in the liver by serving as a precursor for GSH. GSH is particularly important for reducing the toxic effects of free radical molecules generated by various substances, including alcohol and paracetamol. The use of SAME to prevent and reverse liver toxicity induced by paracetamol, cytokine, ethanol, carbon tetrachloride and ischaemia-reperfusion has been explored in animal models (Cederbaum 2010, Song et al 2004, Wallace et al 2002). An animal study confirmed that paracetamol reduces SAME levels in liver tissue nuclei and mitochondria, and coadministration of SAME prevented damage associated with paracetamol toxicity (Brown et al 2010). SAME also acts as the main methylating agent in the liver. Research with people with alcoholic and non-alcoholic liver diseases confirms that SAME supplementation significantly increases hepatic GSH levels (Vendemiale et al 1989). Additionally, in vitro and in vivo research has identified antifibrotic activity and enhanced production of interleukin-6, a key anti-inflammatory cytokine in the liver that assists regeneration and downregulation of tumour necrosis factor (Arteel et al 2003, Casini et al 1989, Song

et al 2004). Furthermore, SAME was found to minimise hepatic fibrogenesis by modulating nuclear factor- $\kappa$ B (NF- $\kappa$ B) signalling and inhibiting collagen processing (Thompson et al 2011).

Animal studies have shown that the availability of S-adenosylmethionine plays a critical role in the progression of liver regeneration via enhancement of GSH and polyamine synthesis (necessary for cell proliferation and differentiation), indicating that regulating hepatic transsulfuration reactions may be capable of modifying the recovery process after liver injury (Jung et al 2013).

### Anticancer activity

Research using animal models demonstrates that SAME is a natural growth regulator in hepatocytes and is antiapoptotic in healthy liver cells, but proapoptotic in hepatic carcinoma cells (Anstee & Day 2012, Lu & Mato 2005). SAME has been shown to inhibit angiogenesis and endothelial cell proliferation in vitro and in vivo (Sahin et al 2011).

The folate-methionine transsulfuration hub has been found to be altered in cancer (Smith et al 2010). Aberrant DNA hypomethylation in the promoter regions of gene, which leads to inactivation of tumour suppressor and other cancer-related genes in cancer cells, has been shown to be one of the most well-defined epigenetic hallmarks in gastric cancer (Qu et al 2013) and epithelial ovarian cancer (Guerrero et al 2012). SAME has been shown to ameliorate this hypomethylation in vitro and has also been shown to block mitogenic signalling in colon cancer cells in vitro (Chen et al 2007).

### OTHER ACTIONS

#### Prolactin and thyroid-stimulating hormone (TSH) effects

A double-blind, placebo-controlled study involving 20 subjects with depression identified a significant reduction in prolactin concentrations following 14 days of SAME treatment (Thomas et al 1987). The results of a study conducted in 1990, however, suggest that the effects on these hormones may be gender-specific, with women demonstrating an augmenting response of TSH and no effect on prolactin levels, whereas release of both TSH and prolactin was inhibited in male subjects (Fava et al 1990). If SAME does exert dopaminergic effects, as presently suspected, then it should also be taken into consideration that dopamine naturally inhibits both TSH and prolactin secretion in humans.

#### Antioxidant

Previous in vitro experimental research suggested that SAME acts as a direct antioxidant mainly by binding iron molecules in an inert form, thereby blocking iron-dependent interaction with molecular oxygen to generate reactive oxygen species (ROS), rather than by free radical scavenging (Caro & Cederbaum 2004). Recent in vitro research has shown that coadministration of SAME and *Saccharomyces*

*boulardii* (a probiotic yeast routinely used to prevent and treat gastrointestinal disorders) enhances the viability of *S. boulardii* in acidic environments, which may improve gastric survival in transit (possibly by preventing apoptosis via reduction of ROS) and the yeast's clinical efficacy (Cascio et al 2013).

## CLINICAL USE

Although SAME is administered as an oral supplement in Australia, it is also used in injectable dose forms in Europe. This is most likely to be because oral SAME has poor bioavailability and is subject to significant first-pass effects. Manufacturers have been investigating different preparations to increase oral bioavailability, such as SAME encapsulated in liposomes derived from cholesterol, which has demonstrated increased activity (Wagner et al 2009). This discussion will mainly focus on oral use.

### Depression

Both oral and parenteral SAME are effective treatments for major mood disorders according to a review of 45 RCTs involving depressed adults in Europe and the United States (Papakostas et al 2012). Papakostas et al (2012) and other authors' reviews have concluded that SAME, at a dose of between 1200 and 1600 mg/day, is superior to placebo and as effective as standard tricyclic antidepressants (imipramine). It is also better tolerated in the treatment of depressive disorders, without any documented increased risk of suicide (Bressa 1994, Delle Chiaie et al 2002, De Vanna & Rigamonti 1992, Dhingra & Parle 2012, Qureshi et al 2013). There has been less research conducted with SAME in combination with standard antidepressants, but what is available has been encouraging for partial responders to selective serotonin reuptake inhibitors (SSRIs) and serotonin noradrenaline reuptake inhibitors. Studies comparing SAME to SSRIs found that SAME has a faster onset of action (10 days) compared to SSRIs (21 days) and relatively few side effects, giving it an advantage (Mischoulon & Fava 2002).

SAME alone or combined with other supplements has also been shown to alleviate depression associated with musculoskeletal disease, liver disease, Parkinson's disease and HIV/AIDS (Qureshi et al 2013).

### Treatment-resistant depression

A number of early open-label studies found benefit of adjunctive treatment with SAME in treatment-resistant depression, with remission rates ranging from 22% to 43% after treatment-resistant depression patients were augmented with SAME (Alpert et al 2004, Rosenbaum et al 1990). A trial implementing 800–1600 mg/day SAME as an adjunctive agent in 30 treatment-resistant patients over 6 weeks revealed a staggering 50% response rate, with 43% of the sample experiencing remission of symptoms (Alpert et al 2004).

More recently, a double-blind RCT of 73 patients with treatment-resistant major depressive

disorder showed that coadministration of SAME (800 mg twice daily) with SSRI treatment produced significantly higher response and remission rates compared to the addition of placebo, using the Hamilton Depression Rating and Clinical Global Impression scales. Furthermore, no serious adverse effects occurred during the trial (Papakostas et al 2010). A secondary analysis of this clinical trial by the same group also confirmed that the coadministration of SAME improved the memory-related cognitive symptoms of major depressive disorder (Levkovitz et al 2012). Positive results such as these warrant further clinical investigation of SAME in an adjunctive role in refractory depression, a view that was shared in recent reviews of treatment-resistant depression (Kupfer et al 2012, Shelton et al 2010).

### Osteoarthritis

Treatment with SAME (1200 mg/day) is effective in the management of osteoarthritis and equally as effective as standard treatments, including celecoxib, piricoxam, indomethacin, ibuprofen and naproxen, according to a 2011 meta-analysis of six RCTs (sample sizes 36–493 participants) (De Silva et al 2011). In all trials, SAME was found to be equally as effective as the NSAID and more effective than placebo for pain and function. Drop-out rates were highest in the NSAID groups and lowest in the SAME groups. Similar results were reported in a previous meta-analysis of 11 RCTs involving almost 1500 patients; it also concluded that SAME was more effective than placebo and as effective as NSAIDs in reducing pain and improving functional limitation in patients with osteoarthritis of the knee. In addition, SAME-treated patients were 58% less likely to experience adverse effects than those treated with NSAIDs (Soeken et al 2002). A 2009 Cochrane systematic review of the use of SAME in osteoarthritis of the knee or hip ( $n = 656$ ) was more conservative and acknowledged that the action of SAME on both pain and function might be clinically significant; however larger trials are required for evidence to be definitive (Rutjes et al 2009).

The longest placebo-controlled study to date was conducted over 2 years and found that a loading dose of oral SAME 600 mg/day taken over the first 2 weeks, followed by a maintenance dose of 400 mg, produced an improvement in symptoms within the first month and no serious adverse effects (Konig 1987).

### Comparative studies

SAME (1200 mg/day) was just as effective in reducing pain intensity as nabumetone (1000 mg/day) over a period of 8 weeks in a 2009 study of 134 Korean patients (Kim et al 2009). Other comparative studies in humans have found that oral SAME (1200 mg) produces similar symptom-relieving effects as piroxicam (20 mg), ibuprofen (1200 mg), indomethacin (150 mg) or naproxen (750 mg) and celecoxib (200 mg/day) (Caruso & Pietrogrande 1987, Clayton 2007, Glorioso et al 1985, Maccagno et al 1987, Muller-Fassbender 1987, Vetter 1987).

In regard to celecoxib (200 mg/day), SAmE is as effective for symptom relief but has a slower onset of action according to a 16-week double-blind, crossover RCT of 61 individuals with osteoarthritis of the knee (Najm et al 2004). In this study, one month of treatment was required for full benefits to be observed.

### Fibromyalgia

Four double-blind trials have investigated the effects of SAmE in fibromyalgia, with all reporting positive findings (Jacobsen et al 1991, Tavoni et al 1987, 1998, Volkmann et al 1997), such as reduced number of trigger points and areas of pain, improved mood and reduced fatigue (Sarac & Gur 2006). Two studies used injectable SAmE (200 mg daily).

The largest study involved 44 patients with primary fibromyalgia and found that, during week 5, the group receiving SAmE (800 mg/day) experienced improvements in clinical disease activity, pain, fatigue, morning stiffness and one measurement of mood. Although encouraging, not all parameters were improved beyond placebo, such as tender point score and isokinetic muscle strength (Jacobsen et al 1991).

These results should not be surprising, given that one-third of all fibromyalgia patients are reported to suffer from depression and a meta-analysis of the effectiveness of antidepressants (including SAmE) in fibromyalgia deemed them a successful treatment strategy (O'Malley et al 2000). It concluded that tricyclic antidepressants, SSRIs and SAmE all improved sleep, fatigue, pain and wellbeing, but not necessarily trigger points.

### Schizophrenia

SAmE has been studied in the treatment of schizophrenia, largely based on biochemical considerations suggesting a possible benefit.

Meta-analyses have implicated polymorphisms in 5,10-methylenetetrahydrofolate reductase (MTHFR), encoding a critical enzyme in folate and homocysteine metabolism, in both schizophrenia and bipolar disorder (van Winkel et al 2010). These polymorphisms are functional and result in diminished enzyme activity, leading to lower folate and higher homocysteine levels, and both have been implicated in schizophrenia risk in two separate meta-analyses (Allen et al 2008, Shi et al 2008).

To date, only one small double-blind RCT has been conducted showing that SAmE (800 mg/day) taken for 8 weeks improved quality of life and reduced aggressive behaviour compared to placebo. The study included 18 people with long-term schizophrenia and also found female patients showed improvement of depressive symptoms and clinical improvement, but this did not correlate with serum SAmE levels. Additionally, two patients in the active group exhibited some exacerbation of irritability; however causality is difficult to determine (Strous et al 2009).

### Parkinson's disease

High-dose SAmE (800–3600 mg/day) treatment was investigated in a pilot study involving 11

depressed patients with Parkinson's disease, all of whom had been previously treated with other antidepressant agents and had no significant benefit or intolerable side effects. After 10 weeks, 10 patients had at least a 50% improvement on the Hamilton Depression Scale, with only one patient showing no improvement. The mean score before treatment was 27.09 and was 9.55 after SAmE treatment (Di Rocco et al 2000).

Numerous studies have demonstrated that treatment with L-dopa in patients with Parkinson's disease induces high levels of homocysteine and depletes SAmE (Chao et al 2012, De Bonis et al 2010). When supplemented with SAmE, folate, vitamin B<sub>12</sub> and vitamin B<sub>6</sub>, homocysteine levels decrease in people with Parkinson's disease taking L-dopa (Lamberti et al 2005).

Further clinical trials in patients with Parkinson's are currently underway (Meissner et al 2011).

### Liver cirrhosis

SAmE deficiency has been studied as a possible pathogenetic factor in several liver diseases, and its administration evaluated in the prevention and treatment of a variety of liver injuries, such as chronic hepatitis, pregnancy-induced liver injury, alcoholic hepatitis and paracetamol-induced liver damage (Vincenzi et al 2012). Depressed hepatic SAmE, especially together with a reduced SAM:SAH ratio, results in impaired transmethylation, producing increased fat deposition, apoptosis and accumulation of damaged proteins — all characteristic features of liver injury (Cave et al 2007, Kharbanda 2007). Primate studies have found that decreased hepatic SAmE concentrations and associated liver lesions, including mitochondrial injury, can be corrected with SAmE supplementation (Lieber et al 1990), with reduced markers of lipid peroxidation, histological evidence of liver injury and maintained mitochondrial GSH (Cave et al 2007).

### Alcoholic liver disease

In alcoholic patients with advanced liver cirrhosis, hepatic SAmE concentration is greatly decreased through alcohol exposure, increasing the risk of nucleotide imbalance, apoptosis and carcinogenesis (Cave et al 2007, Gao & Bataller 2011, Halsted 2013, Kharbanda 2007, Lieber 2002). While transient SAmE depletion is necessary for the liver to regenerate, chronic hepatic SAmE depletion may lead to malignant transformation as SAmE is a substrate for all DNA and histone methyltransferases, including those involved in activation of liver injury/repair genes (Halsted 2013, Lu & Mato 2005, 2008). A 2010 double-blind RCT of 13 participants with alcoholic liver disease asked to abstain from alcohol showed that both placebo and SAmE (1200 mg/day) for 24 weeks improved serum aspartate aminotransferase (AST), alanine aminotransferase (ALT) and bilirubin levels (due to abstinence from alcohol), but no significant improvements in steatosis, fibrosis or inflammation were noted in the SAmE group. These results may be due to the small

sample size and likely underpowering of the study, relatively short treatment timeframe or high dropout rate (30%) due to resumption of alcoholism during the study (Medici et al 2011).

A small follow-up expansion of this study found similar non-significant results; however this study was severely limited due to all 12 participants suffering severe fibrosis and/or metaplasia, with very few functioning hepatocytes at baseline (Le et al 2013). Two previous European clinical studies suggested that a longer treatment period with oral 1200 mg SAME may be effective in alcoholic liver disease, and in a 6-month Italian RCT of 17 patients with initially low hepatic GSH levels, oral SAME (1200 mg/day) normalised levels (Vendemiale et al 1989). In a subsequent 2-year European multicentre trial of 123 patients with alcoholic liver disease, total mortality or liver transplant incidence was reduced from 30% in the placebo group to 16% in the SAME group, but this was only noted after excluding the most severely ill patients from the analysis (Mato et al 1999).

A 2006 Cochrane review (updated in 2009) of SAME in alcoholic liver disease analysed results from nine RCTs that included a heterogeneous sample of 434 patients (Rambaldi & Gluud 2006). The methodological quality was considered low; however, eight of the trials were placebo-controlled. As a result, the analysis was based mainly on one trial that found no significant effects of SAME on all-cause mortality, liver-related mortality, liver transplantation or complications. The authors concluded that, based on such limited evidence, more long-term, high-quality randomised trials of SAME for these patients are required before SAME may be recommended for clinical practice. More recent reviews note that improved survival and reduction in liver transplants in patients receiving SAME are important positive outcomes (Halsted 2013, Vazquez-Elizondo & Bosques-Padilla 2012).

#### **Non-alcoholic fatty liver disease (NAFLD) or non-alcoholic steatohepatitis (NASH)**

Human studies have demonstrated that patients with liver disease have an impaired ability to convert methionine to SAME and decreased plasma and hepatic GSH levels (Cave et al 2007). SAME has been shown to improve GSH in patients with liver disease after 6 months of oral therapy. Of particular interest is recent evidence from animal studies which suggest that SAME depletion in the early stages of NASH may be a key point of disease progression into NAFLD (Lu & Mato 2008, Wortham et al 2008). Clinical trials have demonstrated benefit from SAME therapy in various forms of liver disease, including alcoholic cirrhosis, intrahepatic cholestasis of pregnancy and chemotherapy-induced NASH (Vincenzi et al 2012). SAME supplementation has also demonstrated attenuation of inflammation and liver injury in a nutritional deficiency model of steatohepatitis and clinical trials were carried out in NASH patients (Cave et al 2007). In lieu of more

solid evidence to support SAME as a therapeutic agent in NASH and NAFLD, the preferred current treatment is betaine, which by virtue corrects methylation by serving as a methyl donor and reduces SAME depletion (Kharbanda 2007, Kwon 2009, Singal et al 2011).

#### **Prevention of drug-induced liver toxicity**

Paracetamol is the leading cause of drug-induced liver failure, hepatotoxicity, and is known to be one of the most frequent side effects associated with different chemotherapy regimens. A recent clinical trial of 78 patients noted that administration of 800 mg/day SAME as adjunctive therapy was effective in reducing chemotherapy-induced liver toxicity from oxaliplatin plus bevacizumab in patients with metastatic colorectal cancer. AST, ALT, lactate dehydrogenase and total bilirubin were significantly reduced in the SAME group compared to placebo, and SAME supplementation significantly reduced chemotherapy course delay and dosage reductions due to liver toxicity (Vincenzi et al 2012). This study confirmed earlier research by the same group that determined SAME supplementation reduces chemotherapy-induced liver toxicity; similarly, in that trial, SAME supplementation was found to be associated with a significant lowering of AST and ALT values in 70% of the treated patients and also reduced chemotherapy delays or dose reductions due to transaminase elevation (Santini et al 2003).

#### **OTHER USES**

SAME is used to reduce pain in migraine headache because analgesic activity was reported at a dose of 400–800 mg/day in a group of migraine sufferers (Gatto et al 1986). A case report of 5 paediatric cases of Lesch–Nyhan disease (a rare X-linked recessive neurogenetic disorder) showed significant improvement in self-injury and aggressive behaviour as well as a milder reduction of dystonia when SAME was administered at a dose of 21–33 mg/kg/day (Chen et al 2013). It is also used in AIDS-related myelopathy and coronary artery disease, as these conditions have been associated with depleted SAME levels. Supplementation has also been prescribed in cases of general fatigue, poor digestion and allergies.

#### **Alzheimer's dementia (AD)**

AD has a multifactorial aetiology that includes nutritional, genetic and environmental risk factors, none of which in isolation is sufficient to account for all cases of AD (Shea & Chan 2008). There is a growing body of evidence indicating that some SAME-mediated reactions are compromised in AD and age-related neurodegeneration: SAME is diminished and its metabolites SAH and homocysteine are increased, the accumulation of which also impairs SAME reactions (Kennedy et al 2004). In patients with AD, decreased SAME concentrations have been observed in cerebrospinal fluid along with increased concentrations of SAH in brain tissue

(Bottiglieri 2013). Inhibited methylation reactions and hypomethylation of proteins that regulate levels of brain tissue phosphorylated- $\tau$  have also been noted in addition to hypomethylation of genes that affect the expression of  $\beta$ -amyloid protein (Bottiglieri 2013).

Interestingly, SAmE supplementation reduced amyloid production, increased spatial memory and reduced plaque spread in a 2012 *in vivo* study, suggesting a possible role in AD (Fuso et al 2012).

To date, no clinical trials have been published to investigate whether supplemental SAmE has benefits in AD, although the theoretical considerations make a good case for further investigation to be undertaken (Panza et al 2009).

### Cholestasis of pregnancy

Cholestasis of pregnancy is characterised by elevated bilirubin and pruritus, and is associated with a high risk of a number of adverse perinatal outcomes, including preterm birth, meconium passage, fetal distress and fetal death (Anstee & Day 2012). A clinical trial of 78 pregnant volunteers with cholestasis showed that treatment with either SAmE or ursodeoxycholic acid (UDCA) effectively reduced pruritus; however the UDCA group showed greater improvement in bile acid secretion (Roncaglia et al 2004). However, a subsequent Cochrane review concluded that there was insufficient evidence to recommend either SAmE or UDCA for the treatment of cholestasis of pregnancy (Burrows et al 2010).

### Hepatitis C management

An open-label pilot study of 29 patients with chronic hepatitis C who failed previous therapy with interferon- $\alpha$  and ribavirin were coadministered SAmE and betaine for 6–12 months, resulting in significant improvement of early virological response rates without significant additional adverse effects (Filipowicz et al 2010). SAmE was also found to improve early viral responses and interferon-stimulated gene induction in hepatitis C non-responders (Feld et al 2011). Larger trials are needed to confirm this combination as an effective adjunct treatment.

### Cancer

There is a paucity of clinical trials exploring the role of SAmE supplementation in cancer; however, pre-clinical research and biochemical considerations provide a basis for its future investigation.

#### Hepatic cancer

Due to its role in the regulation of growth and apoptosis of hepatocytes, SAmE is being investigated as a possible preventive or treatment agent in hepatocellular carcinoma (Lu & Mato 2005, 2008), and has been administered in postradiofrequency ablation formulas to enhance recovery of hepatic tissue at an intravenous dose of 1000 mg for 2–3 days in conjunction with *Silybum marianum* (Feng et al 2012).

### Colorectal cancer

There is considerable evidence that aberrant DNA methylation plays an integral role in oncogenesis, and genomic DNA hypomethylation has been reported in colorectal tumour tissue (Nagaraju & El-Rayes 2013). However few studies examine changes in intermediate methylation compounds: one study determined that folate concentration is diminished and SAmE and SAH is increased in neoplastic colonic mucosa when compared to healthy colon tissue (Alonzo-Aperte et al 2008). More studies are needed to confirm whether genomic DNA methylation measurements are functional biomarkers in colorectal cancer.

### Breast and cervical cancer

A number of studies have explored the association between MTHFR C677T polymorphism and susceptibility to cervical and breast cancer and cervical intraepithelial neoplasia (Alshatwi 2010, Luo et al 2012). A recent meta-analysis confirmed that SAmE is known as an important DNA methylator, which may have a role in the prevention of pro-oncogene expression in cervical cancer; however, results remained controversial and further studies are needed (Luo et al 2012).

### DOSAGE RANGE

Because SAmE is rapidly oxidised when exposed to air, the quality of the tablets is important in preserving potency. SAmE is better absorbed when taken at least 20 minutes before breakfast and 20 minutes before lunch. As an activating antidepressant, it can disturb sleep if taken after 4 pm (Bottiglieri 2013).

### Based on clinical studies

- Depression: 1200–3200 mg/day in divided doses have been used in practice. Sometimes it is started as 200 mg twice daily, increased on day 2 to 400 mg twice daily and then increased again to 400 mg three times daily on day 10, until reaching a therapeutic dose of 400 mg four times daily by day 20.
- Osteoarthritis: 1200 mg/day in divided doses, taken as above, with a reduced dose of 400 mg/day used as a maintenance dose once a response occurs.
- Fibromyalgia: 600–800 mg/day in divided doses.
- Liver disease: 400–1200 mg/day in divided doses, although larger doses have been used.
- Parkinson's disease: 800–3600 mg/day in divided doses.
- Migraine: 400–800 mg/day in divided doses.
- Reducing aggression in schizophrenia: 800 mg/day (only under supervision).

### ADVERSE REACTIONS

Orally, SAmE is generally well tolerated. Mild gastrointestinal discomfort (nausea) is the most common side effect reported in clinical studies, although

anxiety, headache, urinary frequency, dizziness, nervousness, sweating and pruritus have also been reported (Ravindran & da Silva 2013). It has been reported that side effects are more likely with higher doses and may be minimised by consuming SAME before food.

### SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

### Tricyclic antidepressants and other serotonergic agents

Coadministration of SAME with SSRIs has shown benefits in partial responders and may be a useful combination under professional supervision.

### Hepatotoxic drugs

SAME may reduce hepatic injury caused by agents such as paracetamol, alcohol and oestrogens — potentially beneficial interaction.

### L-Dopa

SAME methylates levodopa, which could theoretically reduce the effectiveness of levodopa given for Parkinson's disease; however, the effect has not been observed clinically — observe patients.

### Thyroxine

Caution and monitoring may be warranted.

### Betaine

In studies supplementing mice with betaine, significant increases in SAME were observed with a three-fold elevation of the activity of methionine adenosyltransferase — observe.

### CONTRAINDICATIONS AND PRECAUTIONS

Previous case reports of agitation and mania in bipolar patients caution that SAME should be avoided in people with bipolar disorder during the depressive phase (Andreescu et al 2008, Bogarapu et al 2008) and used with caution by people with schizophrenia or schizoaffective disorder (Guidotti et al 2007). However, separate research of coadministration of SAME with SSRIs or venlafaxine reported no unmasking of hypomanic or manic symptoms (Alpert et al 2004, Papakostas et al 2010). Use under professional supervision to promote patient safety.

### PREGNANCY USE

SAME has been used intravenously in the last trimester of pregnancy with no adverse effects to mother or fetus. However, safety has not yet been conclusively established for either injectable or oral dose forms and possible effects on prolactin levels need to be considered.

### PATIENTS' FAQs

#### What will this supplement do for me?

SAME has anti-inflammatory, analgesic, antidepressant and protective effects on the liver. It effectively reduces pain and inflammation in osteoarthritis and elevates mood in depression. In fibromyalgia, SAME reduces pain, fatigue and morning stiffness and may also reduce pain in migraine headache.

#### When will it start to work?

Beneficial effects are usually seen within 4–5 weeks for osteoarthritis, whereas antidepressant effects are experienced within 1 week. Benefits in fibromyalgia can take up to 6 weeks to establish.

#### Are there any safety issues?

SAME should only be used under professional supervision by people with bipolar disorder, schizophrenia or schizoaffective disorder, Parkinson's disease or taking antidepressant medicines. Monitoring of homocysteine levels may be required with long-term supplementation.

### Practice points/Patient counselling

- SAME is involved in myriad biochemical reactions within the body. It is found within every cell and is a precursor for the synthesis of the antioxidant GSH and an important methyl donor.
- Clinically, it has significant anti-inflammatory, analgesic and antidepressant effects and is an effective treatment in depression and osteoarthritis.
- A 2011 meta-analysis concluded that SAME is as effective as commonly used NSAIDs in reducing pain and improving functional limitation in patients with osteoarthritis without the adverse effects associated with NSAIDs. A recent study has found that it is as effective as celecoxib for providing symptom relief; however, SAME has a slower onset of action.
- Clinical trials have also shown it to be a safe and effective treatment for depression — comparable with tricyclic antidepressant drugs, yet with a faster onset of action. SAME also provides additional benefits when coadministered with SSRIs in treatment-resistant depression.
- It may also have benefits for patients with alcoholic liver disease and hepatitis C and for the prevention of drug-induced liver toxicity.
- SAME may also be useful in fibromyalgia, and possibly migraine headache. Other uses include treatment of general fatigue, elevated homocysteine levels, allergies and poor digestion.

# Saffron

**HISTORICAL NOTE** Saffron's name is derived from the Arab word for yellow, reflecting the high concentration of carotenoids present in the saffron flowers' stigmas, which contribute most to the colour profile of this spice (Melnik et al 2010). Saffron has long been revered as both spice and medicine by many cultures including ancient Greece, the Middle East, China and Europe. Frescos uncovered in Greece clearly depict the use of saffron stigma as a medicine over 3600 years ago (Dwyer et al 2011). The famous Persian academic and physician Avicenna listed the traditional uses of saffron and its pharmacological activities in Book II, Canon of Medicine (al-Qanun fi al-tib) and described it as an antidepressant, hypnotic, anti-inflammatory, hepatoprotective, bronchodilatory and aphrodisiac and others. It is interesting to note that many of these effects have been tested in modern times and confirmed in vivo (Hosseinzadeh & Nassiri-Asl 2013). The mood elevating activity of saffron were also reported in a traditional Chinese medicine (TCM) text from the Mongol dynasty and in the mid-1800s by an English herbalist, Christopher Catton (Dwyer et al 2011). Today, saffron is cultivated in many countries such as Iran, Europe, Turkey, Central Asia, India, China, Algeria, Australia and New Zealand, and is considered the most expensive spice in the world.

## LATIN BINOMIAL/CLASS

*Crocus sativus* — Iridaceae family

## OTHER NAMES

Azafrán, azafron, crocus cultivé, Indian saffron, kashmira, kesar, kumkuma, safran cultivé, safran Espagnol, safran des Indes, safran véritable, Spanish saffron, true saffron, zafran.

## PLANT PART USED

Dried stigma and petal.

It is estimated that it takes approximately 75,000 crocus blossoms or 225,000 stigmas to produce just one pound (454 g) of saffron. The stigmas must be hand-picked from the delicate blossoms upon opening to preserve the desirable volatile components before they evaporate in the heat of the day (Melnik et al 2010).

## CHEMICAL COMPONENTS

There are over 150 volatile and non-volatile compounds in saffron; however, not all have been identified. The most important constituents of stigmas of *C. sativus* are carotenoids (e.g. crocetin, crocins,  $\alpha$ -carotene, lycopene, zeaxanthin), monoterpene aldehydes (e.g. picrocrocin and safranal), monoterpenoids (e.g. crocusatines), isophorones and flavonoids. The water-soluble crocins are the primary colouring pigment in saffron and make up ~10%. Picrocrocin is the precursor to safranal and provides the bitter taste, whereas safranal provides the aroma (Hosseinzadeh & Nassiri-Asl 2013). The crocin concentration varies depending on growing geographical location and processing methods. For example, Greek saffron has the highest concentration of crocins followed by India and New Zealand (Alavizadeh & Hosseinzadeh 2014).

## MAIN ACTIONS

Many in vivo studies have been conducted for saffron, crocin and safranal and revealed numerous pharmacological effects.

### Antidepressant

This has been demonstrated in numerous double-blind RCTs and confirmed in a recent meta-analysis (Hausenblas et al 2013). Both the saffron stigma and petal display antidepressant activity.

The antidepressant-like action appears to be due to increasing cAMP response element-binding protein (CREB), BDNF and VGF levels in hippocampus (Vahdati et al 2014). Crocin physically binds to a wide range of cellular proteins such as structural proteins, membrane transporters, and enzymes involved in ATP and redox homeostasis and signal transduction (Hosseinzadeh et al 2014). In vivo research has also identified that safranal and crocin induce uptake inhibition of dopamine, noradrenaline and serotonin (Hosseinzadeh et al 2004).

### Improved learning, memory and neuroprotection

Multiple preclinical studies using different animal models consistently demonstrate that saffron and crocin improves various aspects of learning and memory. Saffron extract demonstrates moderate acetyl choline esterase inhibition with crocetin and dimethylcrocetin binding simultaneously to the catalytic and peripheral anionic sites and safranal interacting with only the binding site of the AChE (Geromichalos et al 2012).

Neuroprotection has also been demonstrated in vivo using different models chiefly via an antioxidant mechanism. In addition, the crocin constituent specifically inhibits neuronal cell death induced by both internal and external apoptotic stimuli. It modulates the expression of Bcl-2 family proteins which

leads to a marked reduction in TNF- $\alpha$ -induced release of cytochrome c from the mitochondria. Crocin also blocks the cytochrome c-induced activation of caspase-3 (Soeda et al 2001).

One study showed that crocetin (8 mg/kg) protected cerebrocortical and hippocampus neurons against ischaemia resulting in improved spatial learning memory in rats after chronic cerebral hypoperfusion (Tashakori-Sabzevar et al 2013). Similarly, crocin (25 mg/kg) and saffron extract (250 mg/kg) given IP significantly improved spatial cognitive abilities following chronic cerebral hypoperfusion in another rat study, most likely due to an antioxidant mechanism (Hosseinzadeh et al 2012).

Crocetin also prevented hippocampal neuron number loss in diabetic rats and improved learning and memory impairments (Tamaddonfard et al 2013). In addition, the long-term IP injection of crocin at doses of 15 and 30 mg/kg improved blood TCA, MDA, glucose, and insulin changes induced by streptozotocin. In vivo research also indicates that pretreatment with saffron saved many dopaminergic cells of the substantia nigra pars compacta (SNc) and retina in a mouse model of Parkinson's disease (Purushothuman et al 2013).

Oral crocin (100 mg/kg) administered for 21 consecutive days to streptozotocin-lesioned rats improved cognitive performance and resulted in a significant reduction in MDA levels and elevation in total thiol content and GPx activity indicating antioxidant activity (Naghizadeh et al 2013). A lower dose of crocin (30 mg/kg) given IP was also found to effectively ameliorate the cognitive deficits caused by streptozotocin-lesioned rats in another study (Khalili & Hamzeh 2010).

The memory impairing effects of chronic stress were attenuated by treatment with saffron and crocin according to another animal study (Ghadroost et al 2011). Those test animals that received saffron extract or crocin had significantly higher levels of lipid peroxidation products, significantly higher activities of antioxidant enzymes including glutathione peroxidase, glutathione reductase and superoxide dismutase and significantly lower total antioxidant reactivity capacity. Interestingly, crocin significantly decreased plasma levels of corticosterone compared to controls receiving vehicle.

Ethanol-induced learning impairment was improved with saffron extract in a study with test mice. It also prevented ethanol-induced inhibition of hippocampal long-term potentiation, a form of activity-dependent synaptic plasticity that may underlie learning and memory (Abe & Saito 2000).

Treatment with crocin (15 and 30 mg/kg) counteracted delay-dependent recognition memory deficits in normal rats, suggesting that these carotenoids modulate storage and/or retrieval of information. In further testing, crocins in high strength (30 mg/kg), and to a lesser extent a lower dose (15 mg/kg) attenuated scopolamine (0.2 mg/kg)-induced performance deficits in a different memory model (Pitsikas et al 2007).

## Anticancer

Anticancer activity for saffron and its constituents has been demonstrated in various in vitro and in vivo studies (Rastgoo et al 2013). For example, crocin exhibits mild cytotoxic effects on a leukemia cell line which might be mediated through the increase of DNA fragmentation (Rezaee et al 2013). Saffron has also been shown to exert a significant chemopreventive effect against liver cancer through inhibition of cell proliferation and induction of apoptosis in vivo. The effect appears to be mediated by modulating oxidative damage and suppressing the inflammatory response (Amin et al 2011).

## OTHER ACTIONS

Diazinon (DZN) is one of the most widely used insecticides in agricultural pest control and has been shown to induce hepatotoxicity and cardiotoxicity with subchronic exposure. Saffron has been shown to attenuate these toxic effects in vivo (Lari et al 2013, Razavi et al 2013).

Hypotensive activity has been reported for the aqueous extract of saffron stigma in vivo, which appear to be attributable, in part, to the actions of two major constituents, crocin and safranal (Imenshahidi et al 2010). It seems that safranal is more important than crocin for producing this effect.

Aqueous and ethanolic extracts of stigma and its constituents interact with the opioid system and reduced morphine withdrawal syndrome in an animal model (Hosseinzadeh & Jahanian 2010).

Anxiolytic and hypnotic activity has also been demonstrated for saffron aqueous extract and safranal in vivo (Hosseinzadeh & Noraei 2009).

Aphrodisiac activity was observed in a study of male rats for an aqueous saffron extract and crocin but not for safranal (Hosseinzadeh et al 2008).

Anti-tussive and anticonvulsant activities have also been demonstrated in vivo for saffron or its derivatives (Hosseinzadeh & Ghenaati 2006, Hosseinzadeh & Talebzadeh 2005).

Saffron showed some effects on blood coagulation and platelet aggregation in vitro and in vivo studies; however, a placebo controlled study of 60 healthy volunteers found that treatment with saffron tablets for 1 week at either 200 mg/day or 400 mg/day did not induce any significant changes to either coagulant or anticoagulant systems (Ayatollahi et al 2013).

## CLINICAL USAGE

Saffron has gained popularity in the treatment of mental health disorders, particularly depression. It is also used for impaired memory in dementia and shows promise in PMS and early age-related macular degeneration.

### Depression

Saffron has been used since antiquity for depression in several different cultures. Numerous controlled studies have been conducted with saffron, either

stigma or petal, preparations and consistently report positive results showing superiority over placebo and effectiveness similar to standard antidepressant medications. The most studied preparations are by Novin Zaferan Co and IMIPRAN, Iran. Of note, studies tend to be small, last no longer than 6 weeks and most research has been conducted in one country, Iran. Ideally, the impressive results reported thus far should be confirmed in other countries involving a larger number of subjects.

A 2013 meta-analysis of five randomised controlled trials (RCTs) ( $n = 2$  placebo controlled trials,  $n = 3$  antidepressant controlled trials) found a large effect size for saffron supplementation compared to placebo for treating depressive symptoms in adults with major depressive disorder (MDD) ( $P < 0.001$ ) (Hausenblas et al 2013). There was no significant difference between saffron and antidepressant treatment, indicating that both treatments were similarly effective in reducing depression symptoms. Importantly, the quality of the trials was considered high, using the Jadad score. Three studies investigated *Crocus sativus* (saffron) stigma, two investigated saffron petal, and one compared saffron stigma to petal.

A 6-week double-blind, placebo-controlled RCT of 40 outpatients with major depression (diagnosed as per structured clinical interview for DSM IV) found that treatment with saffron petal (30 mg/day) was significantly superior to placebo for improving patients' mood according to the Hamilton Depression Rating Scale (HAM-D) ( $P < 0.001$ ) (Moshiri et al 2006). Significant superiority over placebo was observed by week 2 of treatment which continued at week 6. At the end of the study, HAM-D scores were reduced by 60% with saffron compared to 22% reduction with placebo ( $P < 0.001$ ).

Previously, stigmas of saffron (30 mg/day) were found to be superior to placebo for producing a significantly better outcome using the HAM-D in a 6-week, double-blind RCT involving 40 outpatients with mild to moderate depression ( $P < 0.001$ ) (Akhondzadeh et al 2005). Mean HAM-D scores reduced by 54% with saffron compared to 23% for placebo by week 6.

#### Compared to standard treatments

The efficacy and safety of saffron (30 mg/day; SaffroMoods, IMPIRAN) was compared to fluoxetine (40 mg/day) over 6 weeks in people with mild to moderate depression ( $n = 40$ ) using a double-blind, RCT design (Shahmansouri et al 2014). Using the HAM-D at weeks 3 and 6, no significant difference was detected between two groups ( $P = 0.62$ ), and remission and response rates were not significantly different either ( $P = 1.00$  and  $P = 0.67$  respectively). In regards to safety, there was no significant difference between two groups in the frequency of adverse events.

Previously, an 8-week pilot double-blind randomised trial of 40 adult outpatients who met the

DSM-IV criteria for major depression found that saffron petal treatment (15 mg twice daily) was as effective as fluoxetine (10 mg twice daily) after 8 weeks ( $P = 0.84$ ) (Akhondzadeh et al 2007). In addition, in both treatments, the remission rate was 25% and no significant differences were observed for side effects. Patients had a baseline HAM-D score of at least 18 in this study.

Saffron (30 mg/day) was found to be as effective as fluoxetine (20 mg/day) in another double-blind RCT of 40 outpatients with mild-to-moderate depression ( $P = 0.71$ ) (Noorbala et al 2005). The 6-week study further confirmed no difference in side effects between the two groups.

Comparisons with imipramine have also been done in RCTs, finding that saffron is as effective a treatment (Akhondzadeh et al 2004). One double-blind RCT involving 30 patients with mild to moderate depression showed that saffron (30 mg/day) produced similar results to imipramine (100 mg/day) ( $P = 0.09$ ). Both treatments reduced HAM-D scores to a similar extent compared to baseline, 55% reduction with saffron and 58% with imipramine (both  $P < 0.0001$ ). As expected, the imipramine group experienced anticholinergic side effects such as dry mouth and sedation to a greater extent than with saffron treatment.

#### Reducing sexual dysfunction side effects of antidepressants

Saffron (30 mg/day) was used over 4 weeks in a double-blind RCT of 34 women stabilised on fluoxetine (40 mg/day) for at least 6 weeks and experiencing a subjective feeling of sexual dysfunction (Kashani et al 2013). By the end of 4 weeks, patients receiving saffron reported significant improvements using the Female Sexual Function Index (FSFI) ( $P < 0.001$ ), arousal ( $P = 0.028$ ), lubrication ( $P = 0.035$ ) and pain ( $P = 0.016$ ), but no changes in the domains for desire, satisfaction or orgasm compared to placebo.

#### Alzheimer's dementia (AD)

Two clinical trials have been conducted in people with Alzheimer's dementia, producing encouraging results (Akhondzadeh et al 2010a, 2010b).

One double-blind RCT involving people with mild to moderate AD compared oral saffron (15 mg twice per day) to placebo over 16 weeks. Active treatment with saffron produced a significantly better outcome on cognitive function than placebo and no significant differences in the two groups in terms of observed adverse events (Akhondzadeh et al 2010a).

#### Compared to standard treatments

Previously, a longer 22-week double-blind RCT involving 54 volunteers aged 55 years or older with mild to moderate AD found that saffron (30 mg/day) was as effective from a clinical and cognitive perspective as donepezil (5 mg twice daily). Saffron was the better tolerated treatment as donepezil was

associated with significantly more episodes of vomiting (Akhondzadeh et al 2010b).

### Premenstrual syndrome (PMS)

Positive results were obtained in a double-blind RCT using saffron stigma (30 mg/day) in women with PMS symptoms starting at least 6 months previously (Agha-Hosseini et al 2008). The treatment was compared to placebo over two menstrual cycles and found to reduce symptoms as measured by the Total Premenstrual Daily Symptoms and HAM-D.

### Age-related macular degeneration (ARMD)

Due to the high concentration of carotenoids in saffron and its traditional history of use in improving vision, saffron has been investigated in ARMD with encouraging results.

A crossover RCT of 25 people with early ARMD found that supplementation with saffron (20 mg/day) over 3 months significantly improved retinal flicker sensitivity compared to placebo (Falsini et al 2010). Similar results were obtained in a recent pilot study of 33 people with early ARMD which also showed that oral saffron (20 mg/day) taken for 3 months significantly improved flicker sensitivity estimate compared to baseline ( $P < 0.01$ ), a change which remained stable throughout the follow-up period of 8 months (Marangoni et al 2013). Piccardi et al (2012) followed the cohort from the previous study by Falsini et al (2010) and found that saffron (20 mg/day) taken over an average treatment period of 14 months maintained the improvements in flicker sensitivity seen at 3 months, suggesting long-term efficacy (Piccardi et al 2012).

### Immunomodulation

A dose of 100 mg/day of saffron increased IgG levels and decreased IgM compared to baseline and placebo after 3 weeks ( $P < 0.01$ ) in a double-blind RCT involving healthy male volunteers. The treatment also decreased the percentage of basophils compared with baseline, but increased the percentage of monocytes compared with placebo ( $P < 0.05$ ).

The effects were short-lived as all parameters returned to baseline levels after 6 weeks (Kianbakht & Ghazavi 2011).

### Other uses

Saffron is used as a culinary spice to colour food yellow and add flavour and also as a dye for clothing and to provide fragrance in perfumes. It is traditionally used as a medicine to improve digestion, elevate mood, as an aphrodisiac, relaxant and hypnotic, anti-inflammatory, hepatoprotective agent and bronchodilator (Hosseinzadeh & Nassiri-Asl 2013). It has also been used traditionally to relieve pain (e.g. toothache and teething infants), to treat both bacterial and fungal infections, for reproductive complaints ranging from amenorrhoea and infertility to pregnancy termination and contraception

and used topically in skin conditions (e.g. psoriasis, eczema and wounds).

Topically, saffron is currently used as an ingredient in some cosmetic preparations in countries such as Japan and has demonstrated a sunscreen activity in vitro (Hosseinzadeh & Nassiri-Asl 2013).

## DOSAGE RANGE

### According to clinical studies

- Mild to moderate depression: saffron petal treatment (15 mg twice daily) or saffron stigma (30 mg/day) with effects starting within 2 weeks.
- Female sexual dysfunction due to fluoxetine: saffron 30 mg/day for at least 4 weeks.
- Alzheimer's dementia: saffron (15 mg twice daily) long-term.
- PMS: saffron (15 mg twice daily) with effects starting after 2 menstrual cycles.
- Early age-related macular degeneration: saffron 20 mg/day long-term.

## ADVERSE REACTIONS

In RCTs for depression, saffron (30 mg/day) is as well tolerated as fluoxetine (20–40 mg/day) and better tolerated than imipramine (100 mg/day). Crocin tablets (20 mg/day) taken for 1 month did not induce any major adverse events or change haematological, biochemical, hormonal or urinary parameters when compared to placebo in healthy adult volunteers (Mohamadpour et al 2013). Less serious side effects reported include nausea and vomiting, diarrhoea and dizziness with high doses.

## Toxicity

Saffron has a high  $LD_{50} = 20$  g/kg, which explains why it is considered safe for human consumption (Bisset & Wichtl 1994).

## Significant interactions

No clinical investigation has been undertaken into the potential for drug interactions with saffron.

## Antidepressants

Due to the fact that saffron exhibits significant antidepressant activity, concomitant use should be carefully supervised. It is theoretically possible that pharmaceutical antidepressant dosage requirements will decrease with the addition of saffron in therapeutic doses.

## CONTRAINDICATIONS AND PRECAUTIONS

Saffron should be used under professional supervision in the treatment of any mental health condition to promote safety. It should not be used by people with an allergy to saffron or its components.

## PREGNANCY USE

Saffron has been used as a spice and food colouring agent for centuries and is likely to be safe when consumed in the usual dietary doses. Whether high dose saffron is safe in pregnancy remains to be confirmed.

An animal study utilising crocin and safranal found these substances reduced length and weight of fetuses, growth retardation and induced mainly skeletal malformations when administered to pregnant mice (Moallem et al 2013). The safety implications for saffron use during pregnancy should be investigated further.

### Practice points/Patient counselling

- Saffron is an expensive and distinctive spice that has also been used as a medicine since ancient times by several different cultures.
- Double-blind studies show that saffron is effective in mild to moderate depression and as effective as fluoxetine, with benefits starting within 1–2 weeks. It may also improve some aspects of sexual dysfunction experienced by women taking fluoxetine.
- Saffron may also improve symptoms in PMS when used for at least two menstrual cycles and improve some aspects of age-related macular degeneration when used long-term.
- Preclinical studies and two human trials also indicate possible cognitive benefits in Alzheimer's dementia.
- Safety in pregnancy has not been confirmed for high-dose saffron treatment.

## PATIENTS' FAQs

### What will this herb do for me?

Saffron is an effective treatment for mild to moderate depression and possibly premenstrual syndrome and for improving cognition in Alzheimer's dementia.

### When will it start to work?

Benefits in mild to moderate depression appear within 1–2 weeks of use, whereas benefits in PMS or dementia take several months of continued use.

### Are there any safety issues?

Saffron is well tolerated. High doses are not recommended in pregnancy until safety can be confirmed.

## Sage

**HISTORICAL NOTE** The *Salvia* genus is one of the largest groups of the Lamiaceae family with over 700 species spread throughout the world (Nickavar et al 2005). Sage has been used since ancient times as an antiseptic, astringent, tonic, carminative, antispasmodic, anti-inflammatory and to reduce sweating in various traditional medicine systems. The name 'Salvia' derives from the Latin *salvere* (to be saved) (Blumenthal et al 2000). Sage oil is used as a culinary spice and as a fragrance in soaps and perfumes. The fragrance is said to suppress the odour of fish.

### OTHER NAMES

Broad-leafed sage, common sage, dalmatian sage, garden sage, meadow sage, Spanish sage, true sage

### BOTANICAL NAME/FAMILY

*Salvia officinalis*, *Salvia lavandulaefolia*, *Salvia hypoleuca* Benth (family Labiatae or Lamiaceae).

### PLANT PART USED

Leaf

### CHEMICAL COMPONENTS

The exact chemical constituents depend on geographical and climatic conditions, as well as harvesting conditions, distillation method and the part of the plant used (Nickavar et al 2005). The leaves contain up to 2.5% essential oil, which contains thujone, cineol and camphor, as well as humulene, pinene, camphene, limonene, carnosol and rosmarinic acid. In addition, the leaves contain catechin-type tannins, diterpene bitter principles, triterpenes, steroids, flavones, and flavonoid glycosides, together with polysaccharides. Sage is a rich source of beta-carotene, vitamins C and B-complex (Fisher &

Painter 1996). The flowering parts of *S. hypoleuca* contain bicyclogermacrene, (E)-beta-caryophyllene, viridiflorol, spathulenol, beta-pinene and delta-pinene. Pharmacopoeial grade sage leaf must contain not less than 1.5% thujone-rich volatile oil (Blumenthal et al 2000).

### MAIN ACTIONS

#### Antimicrobial

Sage is reported to have antimicrobial activity attributed to the thujone, thymol and eugenol contents of the volatile oil (Shapiro et al 1994), as well as its rosmarinic acid content (Petersen & Simmonds 2003). The phenolic acids, salvins and monomethyl ethers have also been attributed with antimicrobial activity. Overall, activity has been reported in vitro against *Escherichia coli*, *Salmonella* spp, *Shigella sonnei*, *Klebsiella ozanae*, *Bacillus subtilis* and various fungi, including *Candida albicans* (Newell et al 1996). Phenolic extracts have also shown antibacterial activity against *Enterococcus* (Feres et al 2005). There is some disagreement over whether sage is an effective

bacteriostatic agent against *Staphylococcus aureus*. Sage had some in vitro antimicrobial effects on saliva samples from periodontally healthy and diseased subjects, although it had less activity than clove or propolis (Feres et al 2005). Sage essential oil has been shown to have effective inhibitory activity against microorganisms, such as *Klebsiella* spp, *Enterobacter* spp, *E. coli*, *Proteus mirabilis* and *Morganella morganii*, isolated from urinary tract infection (Santos Pereira et al 2004). There are also reports that sage may also be fungistatic and virustatic (Eidi et al 2005).

In vitro studies investigating the effect of digestive secretions on oral doses of sage concluded that any antimicrobial effects will probably be deactivated in the gastrointestinal tract after oral ingestion and thus *S. officinalis* is unlikely to demonstrate a systemic antibiotic action (Vermaak et al 2009).

Sage extracts are used as sources of antioxidant and antimicrobial protection against food decay in the food industry.

### Antioxidant

Sage extracts have been shown to have strong antioxidant activity (Matsingou et al 2003, Pizzale et al 2002), with labiatic acid and carnosic acid reported to be the active compounds (Perry et al 2003). According to in vivo studies with animal models, ingestion of sage infusion improves the liver's antioxidant status (Lima et al 2005) and protects against azathioprine-induced toxicity (Amin & Hamza 2005). However, sage essential oil did not show protective effects against toxicity from an oxidative compound in isolated rat hepatocytes (Lima et al 2004).

### Astringent

The high tannin content of sage supports its reported astringent activity.

### Antispasmodic

Sage oil has antispasmodic effects in laboratory animals (Newell et al 1996) and this is likely to be due to the irritating effects of the volatile oil. There is some evidence that sage oil may also exert a centrally mediated antisecretory action.

### Anxiolytic

Rosmarinic acid, which is a component of sage essential oil, produces an anxiolytic-like effect without exerting locomotor alterations or DNA damage in the brain tissue of rats (Pereira et al 2005). According to in vitro tests, compounds in the methanolic extract have an affinity for human brain benzodiazepine receptors (Kavvadias et al 2003).

### Anticholinesterase

In vitro and in vivo studies suggest that sage essential oil and some individual monoterpenoid constituents inhibit acetylcholinesterase activity (Perry et al 2003). An extract of the sage leaf exhibited

dose-dependent, in vitro inhibition of acetylcholinesterase (Kennedy & Scholey 2006).

### Antidiabetic and lipid lowering effects

Sage ethanolic extract exhibits a number of mechanisms of relevance in diabetes according to animal studies. It significantly decreased serum glucose in diabetic rats without affecting insulin release (Eidi et al 2005). Oral administration of 0.2 and 0.4 g/kg body wt. of sage extract for 14 days exhibited a significant reduction in serum glucose, triglycerides, total cholesterol, urea, uric acid, creatinine, AST, ALT and increased plasma insulin in streptozotocin-induced diabetic rats but not in normal rats. Glibenclamide was used as reference and showed similar antidiabetic effect (Eidi & Eidi 2009).

It has been suggested that extracts of sage containing carnosic acid may act as a new class of lipid absorption inhibitor. A methanolic extract of sage has also shown significant inhibitory effect on serum triglyceride elevation in olive oil-loaded mice, and inhibitory activity against pancreatic lipase, mainly because of the carnosic acid content. Carnosic acid was also found to reduce the weight gain and accumulation of epididymal fat in high-fat diet-fed mice after 14 days (Ninomiya et al 2004).

### OTHER ACTIONS

The water-soluble polysaccharide complex from sage has demonstrated immunomodulatory activity (Capek & Hribalova 2004) and the terpenoid fractions have shown antimutagenic properties in vivo (Vujosevic & Blagojevic 2004). In vitro and in vivo studies indicate that sage essential oil and some individual monoterpenoid constituents demonstrate antioxidant, anti-inflammatory and oestrogenic effects (Perry et al 2003).

Sage has demonstrated significant anti-inflammatory and antinociceptive effects in animal models (Rodrigues et al 2012).

### CLINICAL USE

Although sage has not been the subject of many clinical studies, many of its constituents demonstrate significant pharmacological effects, providing a theoretical basis for some of its uses.

#### Reduces secretions

Sage has been traditionally used to treat excessive perspiration and salivation, dysmenorrhoea, diarrhoea, galactorrhoea and sweats associated with menopause and to cease lactation (Fisher & Painter 1996). An open study of 80 patients confirmed that it can reduce perspiration (Blumenthal et al 2000). The high tannin content of the herb provides a theoretical basis for its use.

#### Dyspepsia and lack of appetite

The reported antispasmodic action and bitter constituents of sage support its use in treating loss of appetite, gastritis, flatulence, bloating and dyspepsia. These uses await support from clinical research.

### Inflammation of mucous membranes

Topically, sage is used as a gargle for laryngitis, pharyngitis, stomatitis, gingivitis, glossitis, minor oral injuries and inflammation of the nasal mucosa (Blumenthal et al 2000). These uses can be based on the pharmacological activity of its chemical components. In an open-label, single-blind randomised controlled trial (RCT) of 420 patients, the non-steroidal anti-inflammatory drug benzydamine hydrochloride was found to be more effective than sage in relieving postoperative pain when used as a mouthwash after tonsillectomy in children and adults (Lalicevic & Djordjevic 2004).

Sage has been found to have less antitussive effects than codeine, but a significantly higher or similar effect to dropropizine (Nosalova et al 2005). A small double-blind study suggested that use of an essential oil spray or gargle formulation that includes sage may help relieve snoring (Prichard 2004).

### Pharyngitis

There have been two randomised trials of throat spray containing sage extract for the treatment of acute sore throat, both demonstrating efficacy. One was a multicentre, randomised, double-blind, double-dummy controlled trial ( $n = 154$ ) in which patients presenting to general practice with acute sore throat  $>72$  hours were given either an echinacea/sage spray or a chlorhexidine/lignocaine spray. Both sprays were well tolerated and found to have similar efficacy in reducing sore throat symptoms during the first 3 days, with the echinacea/sage group experiencing greater response rates after 3 days (Schapowal et al 2009). The other, a randomised, double-blind, parallel group study, compared the efficacy and tolerability of a spray containing sage against placebo in the treatment of patients with acute viral pharyngitis (Hubbert et al 2006). A total of 286 patients were randomised to receive placebo or treatment for 3 days, including one baseline visit and one final visit. The 15% spray containing 140 microlitre sage extract per dose was statistically significantly superior to placebo in reducing the throat pain intensity score. Symptomatic relief occurred within the first 2 hours after first administration and only minor side effects were seen, such as dry pharynx or burning of mild intensity.

### Memory enhancement

Since ancient times, sage has been used to enhance memory and treat dementia. More recently, cholinergic activities have been demonstrated in vitro and in vivo, suggesting that it may be useful in treating Alzheimer's disease (Orhan et al 2013, Perry et al 2001). A randomised placebo-controlled study undertaken at three centres assessed the effects of sage extract (60 drops/day) in 42 subjects with mild-to-moderate Alzheimer's disease (Akhondzadeh et al 2003). Initially, subjects had a score of 12 or less on the cognitive subscale of Alzheimer's

Disease Assessment Scale (ADAS-cog) and two or less on the Clinical Dementia Rating (CDR). At 4 months, sage extract produced a significantly better outcome on cognitive functions than placebo in both test scales and was well tolerated.

In 2003, two placebo-controlled, double-blind, crossover studies involving 44 healthy young adults investigated the effects of different strengths of standardised essential oil of *S. lavandulaefolia* on memory (Tildesley et al 2003). Both studies found that a 50-microlitre dose of Salvia essential oil significantly improved immediate word recall and was able to modulate cognition. In another placebo-controlled, double-blind, crossover study involving 24 subjects, Spanish sage (*S. lavandulaefolia*) essential oil was found to enhance cognitive performance and mood in healthy young adults (Tildesley et al 2005).

In 2006, results of a double-blind, placebo-controlled, crossover study were published involving 30 healthy participants who received a series of different treatments on each visit to the research laboratory (placebo, 300, 600 mg dried sage leaf) (Kennedy & Scholey 2006). The results confirm previous observations of the cholinesterase inhibiting properties of *S. officinalis*, and improved mood and cognitive performance following the administration of single doses to healthy young participants.

### Hypercholesterolemia

Promising new research suggests that sage may be useful in lowering total cholesterol and triglycerides in hyperlipidaemic patients. A randomised double-blind placebo-controlled clinical trial ( $n = 67$ ) using 500 mg of sage leaf extract (three times daily) standardised to 2.16% quercetin content significantly reduced total cholesterol ( $P < 0.001$ ), triglyceride ( $P = 0.001$ ), LDL ( $P = 0.004$ ) and VLDL ( $P = 0.001$ ), and increased the blood HDL levels ( $P < 0.001$ ) significantly compared with the placebo control after 2 months of treatment. No toxic effects were observed on hepatic and renal functions and no adverse effects were reported by the patients (Kianbakht et al 2011).

### Reducing hot flushes

Sage is commonly used by modern herbalists in prescriptions for menopause in order to treat hot flushes, night sweats, and for its oestrogenic effect. As yet, there is no clinical evidence available to confirm effectiveness for these indications (Blumenthal et al 2000).

A pilot study evaluating efficacy and safety of sage (150 mg three times daily) in controlling hot flushes in prostate cancer patients treated with androgen deprivation therapy ( $n = 10$ ) found that hot flushes reduced significantly in the first 3 weeks of treatment, with the effect maintained for the rest of the 8-week trial. There was a non-significant decrease in LH and FSH levels and no significant effect on testosterone, free testosterone, SHBG, blood pressure, haemoglobin concentration or on cholesterol levels and no side effects were observed.

Despite this, there was no improvement on quality of life measures (Vandecasteele et al 2012).

## OTHER USES

As an inhalant, sage is used for asthma. In foods, it is used as a culinary spice. In manufacturing, sage is used as a fragrance component in soaps and cosmetics. Topically, sage is used to treat herpes labialis, laryngitis, pharyngitis, stomatitis, gingivitis, glossitis, minor oral injuries and inflammation of the nasal mucosa. Sage oil exhibited anticandidal activity against *C. albicans* (Sookto et al 2013).

## Cancer prevention

Promising in vitro research suggests that various constituents of sage may have a role in cancer prevention. The carnosic acid component has demonstrated cytotoxic activity, probably mediated by nitric oxide-induced apoptosis (Kontogianni et al 2013). Carnosic acid also efficiently suppresses the formation of PGE<sub>2</sub> which may contribute to its anti-inflammatory and anticarcinogenic properties (Bauer et al 2012). The linalyl acetate component demonstrated anticancer activities in another in vitro study, partly mediated through the suppression of NF-kappaB activation, suggestive that this could be utilised in combination with chemotherapeutic agents to induce apoptosis (Deeb et al 2011). Sage water extracts have demonstrated inhibitory effects on proliferation and induced apoptosis in human colorectal carcinoma cell lines (Xavier et al 2009) and sage tea was also found to be protective against oxidative DNA damage in HCT15 colon cells (Ramos et al 2012).

A case-control study in patients diagnosed with lung cancer evaluated the relationship between components of the Mediterranean diet and lung cancer. A decreased overall risk of developing lung cancer was associated with intake of some culinary herbs, particularly sage, presumed to be due to its polyphenol content, such as carnosol and carnosic acid (Johnson 2011).

## DOSE RANGE

### Internal use

- Infusion of dried herb: 1–4 g three times daily.
- Tincture (1:1): 1–4 mL three times daily.
- Essential oil: 2–3 drops in 100 mL water several times daily.
- Gargle or rinse (use warm infusion): 2.5 g cut leaf in 100 mL water; or 2–3 drops essential oil in 100 mL water; or use 5 mL fluid extract diluted in a glass of water, several times daily.

## TOXICITY

Sage is likely to be safe when taken in amounts typically found in foods. Essential oil of sage may be toxic in large doses and any case reports of toxicity are usually due to ingestion of sage oil rather than sage extract. In large amounts, the camphor and thujone content of sage oil have been shown

to have convulsant properties in rats (Millet et al 1981). When taken internally in large amounts, sage may cause restlessness and seizures in humans (Blumenthal et al 2000, Newell et al 1996) and there have been two case reports of epileptic seizures in young children caused by accidental ingestion of sage oil (Lachenmeier & Walch 2012). Sage tea has also been reported to cause cheilitis and stomatitis, dry mouth and local irritation.

A risk assessment of thujone in foods and medicines such as sage suggests that 0.11 mg/kg body weight/day is an acceptable daily intake (ADI), an amount unlikely to be consumed in normal dietary intake. Between 2 and 20 cups of sage tea would be required to reach this ADI (Lachenmeier & Uebelacker 2010).

## ADVERSE REACTIONS

One double-blind, randomised trial found that sage was well tolerated and produced fewer side effects than placebo (Akhondzadeh et al 2003). There have been two case reports of contact dermatitis from sage products (Mayer et al 2011).

### CONTRAINDICATIONS AND PRECAUTIONS

Sage oil can irritate the skin when used topically. Internal use of the essential oil should be closely monitored.

### PREGNANCY USE

Traditionally, sage is reported to have abortifacient properties. Its use in pregnancy is therefore not recommended (Mills & Bone 2000, Newell et al 1996).

### Practice points/Patient counselling

- Sage is a widely used, popular spice and sage oil is used in a variety of culinary applications. It has antioxidant, antibacterial and some antifungal activities.
- Sage has a long history of use in traditional medicine as an antispasmodic and carminative, to relieve excess sweating and as a gargle for inflammations of the mouth.
- It is also commonly prescribed in combination with other herbs to relieve menopausal symptoms such as night sweats with some preliminary research showing a reduction in hot flushes.
- Clinical research suggests it may be useful in mild-to-moderate Alzheimer's disease. Other studies report that it improves memory in healthy subjects.
- Standardised sage extract significantly reduces cholesterol levels according to a human study suggesting a possible benefit for people with elevated blood lipids.

## SIGNIFICANT INTERACTIONS

Iron, calcium, magnesium.

Due to the tannin content, sage may reduce the absorption of these minerals — separate doses by 2–3 hours.

## ! PATIENTS' FAQs

### *What will this herb do for me?*

Sage is used to reduce symptoms of menopause such as night sweats; however, scientific testing has not been conducted to confirm whether it is effective. Recent research demonstrates effectiveness of sage spray for sore throat, a reduction in total cholesterol levels for people with elevated blood lipids and that it may improve memory in Alzheimer's disease and in healthy subjects.

### *When will it start to work?*

The study in Alzheimer's disease found effects established within 4 months' use. In the case of menopause, a time frame is unknown.

### *Are there any safety issues?*

When used in appropriate doses, it appears to be a safe herbal medicine; however, it should not be used in pregnancy.

## Saw palmetto

**HISTORICAL NOTE** Saw palmetto was used traditionally as a treatment for urogenital irritations, impotence and male infertility, among other conditions, and was described by the American Eclectic physicians as the 'old man's friend'. Between 1906 and 1917 saw palmetto was listed in the US Pharmacopoeia and between 1926 and 1950 it was in the National Formulary as a treatment for urogenital ailments; however, it fell out of favour for several decades as pharmaceutical medicines came to the forefront of mainstream medicine. Not so in Europe where, in the 1960s, French researchers began to chemically analyse the saw palmetto berry, and a breakthrough lipophilic preparation was eventually developed and subjected to countless clinical trials.

### COMMON NAME

Serenoa or saw palmetto

### OTHER NAMES

American dwarf palm tree, cabbage palm, dwarf palmetto, fan palm, sabal fructus, sabal, serenoa

### BOTANICAL NAME/FAMILY

*Sabal serrulata*, *Serenoa repens* (family Arecaceae or Palmaceae)

### PLANT PART USED

Dried ripe fruit

### CHEMICAL COMPONENTS

An ethanol extract of the berry contains free fatty acids rich in shorter-chain-length fatty acids, such as capric, caprylic, lauric and myristic acids (Nemecz 2003). Palmitic, stearic, oleic, linoleic and linolenic acids are also present in the extract. There are also lesser amounts of phytosterols (such as beta-sitosterol, stigmasterol, ampesterol and cycloartenol), aliphatic alcohols and polyphenolic compounds. The lipophilic extract is used medicinally.

### MAIN ACTIONS

The mechanism of action is not fully elucidated; however, it appears that several mechanisms are at work.

#### Inhibition of 5-alpha reductase

In different cell systems, the lipid-sterolic extract acts as a non-competitive inhibitor of both type 1 and type 2 5-alpha reductase activity, thereby preventing the conversion of testosterone to dihydrotestosterone (Bayne et al 2000, Raynaud et al 2002, Sultan et al 1984). However, it is currently unclear whether the effect is apparent in humans, as contradictory evidence exists. Raynaud et al (2002) explained that the discrepancies found by different authors were due to different experimental conditions and selectivity for fatty acids, as only

specific aliphatic unsaturated fatty acids have been shown to inhibit 5-alpha reductase activity.

One study that analysed and compared benign prostatic hyperplasia (BPH) samples taken from both untreated and treated subjects (320 mg saw palmetto extract taken for 3 months) found that local levels of testosterone were raised, whereas dihydrotestosterone levels were reduced, suggestive of local 5-alpha reductase inhibition (Di Silverio et al 1998). An earlier short-term study found that a dose of 160 mg of a liposterolic extract (Permixon) produced no changes to serum dihydrotestosterone levels, whereas finasteride 5 mg induced a significant reduction (Strauch et al 1994). Since prostate levels were untested in this study, it is not known whether a local effect occurred, even though serum levels remained unchanged.

Unlike other 5-alpha reductase inhibitors, there is no interference with the cell's capacity to secrete prostate-specific antigens (PSAs) because it does not affect the transcription of the gene for PSA, as demonstrated both in vitro and in vivo (Maccagnano et al 2006). Although having an obvious clinical advantage with regard to PSA screening for prostate cancer, this also suggests that 5-alpha reductase inhibition is not a major mechanism of action.

#### Inhibits binding of dihydrotestosterone and testosterone to androgen receptors

Saw palmetto reduces receptor binding of dihydrotestosterone and testosterone by an average of 41%, as tested in 11 different tissue specimens from BPH patients (el Sheikh et al 1988). In 2003, results from two animal studies showed that saw palmetto (whole berry and extract) influenced prostatic hyperplasia via effects on androgen metabolism (Talpur et al 2003).

#### Inhibits prolactin

In vivo research has identified an inhibitory effect not only on androgens, but also on the trophic effect of prolactin in the rat prostate (Van

Coppenolle et al 2000). The inhibitory effect on prolactin activity appears to be due to inhibition of several steps in prolactin receptor signal transduction, according to one animal model (Vacher et al 1995).

### Anti-inflammatory

Saw palmetto is a dual inhibitor of the cyclooxygenase (COX) and 5-lipoxygenase pathways, according to in vitro research (Breu et al 1992, Paubert-Braquet et al 1997). Decreased expression of COX-2 has also been identified, providing a further explanation for the observed anti-inflammatory activity (Goldmann et al 2001).

### Antispasmodic

Both the lipid and the saponifiable fractions have demonstrated antispasmodic activity in several in vitro studies (WHO 2003).

### Cytochromes

Saw palmetto failed to have a significant effect on CYP3A4 or CYP2D6 when tested in healthy individuals (Markowitz et al 2003).

### Antiproliferative effects

In recent years, there has been interest in determining whether saw palmetto may have a role in prostate cancer, as an inhibitory activity has been observed in several test tube studies for prostatic cancer cell lines (Goldmann et al 2001, Ishii et al 2001, Scholtyssek et al 2009).

In 2009, results of an in vitro study were published which tested a saw palmetto ethanolic berry extract (SPBE) and compared its activity on prostatic cancer cells (DU-145) to individual fatty sterol components  $\beta$ -sitosterol, stigmasterol and cholesterol. Most significant findings included an increased expression of nuclear protein p53, and a reduced expression of p27 and p21, with resulting inhibition of tumour cell growth greatest in SPBE, followed by  $\beta$ -sitosterol and  $\beta$ -stigmasterol respectively. It was also observed that p53 had a mechanical effect of binding to F-actin, increasing adhesive properties of cells, reducing the likelihood of cellular migratory effects. This may in the future have an impact on the knowledge and treatment of tumour invasion (Scholtyssek et al 2009).

### OTHER ACTIONS

Although alpha-1 adrenoreceptor activity has been reported in vitro, a clinical study found no evidence of this activity (Goepel et al 1999, 2001). Saw palmetto does not affect platelet function in vivo (Beckert et al 2007).

Traditionally, saw palmetto is believed to act as a mild diuretic, urinary antiseptic and expectorant.

### CLINICAL USE

The most studied saw palmetto preparation is a commercial product known as Permixon (Pierre Fabre Médicament, France), which is a liposterolic extract consisting of 80% free (e.g. 94 g/100 g

extract) and 7% esterified fatty acids, as well as small amounts of sterols ( $\beta$ -sitosterol, campesterol, stigmasterol, cycloartenol), and a minimum percentage of polyphenolic compounds, arabinose, glucose, galactose, uronic acid and flavonoids. More recently, some other saw palmetto extracts have also been studied; however, there is concern that variations in chemical constituents may be a key factor behind the inconsistent results sometimes seen. In particular, in the United States, common saw palmetto products include ethanol and CO<sub>2</sub> extracts, whereas in Germany, fruit extracts obtained with 90% ethanol are very popular, and contain a hexane extract. A study comparing saw palmetto extracts produced using 90% ethanol versus under an optimised CO<sub>2</sub> condition found that levels of free fatty acids differed and the ethanolic extract contained a large amount of ethyl esters that were not present in the CO<sub>2</sub>-produced extract (Bombardelli & Morazzoni 1997).

### Benign prostatic hypertrophy

Saw palmetto extracts are extremely popular in Europe where herbal preparations represent approximately one-third of total sales of all therapeutic agents sold for the treatment of BPH (Levin & Das 2000). In Germany, for instance, more than 30 different preparations containing saw palmetto are on the market. By far the most intensively studied product of this group is an *n*-hexane-liposterol-extract (Permixon), which is very popular in France and Italy. It is a complex mixture of free fatty acids and their esters, phytosterols, aliphatic alcohols and various polyphenolic compounds (Madersbacher et al 2007).

Many clinical studies demonstrate mild to moderate improvements in several common urinary symptoms associated with BPH and with fewer side effects than alpha-blocker and 5-reductase inhibitor drugs. Some more recent study results are less consistent than previously, which is suspected to be mainly due to differences in chemical composition of test products. This is apparent when reviewing the Cochrane systematic reviews and other literature published in the last decade. In particular, differences in test dosages, treatment time frames, severity of disease and, importantly, herbal extract are likely to be contributing factors making the interpretation of results difficult. The possibility of inadequate blinding in some previous studies is yet another factor.

A 2002 Cochrane review assessing the results from 21 randomised controlled trials (RCTs) involving 3139 men concluded that saw palmetto improves urinary scores, symptoms and urinary flow measures compared with placebo, with effects on symptom scores and peak urine flow similar to the pharmaceutical drug finasteride (Wilt et al 2002). Additionally, its use is associated with fewer adverse effects compared with finasteride and, typically, symptomatic relief is reported more quickly.

In 2004, an updated meta-analysis of 14 RCTs and three open-label studies was published (Boyle

et al 2004). The analysis used data from 4280 patients derived from clinical studies that had used Permixon. Three randomised trials had a study period of 6 months or longer. Peak urinary flow rate and nocturia were the two common endpoints. Active treatment was associated with a mean reduction in the International Prostate Symptom Score (IPSS) of 4.78, and a significant improvement in peak flow rate and reduction in nocturia were also reported.

In contrast to previous systematic reviews, a 2012 Cochrane review of 32 RCTs (27 double-blinded) concluded that saw palmetto was no better than placebo in the control of urinary symptoms, peak urine flow and nocturia (Wilt et al 2012). The review analysed results obtained from 5666 men. The negative CAMUS study had a substantial influence on the results. It involved 369 men and compared standardised saw palmetto extract (Prosta-Urgenin Uro) at three different daily doses (320 mg, 640 mg and 960 mg) over 72 weeks. In the CAMUS study, herbal treatment had no significant effect on the American Urological Association Symptom Index (AUASI) or secondary outcomes, including nocturia, peak urine flow and prostate size as compared to placebo (Barry et al 2011). Similarly, an earlier double-blind study of 1 year of continuous treatment with saw palmetto extract (160 mg twice daily containing 92.1% total fatty acids) failed to produce significant differences compared with placebo measured by AUASI, maximal urinary flow rate, prostate size, residual volume after voiding, quality of life or serum PSA levels in subjects with moderate to severe BPH (Bent et al 2006).

#### IN COMBINATION

In 2013, positive results were demonstrated for a combination product in a randomised, double-blind placebo-controlled trial of 57 men between the ages of 40 and 80 years with medically-diagnosed BPH (Coulsen et al 2013). The product tested was ProstateEze Max, a herbal formulation containing *Cucurbita pepo* seed oil (160 mg), *Epilobium parviflorum* extract (equivalent to 500 mg dry herb), lycopene (2.1 mg), *Prunus africana* (equivalent to 15 g dry stem, standardised to  $\beta$ -sitosterol) and *Serenoa repens* (equivalent to 660 mg dry leaf). At the end of the 12-week trial period the active treatment group had 35% symptom reduction in the median score (IPSS) of 36% compared to placebo (8%;  $P < 0.05$ ). Daytime frequency of urination was reduced by 15.5% compared to no significant reduction in placebo group ( $P < 0.03$ ) and night frequency was reduced by 39% compared to placebo (7% ( $P < 0.004$ )).

#### Comparisons with alpha-adrenoreceptor antagonists

Although several comparative trials have been undertaken with finasteride, only a few have compared it with alpha-adrenoreceptor antagonist drugs, which are also commonly used in BPH (Adriazola et al 1992, Debruyne et al 2002).

A large, randomised, double-blind study involving 811 men with symptomatic BPH, who were

#### Clinical note — BPH

BPH occurs in more than 50% of men over the age of 50 years. It is a slow, progressive enlargement of the fibromuscular and epithelial structures of the prostate gland, which can lead to obstruction of the ureter and urine retention. Symptoms such as frequent and/or painful urination, painful perineal stress and a decrease in urine volume and flow can develop. The condition has four stages, with stage 1 considered mild, stages 2 and 3 more severe and often requiring pharmacological treatment, and stage 4 severe and necessitating surgery.

recruited from 11 European countries, showed that Permixon 320 mg/day produced similar results to tamsulosin 0.4 mg/day (Omnic) (Debruyne et al 2002). More specifically, both treatments reduced the IPSS by an average of 4.4 in 80% of subjects. Those patients with the most severe disease experienced the greatest improvement in IPSS total score, with mean changes greater in the Permixon group than in the tamsulosin group (−8.0 and −6.8, respectively). With regard to safety, both treatments were considered well tolerated; however, ejaculation disorders were significantly more frequent with tamsulosin (4.2%) than with Permixon (0.6%). Although these results are promising, this study has been criticised for not including a placebo group as a comparator.

In a short 3-week study, Grasso et al (1995) compared the effects of alfuzosin (7.5 mg/day) with saw palmetto (320 mg/day) in 63 BPH subjects under double-blind test conditions. Both treatments were found to be equally effective with regard to improving irritative score and with maximum and mean urine flow; however, alfuzosin was shown to more rapidly reduce symptoms of obstruction. Considering most studies have shown that 4–8 weeks' treatment with the herb is required to produce maximal effects, the effect seen at 3 weeks is encouraging.

An earlier study compared the effects of prazosin with saw palmetto in 45 patients with BPH over a 12-week period (Adriazola et al 1992). This study found that, although both treatments reduced symptoms, prazosin was slightly more effective.

In the TRIUMPH study, an observational study across six European countries involving 2351 men with newly diagnosed lower urinary tract symptoms suggestive of BPH, significant improvements were seen in 43% of patients taking *Serenoa repens*, 68% of people taking alpha blockers (tamsulosin), and 58% taking 5-alpha reductase (Hutchison et al 2007).

#### Changes to prostate size

It is still open to speculation as to whether saw palmetto affects prostate size, because studies have produced contradictory results (Aliaev et al 2002, Barry et al 2011, Bent et al 2006, Pytel et al 2002).

One open study of 155 men tested the effectiveness and tolerability of Permixon (160 mg twice daily) over 2 years (Pytel et al 2002) and not only detected a significant improvement in the IPSS and quality of life marker, but also a decrease in prostate size and significant improvement in sexual function after the first year of treatment.

A longer 5-year study using Permixon in 26 subjects with BPH showed that a total daily dose of 320 mg twice daily also significantly reduced disease symptoms and improved quality of life, while reducing prostate size by an average of 30% (Aliaev et al 2002). In 2003, results from animal models showed that saw palmetto (whole berry and extract) significantly diminished prostatic hyperplasia (Talpur et al 2003). In contrast, two previous studies from 2006 and 2011 failed to detect a significant effect on prostate size (Barry et al 2011, Bent et al 2006).

### Androgenetic alopecia

The idea of using saw palmetto for androgenetic alopecia arose from the observation that finasteride appears to have some effect on this condition. One double-blind study has investigated the effects of saw palmetto as a potential therapeutic option, finding a highly positive response in 60% of subjects (Prager et al 2002). A second double-blind study of 48 men and women with androgenetic alopecia noted that mean hair density increased by 17% after 10 weeks of treatment with a topical lotion containing saw palmetto and by 27% after 50 weeks of treatment compared to baseline (Morganti et al, as reported in Linde et al 2006, Ulbricht & Basch 2006).

### Chronic prostatitis and pelvic pain

Evidence to support the herb's use in prostatitis is scarce. However, in April 2003, positive findings from a preliminary study using Permixon to treat symptoms of chronic prostatitis and chronic pelvic pain syndrome (CP/CPPS) were presented at the annual meeting of the American Urological Association (AUA 2003). The RCT involving 61 patients with category IIIB CP/CPPS found that 75% receiving active treatment experienced at least mild improvement in symptoms, compared with 20% of the control group. Furthermore, 55% of patients receiving Permixon reported moderate or marked improvement, compared with 16% of the control group. In contrast, results from a 2004 prospective, randomised, open-label study failed to find benefits for saw palmetto (325 mg daily) in men diagnosed with category III CP/CPPS (Kaplan et al 2004). After 1 year, the mean total National Institutes of Health Chronic Prostatitis Symptom Index score decreased from 24.7 to 24.6 ( $P = 0.41$ ) and no benefits were seen for quality of life or pain with saw palmetto treatment.

### IN COMBINATION

More promising is a 2009 trial of 143 patients with chronic bacterial prostatitis which had two treatment arms, group A receiving the antibiotic prulifloxacin

### Practice points/Patient counselling

- Many clinical studies demonstrate mild to moderate improvements in several common urinary symptoms associated with BPH, but the effect is most consistent for European preparations. Due to its good safety profile, a trial of treatment is still worthwhile for patients with mild to moderate BPH who have been advised to watch and wait with regard to conventional treatment.
- Typically, if symptom reduction is experienced, this develops within 1–2 months' treatment. It is well tolerated and associated with fewer side effects than finasteride and tamsulosin.
- The herb does not affect PSA levels; therefore PSA test results will be unaffected.
- If symptoms worsen, blood is detected in the urine or acute urinary retention occurs, patients should be advised to seek professional advice.
- If the patient is receiving radiotherapy for prostate cancer, saw palmetto supplementation should be ceased.

600 mg, while group B were given the antibiotic plus saw palmetto 160 mg, nettle 120 mg, curcumin 200 mg and quercetin 100 mg extracts for 14 days. After 1 month 87% of group B had no further symptoms compared to 27% of group A (Cai et al 2009).

### OTHER USES

Traditionally, saw palmetto has been used to treat a variety of urogenital conditions, such as impotence, male infertility and also as an aphrodisiac. It has also been used in female hirsutism, although its effectiveness in this condition is unknown.

### DOSAGE RANGE

- Liposterolic extract: 320–960 mg/day in divided doses has been proved safe in a clinical trial (Barry et al 2011).
- Dried berry: 2–4 g.
- Liquid extract (1:2): 2–4.5 mL/day.

### According to clinical studies

- 160 mg twice daily of liposterolic extract taken long term.

### ADVERSE REACTIONS

The herb is generally well tolerated, with only non-specific symptoms reported, such as gastrointestinal upset, constipation, nausea, abdominal pain and diarrhoea. These minor complaints are generally resolved by taking the herb in association with meals (Agbabiaka et al 2009, Maccagnano et al 2006).

The 1-year STEP study provided a detailed assessment of the potential toxicity of saw palmetto, including both symptomatic adverse effects as well as asymptomatic laboratory abnormalities (Avins & Bent 2006). It found no evidence that consumption

of saw palmetto extract (160 mg twice daily) over a period of 1 year was associated with any clinically important adverse effects. Relatively few participants suffered serious adverse events, and these were more common in the placebo-allocated participants. Additionally, no statistically significant differences were observed between the saw palmetto and placebo groups in the measured domains of sexual functioning, with the exception of the perception-of-sexual-problems domain, which showed a small but significantly greater improvement in the placebo group.

A 74-week trial which used doses up to 960 mg of a standardised extract daily produced no evidence of toxicity (Avinis et al 2012).

### SIGNIFICANT INTERACTIONS

No controlled studies are available and theoretical interactions are difficult to predict, due to the poorly understood nature of the herb's mechanism of action.

### Finasteride (and other 5-alpha reductase inhibitor agents)

Additive effect theoretically possible — potential beneficial effect, although the clinical significance is unknown.

### Androgenic drugs

Theoretically, saw palmetto may reduce the effectiveness of therapeutic androgens such as testosterone — observe patient for lack of drug effect.

### CONTRAINDICATIONS AND PRECAUTIONS

If symptoms of BPH worsen, blood is detected in the urine or acute urinary retention occurs, professional reassessment is required.

Avoid saw palmetto products if undergoing radiotherapy for prostate cancer as preliminary in vitro studies suggest they may radiosensitise normal prostatic cells by inhibiting normal DNA repair (Hasan et al 2009).

### PREGNANCY USE

Use of saw palmetto during pregnancy is contraindicated due to the herb's hormonal effects. In clinical practice, it is not used in pregnancy.

### PATIENTS' FAQs

#### *What will this herb do for me?*

Saw palmetto has been extensively investigated as a treatment to relieve symptoms in BPH (enlarged prostate). Overall, it is more effective than placebo and most consistent results have been obtained for European preparations. There is some research suggesting that it may be useful in some forms of hair loss and prostatitis.

#### *When will it start to work?*

Symptom relief for enlarged prostate, if achieved, is generally experienced within 4–8 weeks.

#### *Are there any safety issues?*

Saw palmetto is well tolerated; however, occasionally mild gastrointestinal disturbances, headaches and rhinitis have been reported.

## Schisandra

**HISTORICAL NOTE** Schisandra has an extensive history of use in traditional Chinese medicine (TCM). It has sour and warm qualities and is used to treat spleen and kidney 'deficiency', to restore Qi and also as a treatment for chronic cough, wheezing, diabetes, insomnia and palpitations.

### OTHER NAMES

Chinese magnolia vine, gomishi, sheng-mai-san, wuweizi

### BOTANICAL NAME/FAMILY

*Schisandra chinensis* (family Schisandraceae)

### PLANT PART USED

Fruit

### CHEMICAL COMPONENTS

Dibenzocyclooctene lignans (schisandrins A–C, deoxyshisandrin,  $\gamma$ -schisandrin, schisandrols, schisantherins, pregomisin, gomisins A–C, E–G, J, K and N), triterpenoids (schincheninins A–H, schinchenin-lactones A–C, henrichinins A–C, schicagenins A–C), essential oil, malic, tartaric, nigranoic and citric acids, resins, pectin, vitamins A, C and E, niacin, beta-carotene, sterols, tannins and several minerals (MG Kim et al 2010, Shi et al 2011, Song et al 2013, Waiwut et al 2011, Wei et al 2013).

### MAIN ACTIONS

Studies have been conducted with schisandra and a number of its constituents in isolation, such as schisandrin B and gomisin A. Currently, most evidence is derived from in vitro and animal studies,

as it has not been significantly investigated in clinical studies. Many studies have also been conducted on schisandra in combination with other herbs. It is difficult to determine the individual efficacy of schisandra in these cases, and further studies of schisandra in isolation are required.

### Antioxidant

In vitro and in vivo tests have identified antioxidant activity (Y Chen et al 2008, Chiu et al 2011, Kim et al 2009, S Ko et al 2008, Leong et al 2012, Liu et al 2009, Meng et al 2008, Ohsugi et al 1999, Smejkal et al 2010, Steele et al 2013, M Wang et al 2008, Yan et al 2009). Seven lignans isolated from schisandra have demonstrated stronger antioxidant activity than vitamin E at the same concentrations, with schisanhenol exhibiting the strongest effects (Lu & Liu 1992). The essential oil from *Schisandra* berries has also demonstrated antioxidant activity (X Chen et al 2012, Liu et al 2012a, Ma et al 2012).

Protective effects against ethanol-induced oxidative stress have been demonstrated by schisandra extract in vitro (Chen et al 2010) and schisandrin B in vivo (Lam et al 2010). While an in vitro study found that schisandra did not protect against oxidative stress-induced lymphocyte DNA damage (Szeto et al 2011), the herb has demonstrated a protective

effect against heat stress (KJ Kim et al 2012) and silica-induced lung damage (Li et al 2009) in rats via antioxidant mechanisms. It appears that several constituents also have indirect antioxidant activity and can increase hepatic and myocardial glutathione levels (Yim & Ko 1999).

An extract of schisandra and the isolated constituent schisandrin B have both demonstrated the ability to significantly decrease alanine aminotransferase and increase glutathione levels in CCL4-damaged liver in vivo (Chiu et al 2002). Schisandrins B and C protected rats against solar irradiation-induced oxidative damage to epithelial tissue (Lam et al 2011). Schisandrin B also demonstrated genoprotective activity in mice with cisplatin-induced oxidative stress (Giridharan et al 2012), and long-term supplementation with schisandrin B enhanced mitochondrial antioxidant capacity and functionality in ageing mice, suggesting schisandrin B may have potential as an antiageing therapy (KM Ko et al 2008).

Deoxyschisandrin protected human intestinal epithelial cells against oxidative stress-induced apoptosis (Gu et al 2010). Schisandra polysaccharides have demonstrated analgesic activity in vivo, which may be due to its antioxidant capacity (Ye et al 2013).

### Hepatoprotective activity

#### Decreases hepatotoxic damage

In vitro and in vivo studies have identified hepatoprotective effects with schisandra against carbon tetrachloride toxicity (Cai et al 2010, Chang et al 2009, Cheng et al 2013, Chiu et al 2007, Ip et al 1995, Mak & Ko 1997, Y Xie et al 2010, Yan et al 2009, Zhu et al 1999, 2000) and mercuric chloride toxicity (Stacchiotti et al 2009). Research with schisandrin B suggests that it is the main constituent responsible for these beneficial effects (Chiu et al 2007, Ip et al 1995, Mak et al 1996, Pan et al 2002). Further investigation reveals that schisandrin B increases the efficiency of the hepatic glutathione antioxidant system, thereby inhibiting carbon tetrachloride-induced lipid peroxidation; however, additional mechanisms appear likely (Ip et al 1995). More recently, the whole extract of schisandra fruit was shown to induce glutathione S-transferases in vitro (EH Choi et al 2008). Several lignans have been found to induce expression of phase II detoxification enzymes in vitro, a factor believed to be important in the prevention of liver cancer (SB Lee et al 2009).

Protection against paracetamol-induced liver damage has been demonstrated in two animal models using gomisin A (Kim et al 2008, Yamada et al 1993). In one study, gomisin A inhibited not only the elevation of serum aminotransferase activity and hepatic lipoperoxide content, but also the appearance of histological changes such as degeneration and necrosis of hepatocytes (Yamada et al 1993). In 2003, protection against paracetamol-induced liver damage

and D-galactosamine-induced liver damage was confirmed for a fractionated extract of *S. chinensis* in an experimental model (Nakagiri et al 2003).

The hepatoprotective effects of gomisin N and  $\gamma$ -schisandrin have been analysed in interleukin-1 $\beta$  (IL-1 $\beta$ )-treated rat hepatocytes. Gomisin N and  $\gamma$ -schisandrin suppressed genetic expression of nitric oxide synthase (NOS), and decreased the transcription of IL1 $\beta$  and inflammatory chemokines (Takitomo et al 2013).

Gomisin A protected against D-galactosamine-induced hepatotoxicity in vivo (Kim et al 2008). The latter also protected against carbon tetrachloride-induced liver fibrosis in rats (HY Kim et al 2011).

Schisandrin B decreased hepatic total cholesterol and triglyceride levels in hypercholesterolaemic mice (Pan et al 2008) and protected mouse hepatocytes against hypoxia/reoxygenation-induced apoptosis (Chiu et al 2009).

An extract of schisandra lignans protected against restraint-induced liver damage in mice. The hepatoprotective effect was potentially mediated via antioxidant mechanisms (Pu et al 2012).

#### IN COMBINATION

Shengmai San (comprised of *S. chinensis*, *Panax ginseng*, and *Ophiopogon japonicus*) reduced hepatic lipids and lipid peroxidation in rats fed a high-cholesterol diet (Yao et al 2008). Another herbal combination preparation (*S. chinensis*, *Vitis vinifera* and *Taraxacum officinale*) protected against D-galactosamine-induced hepatotoxicity in vivo (JW Kang et al 2012).

#### Liver regeneration

Two animal studies have demonstrated that oral administration of gomisin A, a lignan isolated from *S. chinensis*, accelerates liver regeneration after partial hepatectomy and hastens recovery of liver function (Kubo et al 1992, Takeda et al 1987). The mechanism for these effects is not fully elucidated; however, gomisin A increases ornithine decarboxylase activity, which is important during the early stages of regeneration and suppresses fibrosis proliferation.

#### Anti-inflammatory

Schisandrin inhibits nitric oxide (NO) production, prostaglandin E<sub>2</sub> release, cyclooxygenase-2, inducible iNOS and nuclear factor-kappaB (NF- $\kappa$ B) in vitro (Guo et al 2008). In vitro and in vivo studies have identified anti-inflammatory activity for gomisin A, gomisin J, wuweizi C (Yasukawa et al 1992), schisandrin B (Checker et al 2012), schisandrin C, gomisin N (Oh et al 2010),  $\alpha$ -iso-cubebene (Choi et al 2009),  $\alpha$ -iso-cubebenol (YJ Lee et al 2010) and schisandrin derivatives (Blunder et al 2010). Several lignans from schisandra, including gomisin N and schisandrol A, have shown potent inhibition of nuclear factor of activated T cells (NFAT) in vitro (Lee et al 2003). Excessive activation of NFAT has a significant role to play in autoimmune disease, but further study is needed to

assess schisandra's usefulness in immunopathological disease states.

Aqueous extracts of schisandra inhibited lipopolysaccharide-induced lung inflammation in mice (Bae et al 2012), and demonstrated potent effects in a mast cell line (Kang et al 2006). The extracts were found to inhibit tumour necrosis factor alpha (TNF- $\alpha$ ), IL-6, IL-1 and granulocyte-macrophage colony-stimulating factor production (Park et al 2011). These effects may be due to schisandra inhibiting the degradation of IkappaB and therefore the translocation and activation of NF- $\kappa$ B. This may indicate a potential role for schisandra in the treatment of allergy. Similarly, another study found that schizandrin decreased scratching behaviour by inhibiting the IgE-antigen complex in vivo (Lee et al 2007).

#### IN COMBINATION

A herbal combination containing schisandra (Jianpi Huoxue) was found to inhibit the liver cytokine secretion pathway in rats (Peng et al 2008).

#### Immunomodulatory

Animal studies have found schisandra to possess immune-modulating activity (D Ma et al 2009). In mice,  $\alpha$ -iso-cubebenol isolated from schisandra protected against induced sepsis by increasing the bactericidal activity of phagocytes, attenuating inflammatory cytokine production and inhibiting leucocyte apoptosis (SK Lee et al 2012). An in vitro follow-up study suggested the immunomodulatory activity of  $\alpha$ -iso-cubebenol was due to stimulated neutrophil activity, including calcium increase, degranulation and chemotactic migration via interaction with chemokine receptor CXCR2 (Jung et al 2013). Alpha-iso-cubebene has demonstrated similar activity in vitro (Y Lee et al 2009).

Administration of schisandra polysaccharides to cyclophosphamide-induced immunosuppressed mice resulted in improved parameters of immune function, including increased phagocytic activity of peritoneal macrophages, increased serum haemolysin (Yang et al 2008), increased organ weight of the thymus and spleen and increased splenocyte proliferation (Y Chen et al 2012).

#### Antidiabetic

Schisandra exhibits multiple mechanisms of relevance in diabetes.

In vitro studies indicate that schisandra possesses antidiabetic activity (Gao et al 2009, Lau et al 2008, S Park et al 2009). Various lignans have been found to improve basal glucose uptake of hepatic cells (HepG2) in vitro. In particular, gomisin N demonstrated a greater effect than rosiglitazone, which has been used as an antidiabetic drug (J Zhang et al 2010).

Moreover, in vivo studies show that schisandra extracts reduce blood glucose levels, improve lipid metabolism, increase liver glycogen content and attenuate diabetes-induced weight loss and

polydipsia in alloxan-induced diabetic mice (Gao et al 2009, Xv et al 2008, Zhao et al 2013a). Aqueous extracts of schisandra reduced postprandial blood glucose levels in rats via inhibition of  $\alpha$ -glucosidase and  $\alpha$ -amylase, enzymes responsible for absorption of monosaccharides in the small intestine (Jo et al 2011).

A fraction containing schizandrin, gomisin A and angeloylgomisin H increased glucose disposal rates and enhanced hepatic insulin sensitivity in type 2 diabetic rats (Kwon et al 2011).

#### IN COMBINATION

A TCM formula containing *S. chinensis*, *Coptis chinensis*, *Psidium guajava* and *Morus alba* significantly decreased non-fasting blood glucose in insulin-resistant mice (Wang & Chiang 2012).

#### Antiobesity

Treatment with schisandra resulted in decreased weight gain and adiposity in obese rats fed a high-fat diet. In vitro results suggest this effect may be mediated by inhibition of adipogenesis and adipocyte differentiation (HJ Park et al 2012).

#### IN COMBINATION

Gyeongshingangjeehwan (GGEx), a product containing *S. chinensis*, *Liriope platyphylla*, *Platycodon grandiflorum* and *Ephedra sinica*, promoted weight loss in one study of obese rats (Shin et al 2010) and decreased food intake, weight and abdominal fat gain, circulating triglycerides and hepatic lipid accumulation in another (Jeong et al 2008).

#### Antiallergic

Schisandra has demonstrated various antiallergic effects, including inhibition of eosinophil recruitment to lung epithelial cells in vitro (Oh et al 2009) and reduced severity of atopic dermatitis in vivo (Kang & Shin 2012). An aqueous extract of schisandra inhibited  $\beta$ -hexosaminidase release and expression of IL-4, IL-13 and TNF- $\alpha$  mRNA and protein in immunoglobulin E-antigen complex-stimulated rat basophilic leukaemia cells (mucosal mast cell-type cells) (Chung et al 2012). It appears that schisandra ameliorates the production of reactive oxygen species that drives allergic inflammation.

In in vitro studies, gomisin N inhibited the production of prostaglandin D<sub>2</sub>, leukotriene C<sub>4</sub>,  $\beta$ -hexosaminidase, IL-6 and cyclooxygenase-2 in bone marrow-derived mast cells (Chae et al 2011) and schizandrin has been found to inhibit the production of thymic stromal lymphopoietin (TSLP) in human mast cell lines. TSLP plays a key role in allergic diseases such as asthma and atopic dermatitis (Moon et al 2012). In vivo, schizandrin demonstrated significant antiasthmatic activity via inhibition of airway eosinophil accumulation, reduction of IL-4, IL-5, interferon- $\gamma$  and TNF- $\alpha$  levels in bronchoalveolar lavage fluid, reduced oxidative stress, and inhibition of goblet cell hyperplasia and

inflammatory cell infiltration in lung tissue (MY Lee et al 2010).

#### IN COMBINATION

Antiasthmatic activity was demonstrated by Xiao Qing Long Tang, a preparation of eight herbs, including *S. chinensis* (Wang et al 2012).

#### Nephroprotective

Schisandra significantly decreased the urine albumin excretion rate and urinary albumin/creatinine ratio, attenuated glomerulosclerosis and protected against podocyte loss in a mouse model of diabetic nephropathy (Zhang et al 2012).

In vitro pretreatment with schisandrin B protected against cyclosporin A-induced nephrotoxicity in mice and human proximal tubular epithelial cell line via antioxidant effects (Zhu et al 2012), and in vivo schisandrin B was also found to protect against mercuric chloride-induced (Stacchiotti et al 2011) and gentamicin-induced (Chiu et al 2008a) nephrotoxicity in rats.

Schisandrin significantly attenuated high-glucose-induced murine mesangial cell (MMC) damage by reducing the proliferation and protein synthesis of MMCs, reducing production of reactive oxygen species and inhibiting the activity of NADPH oxidase. These results suggest that it may be useful in the treatment of diabetic nephropathy (Jeong et al 2012).

#### Cardiovascular effects

Schisandrin B demonstrated protective effects against ischaemia-reperfusion-induced myocardial damage in animal models (Chiu et al 2008b, Yim & Ko 1999). The myocardial protection was associated with an enhancement in myocardial glutathione antioxidant status. Schisandrin B has also been found to inhibit signalling of transforming growth factor- $\beta_1$  (TGF- $\beta_1$ ) in vascular smooth-muscle cells (EJ Park et al 2012). TGF- $\beta_1$  is implicated in the pathogenesis of a number of vascular disease processes, including hypertension, atherosclerosis and restenosis. Schisandrin B stereoisomers protected rat cardiomyocytes against hypoxia/reoxygenation-induced apoptosis.

The whole extract, deoxyschizandrin, schisandrin A and gomisin A, has demonstrated vasorelaxant properties in isolated rat thoracic aorta, suggesting cardioprotective effects (JY Park et al 2007, J Park et al 2009a, Rhyu et al 2006, Seok et al 2011, X Yang et al 2011). An aqueous schisandra extract restored endothelial function in rats that underwent balloon-induced carotid artery injury. Similar to oestradiol therapy, it also reduced serum cholesterol levels and exhibited hypotensive effects in ovariectomised rats (EY Kim et al 2011).

Gomisin J (J Park et al 2012a) and gomisin A (J Park et al 2009b) have demonstrated vasorelaxant effects in vitro via increased activation of calcium-dependent endothelial NOS and subsequent production of endothelial NO. Administration of

gomisin A to hypertensive mice ameliorated the increase in blood pressure and reactive oxygen species production, and decrease in aortic vascular NO and phosphorylated endothelial NOS induced by treatment with angiotensin II (J Park et al 2012b).

#### IN COMBINATION

A Cochrane review of nine randomised controlled trials assessed the use of Shengmai (a TCM combination of *Panax ginseng*, *Ophiopogon japonicus* and *S. chinensis*) in patients with heart failure. While issues of poor study design, small sample size and heterogeneity of particular outcomes were cited, there was some evidence to show that Shengmai may improve heart function in patients with heart failure (Chen et al 2012).

#### Antitumour

Extracts of schisandra and several isolated constituents have demonstrated anticancer activity against various cancer lines, including leukaemia, breast, liver, gastric, colon and lung in vitro (Gnabre et al 2010, Hwang et al 2011, Jie et al 2009, JH Kim et al 2010, JE Kim et al 2012, SJ Kim et al 2010, Lin et al 2008, 2011, Min et al 2008, Nishida et al 2009, C Park et al 2009, Waiwut et al 2012, Yim et al 2009, Yuezhen 2010, Zhao et al 2013b). Several schisandra lignans have been found to inhibit fatty acid synthase, a potential oncogenic enzyme (Na et al 2010). Gomisins J and N inhibited Wnt/ $\beta$ -catenin signalling in human colon carcinoma cells. The Wnt/ $\beta$ -catenin signalling pathway is involved in regulating cell growth and apoptosis, and has been implicated in the aetiology and progression of various forms of cancer (K Kang et al 2012).

Gomisin N was found to enhance apoptosis induced by TNF- $\alpha$  (Waiwut et al 2011) and TNF-related apoptosis-inducing ligand (TRAIL) (Inoue et al 2012) in vitro. A schisandra polysaccharide, WLSLSCP, significantly inhibited the proliferation of lymphoma cells, increased secretion level of serum TNF- $\alpha$ , and improved survival rate of lymphoma-bearing mice. WLSLSCP was also found to enhance phagocytic activity and NO and TNF- $\alpha$  secretion of macrophages in vitro (C Xu et al 2012). Another isolated schisandra polysaccharide (SCPP11) exhibited indirect cytotoxic activity against tumour cells in vitro, and significantly inhibited the growth of hepatic tumour cells (HepS) in vivo. SCPP11 also increased thymus indexes, serum IL-2 and TNF- $\alpha$  levels in vivo, and significantly enhanced NO production and phagocytosis in mouse macrophage-like cell lines in vitro (Zhao et al 2013b). These results suggest that schisandra's immunomodulatory activity may contribute to its antitumour effects.

Other constituents of the herb, such as deoxyschizandrin and  $\gamma$ -schisandrin, restored the cytotoxic action of the chemotherapy drug doxorubicin in multidrug-resistant human lung carcinoma cell lines. They also enhanced cellular accumulation of doxorubicin, and induced cell cycle arrest when

combined with subtoxic doses of doxorubicin (Slaninova et al 2009).

Schisandra has been found to inhibit the proliferation of cancer cells in rodents with induced hepatocellular carcinoma (He et al 2010, Loo et al 2007). An extract of schisandra lignans inhibited hepatic metastases of mastocytoma tumour cells in mice (Tang et al 2011).

An isolated compound from schisandra (1-O-MFF) inhibited melanogenic processes in mouse melanoma cells (Oh et al 2010), and gomisin A has been found to inhibit skin cancer formation in mice (Yasukawa et al 2009).

#### IN COMBINATION

Shu Gan Liang Xue decoction, a TCM product that contains schisandra and is often used in menopause, inhibited the growth of human mammary epithelial carcinoma cell line, but did not display any oestrogenic activity (Zhang & Li 2009).

#### Neuroprotective

In vitro data suggest that certain lignans from schisandra (Kim et al 2004) are protective against L-glutamate-induced neurotoxicity in rat cortical cells. Schisandrin C has been shown to decrease the membrane action potential in glioma and neuronal cells lines (Y Choi et al 2008). Schisandrin has demonstrated neurogenic activity in rat hippocampal neurons (SH Yang et al 2011), and demonstrated the ability to reverse hyoscine-induced memory impairment in vivo by enhancing cholinergic function (Egashira et al 2008). Extracts of schisandra ameliorated the depressed hippocampal acetylcholinesterase activity and behavioural learning impairments seen in ovariectomised mice (X Xie et al 2010).

Schisandrin (N Zhang et al 2010) and schisandrin B (Zeng et al 2012) have been found to inhibit lipopolysaccharide-induced microglia activation and significantly ameliorate neuronal cell death in vitro and in vivo via inhibition of the microglial-mediated neurotoxic inflammatory response. Microglia activation is implicated in the pathophysiology of Alzheimer's and Parkinson's disease.

Extracts of schisandra (M Miao et al 2009, Y Miao et al 2009) and schisandrin B (N Chen et al 2008) have been shown to improve the outcome in cerebral ischaemia/reperfusion models in vivo. Schisandrin B protected against damage by enhancing the cerebral antioxidant status. Schisandrin B also exhibited significant neuroprotective effects in a rat model of transient focal cerebral ischaemia. Schisandrin B demonstrated inhibition of TNF- $\alpha$  and IL-1 $\beta$ , and decreased expression of matrix metalloproteinases-2 and -9, all of which are involved in microglial activation after ischaemic events (TH Lee et al 2012).

Schisandrin B appears to improve cognition and hepatic functions in mice treated with tacrine, the common Alzheimer's dementia medication (Pan et al 2002). Pretreatment with schisandrin B pre-

vented scopolamine-induced oxidative stress and impairment of learning and memory in vivo. Schisandrin B was found to ameliorate the scopolamine-induced increase in acetylcholinesterase activity, and maintain normal acetylcholine levels (Giridharan et al 2011). Similarly, schisandrin was found to prevent dexamethasone-induced cognitive deficits in vitro and in vivo (X Xu et al 2012).

Schisandrins B and C reversed beta-amyloid (A $\beta$ ) and homocysteine-induced neurotoxicity in vitro (Song et al 2011). Both deoxyschisandrin (Hu et al 2012) and ESP-806, a lignan-rich extract of schisandra (Jeong et al 2013), significantly ameliorated A $\beta$ -induced memory impairment in mice. Deoxyschisandrin acted via antioxidative mechanisms, while ESP-806 attenuated the elevation of  $\beta$ -secretase activity, significantly inhibited hippocampal acetylcholinesterase activity and increased levels of reduced glutathione in the cortex and hippocampus. Deoxyschisandrin has also been found to inhibit the spontaneous and synchronous oscillations of intracellular Ca<sup>2+</sup> in hippocampal neurons by depressing influx of extracellular calcium, and inhibiting spontaneous neurotransmitter release, suggesting deoxyschisandrin may be of benefit in regulating the excitability of neural networks (Fu et al 2008).

#### IN COMBINATION

A combined extract of *Schisandra chinensis*, *Angelica gigas* and *Saururus chinensis* is protective against L-glutamate-induced neurotoxicity in rat cortical cells (CJ Ma et al 2009). AdMax (Nulab, Florida), a product containing *Schisandra chinensis*, *Leuzea carthamoides*, *Rhodiola rosea* and *Eleutherococcus senticosus*, has been found to enhance expression of PANK2, which encodes the mitochondrial enzyme pantothenate kinase 2. Impaired PANK2 gene activity leads to pantothenate kinase-associated neurodegeneration (Antoshechkin et al 2008).

#### Gastrointestinal actions

Schisandra has demonstrated gastrointestinal antispasmodic activity in isolated rat colon (J Yang et al 2011a). Schisandra was also found to reverse visceral hypersensitivity in an irritable bowel syndrome rat model. The observed normalisation of elevated serotonin (5-HT) levels and a decline in the mRNA level of 5-HT receptors in the distal colon suggest the effect may be mediated via the colonic 5-HT pathway (Yang et al 2012). Extracts of schisandra inhibited acetylcholine- and 5-HT-induced contractions of guinea pig ileum, potentially via inhibition of both calcium ion influx and intracellular calcium ion mobilisation (J Yang et al 2011b).

#### Antibacterial

Schisandra has demonstrated bactericidal activity against *Staphylococcus epidermidis*, *S. aureus*, *Bacillus subtilis*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus vulgaris* (X Chen et al 2011, Wang 2008), *Bacillus*

*anthracis*, *Shigella* (Wen-qiang 2009) and *Salmonella gallinarum* (Choi & Chang 2009).

## OTHER ACTIONS

### Lipid lowering

Schisandra may also help to reduce cholesterol, as it has been found to decrease triglycerides and low-density lipoprotein, and increase high-density lipoprotein cholesterol in vivo (Junshu & Anshan 2008). Schisandrin B (50–200 mg/kg) was co-administered with either a high-lipid diet or a cholesterol/bile salts mixture in vivo (Pan et al 2008). Hepatic total cholesterol and triglyceride levels were reduced by up to 50% and 52%, respectively, as compared to control animals. Similar results were found using an ethanol extract of schisandra (Pan 2011).

### Improved erectile function

Corporal smooth-muscle (CSM) relaxation is required for penile erection. Several schisandra lignans were found to induce CSM relaxation via inhibition of calcium ion influx (Han et al 2012). Schisandrol A, schisandrol B and an ethanol extract of schisandra were found to potentiate sildenafil citrate-induced relaxation of rabbit penile corpus cavernosum. Clinical studies are required to determine whether schisandra has a therapeutic role in patients with a poor response to sildenafil alone (HK Kim et al 2011).

### IN COMBINATION

A combination of *Schisandra chinensis*, *Lycium chinense*, *Cornus officinalis*, *Rubus coreanus* and *Cuscuta chinensis* improved intracavernous pressure of corpus cavernosum in spontaneous hypertensive rats (Sohn et al 2008).

### Anxiolytic and sedative

Schisandra has demonstrated sedative and hypnotic activity in mice, reducing sleep latency and prolonging sleep time (W Wang et al 2008a). Schisandra was found to decrease behavioural signs of anxiety in stressed mice, and ameliorated elevations in cerebral cortex noradrenaline, dopamine and 5-HT and plasma corticosterone levels (W Chen et al 2011). It is possible the anxiolytic effect is mediated by modulation of the hypothalamic-pituitary-adrenal axis activity.

### Inhibits leukotriene formation

Various schisandra lignans decrease leukotriene production via inhibition of 5-lipoxygenase activity in vitro (Lim et al 2009). Gomisins A has been found to inhibit the biosynthesis of leukotrienes by preventing the release of arachidonic acid in vitro (Ohkura et al 1990).

### Platelet-activating factor antagonist

Several lignans inhibit platelet-activating factor in vitro (Lee et al 1999). Pregomisin and gomisins N have demonstrated more potent inhibition of

platelet-activating factor than aspirin (MG Kim et al 2010).

### Enhanced exercise endurance

Schisandra (Cao et al 2009, W Wang et al 2008b) and ADAPT-232 (a standardised combination of *S. chinensis*, *Rhodiola rosea* and *Eleutherococcus senticosus*) (Panossian et al 2009) have been found to increase exercise endurance in mice.

### Bone mineralisation

Lignans isolated from the fruit and seeds of schisandra may be able to protect against bone loss. An in vitro study using UMR 106 cells demonstrated that the lignans (extracted in 95% ethanol) stimulated the proliferation and activity of alkaline phosphatase in osteoblasts (Caichompoo et al 2009).

### Cytochromes and P-glycoprotein

Schisandra extract and different isolated compounds have been tested for the effects of various cytochromes and P-glycoprotein in in vitro and animal model studies.

#### Cytochrome 3A4

In vitro evidence indicates that schisandrol A and gomisins A are inhibitors of CYP 3A4 (Wan et al 2010). Conflicting in vivo evidence has found schisandra to have both inhibitory and inducing effects on CYP 3A4 activity (Q Chen et al 2010, Iwata et al 2004, Li et al 2013, Su et al 2013, Wang et al 2011). In addition, schisandra has been found to increase the activation of the pregnane X receptor (PXR) signalling pathway. PXR is a transcription factor that, when activated, binds to the promoter region of CYP3A4 gene, resulting in increased CYP3A4 transcription (Yu et al 2011). The discrepancy between results from animal studies appears to be dependent on the duration of administration. Short-term treatment with schisandra (single dose) had an inhibitory effect on CYP 3A4, while longer-term treatment (6–14 consecutive days) resulted in induction of CYP 3A4 (Lai et al 2009, Yao et al 2011). Clinical studies are not available to clarify the effect of *S. chinensis* on CYP 3A4 in humans. One case study found that administration of deoxyschisandrin (22.5 mg after meals for 3 days) resulted in an increase of blood tacrolimus (a P-glycoprotein and CYP 3A4 substrate) concentration from 2.3 ng/mL to 17.7 ng/mL (Jiang et al 2010a). It was not clear whether the increased tacrolimus concentration was due to inhibition of P-glycoprotein, CYP 3A4, or a combination. Small-scale human studies have found that oral administration of *Schisandra sphenanthera* for 7–14 days resulted in increased area under the curve for tacrolimus (Jiang et al 2010b, Xin et al 2007) and midazolam (Xin et al 2009). Considering the two species share many of the same constituents (including deoxyschisandrin and schisandrin B), it is possible that *S. chinensis* may have the same effect.

It has been suggested that discrepancies between human and animal studies are due to lower mg/kg doses of schisandra in humans than animals, and the fact that gomisin C concentrations necessary for PXR activation in humans are twice those required for murine species (Gurley et al 2012). A 2012 review suggests that, based upon the human studies of *Schisandra sphenanthera*, *S. chinensis* is likely to have an inhibitory effect on CYP 3A4 in humans, and the potential for herb–drug interactions between schisandra extracts and drugs that are CYP 3A4 substrates is high (Gurley et al 2012).

### P-glycoprotein

Various lignans from schisandra, including schisandrol A, gomisin A, schisandrin A and B and schisandrin B have demonstrated an inhibitory effect on P-glycoprotein in vitro (Fong et al 2007, Pan et al 2006, Qiangrong et al 2005, Wan et al 2006, Yoo et al 2007). Pretreatment with schisandrol B significantly increased the oral bioavailability of paclitaxel (a drug with notoriously poor oral bioavailability) in rodents, potentially via enhanced intestinal absorption due to inhibition of P-glycoprotein (Jin et al 2010). In vitro studies indicate that inhibition of P-glycoprotein by schisandra lignans can reverse multidrug resistance in cancer cells (Huang et al 2008); however clinical studies are required to confirm this.

In a small clinical trial ( $n = 12$ ), pretreatment with schisandra extract (300 mg twice daily for 14 days) followed by a single dose of talinolol (100 mg) resulted in increased area under the curve and  $C_{max}$  of talinolol by 47% and 51% respectively, suggesting P-glycoprotein activity was inhibited (Fan et al 2009).

### CLINICAL USE

While schisandra has not been extensively tested in clinical trials, it has been tested in numerous animal models and displays multiple mechanisms of action, thereby providing biological plausibility for some of its uses. It is often prescribed in combination with other herbal medicines, a factor which accounts for its investigation as part of multi-component treatments in some studies.

### Liver damage, hepatoprotection

Traditionally, schisandra has been used to treat a variety of liver disorders. Hepatoprotective effects have been observed in test tube and animal studies; however, the clinical significance of these findings in humans remains unknown. Several encouraging clinical reports using an analogue of schisandrin C are available; however, it is not known whether these effects will be seen with *S. chinensis* (Akbar et al 1998). A pilot clinical study in 10 healthy subjects has evaluated the effects of schisandra and sesamin (a constituent of sesame oil) on blood fluidity due to the link between blood viscosity and liver dysfunction (Tsi & Tan 2008). The mixture was given for 1 week and blood fluidity was tested over

2 weeks, including 1 week postintervention. Blood passage time was reduced by 9.0% and 9.7% at 1 and 2 weeks, respectively, showing that the effect could be sustained for at least 1 week after cessation of treatment. The exact effects of schisandra in this formula are unknown.

### Adaptogen

In TCM, schisandra is viewed as an adaptogen and prescribed with other herbs to increase resistance to physical and emotional stressors and to improve allostasis (see monographs on Korean ginseng and Siberian ginseng for further information about adaptogenic activity and allostasis).

### IN COMBINATION

A randomised, double-blind, placebo-controlled pilot study assessed the effect of a single dose (270 mg) of ADAPT-232 (a standardised combination of *S. chinensis*, *Rhodiola rosea* and *Eleutherococcus senticosus*) on cognitive function in 40 healthy females aged 20–68 years. At 2 hours posttreatment, the treatment group demonstrated improvements in attention and increased speed and accuracy when performing stressful cognitive tasks compared to controls (Aslanyan et al 2010).

In a randomised, double-blind, placebo-controlled study, 30 subjects were assigned to three groups of 10: placebo group, *Rhodiola rosea* group (providing 144 mg SHR-5 extract twice daily) and ADAPT-232 group (140 mg of standardised combination twice daily) for 7 days. Experienced levels of fatigue significantly decreased in the *R. rosea* group but not in the ADAPT-232 group compared to placebo (Schutgens et al 2009).

### Infection

Schisandra is also used in combination with other herbal medicines to treat infection. One double-blind, randomised, placebo-controlled pilot study found that a commercial product known as ImmunoGuard significantly reduced the duration, frequency and severity of attacks in patients with familial Mediterranean fever (Amaryan et al 2003). The dose regimen used was four tablets taken three times daily for 1 month. The ImmunoGuard product contains a fixed combination of *Andrographis paniculata* Nees., *Eleutherococcus senticosus* Maxim., *Schisandra chinensis* Bail. and *Glycyrrhiza glabra* L. special extracts, which are standardised for the content of andrographolide (4 mg/tablet), eleutheroside E, schisandrins and glycyrrhizin, respectively. Although these results are encouraging, it is not known to what extent schisandra contributed to the outcome.

A double-blind, placebo-controlled, randomised pilot study investigated the effects of another preparation known as Chisan (containing schisandra 51.0%, rhodiola 27.6% and Siberian ginseng 24.4%) on recovery time and quality-of-life scores in patients with acute non-specific pneumonia (Narimanian et al 2005). Sixty participants were randomised to receive the standard treatment of cephazoline, bromhexine and theophylline or the standard

treatment plus the herbal mixture (20 mL twice a day standardised to contain schisandrin 0.177 mg/mL and gamma-schisandrin 0.105 mg/mL) for 10–15 days. Participants in the active group reported significant improvements in recovery time and quality-of-life scores. The requirement for antibiotics was on average 2 days shorter for those participants taking Chisan. All of these herbs have been celebrated for their adaptogenic effects and this may, at least in part, be responsible for the results. The individual effects of schisandra in this formula, however, are unknown.

## OTHER USES

Traditionally, schisandra has been used to treat chronic cough and dyspnoea, diarrhoea, night sweats, irritability, palpitations and insomnia. Based on the herb's inhibitory effects on leukotriene biosynthesis and platelet-activating factor activity and anti-inflammatory effects, it is also used for asthmatic symptoms.

## DOSAGE RANGE

As clinical research is lacking, the following dosages come from Australian manufacturers' recommendations.

- Dried fruit: 1.5–6 g/day.
- Liquid extract (1:2): 3.5–8.5 mL/day or 25–60 mL/week.

## TOXICITY

Insufficient reliable information is available.

## ADVERSE REACTIONS

Mild gastrointestinal discomfort

## SIGNIFICANT INTERACTIONS

### CYP3A4 substrates

Increased serum levels of drugs chiefly metabolised by CYP 3A4 are possible, based on current evidence. Practitioners are advised to carefully monitor patients who are already taking drugs that are CYP3A4 substrates to avoid inducing drug side effects caused by increased serum levels.

Schisandra should not be prescribed together with CYP3A4 substrates that have a narrow therapeutic index in order to avoid inducing drug toxicity.

### P-glycoprotein substrates

Based on current evidence, it appears that P-glycoprotein inhibition is possible. As a result, serum levels of P-glycoprotein substrates could be increased. Practitioners are advised to carefully monitor patients who are already taking drugs that are P-glycoprotein substrates to avoid inducing drug side effects caused by increased serum levels.

Schisandra should not be prescribed together with P-glycoprotein substrates that have a narrow therapeutic index in order to avoid inducing drug toxicity.

## Drugs metabolised by UGT1A3

Deoxyschizandrin and schisantherin A have demonstrated an inhibitory effect on UDP-glucuronosyltransferase 1A3 (UGT1A3) in vitro. This suggests a potential for herb–drug interactions between schisandra and drugs that mainly undergo UGT1A3-mediated metabolism; however the effect has not been confirmed clinically (Liu et al 2012b).

## CONTRAINDICATIONS AND PRECAUTIONS

Insufficient reliable information is available.

## PREGNANCY USE

Insufficient information is available to establish safety.

## Practice points/Patient counselling

- *S. chinensis* is popular in TCM and is used to increase resistance to physical and emotional stressors and is regarded as an adaptogen.
- Traditionally, schisandra has been used to treat chronic cough and dyspnoea, diarrhoea, night sweats, irritability, palpitations and insomnia.
- It is commonly used as a liver tonic, and preliminary evidence has identified significant hepatoprotective effects.
- Schisandra exerts direct antioxidant activity and increases hepatic and myocardial glutathione levels, thereby increasing antioxidant systems within the heart and liver.
- Overall, little clinical evidence is available; therefore, much information is still speculative and based on in vitro and animal research and traditional use.

## PATIENTS' FAQs

### What will this herb do for me?

Schisandra is often prescribed to increase physical and emotional resilience and as a liver tonic. It has antioxidant activity, and early research suggests that it may have significant protective benefits for the liver.

### When will it start to work?

This is uncertain due to insufficient research being available.

### Are there any safety issues?

This is uncertain due to insufficient research being available.

# Selenium

**HISTORICAL NOTE** During his travels in the 13th century, Marco Polo first reported what is thought to be selenium toxicity in grazing animals. He observed that certain grazing areas in China were associated with horses developing diseased hooves (Hendler & Rorvik 2001). It is now known that parts of China have the highest selenium soil concentrations in the world and diseased hooves were likely to be due to selenium toxicity. It was not until nearly 500 years later, in 1817, that selenium was actually discovered (Tinggi 2003), and the fact that it is essential in mammals was not discovered until 1957 (Navarro-Alarcon & Lopez-Martinez 2000). In 1979, the importance of selenium in human nutrition was further reinforced when Chinese researchers reported that selenium supplementation prevented the development of Keshan disease, a cardiomyopathy seen in children living in selenium-replete areas, and New Zealand workers reported a clinical response to selenium supplementation in a selenium-depleted patient (Shils et al 2006).

## BACKGROUND AND RELEVANT PHARMACOKINETICS

Selenium is an essential trace element that enters the food chain through incorporation into plants from the soil. Selenium is mainly present in the form of selenite in acid soils, which is poorly assimilated by crops, whereas for alkaline soils it is in the form of selenate, which is more soluble and assimilated by crops. When taken in supplement form, animal and human trials demonstrate that bioavailability of organic forms of selenium (Se-methionine and Se-cysteine) is higher than that obtained for inorganic forms (selenite and selenate) (Navarro-Alarcon & Lopez-Martinez 2000).

The variation in selenium content of adult humans living in different parts of the world is testimony to the influence of the natural environment on the selenium content of soils, crops and human tissues. According to a WHO report, adults in New Zealand have approximately 3 mg selenium in their bodies and a daily intake of about 30 gm (100 gm/day is common) compared with 14 mg body content in some Americans and a daily intake around 100 g/day in North America. Intakes in Europe are in the range of 30 to 60 g/day.

Selenium is readily absorbed, especially in the duodenum and also in the caecum and colon. Vitamins A, E and C can modulate selenium absorption, and there is a complex relationship between selenium and vitamin E that has not been entirely elucidated for humans (Bates 2005). Selenium enters the body in two major forms: Se-methionine, which is derived from plants, and Se-cysteine, which is mainly derived from animal selenoproteins (Shils et al 2006). Metabolism is complex and occurs via several routes for the different selenoproteins. Se-methionine enters the methionine pool where it undergoes the same fate as methionine until catabolised. Once the selenium from Se-methionine is liberated by the trans-sulfuration pathway in the liver or kidney, it is able to be used by peripheral cells. Ingested selenite, selenate and selenocysteine are metabolised to selenide. Urinary excretion accounts for 50–60% of total excretion of selenium

and homeostasis is achieved through regulation in the kidney. Volatile forms of selenium are exhaled when intake is very high and presents a significant route of excretion at this level.

## CHEMICAL COMPONENTS

In human tissues, it is found as either L-selenomethionine or L-selenocysteine.

## FOOD SOURCES

Most dietary selenium is in the form of selenomethionine which is virtually completely bioavailable. The amount of selenium in a food greatly depends on the amount of selenium in the soil where it was grown. As such, a single food plant can vary greatly in its selenium content. By contrast, animal and marine sources tend to have more consistent selenium content. In general, the most concentrated food sources are brewer's yeast, wheatgerm, meats, fish and seafood, Brazil nuts, garlic and organ meats.

## DEFICIENCY SIGNS AND SYMPTOMS

Selenium deprivation reduces the activity of selenium-dependent enzymes and has widespread effects. Characteristic signs of selenium deficiency have not been described in humans, but very low selenium status is a factor in the aetiologies of a juvenile cardiomyopathy (Keshan disease) and a chondrodystrophy (Kashin-Beck disease) that occur in selenium-deficient regions of China.

Low selenium status has been associated with:

- loss of immunocompetence (Ongele et al 2002)
- increased risk of developing certain cancers (Clark et al 1998)
- reduced male fertility (Scott et al 1998, Xu et al 2003)
- poorer prognosis in HIV infection and AIDS (Baum et al 1997, Campa et al 1999)
- greater incidence of depression, anxiety, confusion and hostility (Rayman 2000)
- compromised thyroid hormone metabolism (particularly when iodine deficiency is also present) (Gartner et al 2002)
- asthma and atopy (Kadrobova et al 1996, Misso et al 1996, Omland et al 2002)

- rheumatoid arthritis (Zamamiri-Davis et al 2002)
  - possibly, increased inflammatory processes (Zamamiri-Davis et al 2002)
  - changes to drug-metabolising enzymes, including the cytochrome P450 system, with some activities increasing and others decreasing (Shils et al 2006).
- Low selenium status may contribute to the aetiology of several diseases, while in others this state exacerbates disease progression, such as in HIV infection.

People at risk of marginal selenium deficiency include those living in areas of low environmental selenium, such as some regions of New Zealand, people receiving long-term total parenteral nutrition (TPN), low-protein diet associated with phenylketonuria and hyperphenylalaninaemia, alcoholics, and those with liver cirrhosis, hepatitis C virus infection, malabsorption syndromes, cystic fibrosis, coeliac disease and AIDS (Procházková et al 2013).

## MAIN ACTIONS

### Antioxidant

Selenium is an integral part of thioredoxin reductase and the glutathione peroxidases and therefore is intimately involved in the body's antioxidant systems. These enzymes are involved in controlling tissue levels of free radical molecules and maintain cell-mediated immunity.

### Chemopreventative

Chemoprotective effects of selenium have been identified through RCTs and by experimental studies of selenium and known carcinogens in the development of specific cell lines. Several mechanisms have been postulated to explain the chemopreventive effect of selenium, including protection against oxidative damage, alterations to immune and metabolic systems, alterations to carcinogen metabolism, production of cytotoxic selenium metabolites, inhibition of protein synthesis, stabilisation of genetic material facilitating DNA repair by activation of p53, inhibition of nuclear factor-kappa B (NF-kappa B) and stimulation of apoptosis (Christensen et al 2007, Chun et al 2006, Clark et al 1996, El Bayoumy 2001, Schrauzer 2000, Seo et al 2002). One study demonstrated that combining vitamin E succinate and methylselenic acid produces a synergistic effect on cell growth suppression, primarily mediated by augmenting apoptosis (Zu & Ip 2003).

In humans, the chemopreventive effect is strongest for individuals with the lowest selenium status; however, it is still unclear whether low selenium status is implicated in the aetiology of cancer or whether it produces a state of increased susceptibility to the effects of carcinogens.

### Immunomodulation

Confirmed in both animal studies and human trials, immunomodulation is in part due to improved activation and proliferation of B-lymphocytes and enhanced T-cell function (Gazdik et al 2002a, 2002b, Hawkes et al 2001, Kiremidjian-Schumacher

& Roy 1998, Ongele et al 2002). A role for selenoprotein S in immune response has been proposed, with a study observing dose-dependent increased expression following influenza vaccine in selenium-supplemented adults (Goldson et al 2011). Interestingly, selenium concentrations significantly decrease during stages of acute infection, suggesting increased use and/or excretion or decreased absorption during this period (Sammalkorpi et al 1988).

### Thyroid hormone modulation

Selenium is required for normal thyroid hormone synthesis, activation and metabolism (Sher 2001). Three different selenium-dependent iodothyronine deiodinases (types I, II, and III) can both activate and inactivate thyroid hormone, making selenium an essential element for normal development, growth and metabolism through the regulation of thyroid hormones. However, it should be noted that selenium supplementation across a number of studies has been found to have no effect on thyroid hormone concentrations (Combs et al 2009, Hawkes et al 2008, Thomson et al 2011). In a randomised controlled trial of elderly UK residents ( $n = 501$ ), supplementation with selenium (100–300 mcg/day) did not have any significant effects on thyroid function despite significant increases in plasma selenium concentration (Rayman et al 2008). A small, statistically significant increase in T3 was observed in males; however, this did not correlate with a corresponding decrease in thyroid stimulating hormone, thus the clinical relevance on this increase in questionable (Combs et al 2009).

## OTHER ACTIONS

### Male fertility

Reduced selenium levels have been observed in infertile males, regardless of inflammatory status, which in turn has been associated with reduced percentage of normal sperm (Türk et al 2013). Selenium is required for testosterone synthesis, normal sperm maturation and sperm motility (Rayman & Rayman 2002). Two clinical studies have confirmed this association (Scott et al 1998, Vezina et al 1996) and identified selenium supplements as able to increase sperm motility. The effect of selenium in spermatogenesis may be due to several mechanisms, including the activity of the selenium-dependent enzyme phospholipid hydroperoxide glutathione peroxidase (GPX4) (Flohe 2007), altering oxidative stress-mediated apoptosis in germ cells (Kaushal & Bansal 2007a, 2007b), and the modulation of transcription factor NF-kappaB (Shalini & Bansal 2006, 2007a). Interestingly, animal studies suggest that detrimental effects on fertility are associated with either too little or excessive selenium intake (Shalini & Bansal 2007b, 2008).

### Anti-inflammatory

Selenium deficiency produces a significantly increased COX-2 protein expression, as well as higher PGE<sub>2</sub> levels, according to one in vitro study

(Zamamiri-Davis et al 2002). It has also been theorised that selenium may decrease leukotriene production (McCarty 1984). In vivo tests have identified anti-inflammatory activity in the lung with selenium, which is thought to relate to an increase in glutathione levels and immune parameters (Jeong et al 2002).

### Reduces heavy metal toxicity

Selenium protects against toxicity of some heavy metals, such as cadmium, arsenic, lead, silver and mercury (Berry & Galle 1994, Bolkent et al 2008, Chuang et al 2007, El-Sharakly et al 2007, El-Shenawy & Hassan 2008, Li et al 2012, Lindh et al 1996, Navarro-Alarcon & Lopez-Martinez 2000, Yiin et al 1999a, 1999b, 2000, 2001). A physiological role for selenium in counteracting heavy metal poisoning has been proposed (Shils et al 2006). It appears that the form of selenium is important, as inorganic selenium has been shown to enhance the toxic effects of inorganic arsenic by increasing its retention in tissues and suppressing its metabolism in vitro (Styblo & Thomas 2001).

### Antiatherogenic activity

Selenium supplementation reduces high-fat diet-induced atherosclerosis, according to an in vivo study (Kang et al 2001). In healthy subjects fed a test meal high in lipid hydroperoxides, selenium supplementation counteracted the postprandial synthesis of the atherogenic form of LDL (Natella et al 2007). By contrast, no association between toenail selenium and markers of subclinical atherosclerosis were found in a longitudinal study over an 18-year period ( $n = 3112$ ) (Xun et al 2010).

According to studies with experimental models, beneficial effects on lipid metabolism are due to significant up-regulation of LDL receptor activity and mRNA expression (Dhingra & Bansal 2006a), and down-regulation of hypercholesterolaemia-induced changes in apolipoprotein B (apoB) and 3-hydroxy 3-methylglutaryl coenzyme A (HMG-CoA) reductase expression during experimental hypercholesterolaemia (Dhingra & Bansal 2006b).

### Bone health

In healthy, euthyroid postmenopausal women, increased plasma selenium levels and selenoprotein P was associated with increased bone mineral density and reduced bone turnover (Hoeg et al 2012).

## CLINICAL USE

### Deficiency states: prevention and treatment

Traditionally, selenium supplementation has been used to treat deficiency or prevent deficiency in conditions such as malabsorption syndromes. In addition, the elderly are at increased risk of selenium deficiency. Poor levels are negatively associated with subjective indicators of quality of life (QOL) in older people, such as self-perceived health, chewing ability, physical activity (Gonzalez et al 2007),

muscle strength (Beck et al 2007, Lauretani et al 2007) and cognitive function (Akbaraly et al 2007, Gao et al 2007). Supplementation in this population where deficiency has been demonstrated is warranted.

### Cancer: prevention and possible adjunct to treatment

The first suggestion of a correlation between low selenium intake and increased cancer incidence arose in the 1970s, an observation which has been supported over time. However, it appears that selenium alone is not the only factor responsible for the protective effect. As such, it is not surprising that a recent Cochrane review determined that no reliable conclusions can be drawn regarding low selenium exposure and increased risk of cancer (Dennert et al 2011). The authors recommend that in many cases, results from available trials should be interpreted cautiously due to potential for confounding, bias and limited heterogeneity.

### Chemoprevention

Collectively, evidence available from a range of human, animal and cell-based studies supports a protective role for selenium against the development of cancer; however, results are not always consistent. Further research is required to better determine characteristics of responders, optimal dosage and dose forms. Populations who live in low-selenium environments and have low selenium intakes tend to have higher cancer mortality rates. However, the results from epidemiological studies have been less consistent and show that the effect may be strongest in males.

### Total cancer incidence and mortality

In a follow-up to the Linxian General Population Nutrition Intervention Trial, patients who received selenium in combination with vitamin E and beta-carotene had a lower overall mortality (HR 0.95, 95% CI 0.91–0.99) than placebo 10 years after the end of active intervention (Qiao et al 2009).

Several large-scale studies, including the Nutritional Prevention of Cancer (NPC) Trial and the Third National Health and Nutrition Examination Survey (NHANES III), have found that 200 mcg/day selenium is associated with reduced total cancer incidence and cancer mortality (Bleys et al 2008, Clark et al 1998, Reid et al 2008). Specifically, the NPC trial was a large multi-centre, double-blind randomised controlled trial (RCT) ( $n = 1312$ ) of patients with a history of basal cell or squamous cell carcinoma which investigated the effects of 200 mcg/day selenium (as 500 mg brewer's yeast). Findings from this study suggest that while supplementation in this population did not alter future incidence of skin cancer, it significantly reduced total cancer mortality, total cancer incidence by 37% and the incidences of lung, colorectal and prostate cancers by 46%, 58% and 63%, respectively (Clark et al 1998). Further studies on this population

suggest the protective effect of selenium may be restricted to people with low baseline plasma levels, and most pronounced for colorectal cancer and current smokers, whereas protective effects in prostate cancer were further restricted to lower baseline levels of prostate-specific antigen (PSA:  $\leq 4$  ng/mL) (Duffield-Lillico et al 2002, 2003, Reid et al 2002, 2006). Although 200 mcg/day selenium was associated with a lowered cancer incidence of 25%, this protective effect was not seen when a double dose was used (Reid et al 2008). At the 12-year follow-up of the NHANES III trial, both all-cause and cancer mortality were found to be reduced with increasing serum selenium levels up to  $<130$  ng/mL, but a gradual increase in mortality was seen at higher levels exceeding 150 ng/mL (Bleys et al 2008).

### Liver cancer

A trial involving 130,471 individuals living in a high-risk area for viral hepatitis and liver cancer (Qidong, China) found that table salt enriched with sodium selenite reduced the incidence of liver cancer by 35% during the 8-year follow-up period, whereas no changes were observed for the control groups (Yu et al 1997). Additionally, incidences of liver cancer began to rise after withdrawal of selenium supplementation. Patients with hepatocellular carcinoma had significantly lower serum selenium levels (along with iron, copper, and zinc) compared to those in the control group. The researchers speculated that lower levels of these minerals may act as biomarkers of the increased severity of viral hepatic damage (Lin et al 2006).

### Prostate cancer

While much epidemiological and clinical data suggest that selenium may prevent prostate cancer, not all studies have shown a protective effect.

The Selenium and Vitamin E Cancer Prevention Trial (SELECT) ( $n = 35,533$ ) determined that selenium (200 mcg/day) with or without concomitant vitamin E supplementation did not prevent prostate cancer among healthy men over age 50 (Se without vitamin E HR 1.09; Se with vitamin E HR 1.05) (Klein et al 2011). Secondary analyses corroborated these primary findings (Se without vitamin E HR 1.04; Se with vitamin E HR 1.05) (Lippman et al 2009). Similarly, among participants in the Prostate Cancer Prevention trial, secondary analysis found no association between selenium, either through dietary intake or supplementation, and risk of prostate cancer (Kristal et al 2010). A recent phase III randomised, double-blinded, placebo-controlled trial found that compared to placebo, selenium supplementation had no effect on incidence of prostate cancer in men ( $n = 699$ ) who were at high risk of the disease (200 mcg/day HR 0.94; 400 mcg/day HR 0.90) (Algotar et al 2013).

Peters et al (2007) observed that there was no inverse association between prediagnostic serum selenium concentration and the risk of prostate

cancer in a large cohort study with 724 cases and 879 matched controls. However, higher serum selenium levels may reduce prostate cancer risk in men who reported a high intake of vitamin E, in multi-vitamin users and in smokers (Peters et al 2007). Another prospective cohort study, the Vitamins And Lifestyle (VITAL) study, investigated the association of vitamin E and selenium supplementation with prostate cancer. No association was found between long-term selenium supplementation (average of 10 years) and prostate cancer risk, with an average intake of  $>50$  microgram/day compared to non-users. Supplementation for longer than an average of 10 years, however, was associated with a statistically non-significant reduction in prostate cancer among older men ( $\geq 70$  years) (Peters et al 2008).

Selenium supplementation has been found to have no significant effect on prostate cancer in a number of populations, men with localised non-metastatic prostate cancer not receiving active treatment (Stratton et al 2010), men with high-grade prostatic intraepithelial neoplasia (HGPIN) (Fleshner et al 2011, Marshall et al 2011). Subset analysis of the study by Marshall and colleagues (2011) found a non-significant reduced risk in men receiving selenium versus placebo in the lowest quartile of baseline plasma selenium, suggesting that future studies on this population alone may be of benefit.

By contrast, a large case-control study involved 33,737 males and identified an association between higher selenium status and a reduced risk of prostate cancer (Yoshizawa et al 1998). The study showed that men consuming the most dietary selenium (assessed indirectly by measuring toenail selenium levels) developed 65% fewer cases of advanced prostate cancer than those with the lowest intake.

Strong evidence for a protective effect of selenium against prostate cancer comes from the Nutritional Prevention of Cancer (NPC) trial, as described above, in which the incidence of prostate cancer was reduced in the selenium group by two-thirds as compared to placebo. Further follow-up has revealed that selenium supplementation continues to show a marked reduction on the incidence of prostate cancer with strongest effects seen in men with a PSA  $<4$  ng/mL and those with the lowest serum selenium levels at study entry (Duffield-Lillico et al 2003). It is interesting to note that the NPC trial was conducted in an area with low soil selenium content, and this may in part explain the conflicting results in studies conducted in various countries around the world.

A meta-analysis of 20 epidemiological studies found an inverse association between selenium levels (assessed in studies by serum, plasma and toenail) and risk of prostate cancer (Brinkman et al 2006). This supports the findings of an earlier meta-analysis of 16 studies (Etminan et al 2005). Similarly, in a prospective, case-control study ( $n = 130$ ), men with newly diagnosed prostate cancer had significantly lower serum selenium compared to healthy controls (66.3 microgram/L versus 77.5 microgram/L,

respectively). An increase of 10 microgram/L in serum selenium concentration was associated with a significant decrease in risk of prostate cancer (Pourmand et al 2008).

### Stomach and oesophageal cancers

A Cochrane review of five trials found that selenium appears to show significant beneficial effects against gastrointestinal cancer incidence (RR 0.59); however, four of these had a high risk of bias, therefore further RCTs are warranted (Bjelakovic et al 2008).

A large study of nearly 30,000 people demonstrated a protective effect for a combination of selenium, beta-carotene and vitamin E against the development of cancer of the gastric cardia and oesophagus (Mark et al 2000). Supplementation also reduced the cancer mortality rate compared with those not receiving supplementation. Protective effects on total cancer deaths developed slowly, appearing after 1 year of treatment, and the effect on stomach cancer appeared after 2 years. Gene-selenium interactions may influence an individual's susceptibility to oesophageal cancer. Individuals with polymorphisms in aldehyde dehydrogenase-2 Lys/Lys, X-ray repair cross-complementing 1399 Gln/Gln or Gln/Arg alleles, glutathione S-transferase isoenzyme Ile/Ile genotype or p53 (tumour suppressor gene) Pro/Pro genotype who consumed a low-selenium diet were at the greater risk of oesophageal squamous cell carcinoma, especially when combined with tobacco and alcohol intake (Cai et al 2006a, 2006b).

The protective role of selenium on gastric cancer risk may occur only in those with low baseline selenium. In a study where the levels of selenium were relatively high in both cases and controls, the lowest risk of gastric cancer was found in those with the lowest quartile of selenium level (assessed by toenail levels), whereas those with the highest risk were in the second highest quartile (Koriyama et al 2008).

### Colorectal cancer

The incidence of colorectal adenomas, the precursor to most colorectal cancers, may be reduced by selenium. An inverse association between selenium and adenomas has been found in numerous studies, particularly among smokers and those with low baseline serum or plasma selenium (Clark et al 1993, Connelly-Frost et al 2006, Fernandez-Baneres et al 2002, Jacobs et al 2004, Peters et al 2006, Reid et al 2006, Russo et al 1997). However, others have reported no association in risk (Early et al 2002, Wallace et al 2003). Compared to age-matched healthy controls, patients with colorectal cancer were found to have statistically lower serum selenium levels. Furthermore, a higher level of selenium was present in the cancerous tissue than in healthy tissue, though it is unclear whether this is the reason for the decreased selenium in the serum or whether the decreased serum levels occur prior to the development of colorectal cancer (Charalabopoulos et al 2006).

### Premalignant skin lesions

Increased selenium status may reduce the incidence of arsenic-related premalignant skin lesions (Chen et al 2007, Huang et al 2008). This is consistent with several observational studies that found a protective association between plasma selenium level and the risk of non-melanoma skin cancer (Breslow et al 1995, Clark et al 1984, Karagas et al 1997). Long-term selenium supplementation may exert a protective effect against arsenic-induced premalignant skin lesions by reversing some of the changes in gene expression (Kibriya et al 2007).

### Female reproductive

Selenium status measured by plasma levels and erythrocyte glutathione peroxidase activity was significantly lower in patients with cancer or benign neoplasia of the reproductive tract (uterus or ovary). Furthermore, examination of tissue margins of the tumours following surgery revealed significantly higher selenium concentrations compared to healthy tissue margins of healthy tissue. This suggests a protective role of selenium in the development of these reproductive tumours and a compensatory up-regulation of antioxidant defence systems in tumours due to persistent oxidative stress (Piekutowski et al 2007).

### Oral cancer

Selenium levels are significantly associated with risk of oral squamous cell carcinoma, with lower levels found in patients compared to both healthy controls and those with precancerous lesions (oral submucous fibrosis and oral leucoplakia) (Khanna & Karjodkar 2006).

### Lymphoma

In combination with chemotherapy, supplementation of selenium (as sodium selenite, 0.2 mg/kg/day) was found to have a synergistic effect, as observed through increased percentage of apoptotic lymphoma cells, reduced cervical and axillary lymphadenopathy, decreased splenic size and decreased bone marrow infiltration (Asfour et al 2009). This suggests that selenium may be a useful adjunct treatment in patients with non-Hodgkin's lymphoma; however, further studies are required with increased sample size and power to fully determine the effect of selenium supplementation.

### Lung cancer

A randomised, double-blind, placebo-controlled, phase III trial, which looked at selenium supplementation in patients with resected stage I non-small-cell lung cancer found that while selenium (200 mcg/day for 48 months) was safe and well tolerated, it did not provide any significant benefit over placebo in the prevention of secondary primary tumours (Karp et al 2013).

### Reducing radiotherapy-related adverse effects

In a multicentre, phase III clinical trial, selenium supplementation during radiotherapy for cervical and

uterine cancers was found to be effective to reduce frequency and severity of radiotherapy-induced diarrhea in cervical and uterine cancers (Muecke et al 2010, 2013).

### Reducing mortality from HIV infection

Selenium appears to be important in HIV infection, with plasma selenium a strong predictor of disease outcome in both adults and children (Baum & Shor-Posner 1998, Baum et al 1997, Campa et al 1999).

Low selenium status is common in HIV-positive patients and associated with a decline in Th (CD4) cell counts (Bates 2005). Low selenium is also associated with an increased incidence of mycobacterial diseases in HIV-1-seropositive drug users (Dworkin 1994, Dworkin et al 1986, 1989, Shor-Posner et al 2002).

In a double-blind, randomised, placebo-controlled trial, selenium supplementation (200 microgram/day) for 9 months suppressed the progression of HIV-1 viral burden and indirectly improved CD4 counts in adult HIV-infected men and women (Hurwitz et al 2007). One small intervention trial using low-dose selenium supplements (80 microgram/day with 25 mg vitamin E) over 2 months showed an improvement in general symptoms, but no alterations to immunological or haematological parameters (Cirelli et al 1991).

In antiretroviral therapy-naïve adults, the combination of selenium with multivitamins over 24 months significantly reduced the risk of immune decline and morbidity association with HIV infection; however, neither selenium nor multivitamins alone resulted in any statistically significant changes (Baum et al 2013).

The protective role of selenium in HIV-infected pregnant women is less clear. A 2012 Cochrane review determined that while selenium may improve child survival and reduce maternal diarrhoeal morbidity, it did not delay maternal HIV progression or improve pregnancy outcomes (Siegfried et al 2012).

One study found that low plasma selenium status was associated with increased risk of intrapartum transmission of HIV, risk of fetal and child mortality and the risk of small-for-gestational age (Kupka et al 2005). Selenium supplementation (200 mcg/day) during pregnancy in an RCT was also associated with reduced diarrhoeal morbidity risk by 40% (RR 0.60, 95% CI 0.42–0.84) in HIV-infected women (Kupka et al 2009). By contrast, in a randomised, double-blind, placebo-controlled trial, 200 microgram/day of selenium during and after pregnancy did not improve HIV disease progression, fetal mortality, prematurity or small-for-gestational age birth. Supplementation may, however, improve child survival after 6 weeks (Kupka et al 2008).

Selenium and selenium-dependent glutathione peroxidase (GSH-Px) are important for antioxidant protection and reducing oxidative damage in HIV. Antioxidant defences are increased in selenium-replete HIV patients due to the increase in oxidative stress induced by the infection (Stephensen et al

2007). However, in those with poor selenium levels and subsequently reduced GSH-Px defences, the increased oxidative stress may increase HIV progression (Ogunro et al 2006).

### Cardiovascular disease prevention

While a number of epidemiological studies have implicated a role for selenium in reducing cardiovascular disease mortality a recent Cochrane review of 12 RCTs ( $n = 19,715$ ) found that of the data available, current evidence does not support the use of selenium for the primary prevention of cardiovascular disease (Rees et al 2013). A 2006 meta-analysis found that while analysis of RCTs had suggested there were no significant changes in coronary events following selenium supplementation, when analysing observational studies, 11 out of 14 cohort studies and 9 out of 11 case-control studies found an overall positive effect associated with selenium (Flores-Mateo et al 2006). These discrepancies may be due to observational studies, including selenium in combination with other vitamins/minerals, which may have confounded results.

No significant primary preventive effect was seen for selenium supplementation (200 microgram/day) and incidence of cardiovascular disease, myocardial infarction, stroke or all cardiovascular disease mortality in the NPC study (Stranges et al 2006). Lack of association was confirmed when analyses were further stratified by tertiles of baseline plasma selenium concentrations. Selenium has also been found to have no significant effect on endothelial function or peripheral artery responsiveness in a randomised placebo-controlled trial of healthy men (Hawkes & Laslett 2009).

Many of the studies investigating selenium and cardiovascular disease have been conducted in European countries that have a lower selenium intake compared to countries such as the United States. It is possible that selenium is most effective at preventing cardiovascular disease in areas with intake levels less than those in the United States (Bleys et al 2008). The dose used in studies may also affect findings, with Bleys et al (2008) identifying that serum selenium levels below 120 ng/mL were associated with reduced cardiovascular and coronary heart disease mortality, while levels above this showed no statistically significant effect (Bleys et al 2008). It has been suggested that low selenium status may contribute to the development of hypertension. In a cross-sectional longitudinal study involving 710 Flemish subjects with an average baseline blood pressure of 130/77 mmHg, an inverse relationship was found between blood selenium and blood pressure in men at follow-up (median of 5.2 years). A 20-microgram/L higher baseline blood selenium concentration was associated with a 37% lower risk of developing high-normal BP or hypertension. No association was found in women (Nawrot et al 2007).

In non-Hodgkin's lymphoma patients receiving selenium supplementation as an adjunct to chemotherapy, supplementation prevented reductions in

cardiac ejection fractions seen in patients who received chemotherapy alone, suggesting a possible cardioprotective effect (Asfour et al 2009).

### Dyslipidaemia

Randomised, placebo-controlled, parallel-group study ( $n = 501$ ) identified that selenium supplementation (100–300 mcg/day) had a beneficial effect on lipid profile in persons aged 60–74 years. Reductions at all doses were seen for total cholesterol and non-HDL cholesterol; however, improvement was seen at 300 mcg/day selenium only in HDL cholesterol (Rayman et al 2011).

Compared to premenopausal women, postmenopausal women had lower erythrocyte selenium levels, which were associated with significantly higher levels of total cholesterol, triglycerides and LDL cholesterol. This association remained after controlling for age, smoking status and body mass index (Karita et al 2008). Further studies with increased sample size and across a wider age range is recommended.

### Diabetes

The relationship between selenium and diabetes is complex. It has been proposed that the association between selenium and cardiometabolic outcomes is U-shaped, with potential harm possible outside of the physiological range (Rayman & Stranges 2013, Zhou et al 2013). Inconsistent evidence available for selenium and its role in diabetes may be a result of differences in biomarker specificity, variability between trial subjects in baseline selenium status as well as inherent variations between population, age or racial groups (Rayman & Stranges 2013).

Selenium and selenoproteins appears to be involved in several key aspects of pancreatic beta-cell and islet function, increasing insulin content and secretion (Campbell et al 2008). Compared to healthy controls, diabetic patients have been found to have lower selenium levels (assessed by toenail levels) (Rajpathak et al 2005). Supplementation with selenium in diabetic patients has been found to reduce activation of NF-kappa B and levels of oxidative stress, and thus may help to prevent vascular complications (Faure et al 2004). Selenium has also been found to inhibit high glucose- and high insulin-induced expression of adhesion molecule via modulation of p38 pathway, and may therefore help to prevent the development of atherosclerosis in diabetics (Zheng et al 2008).

A randomised, double-blind, placebo-controlled trial ( $n = 84$ ) determined that selenium supplementation (200 mcg/day) significantly lowered fasting serum insulin levels after 6 weeks, and, in combination with L-arginine (5 g/day), reduced the fasting nitric oxide concentration (Alizadeh et al 2012).

However, some evidence suggests that chronically high selenium levels in selenium-replete populations may increase the risk of developing diabetes. Results from the NHANES III found that those in the highest quintile of serum selenium had a

statistically significant increased prevalence of diabetes compared with those in the first quintile (Bleys et al 2007). Similarly, secondary analysis of the NPC trial found that 200 microgram/day of selenium for an average of 7.7 years did not prevent diabetes and statistically significantly increased the risk of type 2 diabetes compared to the placebo group (Stranges et al 2007).

Selenium may play a protective role in gestational diabetes. A cross-sectional study involving 178 pregnant women (24–28 weeks of gestation) found a significant inverse correlation between selenium and blood glucose levels in patients with gestational diabetes mellitus or glucose intolerance having lower serum selenium levels compared to healthy controls (Kilinc et al 2008). This supports similar findings (Al-Saleh et al 2004, 2007, Bo et al 2005, Hawkes et al 2004, Molnar et al 2008, Tan et al 2001).

### Adiposity

Associations between selenium and adiposity have been identified through a number of studies. A cross-sectional analysis of the National Diet and Nutrition Survey from the United Kingdom identified an inverse association between plasma selenium and waist circumference, and a positive association between red blood cell waist-to-hip ratio, although causality and underlying mechanisms were not investigated (Spina et al 2013).

### Respiratory diseases

#### Asthma

Despite a number of observational studies suggesting that asthma, respiratory symptoms and ventilatory function may be associated with lowered circulatory selenium status and glutathione peroxidase activity (Devereux & Seaton 2005, Hasselmark et al 1990, Kadrabova et al 1996, Misso et al 1996, Omland et al 2002), a small number of intervention studies have been conducted, producing mixed results (Gazdik et al 2002a, 2002b, Hasselmark et al 1993).

Meta-analysis of data from a case-control study involving 569 asthmatic patients and 576 healthy controls in 14 European centres found no overall effect between plasma selenium levels and the risk of asthma (Burney et al 2008). These results are similar to those from a randomised, double-blind, placebo-controlled trial involving 197 asthmatic subjects given either a selenium supplement (high-selenium yeast preparation of 100 microgram) daily or placebo for 6 months. While the baseline plasma selenium levels increased by 48% in the treatment group, there was no significant difference between the groups with regard to either the primary outcome (asthma-related QOL score) or the secondary outcomes, including lung function, asthma symptom scores, peak flow and bronchodilator usage (Shaheen et al 2007).

A small randomised, double-blind study ( $n = 24$ ) of patients with intrinsic asthma found that while

100 mcg sodium selenite daily for 14 weeks significantly increased serum selenium and platelet glutathione peroxidase activity, no significant improvements over baseline in any clinical parameters were observed (Hasselmark et al 1993). By contrast, a small pilot study of 17 asthmatics dependent on corticosteroid medication found that a dose of 200 microgram selenium daily taken over a 96-week period reduced both inhaled and systemic corticosteroid requirements. The same study observed selenium supplementation enhancing immunity (Gazdik et al 2002a, 2002b).

Selenium appears to have a protective role in reducing childhood wheezing. Low plasma selenium levels during early pregnancy and in the neonate have been found to increase the risk of early childhood wheezing, although this positive association was no longer found at the age of 5 (Devereux et al 2007). Similarly, in a study of 61 children aged 0.3–5 years with no atopic history, lower serum selenium levels were found in those with frequent wheezing compared with those in healthy controls, and selenium levels were significantly correlated with the number of wheezing episodes experienced in the previous year. This protective effect may be due to preventing the progression of respiratory infections, which subsequently contribute to the development of wheezing (Kocabas et al 2006).

#### UPPER RESPIRATORY TRACT INFECTION — IN COMBINATION

*Echinacea purpurea* in combination with selenium, zinc and ascorbic acid, but not *E. purpurea* alone, in chronic obstructive pulmonary disease patients with upper-respiratory tract infection significantly reduced severity and duration of infection compared to placebo. Further studies are warranted to determine the role of selenium within this multiple micronutrient supplementation (Isbaniah et al 2011).

#### Autoimmune thyroiditis

Selenium appears to play an important role in the health of thyroid gland function and the prevention of disease. In a study of differences in selenium levels between those with thyroid disease and those without, selenium levels were significantly decreased in those with both benign thyroid disease (subacute and silent thyroiditis) and malignant thyroid disease (follicular and papillary thyroid carcinoma) compared to healthy controls (Moncayo et al 2008). Similarly in a study of patients with Graves' disease, those with the highest serum selenium levels (>120 microgram/L) were more likely to be in disease remission (Wertenbruch et al 2007). Following 6 months selenium treatment (100 microgram twice daily), patients with mild Graves' orbitopathy were found to have a slowed disease progression and an increased quality of life compared to placebo in a randomised, controlled, clinical trial (Marcocci et al 2011). These data suggest selenium may be of benefit in those patients with Graves' disease.

Selenium supplementation may improve inflammatory activity in chronic autoimmune thyroiditis patients, as evidenced by a significant reduction in the concentration of thyroid peroxidase antibodies (TPO-Ab) to 63.8% in selenium-supplemented subjects versus 88% ( $P = 0.95$ ) in placebo subjects (Gartner et al 2002). The randomised study of 70 females (mean age 47.5 years) compared 200 microgram sodium selenium daily orally for 90 days to placebo. A follow-up crossover study of 47 patients from the initial 70 was conducted for the further 6 months (Gartner & Gasnier 2003). The group that continued to take sodium selenite (200 microgram/day) experienced further significant decreases, whereas the group that ceased selenium use experienced a significant increase. The patients who received 200 microgram sodium selenite after placebo also experienced a significant decrease in levels of TPO-Ab.

A recent Cochrane review of four RCTs found that selenium supplementation in Hashimoto's thyroiditis determined that currently there was insufficient evidence to support use of selenium in this disorder (van Zuuren et al 2013). A total of 463 participants across four RCTs (279 selenium treated, 184 controls) were included in the meta-analysis, with duration of treatment ranging from 3 to 18 months. The Cochrane review concluded that there is a need for high-quality RCTs to properly evaluate the effects of selenium in this population, with three currently ongoing studies that may aid in clarifying current evidence.

In a prospective study of 80 patients with Hashimoto's thyroiditis receiving 200 microgram selenium (as selenomethionine) there was a significant 9.9% decrease in TPO-Ab levels after 6 months. In those patients who continued to take the selenium for another 6 months TPO-Ab levels decreased by another 8%, while those who ceased treatment experienced a 4.8% increase (Mazokopakis et al 2007).

#### Rheumatoid arthritis (RA)

Selenium supplements have been used in RA because of its antioxidant activity and the observation that some patients with RA have been reported with low selenium status (O'Dell et al 1991, Rosenstein & Caldwell 1999). One double-blind, placebo-controlled intervention study of 55 patients with moderate RA found that both placebo and selenium appeared to have significant effects on a number of symptoms; however, only selenium significantly improved arm movements and sense of wellbeing (Peretz et al 2001).

#### Lowered male fertility

Xu et al (2003) identified a significantly positive correlation between selenium levels and sperm density, sperm number, sperm motility and sperm viability in human volunteers. Similarly, Akinloye et al (2005) reported a significant inverse correlation between serum selenium level and sperm count and

serum testosterone, and seminal plasma selenium with spermatozoa motility, viability and morphology (Akinloye et al 2005). Supplementation with selenium in selenium-replete subfertile men has been shown to improve sperm motility and the chance of successful conception in over half the treated patients (Scott et al 1998). When taken with vitamin E over 6 months, selenium produces a statistically significant increase in sperm motility, per cent live and per cent normal spermatozoa, with effects reversing after supplement cessation (Vezina et al 1996). Although results are encouraging, particularly for subfertile men with low selenium status, some studies have found no effect of selenium supplementation (Hawkes et al 2009, Iwanier & Zachara 1995).

### General immune enhancement

Several intervention trials of either double-blind or open design have shown that selenium supplementation can enhance immune function and decrease the risk of developing certain infections in selenium-replete subjects, healthy adults and the elderly (Girodon et al 1999, Kiremidjian-Schumacher et al 1994, Roy et al 1994, Yu et al 1989).

The largest was a 3-year study of 20,847 people that showed substituting conventional table salt with table salt fortified with sodium selenite significantly reduced the incidence of viral hepatitis compared with controls provided with normal table salt (Yu et al 1989).

### Critically ill patients

Selenoproteins play an important role in the immunomodulation of critically ill patients, and low levels of plasma selenium have been associated with increased markers of oxidative stress, risk of organ failure and higher mortality rates. Clinical trials of selenium supplementation in critically ill patients however have produced mixed results. A recent systematic review and meta-analysis found that selenium supplementation ( $\leq 500$  microgram/day) may be associated with a beneficial effect on 28-day mortality in critically ill patients. However, it should be acknowledged that due to several factors relating to study quality, the authors state that further evaluation is required before routine adjuvant use of selenium is recommended in a clinical setting (Lan-ducci et al 2014).

The long-term effect of selenium on mortality remains unclear. A 2011 RCT ( $n = 502$ ) found selenium supplementation did not affect the risk of developing a new infection, 6-month mortality, length of stay, days of antibiotic use or modified sepsis-related organ failure assessment (Andrews et al 2011). One possible explanation suggested for negative findings is sodium selenite having a direct pro-oxidant action in these patients (Forceville 2007).

Daily infusion of 1600 microgram Se (as selenite) over 10 days was also found to significantly decrease incidence of hospital-acquired pneumonia, including early ventilator-associated pneumonia, in

critically ill patients with SIRS (Manzanares et al 2011).

### Mood elevation and reduced anxiety

Considering that low dietary intake of selenium has been linked with greater incidence of anxiety, depression and tiredness, several research groups have investigated whether higher dietary intake or selenium supplementation will elevate mood and/or reduce anxiety. Currently, results are equivocal; however, it appears that selenium-replete individuals are most likely to respond to supplementation, if a response is observed.

A randomised double-blind placebo-controlled trial of primigravida women ( $n = 166$ ) found that 100 microgram/day selenium supplementation was associated with reduced symptoms of depression compared to those receiving placebo in the 8 weeks following delivery (Mokhber et al 2011).

Similarly, an early double-blind, crossover study showed that short-term selenium supplementation (100 microgram/day for 5 weeks) significantly elevated mood and decreased anxiety, depression and tiredness, with effects most marked in people with low dietary intake (Benton & Cook 1991). A study of 30 selenium-replete men who were fed either a low (32.6 microgram/day) or a high (226.5 microgram/day) selenium diet for 15 weeks found that the mood of those with the higher selenium intake improved, whereas mood worsened with low intake (Finley & Penland 1998 as reported in Rayman 2005). Alternatively, another study involving 11 men of adequate selenium intake failed to show effects on mood when high (356 microgram/day) and low (13 microgram/day) selenium diets were followed for 99 days (Hawkes & Hornbostel 1996). Similarly, a large ( $n = 448$ ) 2-year randomised study also failed to find evidence that additional selenium enhanced mood or any of its subscales, despite significant increases in plasma selenium levels (Rayman et al 2006). This study compared the effects of 100, 200 or 300 microgram/day of selenium to placebo for effects on mood and QOL. Selenium supplementation was given as high-selenium yeast, SelenoPrecise (Pharma Nord, Vejle, Denmark).

### Reducing morbidity in preterm babies

Preterm infants are born with slightly lower selenium and glutathione peroxidase concentrations than full-term infants and have low hepatic stores of selenium. In very preterm infants, low selenium concentrations have been associated with an increased risk of chronic neonatal lung disease and retinopathy of prematurity (Darlow & Austin 2003). Although the full consequences of low selenium concentrations in this population are not fully known, observation from animal studies has found an association between selenium deficiency and increased susceptibility to oxidative lung injury. This has special significance for sick, very preterm infants as they are exposed to many possible sources

of oxygen radical products, including high concentrations of inspired oxygen. A Cochrane review of three randomised studies that reported outcomes on 297 infants receiving selenium supplements and 290 control infants concluded that selenium supplementation in very preterm infants is associated with benefit in terms of a reduction in one or more episodes of late-onset sepsis, but is not associated with improved survival, a reduction in neonatal chronic lung disease or retinopathy of prematurity (Darlow & Austin 2003). It should be noted that most of the evidence derives from research conducted in New Zealand, a country with low soil and population selenium concentrations, and may not be readily translated to other populations. In one study, despite preterm infants having lower selenium levels compared to term infants, selenium levels did not correlate with chronic lung disease or septicemia (Loui et al 2008).

### OTHER USES

Used in combination with other antioxidants or administered intravenously, selenium has been used in pancreatitis and as adjunctive therapy in cancer patients.

Supplementation of selenium with coenzyme Q10 and vitamin E has been found to improve clinical conditions associated with severe psoriasis, including reduced oxidative stress markers in both plasma and lesional epidermis (Kharaeva et al 2009).

Oral sodium selenite (350 microgram/m<sup>2</sup> body surface area) was given daily for 4–6 weeks to 52 patients with extensive, persistent or progressive lymphoedema from radiation and resulted in the majority experiencing some reduction in oedema (Micke et al 2002). A further study (Micke et al 2003) of 48 patients found that sodium selenite supplementation had a positive effect on secondary lymphoedema caused by radiation therapy alone or by irradiation after surgery. The group consisted of 12 patients with oedema of the arm and 36 with oedema of the head and neck region. Increased dietary intake of selenium over 1 year was found to be positively correlated with capillary recruitment in skin of healthy men ( $P = 0.038$ ), suggesting it may have a role in microvascular function and health (Buss et al 2013). In patients with leukaemia, undergoing allogeneic haematopoietic stem cell transplantation, selenium treatment was found to reduce the incidence of oral mucositis, as well as the duration of objective oral mucositis compared to placebo (Jahangard-Rafsanjani et al 2013).

Cancer treatment often induces toxicity associated with the oxidative damage to normal cells. A Cochrane review of selenium in the prevention of side effects associated with cancer treatment (Dennert & Horneber 2006) found only three trials that met inclusion criteria. One study found a lower incidence of recurrent erysipela infections of lymphoedematous upper limbs after breast cancer treatment in the selenium group, with a second study finding reduced facial swelling in selenium-treated patients

in a 2-week period following surgical tumour resection. Preliminary results from another study suggest a lower incidence of diarrhoea in those receiving pelvic radiotherapy. On the whole, the authors concluded that there was still insufficient evidence to support selenium supplementation to reduce adverse effects of tumour-specific chemotherapy.

In an animal model, moderate selenium supplementation increased the total antioxidant activity leading to a lower generation of reactive oxygen metabolites, which helped to counteract the cardiotoxicity associated with the chemotherapeutic drug Adriamycin (Danesi et al 2006).

### DOSAGE RANGE

The Therapeutic Goods Act altered the allowed amount of selenium in listed products to be raised to 150 microgram. Supplements containing selenium carry the following caution on their label: 'This product contains selenium which is toxic in high doses. A daily dose of 150 microgram for adults of selenium from dietary supplements should not be exceeded.'

### Australian RDI

#### Children

- 1–3 years: 25 microgram
- 4–8 years: 30 microgram
- 9–13 years: 50 microgram

#### 14–18 years

- Boys: 70 microgram
- Girls: 60 microgram

#### Adults

- Males >18 years: 70 microgram
- Females >18 years: 60 microgram
- Pregnancy: 65 microgram
- Lactation: 75 microgram

### According to clinical studies

- Asthma: 100–200 microgram/day of sodium selenite.
- Cancer prophylaxis: 200 microgram/day selenium (supplied as 500 mg brewer's yeast).
- Infertility: 100 microgram/day.
- Mood disturbances: 100 microgram/day.
- Post myocardial infarction: selenium-rich yeast 100 microgram/day.
- Rheumatoid arthritis: 200 microgram/day.
- Autoimmune thyroiditis: 200 microgram/day sodium selenite.
- HIV-positive status: 80 microgram/day has been used but it is most likely that higher doses are required.

### TOXICITY

Long-term ingestion of excessive levels of selenium (>1000 microgram/day) may produce fatigue, depression, arthritis, hair or fingernail loss, garlicky breath or body odour and gastrointestinal disorders

or irritability (Fan & Kizer 1990). Chronic low-level overexposure has been associated with lethargy, dizziness, motor weakness and paraesthesia (Vinceti et al 2013).

### ADVERSE REACTIONS

Nausea, vomiting, nail changes, irritability and fatigue have been reported.

The organic form of selenium found in high-selenium yeast is often preferred because it is less toxic.

The National Health and Medical Research Council of Australia states that selenium intake should not exceed 600 microgram/day.

### SIGNIFICANT INTERACTIONS

#### Cisplatin

Selenium may reduce associated nephrotoxicity, myeloid suppression and weight loss, according to in vitro and in vivo tests (Camargo et al 2001, Ohkawa et al 1988) — potentially beneficial interaction.

#### Heavy metals (e.g. mercury, lead, arsenic, silver and cadmium)

Selenium reduces toxicity of heavy metals such as mercury, lead, arsenic, silver and cadmium by forming inert complexes — beneficial interaction.

#### Practice points/Patient counselling

- Selenium is a trace element that is essential for health.
- Low selenium states have been associated with a variety of conditions, such as cardiovascular disease, cancer, asthma, atopy, male subfertility, rheumatoid arthritis, depression and anxiety and compromised immune function.
- High-intensity sports training has been associated with a reduction in plasma selenium levels (Wang et al 2012).
- Studies have identified selenium deficiency in a significant number of people with the HIV infection and suggested a link between selenium levels and mortality rate.
- It is also involved in the detoxification of some heavy metals and xenobiotics.
- Selenium-enriched yeast is the safest way to supplement the diet, but other forms are also used.

#### CONTRAINDICATIONS AND PRECAUTIONS

Sensitivity to selenium.

#### PREGNANCY USE

Considered safe in usual dietary doses; safety at higher levels is unknown.

## PATIENTS' FAQs

### What will this supplement do for me?

Adequate selenium intake, and in some cases supplementation may reduce the risk of developing certain cancers and heart disease and help to improve a range of conditions such as rheumatoid arthritis, asthma, autoimmune thyroiditis, male subfertility, depression and anxiety.

### When will it start to work?

If a protective effect is to occur with selenium against cancer or cardiovascular disease, the effect appears to develop slowly over several years' consistent intake.

### Are there any safety issues?

High intakes of selenium above 1000 microgram/day have been associated with a number of adverse effects and should be avoided.

## Shark cartilage

**HISTORICAL NOTE** Shark cartilage became a popular supplement in the 1980s, largely based around the claim that sharks rarely get cancer and therefore must have some protection against the disease. By 1995, the annual world market for shark-cartilage products exceeded US\$30 million and dozens of shark cartilage products were available in retail stores and usually sold as food supplements (Ernst 1998). Over the past few decades, progress has been made in identifying various naturally occurring molecules in avascular tissue, such as cartilage, which exhibit antiangiogenic properties and could be investigated as treatments in cancer. Shark cartilage is one such tissue and numerous shark cartilage derivatives and extracts have been investigated for effects on tumours, including squalamine lactate, AE-941 and U-995. Previously, much work had been conducted with bovine cartilage, which also exhibits anti-angiogenic properties, although to a lesser extent.

### CHEMICAL COMPONENTS

Shark cartilage is mainly composed of proteins, calcium, phosphorus, water, collagen and proteoglycans, chiefly chondroitin sulfates. Collagen imparts tensile strength and proteoglycans impart resilience to cartilage.

### MAIN ACTIONS

#### Analgesic and anti-inflammatory

Both analgesic and anti-inflammatory activities have been reported for shark cartilage preparations in animal studies (Fontenele et al 1996, 1997). The mechanism of action is unknown; however, tests with the opioid antagonist naloxone have found it does not involve the opioid system (Fontenele et al 1997). One mechanism of action suggested is that shark cartilage significantly inhibits IL-1-induced PGE<sub>2</sub> synthesis (Pearson et al 2007).

Suppression of airway inflammation, by down-regulating vascular endothelial growth factor, was demonstrated in an animal model, suggesting a possible novel therapeutic application to treat bronchial asthma. This research was carried out with a marine cartilage pharmaceutical formula called Neovastat (AE-941) (Lee et al 2005, Lee & Chung 2007).

There is also research indicating that shark cartilage might be useful for some but not all inflammatory conditions. A number of different commercial shark cartilage extracts were tested and found to induce TH1 type inflammatory cytokines. In

addition, the acid extracts of shark cartilage tested produced higher amounts of TNF (alpha) than the other aqueous extracts. As well as stimulating a TH1 response, the cartilage extracts appeared to inhibit TH2 cells, which may be useful for hypersensitive individuals who would benefit from downregulation of the IgE response (Merly et al 2007).

#### Anti-angiogenic

Neovastat and shark cartilage extract (SCE) are preparations with demonstrated antiangiogenesis activity occurring via multiple mechanisms (Patra & Sandell 2012).

Shark cartilage extract appears to block the two main pathways that contribute to the process of angiogenesis, matrix metalloproteases and the vascular endothelial growth factor signalling pathway (Anon 2004). The effect is due to several different constituents that have been isolated from shark cartilage and identified as exerting anti-angiogenic activity (Bargahi & Rabbani-Chadegani 2008, Dupont et al 1998, Gonzalez et al 2001, Rabbani-Chadegani et al 2008, Shen et al 2001, Sheu et al 1998, Zheng et al 2007) in various experimental models.

Neovastat, a shark cartilage preparation containing a mix of water soluble components, also demonstrates antiangiogenic activity in various models. A concentration-dependent inhibition of cell proliferation in human umbilical vein endothelial and bovine endothelial cells has been observed. It also

inhibited angiogenesis induced by basic fibroblast growth factor (FGF) in the chicken chorioallantoic membrane model and also significantly retarded vascularisation of bFGF-containing Matrigel implanted in mice after oral administration (Dupont et al 2002).

### Antineoplastic effects

Due to its anti-angiogenic activity, shark cartilage has been investigated for antineoplastic effects. In one study, oral administration of powdered shark cartilage significantly delayed the development of papillary and solid tumours in a murine renal tumour model in experimental animals (Barber et al 2001). Shark cartilage proteoglycan was found to inhibit pancreatic carcinogenesis when administered to hamsters for 50 days (Kitahashi et al 2006). Neovastat has demonstrated activity against lung metastases in the murine Lewis lung carcinoma model and when Neovastat (0.5 mL/day) was used with a sub-optimal dose of cisplatin (2 mg/kg, IP) a greater anti-metastatic effect was observed by exerting a protective activity against cisplatin-induced body weight loss and myelosuppression (Dupont et al 2002).

### Immunostimulant

Shark cartilage stimulates cellular and humoral immune responses as demonstrated in vitro (Bargahi et al 2011). A complex mixture of constituents is responsible for the immunostimulating properties of shark cartilage, according to in vitro research (Kralovec et al 2003). Of these, a protein fraction composed of two proteins with molecular weights of approximately 14 and 15 kDa have exhibited the most immunostimulatory effects (Hassan et al 2005).

## OTHER ACTIONS

### Antibiotic

Squalamine, isolated from dogfish shark cartilage, is a broad-spectrum antibiotic with activity against protozoa, fungi and both Gram-positive and Gram-negative bacteria (Moore et al 1993).

### Antioxidant

Antioxidant activity has been demonstrated in vitro (Gomes et al 1996).

### Fibrinolytic

Fibrinolytic activity of a shark cartilage extract was demonstrated in an in vitro study (Ratel et al 2005).

## CLINICAL USE

One of the most studied shark cartilage preparations is known as Neovastat (or AE-941), which is a mix of water-soluble components derived from shark cartilage prepared by a proprietary manufacturing process developed by Aeterna Laboratories (Quebec, Canada). The few studies conducted with shark cartilage preparations have been disappointing from a clinical perspective.

### Osteoarthritis

Based on its analgesic and anti-inflammatory activities, shark cartilage has been used to relieve symptoms in osteoarthritis (OA). To date, no clinical studies are available to determine its effectiveness; however, positive results have been obtained in several clinical studies for one of its constituents, chondroitin sulfate (see *Chondroitin* monograph for details).

### Cancer

Shark cartilage used to be a popular supplement with cancer patients, although results from the few clinical trials conducted using shark cartilage in people with advanced cancers have generally been disappointing. Several theories have been proposed to explain the lack of correlation between the highly promising in vitro and in vivo studies and the clinical trials conducted to date, mainly calling into question the bioavailability of shark cartilage and the key active constituents responsible for the anti-angiogenic effect (de Mejia & Dia 2010).

One study of 60 people with advanced, previously treated cancer (breast, colorectal, lung, prostate, non-Hodgkin's lymphoma, brain) failed to demonstrate an effect for orally administered shark cartilage (1 g/kg) on tumour growth or QOL (Miller et al 1998). A larger study of 83 patients with advanced breast and colorectal cancers, which was published in 2005, also found that shark cartilage failed to improve survival or QOL (Loprinzi et al 2005). This study was a two-arm, randomised, placebo-controlled, double-blind, clinical trial. Of note, there was a high drop-out rate as only half the patients receiving shark cartilage powder continued with treatment beyond 1 month and only 10% were still using the treatment by 6 months. It was thought that gastrointestinal symptoms may have contributed to the poor patient compliance.

Several smaller preliminary studies have produced positive results, with some patients experiencing less tumour progression and weight loss, improved appetite or decreased pain. Unfortunately, details of these studies are difficult to locate and much remains unanswered, such as doses used, time frames for use and criteria for improvement.

Investigation with Neovastat (AE-941), a standardised shark cartilage extract, has produced more promising results and demonstrated inhibitory effects on the growth and metastasis of tumours; however, research has mainly been conducted in animal models (Hassan et al 2005). One clinical study conducted with Neovastat did report a significant survival advantage for the patients with unresectable stage IIIA, IIIB or IV non-small-cell lung cancers receiving treatment (Hassan et al 2005). Similarly, an open-label, multicentre study testing four different strengths of Neovastatin (30, 60, 120, or 240 mL/day) in 80 patients with histologically confirmed lung cancer reported a significant survival advantage for patients receiving doses >2.6 mL/kg/

day (which correspond to approximately 180 mL/day in a 70-kg patient) compared to patients receiving lower doses (median, 6.1 months vs 4.6 months;  $P = 0.026$ ). Interestingly, no tumour response was observed in this study (Latreille et al 2003). The treatment was considered well tolerated and the most common side effects were nausea (9%), pruritus (5%), anorexia (4%), and vomiting (4%).

A Phase II trial tested two different doses of Neovastat (60 or 240 mL/day) given twice daily in patients with solid tumours (renal cell carcinoma) who were refractory to standard treatment (Batist et al 2002). A survival analysis conducted on 22 patients with a primary diagnosis of refractory RCC found a significant relationship between dose and survival; the median survival time was significantly longer (16.3 versus 7.1 months;  $P = 0.01$ ) in patients treated with Neovastat 240 mL/day ( $n = 14$ ) compared with patients receiving 60 mL/day ( $n = 8$ ). The treatment was well tolerated and the most common side effect was taste alteration (14%).

In contrast, a double-blind RCT of patients with breast or colorectal carcinoma considered incurable but receiving standard care compared a shark cartilage product to placebo given three to four times each day. Data on a total of 83 evaluable patients revealed there were no differences in overall survival between patients groups or in QOL beyond placebo (Loprinzi et al 2005).

More recently in 2010, Lu et al conducted a double blind RCT involving people with unresectable stage III non-small cell lung cancer who were treated with chemoradiotherapy (Lu et al 2010). Unfortunately, the study was unable to recruit a sufficient number of people to meet the sample size target making results difficult to interpret. All volunteers received both chemotherapy (either carboplatin and paclitaxel, or cisplatin and vinorelbine) and chest radiotherapy. Treatment with Neovastatin + standard treatment ( $n = 188$ ) failed to significantly alter overall survival beyond placebo ( $n = 191$ ). Additionally, there were no differences between the groups for time to progression, progression-free survival, and tumour response rates and no protection against toxic effects attributable to chemoradiotherapy.

## OTHER USES

There is one case report of a man with Kaposi's sarcoma whose lesion disappeared after taking shark cartilage (3.75–4.5 g/day for 9 months) (Hillman et al 2001).

## DOSAGE RANGE

Depending on the purity of the supplement, 500–4500 mg/day in divided doses.

Various doses of cartilage have been used in different studies, ranging from 2.5 mg to 100 g/day (Simone et al 1998).

## Practice points/Patient counselling

- Shark cartilage is mainly composed of calcium, phosphorus, water, collagen and proteoglycans, chiefly chondroitin sulfates.
- Anti-angiogenic, antineoplastic, immunostimulant and broad-spectrum antibiotic activities have been reported in preliminary studies.
- Both analgesic and anti-inflammatory activities have been reported for shark cartilage preparations in animal studies, most likely due to its chondroitin content. As a result, it is used to relieve symptoms in arthritic conditions.
- It is a popular supplement among cancer patients; however, the few clinical trials conducted so far with people with advanced cancers have generally produced negative results, suggesting no benefit.
- Its use is contraindicated in people with seafood allergy, and in pregnancy. Do not use 3 weeks before and 6 weeks after surgery, or in children or teenagers still experiencing growth.

## Clinical note — Angiogenesis and tumour growth

Angiogenesis is defined as the formation of new capillary blood vessels from existing microvessels and is a process regulated by inducers and inhibitors. It is critical for development, reproduction and repair and dominates many pathological conditions (Folkman 2003). In 1971, the hypothesis that tumour growth is angiogenesis-dependent was first proposed and since then, the study of angiogenesis inhibitors in cancer research has developed. It has now been demonstrated that solid tumours that exceed 1–2 mm in diameter require new blood vessels or angiogenesis to feed their growth (Patra & Sandell 2012). They secrete angiogenic substances to set up an internal network of blood vessels to support further growth and there is a correlation between tumour microvessel density and the risk of metastases. In the absence of angiogenesis, tumour growth is restricted to a microscopic size and tumour cells do not shed into the circulation. Cartilage is an avascular tissue and therefore must contain substances which prevent blood vessel growth, making it a prime target for anti-angiogenesis research.

## ADVERSE REACTIONS

The most common side effects reported in clinical trials are: taste alteration (14%), nausea (9%), pruritus (5%), anorexia (4%) and vomiting (4%).

## SIGNIFICANT INTERACTIONS

Controlled studies and sufficient reliable information are not available to predict or determine interactions.

## CONTRAINDICATIONS AND PRECAUTIONS

Contraindicated in people with seafood allergy.

Do not use 3 weeks before until 6 weeks after surgery, or in children or teenagers still experiencing growth.

Hypercalcaemia: Due to the high calcium content of this supplement, it should be used with caution in people with hypercalcaemia.

## PREGNANCY USE

Although not scientifically investigated in this population, it is not recommended in pregnancy or lactation based on theoretical considerations.

## PATIENTS' FAQs

### What will this supplement do for me?

Shark cartilage has a number of different actions, such as anti-inflammatory, antibiotic, anti-tumour and pain-relieving effects. However, these have not been confirmed in controlled human studies. As a result, it is difficult to determine what effects will be experienced.

### When will it start to work?

Due to the lack of human research, this is unknown.

### Are there any safety issues?

Shark cartilage products are not to be used in people with seafood allergy or in pregnancy. They should not be used by children or teenagers still experiencing growth or 3 weeks before and for 6 weeks after surgery.

# Shatavari

**HISTORICAL NOTE** There are approximately 300 species of 'asparagus' (derived from the Greek word for 'stalk' or 'shoot'), including the popular European vegetable *Asparagus officinalis*. The medicinal use of *Asparagus racemosus* (shatavari) has been recorded in traditional systems of medicine such as Ayurveda, Unani and Siddha (Bopana & Saxena 2007). It is a different form of asparagus from *Asparagus officinalis*. Shatavari, meaning 'she who possesses a hundred husbands', is often considered an aphrodisiac (Sharma et al 2000) and a 'female tonic'. It is recommended in Ayurvedic texts for the prevention and treatment of gastric ulcers and dyspepsia; for threatened miscarriage and as a galactagogue; and is known as a 'rasayana' (a substance that promotes general physical and mental wellbeing by improving defence mechanisms and vitality) (Goyal et al 2003). Demand for shatavari in combination with destructive harvesting techniques and deforestation has resulted in the plant becoming 'endangered' in its natural habitat (Bopana & Saxena 2007).

## OTHER NAMES

Asparagus bush, Inli-chedi, Kairuwa, Majjigegadde, Narbodh, Norkanto, Philli-gaddalu, Satavari, Satawar, Shatmulu, Shimaishadavari, Toala-gaddalu, wild asparagus

## BOTANICAL NAME/FAMILY

*Asparagus racemosus* Willd. (family Asparagaceae [previously Liliaceae, subfamily Asparagae]) (Goyal et al 2003)

It should be differentiated from numerous other species reported in the scientific literature, including *A. acutifolius*, *A. adscendens*, *A. africanus*, *A. curillus*, *A. dumosus*, *A. filicinus*, *A. gonocladus*; and from *A. officinalis* (the stalks of which are consumed as a vegetable).

## PLANT PART USED

Root

## CHEMICAL COMPONENTS

Steroidal saponins (shatavarins VI–X); saponins (shatavarin I [or asparoside B], shatavarin IV [or asparinin B, a glycoside of sarsasapogenin], shatavarin V, immunoside and schidigera saponin D5 [or asparanin A] (Hayes et al 2008); isoflavones (Saxena & Chourasia 2001), racemofuran, asparagamine A and racemosol (Wiboonpun et al 2004), ascorbic acid (vitamin C) (Visavadiya & Narasimhacharya 2005). Sarsasapogenin and kaempferol have also been isolated from the woody portion of the roots (Bopana & Saxena 2007). However, a recent study (Kumeta et al 2013) revealed that *A. racemosus* does not contain pyrrolo[1,2-a]azepine alkaloid, asparagamine A as reported in previous studies. Kumeta et al (2013) report that studies that identified asparagamine A may have wrongly identified stemonia plants as *A. racemosus*.

Steroidal saponins (racemosides A, B and C) have also been isolated from the fruit (Mandal et al 2006). Shatavarioside A (1) and shatavarioside B (2) have been isolated from the root (Sharma et al 2009). Quercetin, rutin and hyperoside have been

identified in the flowers and fruits, and diosgenin and quercetin-3 glucuronide in the leaves (Bopana & Saxena 2007). More recently, an isoflavone, 8-methoxy-5,6,4'-trihydroxyisoflavone-7-O-β-D-glucopyranoside, has been found in *A. racemosus* roots (Negi et al 2010).

## MAIN ACTIONS

### Adaptogenic (modulates stress response)

In Ayurvedic medicine herbs are usually used in combination and shatavari is used in approximately 64 Ayurvedic formulations. Research is usually conducted with herbal combinations containing shatavari, thereby making it difficult to ascertain the pharmacological and clinical effects of the individual herb (Bopana & Saxena 2007).

A polyherbal formula, known as EuMil, which contains standardised extracts of *A. racemosus* in combination with *Withania somnifera*, *Ocimum sanctum* and *Emblia officinalis*, ameliorates chronic stress-induced neurochemical perturbations and normalises noradrenaline, dopamine and 5-hydroxytryptamine (5HT) levels in animal experiments (Bhattacharya et al 2002). Other animal studies using EuMil have demonstrated attenuation of stress-induced glucose intolerance and immunosuppression, increased male sexual behaviour, and improvements in depression and cognitive dysfunction (Muruganandam et al 2002). These results were also found in a similar polyherbal known as Siotone, containing *A. racemosus*, *Withania somnifera*, *Ocimum sanctum*, *Tribulus terrestris* and shilajit (a composted plant exudate high in minerals) (Bhattacharya et al 2000). Methanolic extract of shatavari has demonstrated physiological modulation of stress pathways by reducing plasma corticosterone and noradrenaline (norepinephrine) in animal models, thus indicating shatavari's possible adaptogenic effect (Krishnamurthy et al 2013). Whether these results are consistent in humans, and which herbs they are attributed to, has not yet been established.

### Digestive effects

Early studies suggested that shatavari could improve digestion by increasing levels of amylase and lipase (Dange et al 1969). A small study of eight healthy males using a crossover design found that oral administration of dried shatavari root had similar effects on gastric emptying time to the antiemetic drug metoclopramide, a synthetic dopamine antagonist which is used in dyspepsia to promote gastric emptying (Dalvi et al 1990). Animal experiments using oral doses of shatavari have also reversed the effects of cisplatin on gastric emptying, while normalising cisplatin-induced intestinal hypermotility (Rege et al 1999).

### Antiulcerogenic

Antiulcerogenic activity comparable to a standard antiulcer drug ranitidine (30 mg/kg/day orally) has been demonstrated in rats. Treatment with a crude extract of shatavari (100 mg/kg/day orally) for fifteen days significantly reduced indomethacin (NSAID)-induced ulceration when compared with the control group. The effect appeared to be related to an inhibition of hydrochloric acid and protection of the gastric mucosa (Bhatnagar & Sisodia 2006). Early studies demonstrated that shatavari could relieve pain and burning due to duodenal ulceration and proposed that these effects may be due to: an increase in the secretion and viscosity of gastric mucus; formation of a shatavari-mucus complex at the base of the ulcer, providing protection from corrosive agents; prolongation of the life span of mucosal cells and/or a cytoprotective effect similar to that of prostaglandins (Goyal et al 2003). Some of these hypotheses have been supported by further research. The antiulcerogenic effect of oral administration of a methanolic extract of fresh shatavari root (25–100 mg/kg) twice daily for 5 days was studied on different gastroduodenal ulcer models in rats (Sairam et al 2003). Doses of 50 mg/kg twice daily demonstrated significant protection against acute gastric ulceration induced by 'cold restraint stress, pyloric ligation, aspirin plus pyloric ligation, and duodenal ulcers induced by cysteamine' and promoted healing of acetic acid-induced chronic gastric ulceration after 10 days of treatment. An effect was not demonstrated for aspirin- or ethanol-induced gastric ulcers. The effect was believed to be due to an increase in mucus secretion, cellular mucus, the life span of cells, as well as a significant antioxidant effect (Sairam et al 2003).

### Immunomodulation

In *in vitro* studies *A. racemosus* increased the phagocytic and killing capacity of macrophages in a dose-dependent manner (up to 200 mg/kg) (Rege & Dahanukar 1993), and an aqueous extract of *A. racemosus* activated T-cells *in vivo*. Experimental models in mice have demonstrated the immunostimulating properties of *A. racemosus*, inhibiting the leucopenia associated with cyclophosphamide by

inducing leucocytosis with neutrophilia (Thatte & Dahanukar 1988). Animal studies have demonstrated that oral administration of *A. racemosus* inhibited some of the deleterious effects of ochratoxin A suppression of chemotactic activity and production of IL-1 and TNF- $\alpha$  by macrophages, and also induced excess production of TNF- $\alpha$  in animals that did not receive ochratoxin A (Dhuley 1997). It also appears to reduce intraperitoneal adhesions induced by caecal rubbing by increasing the activity of macrophages (Rege et al 1989), and may act as an immunoadjuvant in animals immunised with diphtheria, tetanus, pertussis (DTP) vaccine, increasing antibody titres to *Bordetella pertussis* and providing improved immunoprotection on challenge (Gautam et al 2004).

Two steroidal saponins, shatavarside A and shatavarside B, extracted from the root of *A. racemosus* exhibited a dose-dependent and potent immunostimulant activity at low concentrations (5 ng/mL) *in vitro* (Sharma et al 2013).

### Antibacterial and anti-leishmanial

*In vitro* studies using different concentrations (50, 100, 150 microgram/mL) of the methanolic extract of shatavari root demonstrated considerable antibacterial efficacy against: *Escherichia coli*, *Shigella dysenteriae*, *Shigella sonnei*, *Shigella flexneri*, *Vibrio cholerae*, *Salmonella typhi*, *Salmonella typhimurium*, *Pseudomonas putida*, *Bacillus subtilis* and *Staphylococcus aureus* (Mandal et al 2000b). Another *in vitro* study using aqueous and ethylacetate extracts of shatavari roots demonstrated antibacterial activity against Gram-negative *Alcaligenes* with the ethyl acetate extract having stronger effects (Phatak et al 2011).

A constituent of *A. racemosus* fruit, racemoside A, exhibits potent anti-leishmanial activity against the dangerous visceral form of leishmaniasis (Dutta et al 2007).

### Hormonal activity

The steroidal saponins (shatavarins) contained in *A. racemosus* may help explain some of the hormonal effects demonstrated in animal models. An alcoholic extract of shatavari root (300 mg/kg bodyweight) was administered orally to pregnant female albino rats during days 1–15 of gestation. The results suggested an oestrogenic effect on the mammary glands and genital organs (Pandey et al 2005). Tests with animal models indicate shatavari competitively blocks the effect of oxytocin, thereby inhibiting oxytocin-induced uterine contraction in rabbits, rats and guinea pigs (Gaitonde & Jetmalani 1969). This action appears to be due to the asparagamine, a polycyclic alkaloid (Sekine et al 1994).

### Galactagogue

Galactagogue activity has been demonstrated in animal models (Patel & Kanitkar 1969, Sabinis et al 1968). One study of weaning rats found shatavari treatment increased the weight of mammary glands, inhibited involution of lobulo-alveolar tissue and

maintained milk secretion (Sabnis et al 1968). It has been proposed that this effect may be due to the action of released corticoids and prolactin (Goyal et al 2003). Oral treatment with a shatavari root capsule (60 mg/kg body weight/day for 30 days) has also been shown to significantly elevate prolactin levels in a double-blind randomised controlled trial (RCT) of lactating mothers indicating the effect is clinically significant at this dose (Gupta et al 2011).

### Antidiarrhoeal

Ethanol and aqueous extracts (200 mg/kg) of shatavari root have been shown to inhibit castor oil-induced diarrhoea, and PGE<sub>2</sub> induced enteropooling (excessive secretion of water and electrolytes); and reduced gastrointestinal motility in rats (Venkatesan et al 2005). A recent study, in which ethanol extract of *A. racemosus* was administered to mice to inhibit castor oil-induced diarrhoea confirmed the previous results showing a delay in the onset of diarrhoea as well as a reduced frequency of defecation at the dose of 250 to 500 mg/kg body weight compared to the standard drug loperamide (Karmakar et al 2012).

### Antioxidant and hepatoprotective

*A. racemosus* contains known antioxidant compounds, including ascorbic acid, polyphenols and flavonoids (Visavadiya & Narasimhacharya 2005). Antioxidant properties have also been identified for racemofuran, asparagine A and racemosol (Wiboonpun et al 2004). In vitro experiments have demonstrated antioxidant effects comparable to that of glutathione and ascorbic acid in inhibiting lipid peroxidation and protein oxidation (Kamat et al 2000). Animal models confirmed the inhibition of lipid peroxidation and also showed an increase in antioxidant enzymes (superoxide dismutase, catalase) and ascorbic acid (Bhatnagar et al 2005, Visavadiya & Narasimhacharya 2005). An alcoholic extract of shatavari root significantly reduces elevated levels of alanine transaminase (ALT), aspartate transaminase (AST) and alkaline phosphatase (ALP) in vivo (Muruganandan et al 2000). *A. racemosus* extract administered in isoniazid induced hepatotoxicity in mice at 50 mg/kg body weight for 21 days showed hepatoprotective effects indicated by an improved liver function profile ( $P < 0.05$ ) and inhibition of cytochrome P4502E1 (CYP2E1). The study suggests that *A. racemosus* inhibits production of free radicals and *A. racemosus* acts as a scavenger by inhibiting CYP2E1 activity.

### Cardiovascular effects

Studies using different animal models indicate various effects on heart function. Goyal et al (2003) found lower doses of shatavari root produce a positive inotropic and chronotropic effect on frog's heart, with higher doses causing cardiac arrest. The extract was also found to produce hypotension in cats (attenuated by atropine) indicating a cholinergic mechanism; and a slight increase in bleeding time in rabbits (Goyal et al 2003).

Studies with animal models have indicated lipid-lowering activity for *A. racemosus* (Visavadiya et al 2009, Zhu et al 2010). In one study, a 5% and 10% dose of *A. racemosus* root powder administered to hypercholesterolaemic rats on a normal diet or hypercholesterolaemic diet respectively for 4 weeks, showed reduction in hepatic lipid profile, increased excretion of faecal cholesterol and increased hepatic HMG-CoA reductase activity. These effects have been attributed to the presence of phytosterols, saponins, flavonoids, ascorbic acid and polyphenols in *A. racemosus* (Visavadiya et al 2009).

### Neuroprotective

Oxidative stress and excitotoxicity are considered to be major mechanisms of neuronal cell death in neurodegenerative disorders such as Alzheimer's and Parkinson's diseases. Experimental studies have demonstrated that shatavari extract may attenuate oxidative damage, elevating glutathione peroxidase (GPx) activity and glutathione (GSH) content; and could result in a protective effect on kainic acid (KA)-induced excitotoxicity (Parihar & Hemnani 2004).

A methanolic extract of *A. racemosus* root administered to test animals at 100 mg/kg body weight daily for 30 days and subjected to 3 hours of swim stress showed higher total normal cell counts in the hippocampus compared to rats subjected to the swim stress test without active treatment, suggesting a potential neuroprotective activity (Saxena et al 2010).

### Antidepressant

Antidepressant activity has been demonstrated in vivo. A methanolic extract of *A. racemosus* root (MAR) (standardised to saponins 62.2% w/w) was given to rats in doses of 100, 200 and 400 mg/kg daily for 7 days. The results show that MAR decreased immobility in forced swim tests (FST) and increased avoidance response in learned helplessness tests (LH), indicating antidepressant activity. Effects were thought to be mediated through the serotonergic and noradrenergic systems, and augmentation of antioxidant defences (Singh et al 2009). A methanolic extract of *A. racemosus* demonstrated inhibition of cholinesterase and monoamine oxidase (MAO) activities in vivo (Meena et al 2011). The saponin content in the extract was thought to be responsible for the observed activity.

### Antineoplastic

An extract of shatavari root has been reported to reduce the incidence of DMBA (7,12-dimethyl benz(a)anthracene)-induced mammary cancer in female rats (Rao 1981). The effect is thought to be due to properties that render the mammary epithelium refractory to the carcinogen. Clinical implications remain to be tested.

Rats pretreated with aqueous extract of *A. racemosus* showed no p53+ foci while rats not receiving *A. racemosus* showed p53+ foci on immunohistochemical staining indicating that *A. racemosus* has the potential to prevent hepatocarcinogenesis induced by diethylnitrosamine (Agarwal et al 2008). Isolated shatavarin IV with shatavarin rich fraction has shown anticancer activity in vitro against human breast cancer, human colon adenocarcinoma and human kidney carcinoma cell lines (Mitra et al 2012). In this study, oral administration of isolated shatavarin IV at doses of 250 and 500 mg/kg body weight to cancer-induced mice showed reduction in tumour volume, per cent increase in body weight and packed cell volume, suggesting anticancer activity (Mitra et al 2012).

### Antilithic

An ethanolic extract of shatavari inhibited experimentally-induced urinary lithiasis (stone formation) in vivo (Christina et al 2005). Administration of shatavari reduced elevated urinary concentrations of calcium, oxalate and phosphate, which contribute to stone formation, and increased urinary concentration of magnesium, which is thought to be protective. Elevated serum creatinine was also reduced. Similar results were obtained in another animal study (Jagannath et al 2012). However, there is little evidence on antilithic activity of *A. racemosus* in clinical trials.

### Antitussive

Strong antitussive activity has been demonstrated in animal models. A methanolic extract of shatavari root (200 and 400 mg/kg orally) showed significant antitussive activity on sulfur dioxide-induced cough in mice. The dose-dependent cough inhibition (40.0 and 58.5%, respectively) was comparable to that of 10–20 mg/kg codeine phosphate (36.0 and 55.4%, respectively) (Mandal et al 2000a).

### Analgesic

Ethanolic extract of *A. racemosus* in acetic acid-induced writhing model in mice showed 52.39% ( $P < 0.05$ ) and 67.47% ( $P < 0.05$ ) writhing inhibition at doses of 250 and 500 mg/kg body weight suggesting analgesic activity of shatavari (Karmakar et al 2012).

### Antihyperglycaemic

Administration ethanol extracts of *A. racemosus* roots orally in diabetic and healthy rats showed improved glucose tolerance by suppressing post-prandial sucrose load. Daily oral administration of *A. racemosus* extracts in type 2 diabetic rats over a period of 28 days resulted in decreased serum glucose and increased pancreatic insulin indicating that *A. racemosus* inhibits carbohydrate absorption therefore *A. racemosus* can be a potentially useful antidiabetic nutritional adjuvant. However, the hyperglycaemic potential of *A. racemosus* needs to be tested in human clinical studies (Hanna et al 2012).

## CLINICAL USE

Shatavari has not been subjected to extensive clinical testing so most information is derived from traditional use and in vivo experiments, thereby providing biological plausibility for some of its uses.

### Stress

Currently, evidence to support the use of shatavari as a sole agent for reducing the deleterious effects of stress on the body is limited. Animal studies using polyherbal formulations (Mukherjee et al 2011), such as EuMil (Bhattacharya et al 2002, Muruganandam et al 2002) and Siotone (Bhattacharya et al 2000), have shown some promise, but further research is required.

### Dyspepsia

Shatavari root is used in Ayurvedic medicine for the treatment of dyspepsia. This may in part be due to improved digestion via increased levels of amylase and lipase (Dange et al 1969), and its ability to promote gastric emptying in a manner comparable to metoclopramide (Goyal et al 2003), and to normalise intestinal hypermotility (Rege et al 1999).

### Gastrointestinal ulcers

In animal models, shatavari has been shown to reduce the incidence and increase the rate of healing of ulcers (Samarakoon et al 2011); while also relieving the pain and burning associated with duodenal ulceration (Goyal et al 2003). Antiulcerogenic activity of a crude extract of shatavari (100 mg/kg/day orally) has been found to be comparable to a standard antiulcer drug ranitidine (30 mg/kg/day orally) in rats. The effect may be related to an inhibition of hydrochloric acid and protection of the gastric mucosa (Bhatnagar & Sisodia 2006). Studies investigating ulcer healing activity of shatavari seem to use poly-herbal formulations (Samarakoon et al 2011), which poses a limitation on interpreting the role of shatavari as a single herb in ulcer healing.

### Prevention of infection

In vitro and animal experiments have demonstrated positive effects on immunity (particularly on the activity of macrophages) (Rege et al 1989, Rege & Dahanukar 1993) as well as antibacterial effects against *Escherichia coli*, *Shigella dysenteriae*, *Shigella sonnei*, *Shigella flexneri*, *Vibrio cholerae*, *Salmonella typhi*, *Salmonella typhimurium*, *Pseudomonas putida*, *Bacillus subtilis* and *Staphylococcus aureus* (Mandal et al 2000b). Shatavari has also shown antibacterial activity against *Alcaligenes* (Phatak et al 2011). Further research is required in clinical trials to ascertain whether these effects can be demonstrated in humans.

## OTHER USES

### Hormonal disturbances in women

Traditionally shatavari is used as a 'rejuvenative tonic' for females and for lowered libido and

infertility in both sexes (Sharma et al 2011). Due to its oestrogenic effects it is often used by herbalists for the treatment of conditions related to low oestrogen, including some presentations of PMS and menopause; and to re-establish normal ovulation and menstruation patterns (Trickey 2003). Human trials have demonstrated positive results for dysfunctional uterine bleeding, dysmenorrhoea, PMS and menopausal symptoms, however these studies used the polyherbal formulations EveCare and Menosan which contain *A. racemosus* (Bopana & Saxena 2007) so it is difficult to ascertain the role played by shatavari alone.

### Promoting lactation

Shatavari root is used traditionally in Ayurvedic medicine to increase milk production and secretion during lactation (Sharma et al 2011). Early animal studies support this use (Sabnis et al 1968, Patel & Kanitkar 1969). Whether shatavari increases prolactin levels and consequently improves lactation remains difficult to determine from the evidence as most studies used it as part of a herbal combination. Previously, polyherbal combinations including *A. racemosus* Ricalex (Alphali Pharmaceutical Ltd, Ahmednagar) (Joglekar et al 1967) and Lactare (TIK Pharma, Chennai) have been shown to increase milk production in women complaining of poor milk supply (Goyal et al 2003). In contrast, a placebo-controlled RCT of 64 lactating women in India found a herbal combination galactagogue formula (including shatavari 15%) had no effect on prolactin levels or lactation compared to placebo (Sharma et al 1996). Since shatavari was only one component of the formulas tested, it is not possible to identify the contribution of shatavari to these results.

Positive results were obtained in a more recent double-blind, randomised, parallel group clinical trial ( $n = 60$ ) which found that use of a shatavari root capsule (60 mg/kg body weight/day) for a duration of 30 days resulted in a 33% increase in prolactin levels compared to an increase of 9.5% in the control group among women aged 20–40 years having trouble lactating and with infants up to 6 months of age (Gupta & Shaw 2011). The galactagogue activity was attributed to the possible steroidal saponins in *A. racemosus*. Although, this study did not find any acute toxicity on oral administration of shatavari, the long-term toxicity of shatavari is not clearly understood and needs further investigation (Mortel & Mehta 2013).

### Diarrhoea

Shatavari root is used traditionally in Ayurvedic medicine for the treatment of diarrhoea and dysentery. Ethanol and aqueous extracts of shatavari root have demonstrated antidiarrhoeal effect by reducing gastrointestinal motility in animal studies (Venkatesan et al 2005, Karmakar et al 2012). Human studies are warranted to confirm these effects.

### DOSAGE RANGE

Fluid extract (1:2): 30–60 mL/week (Australian manufacturer's recommendations).

### ADVERSE REACTIONS

No significant adverse events or biochemical liver dysfunction was noted in a randomised controlled trial of shatavari (Sharma et al 1996). Due to the saponin content, gastric irritation may occur in some individuals.

#### Practice points/Patient counselling

- In Ayurvedic medicine shatavari is used in approximately 64 Ayurvedic polyherbal formulations. As much of the current research focuses on these preparations, it is difficult to ascertain the pharmacological and clinical effects of the individual herb.
- Shatavari may exert beneficial effects on digestion by increasing levels of lipase and amylase, promoting gastric emptying, normalising intestinal motility and protecting against ulceration.
- Shatavari is used, often in combination with other herbs, to improve milk production in lactating women, although human data supporting this effect are currently lacking. More promising was a recent study using shatavari as a stand-alone treatment.
- Animal models suggest that the steroidal saponins contained in *A. racemosus* may exert some hormonal effects, which may account for its reputation as a female tonic and aphrodisiac.
- As teratogenicity has recently been demonstrated in rats, caution should be exercised in pregnancy until more is known about effects in humans.
- Demand for shatavari in combination with destructive harvesting techniques and deforestation has resulted in the plant becoming 'endangered' in its natural habitat.

### SIGNIFICANT INTERACTIONS

As controlled studies are not available, interactions are currently speculative and based on evidence of pharmacological activity. No evidence could be located that suggested any negative drug interactions.

### Metoclopramide

As shatavari root was found in animal studies to have similar effects on gastric emptying time to the antiemetic drug metoclopramide (a synthetic dopamine antagonist), an additive effect is possible (Dalvi et al 1990, Sharma et al 2011).

### Diphtheria, tetanus, pertussis (DTP) vaccine

Experimental studies have suggested a possible immunoadjuvant effect in animals immunised with

diphtheria, tetanus, pertussis (DTP) vaccine, increasing antibody titres to *Bordetella pertussis* and providing improved immunoprotection on challenge (Gautam et al 2004). Beneficial effects possible.

### **? CONTRAINDICATIONS AND PRECAUTIONS**

No toxic effects or mortality have been observed with doses ranging from 50 mg/kg to 1 g/kg for 4 weeks, and acute and subacute (15–30 day) toxicity studies have not detected any changes in results of vital organ function tests. The LD<sub>50</sub> is >1 g/kg (Rege et al 1999).

As inhibition of hydrochloric acid has been proposed as a possible factor contributing to the antiulcer effects of shatavari (Bhatnagar & Sisodia 2006), those with hypochlorhydria may need to be observed.

Herbs with theoretical oestrogenic effects may not be suitable for those with or at risk of oestrogen-dependent tumours. However, the clinical significance is unclear.

The Commission E has approved the use of *A. officinalis* root in irrigation therapy for inflammatory diseases of the urinary tract and for prevention of kidney stones; however, this should be avoided if oedema exists due to functional heart or kidney disorders (Blumenthal et al 2000). Similar cautions might be expected for *A. racemosus*.

### **PREGNANCY USE**

Although shatavari has been used traditionally to promote conception and for threatened miscarriage, teratogenicity has been demonstrated in rats at doses of 100 mg/kg/day for 60 days (Goel et al 2006). Caution should be exercised in pregnancy until more is known about effects in humans. Little evidence is available about the safe use of shatavari in breast-feeding; however, what is available suggests no significant side effects (Sharma et al 1996).

### **! PATIENTS' FAQs**

#### **What will this herb do for me?**

It is difficult to determine what effects shatavari will display when used as a sole treatment, as it is most often tested as part of a polyherbal combination formula. The herbal combinations containing shatavari have a myriad of uses, such as improving digestion, promoting lactation and increasing libido. Shatavari root is used traditionally in Ayurvedic medicine for the treatment of diarrhoea and dysentery, gastric ulcers and dyspepsia, threatened miscarriage and as a galactagogue.

#### **When will it start to work?**

This is difficult to estimate as the majority of human trials have been conducted with polyherbal

preparations containing shatavari and not with shatavari as a sole treatment.

#### **Are there any safety issues?**

Caution should be exercised in pregnancy until more is known about the potential teratogenic effects.

## Slippery elm

**HISTORICAL NOTE** The dried inner bark of the slippery elm tree was a popular remedy used by many Native American tribes, and subsequently taken up by European settlers. It was mixed with water and applied topically to treat wounds, bruises and skin irritations, and used internally for sore throat, coughs and gastrointestinal conditions. When mixed with milk, it was used as a nutritious gruel for children and convalescents. It also gained a reputation as an effective wound healer among soldiers during the American Civil War. From 1820 until 1960, it was listed in the US Pharmacopeia as a demulcent, emollient and antitussive (Ulbricht & Basch 2005). The name 'slippery elm' refers to the slippery consistency of the inner bark when it comes into contact with water.

### COMMON NAME

Slippery elm

### OTHER NAMES

American elm, Indian elm, moose elm, red elm, sweet elm, winged elm

### BOTANICAL NAME/FAMILY

*Ulmus fulvus* or *Ulmus rubra* (family Ulmaceae)

According to current botanical nomenclature, it should now be referred to as *Ulmus rubra*.

### PLANT PART USED

Dried inner bark

### CHEMICAL COMPONENTS

The inner bark chiefly contains mucilage (various hexoses, pentoses, methylpentoses), glucose, polyuronides, tannins, galacturonic acid, L-rhamnose, D-galactose, starches, fat, phytosterols, sesquiterpenes, oxalate acid, flavonoids, salicylic acid, capric acid, caprylic acid, decanoic acid and cholesterol (Beveridge et al 1969, Duke 2003, IM Gateway Database

2003, Newell et al 1996, Rousseau & Watts 2012). The bark provides 2740 kcal/kg. It contains a variety of nutritional factors, such as glucose, calcium, iron, vitamin C, thiamine, zinc, magnesium and potassium, providing support for its traditional use as a nutritious gruel.

#### **Clinical note — Mucilages**

Mucilages are hydrophilic structures, capable of trapping water, which causes them to swell in size and develop a gel-like consistency. The gels tend to have soothing properties and can be broken down by bowel flora when taken internally (Mills & Bone 2000). Mucilages are known to have beneficial effects on burns, wounds and ulcers when applied externally and on gastric inflammation, irritations and diarrhoea when taken internally.

## **MAIN ACTIONS**

The pharmacological actions of slippery elm have not been significantly investigated in clinical studies. Therefore, information is generally based on what is known about key constituents found within the herb.

### **Soothes irritated and inflamed tissue**

The large amount of mucilage found in slippery elm bark will coat the surface of mucous membranes or wounds and sores when it comes in contact with water, and form a gel-like layer. Mucilaginous medicinal plants, such as slippery elm, have beneficial effects on burns, wounds, ulcers, external and internal inflammations and irritations (Morton 1990). They provide a moist, protective barrier which can soothe and promote healing.

### **Nutritive demulcent**

A number of constituents, such as starch, glucose, calcium, iron, vitamin C, thiamine, zinc, magnesium and potassium are present in slippery elm, making it a source of many nutritional factors (Duke 2003).

### **Antioxidant**

In vitro studies show a free radical-scavenging activity that may relate to its anti-inflammatory action (Langmead et al 2002). Compounds with antioxidant activity are sometimes investigated for their tumoricidal activity; however an in vitro study found slippery elm to exhibit only weak tumoricidal properties (Mazzio & Soliman 2009).

## **CLINICAL USE**

The therapeutic effectiveness of slippery elm has not been significantly investigated under clinical trial conditions, so evidence is derived from traditional, in vitro and animal studies.

## **Gastrointestinal conditions**

Based on traditional evidence, slippery elm is taken internally to relieve the symptoms of gastritis, acid dyspepsia, gastric reflux, peptic ulcers, irritable bowel syndrome (IBS) and Crohn's disease.

It is widely accepted that, when orally ingested, the mucilage forms a physical barrier protecting the oesophageal and stomach walls from the damaging effects of stomach acid and possibly also exerting mild anti-inflammatory activity locally. Currently, clinical research is not available to determine the effectiveness of slippery elm in these conditions; however, anecdotally the treatment appears to be very successful and patients report rapid improvement in upper gastrointestinal symptoms.

Solid-dose tablets and capsules are used in the treatment of lower gastrointestinal conditions such as diarrhoea, where it is believed the fibre will slow down gastric transit time and act as a bulking agent. Although clinical studies are not available to determine its effectiveness, the high mucilaginous content and presence of tannins in the herb provide a theoretical basis for its use.

## **IN COMBINATION**

A small, open pilot study investigated the use of a herbal formula containing slippery elm in the treatment of 31 patients with IBS, with promising results. Twenty-one patients with diarrhoea-predominant or alternating bowel habit IBS were given the herbal formula containing slippery elm (4.5 g), powdered bilberry fruit (10.0 g), agrimony (3.0 g) and cinnamon (1.5 g) twice daily for 3 weeks. Ten patients with constipation-predominant IBS were given a herbal formula containing slippery elm (7.0 g), lactulose (3.0 g), oat bran (2.0 g) and licorice root (1.5 g) twice daily for 3 weeks. The diarrhoea-predominant or alternating bowel habit IBS group reported no improvements in bowel habit, although they did report a significant improvement in a number of IBS symptoms, including straining, abdominal pain, bloating, flatulence and global IBS symptoms. There was a significant improvement in bowel habits in the constipation-predominant IBS group, with a 20% increase in bowel movement frequency and improvements in stool consistency, and IBS symptoms, including reductions in straining, abdominal pain, bloating and global IBS symptom severity (Hawrelak & Myers 2010). While some of these results are promising, the role of slippery elm in achieving the reported benefits is unclear. Further research is required to expand upon the findings of this pilot study.

## **Dermatitis and wounds**

Slippery elm has also been used as a topical agent to soothe irritated and/or inflamed skin conditions, wounds and burns and to draw out boils and abscesses (Fisher & Painter 1996). When applied, it forms a protective gel-like layer, which is considered to have soothing properties.

## **Laryngeal 'soothing' effect**

A single oral dose of 3 g of slippery elm taken in warm water as a tea had no 'soothing' effect

according to a randomised, controlled, single-blind study of 24 volunteers without pharyngeal or laryngeal complaints (Rousseau & Watts 2012). A 'soothing' effect was defined as 'when the [tissue] surface feels as if it were coated with something, such as a layer of protective covering'. Further research should be conducted testing the preparation in people with current inflammation and discomfort.

### OTHER USES

Traditionally, slippery elm is used to treat bronchitis, cystitis and intestinal parasites. Externally, it has been used to treat gout, inflamed joints and toothache (Fisher & Painter 1996).

#### Clinical note — Essiac tea

Slippery elm is one of the key ingredients in Essiac tea, which was reportedly developed by the Ojibwa tribe of Canada and named after an Ontario nurse (Rene Caisse) to whom the formula for the herbal tea was given by an Ojibwa healer in 1922 (Smith & Boon 1999). It is used to treat a variety of diverse conditions, such as allergies, hypertension and osteoporosis. The tea is made up of a mixture of four herbs, *Arctium lappa* (burdock root), *Rumex acetosella* (sheep sorrel), *Ulmus rubra* (slippery elm) and *Rheum officinale* (rhubarb) and is considered to possess antioxidant and, possibly, anticancer activities (Leonard et al 2006). As a result, it is used widely by North American cancer patients during chemo- and radiotherapies (Cheung et al 2005) for reduction in symptoms associated with cancer treatment and as a possible adjunctive treatment. In vitro tests with Essiac have identified anticancer activity, although its effects in vivo are controversial and evidence of efficacy is anecdotal (Leonard et al 2006). A recent study demonstrated that Essiac tea effectively scavenges several types of radicals and possesses DNA-protective effects (Leonard et al 2006). A retrospective cohort study of 510 women with breast cancer found that Essiac did not improve quality-of-life scores or mood (Zick et al 2006). Daily doses of Essiac range from 12 to 114 mL, with the average dose being 43.6 mL, corresponding to doses recommended on popular products. Duration of treatment ranged from 1 to 28 months, with the average being 11.1 months. The formula was well tolerated, with only two women reporting minor adverse events, while many women reported beneficial effects. In contrast, an in vitro study found Essiac tea stimulated the growth of human breast cancer cells via both oestrogen receptor-dependent and oestrogen receptor-independent mechanisms (Kulp et al 2006). Patients and health practitioners should consider these findings when making clinical decisions regarding treatment protocols.

### DOSAGE RANGE

Owing to insufficient data available from clinical studies, doses have been derived from Australian manufacturers' recommendations.

#### Practice points/Patient counselling

- Slippery elm inner bark is a highly mucilaginous substance, which has been traditionally used as a topical application to soothe irritated and inflamed skin conditions and promote wound healing.
- It is used internally to soothe an irritated throat and is often combined with antiseptic herbs.
- Slippery elm is used to provide symptomatic relief in acid dyspepsia, gastrointestinal reflux and inflammatory bowel diseases, but has not been scientifically studied to any significant extent.
- Overall, slippery elm has not been significantly investigated in clinical studies, so most information is derived from traditional sources and the known activity or key constituents.

### Gastrointestinal symptoms

- One to two capsules containing 150 mg of slippery elm before meals.
- Fluid extract (60%): 5 mL three times daily.
- Half a teaspoon of slippery elm bark powder is mixed with one cup of hot water and taken up to three times daily. For added flavouring, cinnamon or nutmeg can be added.

### External use

- Mix the coarse powdered bark with enough boiling water to make a paste and use as a poultice (Hoffman 1983).

### TOXICITY

Insufficient reliable information is available.

### ADVERSE REACTIONS

Insufficient reliable information is available.

### SIGNIFICANT INTERACTIONS

Controlled studies are unavailable, but interactions are theoretically possible with some medicines.

Since slippery elm forms an inert barrier over the gastrointestinal lining, it may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. barbiturates, digoxin, lithium, phenytoin, warfarin). The clinical significance of this is unclear. Separate doses by 2 hours.

#### CONTRAINDICATIONS AND PRECAUTIONS

Insufficient reliable information is available.

**PREGNANCY USE**

It is likely to be safe, but safety is still to be established.

**PATIENTS' FAQs****What will this herb do for me?**

The inner bark of slippery elm is highly mucilaginous, meaning that it forms a thick gel-like substance when combined with water. Traditionally, it has been used internally to relieve symptoms of dyspepsia and inflamed bowel conditions and topically to soothe irritated skin and promote wound healing.

**When will it start to work?**

Whether used internally for upper gastrointestinal symptoms (such as reflux and dyspepsia) or applied topically to irritated skin, it should theoretically provide quick symptomatic relief; however, research to confirm this is not available.

**Are there any safety issues?**

Although slippery elm has not been scientifically investigated, the US Food and Drug Administration has approved it as a safe demulcent substance.

**Soy**

**HISTORICAL NOTE** Soybeans were one of the first crops grown by humans and have been consumed for approximately 5000 years in China, where they are regarded as both a food and a medicine. During the Chou dynasty (1134–246 BC), fermentation techniques were developed to produce tempeh, miso and tamari soy sauce, with tofu being invented around the second century BC. Soy first reached the West as imported soy sauce, and soybean cultivation began in the 1770s, primarily for animal feed. It was not until World War I that soy became a significant crop for human consumption ([Natural Standard Patient Monograph 2005](#)). Soy protein was first produced in the 1930s for its functional properties and used as a pigment binder for paper, as a foam for fire extinguishers and as a fibre for making artificial silk before being used as a food supplement in the 1960s.

**COMMON NAME**

Glycine max

**OTHER NAMES**

*Glycine max*, *Glycine soja*, *Dolichos soja*, *Glycine gracilis*, *Glycine hispida*, *Phaseolus max*, *Soja hispida*, *Soja max*

**BOTANICAL NAME/FAMILY**

*Glycine max* (family Fabaceae [Leguminosae])

**PLANT PART USED**

Bean

**CHEMICAL COMPONENTS**

Soybeans are a high-nutrient food containing up to 40% protein. Soy protein contains all of the essential amino acids in sufficient quantities to act as a sole protein source ([Yimit et al 2012](#)).

Soy is a major food source of phyto-oestrogens (isoflavones and lignans), with each gram of soy

protein containing approximately 3.5 mg of isoflavones (Hamilton-Reeves et al 2010), including glycosides of genistein, daidzein and glycitein (Cederroth et al 2012, Napora et al 2011). Soy also contains the lignans secoisolariciresinol, matairesinol, syringaresinol, lariciresinol, isolariciresinol and pinoresinol (Peterson et al 2010), as well as soy lecithin (a phospholipid containing linoleic and linolenic acid), vitamin E (in its four isomeric forms as alpha, beta, gamma and delta-tocopherol), oligosaccharides, the phytosterols beta-sitosterol, campesterol and stigmastrol, phytates and protease inhibitors, inositol hexaphosphate, saponins and oligosaccharides (Cederroth & Nef 2009).

Soybeans are usually consumed as fermented and non-fermented soy foods such as miso, tempeh and tofu as well as whole soybeans, soy nuts, soy milk or soy cheese. In addition soy flour is a common ingredient in foods, beverages and condiments (Larkin et al 2008). Wide variability has been reported in the total amount of isoflavones in commercial soy products (Nummi et al 2002).

Theories of whether cooking soy is more beneficial are still unclear as cooking increases some compounds in soy, such as daidzin, genistin, daidzein and antioxidants, but decreases genistein (Dong et al 2012).

## MAIN ACTIONS

Trials have reported improvements in vasomotor symptoms, osteoporosis (as measured by increasing bone mineral density), prostate cancer and the cardiovascular risk biomarkers.

Daidzein, an isoflavone found in soy, is metabolised to the more metabolically active equol and O-desmethylandrogenin (O-DMA) by intestinal bacteria (Cederroth et al 2012). In vitro studies have shown strains of *Eubacterium ramulus* and *Clostridium* spp. produce O-DMA. Recently a strain from *Clostridium* was isolated in human faeces and shown to produce O-DMA (Frankfield 2011). Following soy or daidzein consumption, approximately 30–50% of the human population produce equol, and approximately 80–90% produce O-DMA. The significance of this is uncertain, despite some studies suggesting that the ability to produce equol and O-DMA may be associated with reduced risk of certain diseases, including breast and prostate cancers (Atkinson et al 2005, Frankfield 2011).

The mechanisms for the clinical effects of soy are yet to be fully evaluated (Balk et al 2005, Setchell & Cassidy 1999). Predicting the effects of isoflavones in vivo is difficult because the route of administration, chemical form of the phyto-oestrogen, its metabolism, bioavailability, half-life, timing and level of exposure, intrinsic oestrogenic state and the non-hormonal secondary mediated actions of isoflavones may all influence their biological and clinical effects (Setchell & Cassidy 1999).

## Oestrogen receptor/hormonal modulation

Soy isoflavones and lignans share structural similarities with oestrogen and are referred to as

phyto-oestrogens and/or selective oestrogen receptor modulators (SERMs) (Cederroth et al 2012, Wei et al 2012). The oestrogenic effects of soy are postulated to contribute to protective effects against cardiovascular disease (CVD), cancer and menopausal symptoms (Napora et al 2011). Although a review of 861 studies on the effects of phyto-oestrogens suggests that they are indeed biologically active in humans (Knight & Eden 1996), major gaps in knowledge still exist regarding the effects of phyto-oestrogen supplements on bone diseases, various cancers, menopausal symptoms and cognitive function (Gratten 2013, Lu et al 2001, Stark & Madar 2002).

The order of oestrogenic activity from soy isoflavones in vivo assays is glycitein > genistein > daidzein (Carmignani et al 2012, PDRHealth 2004). Soy isoflavone glycosides bind weakly to both oestrogen receptors, with the binding affinity of genistein, dihydrogenistein and equol being comparable to the binding affinity of 17-beta-oestradiol (Cederroth et al 2012, Morito et al 2001).

Isoflavones have complex actions that may be tissue-specific and may act as partial oestrogen agonists and antagonists, as well as having non-classical effects on plasma membranes and cell signalling pathways (Barrett 2006, Setchell & Cassidy 1999).

Interestingly, soy has a greater affinity for the oestrogen beta-receptor than the alpha-receptor (Carmignani et al 2012). The beta-receptor is found in brain (Weiser et al 2008), bone and vascular epithelia, tissues in which isoflavones purportedly have activity. To a lesser extent, the beta-receptor is also found in the dome of the bladder (Ablove et al 2009, Setchell & Cassidy 1999).

Genistein has been found to have an oestrogen-like effect on the serum lipid profile, having a particular effect on CYP19 in the liver (Ye et al 2009). However, in a double-blind, placebo-controlled trial in 40 healthy postmenopausal women aged 50–75 years, 40 g of soy protein containing 118 mg isoflavones did not produce biologically significant oestrogenic effects on coagulation, fibrinolysis or endothelial function (Teede et al 2005).

## Hormonal effects in men

To date the evidence on soy and male reproductive health is unclear and requires further longer-term studies (Cederroth et al 2012). A meta-analysis found no significant effects of soy protein or isoflavone intake on measures of bioavailable testosterone concentrations in men. This included testosterone, sex hormone-binding globulin, free testosterone and free androgen index (Hamilton-Reeves et al 2010).

## Cardiovascular disease

There are many potential mechanisms by which soy isoflavones may improve cardiovascular outcomes, including reduction in total cholesterol, low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglycerides, lipoprotein A, blood pressure (Rebholz et al 2013) and endothelial function (Cano et al 2010). While soy has anti-inflammatory properties,

there appears to be little effect on reducing C-reactive protein (CRP), other inflammatory markers (Bakhtary et al 2012) or homocysteine (Marini et al 2010). However study results are limited and inconclusive (Rebholz et al 2013) and reducing vascular inflammation and homocysteine concentrations are unlikely to be the mechanisms by which soy reduces the risk of CVD (Greany et al 2008).

It has been postulated that soy isoflavones influence nitric oxide-dependent vasorelaxation. However, in a small randomised controlled trial ( $n = 24$ ), postmenopausal women with high-normal blood pressure and a body mass index  $<30$  were supplemented with 80 mg of soy per day (or placebo) for 6 weeks. The study found no change in nitric oxide, arginine or rulline flux from baseline measures (Wong et al 2012). Conversely, in an earlier study, postmenopausal women ( $n = 22$ ) received a low-fat test meal, with or without 80 mg isoflavones (containing both genistein and daidzein), in random order 1 week apart. Flow-mediated dilatation and plasma nitric oxide concentrations were greater in the treatment group compared with control, demonstrating that isoflavones have an acute effect on endothelial function in postmenopausal women. This suggests possible effects on endothelial function. Furthermore, the anti-inflammatory and vasodilatory actions of nitric oxide may potentially retard atherosclerosis development in postmenopausal women, but large, robustly designed, randomised, controlled dietary intervention trials are required to confirm this. It should also be noted that 80 mg is a relatively large dose of isoflavones compared with dietary intakes of between 30 and 50 mg/day in Asian countries such as China and Japan, although not so large as to be a physiological impossibility (Hall et al 2008).

Additional mechanisms include an inhibition of proinflammatory cytokines, cell adhesion proteins and inducible nitric oxide production, potential reduction in the susceptibility of the LDL particle to oxidation, inhibition of platelet aggregation and an improvement in vascular reactivity (Rimbach et al 2008).

Consumption of soy protein may also produce cardiovascular benefits through various mechanisms, including the low methionine content reducing serum homocysteine concentration (Nagata et al 2003), reduction of the insulin/glucagon ratio (Imani et al 2009, Napor et al 2011, Sanchez & Hubbard 1991) and downregulation of the hepatic transcription factor sterol regulatory element binding protein-1, which in turn reduces lipotoxicity in the liver (Torres et al 2006). Other possible mechanisms include: regulation of hepatic lipid metabolism through upregulation of LDL receptors and increase in bile acid secretion (Potter 1995), although the mechanisms are unclear (Maki et al 2010), reducing hepatic fatty acid and triglyceride biosynthesis and increasing fatty acid oxidation (Tovar et al 2005), preventing the transfer of fatty acids to extra adipose tissues by increasing the adipocyte hormone adiponectin (Nagasawa et al 2003) and increasing bile

acid secretion and bacterial conversion of cholesterol to the non-absorbable coprostanol (Huff & Carroll 1980).

Soybean protein has been shown to reduce E-selectin and leptin levels (Rebholz et al 2013). Soy protein peptides may also act to decrease intestinal cholesterol absorption and bile acid uptake, reduce aortic accumulation of cholesterol esters and suppress food intake and gastric emptying by increasing cholecystokinin and inhibiting angiotensin-converting enzyme (Torres et al 2006).

It is unclear how soy exerts its beneficial effects on lipid metabolism or exactly which components are most active. It is suspected that these include soy protein, bioactive peptides, interaction of isoflavones within the intact soy matrix or other compounds (Cassidy & Hooper 2006, Torres et al 2006). It is reported that isolated soy protein that maintains the native protein structure is more effective in reducing serum lipids than denatured protein (Hoie et al 2007). Soy protein is also reported to have beneficial effects on renal function, with suggestions that the isoflavones genistein and daidzein reduce glomerular damage by protecting LDL from oxidation and the high arginine content acts as a precursor for nitric oxide, thus improving renal flow (Torres et al 2006).

There may be variations in the response to soy and its components in different population groups. Greater isoflavone intake is associated with better vascular endothelial function and lower carotid atherosclerotic burden in people at high risk of cardiovascular events (Chan et al 2007). Soy supplementation improves endothelial function in renal transplant patients (Cupisti et al 2007) and soy isoflavones improve systemic arterial compliance in perimenopausal and menopausal women (Nestel et al 1997). Soy protein, regardless of isoflavone content, modulates serum lipid ratios in a direction beneficial for CVD risk in healthy young men (McVeigh et al 2006) and soy consumption is associated with decreased carotid intima media thickness and plasma lipids, with the association being stronger for men than women (Zhang et al 2008). Interestingly, studies have revealed improvements in biomarkers such as LDL-cholesterol and CRP in those with plasma S-equol levels of  $>5$ – $10$  ng/mL (Jackson et al 2011), so individuals may vary in their response to soy and its components.

### Antiosteoporotic

There has been speculation that the oestrogenic effects of soy isoflavone may help prevent osteoporosis (Cvejić et al 2012). Recent systematic reviews of over 30 studies suggest that soy protein prevents bone loss and inhibits excretion of urinary deoxypyridinoline. In human trials, 35 g/day soy protein for 12 weeks was found to significantly reduce urinary deoxypyridinoline and increase total alkaline phosphatase in a small study of 15 women aged 45–64 years (Roudsari et al 2005). However further studies are required to address the clinical effect of soy isoflavones on bone turnover markers and bone

alkaline phosphatase (Taku et al 2011, Wei et al 2012).

### Anticancer

Soy phyto-oestrogens are converted by gut bacteria to derivatives with weak oestrogenic and antioxidant properties, and epidemiological studies suggest that the highest plasma levels of their metabolites are found in individuals living in countries or regions with a low incidence of both cancer and CVD (Cederroth et al 2012, Jackson et al 2011). Although soy phyto-oestrogens have been implicated in soy's anticarcinogenic activity, a causal relationship to disease prevention is hypothetical, as the exact mechanisms have not been fully elucidated (Adlercreutz 2002a, 2002b).

There are multiple mechanisms by which soy protein may protect against cancer, as there is evidence for soy isoflavones having oestrogenic, anti-oestrogenic, antioxidant and antiproliferative activities (Leclercq & Jacquot 2014, Zhang et al 2012). Soy also contains other putative anticarcinogenic compounds, such as lignans, saponins, phytates, protease inhibitors and phytosterols (Cederroth & Nef 2009), and it is possible that soy consumption may be a marker for other dietary factors that provide anticancer properties.

Soy isoflavones inhibit transcription factors and genes that are essential for tumour cell growth (Hillman & Singh-Gupta 2011). Both in vitro and in vivo studies have shown genistein (the main active compound found in soy) inhibits cell growth of malignant tumours (Hillman & Singh-Gupta 2011). In vitro experiments also have shown that isoflavones inhibit the activity of aromatase and 17 $\beta$ -hydroxysteroid dehydrogenases involved in the synthesis of oestradiol from circulating androgens and oestrones (Brooks & Thompson 2005, Chi et al 2013, Lacey et al 2005).

The effects of soy on oestrogen metabolism and synthesis may contribute to the anticancer activity, as studies have shown that oestrogen inhibits cancer cell proliferation by promoting a more beneficial 2-OH E1:16-alpha-OH E1 ratio (Morimoto et al 2012).

Furthermore, soy phyto-oestrogens may influence cancer growth through effects on oestrogen receptors, through inhibition of tyrosine and other protein kinases, and aromatase enzymes, alteration of growth factor activity and inhibition of angiogenesis (Cederroth et al 2012, Nynca et al 2013). In terms of initiation or progression of breast cancer, soy isoflavones may have a protective effect due to their ability to inhibit the local production of oestrogens from circulating precursors in breast tissue (Kang et al 2010).

After menopause, oestrogens are synthesised in peripheral tissue and exert their effects locally. In vitro studies have shown that isoflavones inhibit aromatase activity, which is thought to have a protective action against breast cancer formation (Kang et al 2010).

Genistein is the most studied of the phyto-oestrogens and has weak oestrogenic activity but is not fully understood (Nynca et al 2013, Yuan-Jing et al 2009). It has also been found to cause apoptosis in cancer cells (Hillman & Singh-Gupta 2011), stimulate several antioxidative enzymes, such as catalase, superoxide dismutase, glutathione peroxidase and reductase, induce tumour cell differentiation, downregulate the epidermal growth factor receptor and erbB2/Neu receptors in cancer cells, and also possibly inhibit tumour cell invasion by inhibiting matrix metalloproteinase-9 (92 kDa type IV collagenase) (Adlercreutz 2002a, 2002b). Genistein and daidzein were shown to suppress breast cancer genes *BRCA1* and *BRCA2* after a 3-day incubation period (Satih et al 2009, Yuan et al 2012).

Genistein is also reported to inhibit angiogenesis, DNA topoisomerase II, protein tyrosine kinases, aromatase, nuclear factor-kappaB and to downregulate transforming growth factor-beta and stimulate the sex hormone-binding globulin (Cederroth & Nef 2009, PDRHealth 2004). Isoflavones have also been shown to inhibit the activity of aromatase (CYP19), thus decreasing oestrogen biosynthesis and producing antioestrogenic effects, which may be important in breast and prostate cancers (Li et al 2011).

Soy isoflavones also demonstrate a variety of oestrogen-independent activities, and some of them are directly associated with the suppression of the invasive behaviour of breast cancer cells (Korde et al 2009). Furthermore, it is suggested that variability in xenobiotic metabolising enzymes and the effect of flavonoid ingestion on enzyme activity may contribute to individual variations in susceptibility to diseases such as cancer (Moon et al 2006).

Although in vitro and animal models point to several pathways by which isoflavones may reduce the incidence of cancer (Rosenberg Zand et al 2002), and experimental evidence also exists for an inhibitory effect of soy bran on prostate cancer growth and of isolated lignans on colon cancer (Adlercreutz 2002a, 2002b), clinical trial data supporting this are still lacking.

Evidence on whether isoflavones are preventive or therapeutic in cancer treatment is inconclusive and unclear, as some in vitro and in vivo studies suggest that isoflavones may induce oestrogen-dependent cancers. Longer-term trials (>4 years) are required to investigate this possibility (Bhoo-Pathy et al 2013, Hooper et al 2010).

## OTHER ACTIONS

### Antioxidant

Oxygen stress is believed to contribute to menopause and degenerative changes associated with ageing and it is suggested that antioxidants, such as soy isoflavones, may help to protect mitochondria against premature oxidative damage (Larkin et al 2008). Although several clinical trials have suggested that soy intake decreases oxidative stress and that

soy isoflavones, such as genistein, have antioxidant properties *in vitro*, results of supplementation in clinical trials are inconclusive. Furthermore, diets relatively high in soy protein or soy-derived isoflavones are reported to have little effect on plasma antioxidant capacity or biomarkers of oxidative stress (Vega-Lopez et al 2005). In equol producers, S-equol may prevent the oxidation of LDL (Jackson et al 2011). Hwang et al (2000) have reported that equol may act synergistically with ascorbic acid to inhibit the metal-induced oxidation of LDL.

### Cognitive function

Soy isoflavones may mimic the actions and functions of oestrogen on the brain, and they have been shown to have positive effects on cognitive function in females, whereas results in males are inconsistent. Soy isoflavones, and particularly genistein, have been suggested to influence cognitive function via an oestrogen receptor-mediated pathway and via the inhibition of tyrosine kinase; however, definitive data are still lacking (Sumien et al 2013).

### CLINICAL USE

Soy protein and soy isoflavones have been the subject of much scientific investigation in recent decades. Several epidemiological studies have shown beneficial effects with high-dose isoflavones in menopausal symptoms, CVD (specifically atherosclerosis and stroke), reducing risk of breast and prostate cancer, possible improvements in bone health and neurodegeneration (Dhananjaya et al 2012, Patisaul & Jefferson 2010). Similarly, soy protein has demonstrated health benefits, chiefly in CVD prevention (via improving lipid profiles) (Anderson & Bush 2011).

### Menopausal symptoms

The natural oestrogen receptor activity of soy isoflavones is popularly considered an alternative to controversial hormone replacement therapy for postmenopausal women (Sliva 2005).

In regard to hot flashes, the effects of phyto-oestrogens are still far from being fully understood. However, in general, studies show isoflavones can reduce the frequency and severity of vasomotor symptoms. Women with a higher consumption of isoflavones tend to have less frequent and less severe hot flashes and night sweats (Bedell et al 2014, Moreira et al 2014). The North American Menopause Society in 2011 also concluded that soy-based isoflavones are modestly effective in relieving menopausal symptoms and supplements providing higher proportions of genistein or increases in S(-)-equol may provide more benefits.

While many people focus on the potential effects of isoflavones on hot flashes, there is also clinical trial evidence that isoflavones significantly improve sleep efficiency and reduce sleep disturbances in postmenopausal women. One double-blind study showed that 80 mg isoflavones over 4 months was significantly superior to placebo and another showed

that doses of either 52 mg or 104 mg daily of isoflavones over 12 months were effective (Drews et al 2007b, Hachul et al 2011).

Determining an optimal dose is difficult; however, it is generally believed that at least 40–104 mg/day of total soy isoflavones is sufficient. This dose is consistent with intakes in countries that consume soy as a staple, and is also the level at which clinical endocrine effects can be seen in premenopausal women (Bedell et al 2014). Whether an individual responds to isoflavones is thought to partly depend on their ability to effectively biotransform daidzein to equol in the intestines, as equol has an oestrogenic activity several magnitudes greater than diadzein, a major metabolite of soy isoflavones (Jackson et al 2011). The conversion is mediated by intestinal bacteria and factors such as diet, antibiotic use and illness will affect the equol-producing ability of an individual (Bedell et al 2014).

Unfortunately, making a definitive conclusion as to whether soy isoflavones reduce the frequency and severity of hot flashes is more complex, as meta-analyses tend to group various soy interventions together, making interpretation difficult. For instance, a 2010 meta-analysis of 19 studies concluded that, even though the overall combined results showed a significant tendency in favour of soy, it was still difficult to establish conclusive results given the high heterogeneity of the studies (Bolanos et al 2010). The studies in the analysis were randomised controlled trials, including a placebo arm, and of a 12-week treatment duration. The intervention was loosely described as 'soy dietary supplement', 'soy extract' or 'isoflavone concentrate' (genistein or daidzein), with greatest results seen for the soy concentrate intervention.

A 2011 systematic review and meta-analysis investigating soy extracts, hormone replacement therapy and hot flashes concluded that both interventions are efficacious in reducing hot flashes in postmenopausal women when compared to placebo (Bolanos-Diaz et al 2011). To tease out the results further, a comparison study was analysed which found that daily hot flashes reduced by 22% with genistein concentrate treatment compared to a 53% reduction with daily oestrogen-progestogen therapy compared to placebo over 12 weeks. As such, while both treatments are effective, isoflavones are a weaker treatment.

A recent Cochrane systematic review of 30 studies looking at phyto-oestrogen treatment of vasomotor symptoms for peri- and postmenopausal women showed that soy extract preparations globally demonstrated mixed results; however, three placebo-controlled studies conducted from 2002 to 2008 showed a significant reduction in flush frequency: 61%, 74% and 50% compared with placebo (21%, 43% and 38% reduction respectively) (Vilaseca 2012). Additionally, significant improvements in vasomotor symptoms have been described in the more recent placebo-controlled trials with soy products.

An older systematic review and meta-analysis that included 17 trials found that isoflavone supplementation significantly reduced hot flushes, with the percentage reduction being related to the number of baseline flushes per day and the dose of isoflavone studied (Howes et al 2006). More recent studies have also reported that isoflavone supplementation reduces hot flushes (Eden 2012). In an Australian randomised controlled trial, 60 postmenopausal women were supplemented with 90 mg of soy isoflavone, 1 mg oestradiol or placebo. After 16 weeks of therapy there was a significant improvement in hot flushes and urogenital symptoms in the soy and oestradiol groups, although there was no statistically significant difference with respect to the overall Menopause Rating Scale or psychological symptoms (Carmignani et al 2012).

One of the largest studies conducted to determine whether soy isoflavones have a favourable effect on hot flushes was the Soy Phytoestrogens as Replacement Estrogens (SPARE) study in 2004, funded by the US National Institutes of Health. This was a double-blinded, single-centre randomised controlled trial involving 248 healthy women with the onset of menopause within 5 years of enrolment who received either daily soy isoflavones (200 mg) or placebo for 2 years (Chalupka 2011). There was no significant difference between the soy group and placebo group regarding hot flush symptoms after 2 years; however this study did not attempt to differentiate between reduced frequency and reduced intensity. As Bedell et al (2014) point out, studies that make the distinction between frequency and severity of hot flushes tend to produce positive results. The example they give is a study by Drews et al (2007a), which involved 169 postmenopausal women and showed treatment with 104 mg of isoflavones daily reduced both the frequency and the intensity of hot flushes. This study also noted that treatment significantly decreased sleep disturbances ( $P < 0.05$ ) and decreased headache, dizziness, arthritis pain, tiredness, palpitation and breathlessness ( $P < 0.05$ ). In addition, treatment with Soyfem (a standardised isoflavone extract) improved the variability and moderation of depressive mood ( $P < 0.05$ ) (Drews et al 2007a).

### Theories explaining inconsistent results

Although some trial data seem to support the efficacy of isoflavones in reducing the incidence and severity of hot flushes, other studies have not found any difference between the isoflavone recipients and the controls (Lethaby et al 2010). These inconsistent results may be due to insufficient sample size, variations in the isoflavone type, content or delivery form of the preparations used or varying responses in different population groups. To add to the confusion, the source of isoflavones is not always reported and the composition and dose of soy supplements and isoflavone content vary considerably between studies, which makes comparisons and interpretations difficult (Low Dog 2005).

Another key factor which is thought to affect response rates is whether an individual can effectively produce equol from daidzein, a metabolite of soy isoflavones (Jackson et al 2011). This is clinically relevant since the oestrogen agonist potency of equol is much greater than its precursor, daidzein. Equol thus serves as the reference compound associated with the health benefits of isoflavone consumption (Bedell et al 2014).

### Clinical note — What are phyto-oestrogens?

Phyto-oestrogens are constituents found in plants which have a similar chemical structure to oestradiol (E2).

They have a phenolic ring which means they can bind to oestrogen receptors. They also have a molecular weight similar to E2 and can work as either agonists or antagonists at oestrogen receptor sites. The cellular effects of phyto-oestrogens are influenced by many factors, including concentration, receptor status, presence or absence of endogenous oestrogens and the target tissue (Moreira et al 2014).

There are four main classes of phyto-oestrogens: isoflavones, lignans, coumestans and stilbenes. Isoflavones from soy and soy derivatives are the most common phyto-oestrogens and genistein and daidzein are the most studied. Lignans are the most prevalent phyto-oestrogens in nature and many are commonly found in the human diet, such as in oilseeds, flaxseed and grains such as wheat, rye and oat and in various types of berries. Coumestans and stilbenes are less abundant in the diet and are less well studied. Coumestrol is a coumestan found in clover and alfalfa sprouts and in lower concentrations in lima bean and sunflower seeds, among other sources, whereas resveratrol is the most studied stilbene, being present in grapes, peanuts and cranberries (Moreira et al 2014). All phyto-oestrogens are SERMs and each has a profile of action of its own (Bedell et al 2014).

### Cardiovascular disease

Both soy-derived isoflavones and soy protein have been investigated for potential benefits in CVD. A meta-analysis of 43 randomised controlled trials concluded that soy protein was protective against CVD due to beneficial effects on lipid profiles (Anderson & Bush 2011). In addition, substantial data from epidemiological surveys and nutritional interventions in humans and animals indicate that soy protein reduces serum total and LDL cholesterol and triglycerides, as well as hepatic cholesterol and triglycerides (Torres et al 2006). Based on this data, the US Food and Drug Administration has approved a food label health claim stating that a diet with a daily intake of 25 g of soy protein and low in saturated fat and cholesterol may reduce the risk of heart disease (Balk et al 2005). This claim, however, is

based largely on studies demonstrating beneficial effects on lipids and other biomarkers rather than hard end points (Anderson & Bush 2011, Cassidy & Hooper 2006).

A recent Cochrane review (five randomised controlled trials) concluded that there is no evidence to suggest that isoflavones have any impact on improving lipid profiles (Qin et al 2013). Despite this, other effects of benefit in CVD have been reported. For example, a reduction in the risk of both cerebral and myocardial infarctions was reported in a cohort study of Japanese women with a high consumption of isoflavones (Kokubo et al 2007). In addition, the World Health Organization CARDIAC study determined the relationship between the mortality rate of coronary heart disease and the consumption of soy products and isoflavones. It was shown that individuals in China and Japan who excreted >10 mmol isoflavones daily experienced a lower rate of coronary heart disease (<100 events per 100,000 people) than those with <1 mmol/day (>500 events per 100,000 people) (Jackson et al 2011, Yamori 2007).

Some population groups may have a better response to soy than others. For instance, thoughts surround an increased risk of CVD amongst postmenopausal women, which may in part be due to a reduction in ovarian function (Cano et al 2010).

Limitations surround many clinical trials, making it difficult to ascertain the true effects of isoflavones on cardiovascular health. Small populations and inconsistent soy forms and doses are the main reasons for such a diverse difference in results.

### Hypercholesterolaemia

A meta-analysis of 43 randomised controlled trials concluded that, on average, a daily intake of 30 g of soy protein per day was protective against CVD, showing a significant reduction in lipoproteins. LDL-cholesterol was reduced by 5.5% and triglycerides by 10%, with a slight (3%) increase in HDL (Anderson & Bush 2011). Soy isoflavones do not appear to be as effective as soy protein, as demonstrated by a Cochrane review which reported on five randomised controlled trials ( $n = 208$ , 104 each in intervention and control groups) which ranged in length from 3 to 6 months and investigated the effect of isoflavone versus placebo on lipid profiles (Qin et al 2013). Overall the authors concluded a lack of substantive evidence for isoflavone use in lowering cholesterol in hypercholesterolaemic patients. When compared with placebo, two trials (Aubertin-Leheudre et al 2007, Dewell 2002) showed a small but significant effect on triglycerides in the isoflavone group (mean difference  $-0.46$  mmol/L; 95% confidence interval  $-0.84$  to  $-0.09$ ;  $P = 0.02$ ;  $n = 52$ ), but no significant difference was found on total cholesterol, LDL-cholesterol and HDL-cholesterol between the treatment and control group. The review reported a potential risk of high (or unclear) level of bias and relatively low participant numbers.

A number of other systematic reviews have been conducted over the years, with varying conclusions (Balk et al 2005, Cassidy & Hooper 2006, Dewell et al 2006, Reynolds et al 2006, Taku et al 2008, Yang et al 2011, Zhan & Ho 2005).

Dyslipidaemia is more prevalent amongst females, particularly postmenopausal, due to endocrine changes and physiological mechanisms (Bakhtiary et al 2012). In a 12-week randomised controlled trial 75 women aged 60–70 and diagnosed with metabolic syndrome were given 35 g of soy nuts per day, 35 g per day soy protein (textured soy protein) or placebo. Both soy groups had improved lipid profiles and apolipoprotein. Significant decreases in serum total cholesterol were also observed in both treatment groups compared with the control group ( $P < 0.005$ ). Comparison of results between treatment groups showed soy nuts were more beneficial. Soy nuts significantly improved LDL-cholesterol, very-low-density-lipoprotein cholesterol and ApoB100 levels ( $P < 0.05$ ). Changes in total cholesterol, HDL-cholesterol, fibrinogen, CRP and blood pressure were not significant between treatment and control groups (Bakhtiary et al 2012). A study investigated the effects of traditional fermented soybean products on body mass index, reproductive hormones, lipids and glucose among 60 postmenopausal Thai women. Along with their usual diet, the experimental group ( $n = 31$ ) were supplemented for 6 months with approximately 60 mg of isoflavone per day from traditional fermented soybean products. Favourable effects on progesterone and cholesterol were found, while oestradiol, glucose and triglycerides were not affected. Interestingly, a decrease of oestradiol and an increase of glucose were found in the control group (Sapbamrer et al 2013). Another randomised controlled trial ( $n = 389$ ) found an improvement in lipid profiles and a reduction in CVD in postmenopausal women. However, both arms of the study were on restricted diets and were supplemented with therapeutic doses of calcium and vitamin D and either 54 mg genistein or placebo (Marini et al 2010).

### Blood pressure

In addition to possible effects on lipids, epidemiological data suggest that soy may affect blood pressure. A systematic review of 11 randomised controlled trials concluded that doses of 65–153 mg soy isoflavones improved blood pressure in hypertensive patients but had no effect on normotensive subjects (Liu et al 2012). Another review supports these findings, concluding that there was a positive effect on systolic (SBP) but not diastolic blood pressure (DBP) (Kyoko et al 2010), although several earlier reviews found no evidence of a reduction in blood pressure (Balk et al 2005, Rosero Arenas et al 2008). Further studies are required to confirm these findings.

The Shanghai Women's Health Study was one of the more influential epidemiological studies

supporting the role of soy in blood pressure reduction. In this observational study of 45,694 participants, aged 40–70 years, with no history of hypertension, diabetes or CVD, the intake of soy foods over 2–3 years was inversely associated with both SBP and DBP, particularly among elderly women. Results of this study found that, compared to women consuming less than 2.5 g/day of soy, consumption of more than 25 g/day was associated with a significant reduction in SBP of 1.9 mmHg and a significant reduction in DBP of 0.9 mmHg, and that the inverse association between soy consumption and blood pressure became stronger with increasing age, with significant reductions of 4.9 mmHg for SBP and 2.2 mmHg for DBP in women aged over 60 years (Yang et al 2005). Once again, equal producers may experience more favourable responses than non-producers (Kreijkamp-Kaspers et al 2005).

### Diabetes and diabetic nephropathy

Replacing animal protein with soy protein has been found to improve various disease markers in patients with type 1 or type 2 diabetes (Yang et al 2011).

Although there are positive results with the use of soy to improve blood glucose levels, a meta-analysis that included 24 trials ( $n = 1518$ ) using soy isoflavones concluded that soy consumption did not significantly affect measures of glycaemic control and there was no improvement in overall fasting glucose or insulin levels (Liu et al 2011). However, in subgroup analysis, a favourable change in fasting glucose concentrations was observed in the studies that utilised whole-soy foods or a soy diet (Liu et al 2011).

Interventions which increase dietary soy intake have revealed a number of potential benefits, including improvements in HbA<sub>1c</sub>, a reduction in weight and in sulfonylureas and metformin use in type 2 diabetes patients (Li et al 2005); and improvements in glycaemic control and lipid profiles in obese individuals (Deibert et al 2004). It may also be of benefit in diabetic nephropathy, with several small studies showing possible improvements in glomerular filtration rate in young adults with type 1 diabetes mellitus (Stephenson et al 2005); reduced urinary albumin and improved lipid profiles in males with type 2 diabetes and nephropathy (Teixeira et al 2004); and improved renal function and lipid profile in patients with type 2 diabetes and nephropathy (Azadbakht et al 2003).

### Cancer prevention

High levels of phyto-oestrogens (lignans and isoflavonoids) are frequently associated with low risk of breast, prostate and colon cancers, and breast cancer and multiple epidemiological studies have identified an inverse relationship between soy consumption and cancer risk (Badger et al 2005, Trock et al 2006, Wu et al 2008b). For example, in a cohort study of over 73,000 Chinese women who

consumed either dietary isoflavones or soy protein, only 546 case reports of breast cancer were recorded, suggesting that soy protein and/or isoflavone consumption may be protective (Lee et al 2009). The protective effect of soy food consumption was reiterated in 2011 by the North American Menopause Society, which concluded that soy foods generally appear to be breast cancer-protective and recommended moderate lifelong dietary soy consumption as part of a healthy lifestyle. They confirmed that, based on the latest evidence, soy food consumption is associated with lower risk of breast and endometrial cancer in observational studies, and soy food consumption or intervention in women does not promote breast cancer growth or cancer recurrence. However, specific recommendations regarding breast cancer survivors and soy or isoflavone consumption could not be reached, as studies in humans imply a null or protective effect, whereas animal studies indicate potential for risk.

It has been suggested that the protective effect is most pronounced for women of Asian background, as a 2011 meta-analysis of 14 studies of breast cancer incidence found that consumption of soy isoflavones was associated with reduced risk of breast cancer incidence (relative risk 0.89); however, the effect was limited to Asian populations, and did not apply to Western populations (Dong & Qin 2011). Encouragingly, a 2011 meta-analysis revealed that, overall, soy may reduce the mortality and morbidity of cancer incidence and increase survival rates (Hillman & Singh-Gupta 2011). Furthermore, soy intake after cancer diagnosis has been associated with reduced mortality and recurrence (Hillman & Singh-Gupta 2011).

In any investigation on the role of soy and its anticancer properties, there are several variables that need to be acknowledged and considered both within the design of any studies, and within systematic reviews and meta-analyses. Some of these variables include different types and amounts of soy consumed amongst different populations. For example, Asian diets generally contain greater amounts of soy compared with Western populations. Thus when a mix of both Asian and Western population-based studies is analysed in the one meta-analysis or systematic review, this requires attention and consideration (Morimoto et al 2012, Wu et al 2008a). Another confounding factor is that Western lifestyle may influence cancer risk due to dietary choices that are independent of soy consumption (Morimoto et al 2012, Wu et al 2008a). Effects are likely to be dose-dependent (Wu et al 2008a). The timing may also be important with reviews suggesting soy may be beneficial if consumed in early life before puberty or during adolescence (Adlercreutz 2002a, 2002b). A further study suggests that the protective effect of soy differs by receptor status, with reduced risk being evident in women who are oestrogen and progesterone receptor-positive and HER2 receptor-negative (Suzuki et al 2008).

Most recently, in a randomised controlled trial of 82 premenopausal women, a low- and high-soy-based diet was compared over 6 months. Following a wash-out period, the participants crossed over to the alternative diet for a further 6 months. The participants were Asian, American and Caucasian. In the high-soy group, participants consumed two daily servings of soy foods per week. In the low-soy group participants consumed less than three servings of soy-based foods per week. Assessment of intake was done using 24-hour diet recall and through urinary analysis to assess the level of isoflavones. The study observed a possible influence of two daily soy food servings on urinary oestrogen excretion; however there was little or no change in oestrone, oestradiol and oestriol. There was a small statistically significant benefit for soy as a protective measure against breast cancer, due to the ability of soy to modify oestrogen metabolism, resulting in a lower exposure to carcinogenic metabolites (Morimoto et al 2012).

### Prostate cancer

Soy proteins, common in the Asian diet, have been shown to inhibit prostate cancer cell growth (Kurahashi et al 2008, Sonn et al 2005). Prostatic tissue appears to readily accumulate potentially anticancerous isoflavones (Gardner et al 2009) and in vitro studies support findings of soy being protective against prostate cancer (Dong et al 2012). For instance, genistein appears to suppress cyclooxygenase-2 pathways, which is often seen to be a leading cause of prostate cancer (Swami et al 2009).

In an epidemiological study of over 82,000 men, legume intake was associated with a moderate reduction in prostate cancer risk but this was unrelated to isoflavone content (Park et al 2008), while a case-controlled study suggests that isoflavones might be an effective dietary protective factor against prostate cancer in Japanese men (Nagata et al 2007). In randomised controlled trials in men aged 50–80 years, 12 months' supplementation with 83 mg/day isoflavones did not alter serum levels of prostate-specific antigen in healthy men (Adams et al 2004), while 60 mg/day of soy isoflavone did alter serum prostate-specific antigen and free testosterone in some men with early-stage prostate cancer (Kumar et al 2004). In another randomised controlled trial involving 29 men with prostate cancer and scheduled to undergo a radical prostatectomy, supplementation with bread containing 50 g of soy grits was found to significantly reduce prostate-specific antigen levels (Dalais et al 2004). A recent randomised controlled trial was unable to demonstrate effects of 20 g of soy protein isolate on the recurrence of prostate cancer following radical prostatectomy (Bosland et al 2013).

### Lung cancer

In non-smoking women, an inverse relationship has been observed between lung cancer survival and soy food consumption prior to diagnosis (Yang et al 2013). Compared with the median intake of soy

#### **Clinical note — Soy and breast cancer patients**

As isoflavones exert oestrogen-like activity, there is some concern about their use in women with a history of breast cancer. When phyto-oestrogens bind to either alpha or beta oestrogen receptors they initiate cell differentiation (Leclercq & Jacquot 2014). They are also reported to increase cortisol, and activate or interfere with some neurotransmitters (Leclercq & Jacquot 2014). Genistein has been shown to stimulate oestrogen-mediated tumour cell growth and induce aromatase activity (van Duursen et al 2011). There are also concerns that soy constituents may interfere with tamoxifen therapy and encourage cancer cell proliferation (Chi et al 2013).

The NSW Cancer Council supports the consumption of soy foods in the diet as part of the national dietary guidelines to eat a diet high in plant-based foods. The current position statement from the Australian Cancer Council does not recommend or support the use of supplements such as soy protein isolates or isoflavone capsules for healthy men and women to prevent cancer. There is evidence to suggest that women with existing breast cancer or past breast cancer should be cautious in consuming large quantities of soy foods or phyto-oestrogen supplements (Cancer Council 2009). However, according to current research, soy consumption may be protective against postmenopausal (but not necessarily premenopausal) breast cancer (Wada et al 2013) and may lower the recurrence of breast cancer, especially in postmenopausal women (Chi et al 2013, Guha 2009, Shu et al 2009). Soy isoflavones consumed at levels comparable to those in Asian populations may reduce the risk of cancer recurrence in women receiving tamoxifen therapy and do not appear to interfere with tamoxifen efficacy (Guha 2009).

A study on children supports the use of dietary soy in reducing breast cancer risk in later life. Although the results are not strong, they are promising and are encouraging for further research in childhood exposure to soy (Korde et al 2009).

food, fully adjusted hazard ratios for total mortality were lower in those with the highest soy intake versus the lowest (90th percentile hazard ratio 0.89 vs 10th percentile hazard ratio 1.81).

### **Osteoporosis prevention and bone mass**

Despite a small number of conflicting studies, the body of evidence available indicates a positive relationship between soy isoflavones and bone health (Bedell et al 2014). Inconsistencies were mainly seen in early studies, whereas the majority of those conducted in the last decade that followed

participants for longer time intervals tended to demonstrate a positive effect on bone mineral density.

A 2013 systematic review of studies investigating isoflavones confirmed that *in vitro* and animal studies show a positive effect on increasing bone mineral density and decreasing bone turnover resorption markers (Castelo-Branco & Soveral 2013, Wei et al 2012). The effect of soy isoflavones on bone mineral density is mediated by equol production, reproductive status, supplement type, isoflavone dose and intervention duration. As such, a key factor is how efficiently an individual produces equol, and equol producers seem to have a more positive response to isoflavone intervention and diets, which could help maintain peak bone mass in premenopausal women. Whether isoflavones in perimenopausal women attenuate bone loss in the menopausal transition is insufficiently studied but current results are promising. In the postmenopausal period, isoflavones may present a modest benefit but their clinical relevance in preventing osteoporotic fractures remain to be determined (Castelo-Branco & Soveral 2013).

It seems that in both animal and human studies the route of administration, the dose and, in animal studies, the type of animal all seem to affect the results (Patisaul & Jefferson 2010). In humans, effects appear to become more significant when more than 90 mg/day of isoflavones is consumed for at least 6 months (Castelo-Branco & Cancelo Hidalgo 2011, Ma et al 2008, Wei et al 2012). More specifically, the effect of isoflavones appears greatest for lumbar spine bone mineral density but not hip, femoral neck and trochanter bone mineral density in menopausal women (Taku et al 2010, 2011). The meta-analysis of clinical studies by Taku et al (2011) investigating bone turnover concluded that, while soy had no specific therapeutic effect on bone, it did significantly decrease urine deoxypyridinoline and increase bone mineral density, reducing the risk of fracture in menopausal women (Taku et al 2011). Previously, Zhang et al (2005) had suggested that the association between soy or isoflavone consumption and fracture risk was more pronounced among women in early menopause (Zhang et al 2005).

The effect may also be life stage-specific and dependent on the number of oestrogen receptors and the endogenous hormone milieu. Perimenopausal and early menopausal women may therefore be more receptive to the therapeutic effects of isoflavones on bone loss prior to the diminution of oestrogen receptors that occurs in the postmenopausal years (Wei et al 2012).

The most recent negative study was a double-blind randomised controlled trial which found that daily administration of tablets containing 200 mg of soy isoflavones for 2 years did not prevent bone loss amongst women who were aged 45–60 years and within 5 years of menopause (Levis et al 2011). Unfortunately, the study did not investigate the role of equol producers or non-producers in achieving this negative result.

## Cognitive function

To date, the body of evidence does not suggest that soy isoflavones have a beneficial effect on cognitive function.

A recent randomised controlled trial in 350 menopausal women who were given 25 g of isoflavones for 30 months showed no significant change in cognition, although there was a possible improvement in visual memory (Henderson et al 2012). A systematic review of soy therapy in postmenopausal woman which included 12 randomised controlled trials found that there was no improvement in cognition; however, the review has several major limitations and should be interpreted accordingly (Clement et al 2011). Only one trial (Ho et al 2007) adequately satisfied all the methodological criteria outlined by the Cochrane collaboration tool for risk of bias assessment. In this study isoflavone supplementation, at 80 mg/day given for 6 months, did not improve cognitive function in generally healthy Chinese postmenopausal women (Clement et al 2011).

In contrast, in a small randomised controlled trial, 34 healthy males and females who were supplemented with 100 mg soy isoflavone for 6 months found that treatment resulted in improvements in all areas of cognition, including visual and spatial memory, construction, fluency, speeded dexterity and motor planning (Gleason et al 2009).

Most studies on soy and cognition have been conducted on menopausal women and previous reviews have identified factors such as variation in the composition of phyto-oestrogen interventions and the heterogeneous characteristics of study populations as contributing to discrepant results (Zhao & Brinton 2007).

## OTHER USES

### Soy infant formula

Soy has been used as an alternative for cow's milk in infant feeding for more than 30 years and may account for as much as 25% of infant formula (Badger et al 2009, Mendez et al 2002). Soy formula is commonly used for infants with cow's milk allergy and there is evidence to suggest that soy milk may be effective in reducing infant colic (Garrison & Christakis 2000). There are few studies, however, examining the effects of phyto-oestrogens in infants. Infants consuming soy formula may be exposed to 6–11 mg/kg/day of phyto-oestrogens and have plasma levels of isoflavones an order of magnitude higher than adults consuming soy foods (Andres et al 2012).

There are inconsistent results from epidemiological studies comparing soy and cow's milk formula during infancy and age of menarche. One study reported no clinically significant difference in age at menarche (Strom et al 2001) between the two formulas, while another reported that those who received soy formula early in life ( $\leq 4$  months to  $\geq 6$

months of age) had earlier menarche (Adgent et al 2011).

Unfortunately, studies assessing the long-term effects of soy-based formulas are limited. There are methodological flaws in the studies available for review, limited by small sample size and variation in the amount and form of soy used (Cederoth et al 2012). There are suggestions that soy-based formulas may exceed the recommended daily intake (RDI) of nutrients, which in itself is not a concern, given that the RDIs are generally the minimum required to prevent deficiency diseases. However, of greater concern is the processing of soy, and whether it leads to heavy-metal contamination (Ljung et al 2011). Furthermore, due to the high phyto-oestrogen levels in soy, the effect on long-term reproductive health requires further research (Badger et al 2009).

### Seasonal allergic rhinitis

Polysaccharides from soy sauce have been shown to have antiallergic activities in vitro and in vivo, and an 8-week double-blind study involving 51 subjects with seasonal allergic rhinitis found that oral supplementation with 600 mg of soy polysaccharides was effective in significantly improving symptom scores such as sneezing, nasal stuffiness and hindrance of daily life, as well as significantly improving the appearance and state of the nasal mucosa (Kobayashi 2005, Kobayashi et al 2005).

### Premenstrual syndrome

Isolated soy protein containing 68 mg/day (aglycone equivalents) soy isoflavones was found to significantly improve specific premenstrual syndrome symptoms, including headache, breast tenderness, cramps and swelling in a seven-menstrual cycle, double-blind, placebo-controlled, crossover intervention study in 23 women (Bryant et al 2005).

### DOSAGE RANGE

Soy foods contain variable amounts of isoflavones. Soy flour contains 1.3 mg/g of isoflavones; tofu contains 0.4 mg/g, soy milk 0.25 mg/g, tempeh 0.4 mg/g, miso 0.92 mg/g, soy sauce 0.023 mg/g, soybean paste 0.57 mg/g and soy cheese 0.05 mg/g (Coward et al 1993). Soy isoflavones are also available in some functional food products. Although soy oils and lecithin are used in many food ingredients, the typical Western diet provides negligible isoflavones, whereas Asian diets typically contain 20–50 mg of isoflavones (Nagata et al 1998, Hall et al 2008). The optimal dose required to have clinical effects is yet to be established; however, it is suggested that optimal soy protein and isoflavone intakes are 15–20 g/day and 50–90 mg/day, respectively, with 25–30 g/day recommended for cholesterol reduction (Anderson & Bush 2011, Messina 2008).

### TOXICITY

Soy and soy isoflavones are considered non-toxic in the doses that are generally consumed as foods. Soy

### Practice points/Patient counselling

- Soy is a component of many foods and a nutritious source of complete, high-quality protein.
- There are many different types and formulations of soy and people may react differently to soy products depending on their diet and the activity of their gut bacteria.
- In countries where people regularly consume soy products there appears to be a lower incidence of CVD, menopausal symptoms and some cancers such as breast and prostate cancer.
- The most active agents in soy are the isoflavones, which are used to treat menopausal symptoms and improve bone health.
- Soy isoflavones are generally shown to have a modest effect, reducing the frequency and severity of hot flushes and improving sleep when taken by menopausal women with sleep disturbances. There is some encouraging evidence that they may improve bone health, but this is not yet conclusive.
- Although there has not been much research on the use of soy in infants, there do not appear to be any adverse effects from feeding infants soy formula.
- The long-term benefits of soy may relate to the lifetime exposure to soy products.

may interfere with the absorption of synthetic thyroid hormone, and there is a theoretical concern based on in vitro and animal data that soy foods may increase the risk of developing clinical hypothyroidism in individuals with compromised thyroid function and/or whose iodine intake is marginal (Messina & Redmond 2006). Soy food consumers should ensure their intake of iodine is adequate, although studies suggest that soy isoflavones in a protein matrix do not significantly influence circulating thyroid hormones in healthy young men (Dillingham et al 2007).

Although the phyto-oestrogens may have hormonal activity, they have relatively short half-lives of approximately 6–8 hours, which is contrasted with the environmental xeno-oestrogens that may persist for years in fat tissue and hence bioaccumulate (Setchell & Cassidy 1999).

### ADVERSE REACTIONS

There is little suggestion of adverse effects of soy or isoflavones at physiological doses, although soy isoflavone supplements have induced gastrointestinal discomfort and menstrual complaints (Cassidy & Hooper 2006). Unconjugated soy isoflavones appear to be safe and well tolerated in healthy postmenopausal women at doses of 900 mg/day (Pop et al 2008).

There is a case report of a 60-year-old man having gynaecomastia and breast tenderness along

with high oestradiol levels due to soy milk consumption (Martinez & Lewi 2008).

There are structural similarities between birch pollen and soy allergens, leading to allergic cross-reactions (Kleine-Tebbe et al 2008) and the potential for anaphylaxis (Jacquet et al 2008).

## SIGNIFICANT INTERACTIONS

It has been suggested that isoflavones can inhibit the oxidative and conjugative metabolism of drugs in vitro and interact with transporters such as P-glycoprotein; however, their ability to interact with drugs remains uncertain until clinical studies can confirm these findings (Evans 2000).

### Antibiotics

Antibiotic administration blocks metabolism of isoflavones to equol through inhibition of the intestinal microflora, whereas a high carbohydrate milieu increases intestinal fermentation and results in more extensive biotransformation of phyto-oestrogens (Setchell & Cassidy 1999). The biotransformation of daidzein (an isoflavone metabolite) to equol in the gut by microflora is considered important for clinical responsiveness.

### Calcium, magnesium, zinc, copper and iron

Soy contains phytic acid, which may bind with certain minerals, such as calcium, magnesium, manganese, zinc, copper and iron, reducing their availability (PDRHealth 2004). Separate by 2–3 hours.

### Tamoxifen

Animal studies have shown that soy enhances the therapeutic effects of tamoxifen, as both have SERM actions (Mishra et al 2011). Additionally, in vivo studies suggest that the isoflavone daidzein may enhance the effect of tamoxifen against breast cancer patients, burden and incidence (Charalambous et al 2013).

Usual dietary intake levels appear safe; however, the safety of concentrated extracts is yet to be established (see [Clinical note — Soy and breast cancer patients](#), above).

While the soy isoflavone genistein may theoretically compete with tamoxifen for oestrogen receptors, thereby reducing drug efficacy, a meta-analysis of five cohort studies found no safety concerns with using soy isoflavones to reduce the recurrence of breast cancer, especially oestrogen-positive tumours (Chi et al 2013). A study found that soy isoflavones consumed at levels comparable to those in Asian populations may reduce the risk of cancer recurrence in women receiving tamoxifen therapy and, importantly, does not appear to interfere with tamoxifen efficacy. Furthermore, it suggests there is no evidence to indicate that soy foods are unsafe in breast cancer patients (Guha 2009) — possible beneficial effect under professional supervision.

## PREGNANCY USE

Soy is likely to be safe when used as a food; however, pregnant women and nursing mothers should avoid the use of high dose soy isoflavone supplements pending long-term safety studies.

## PATIENTS' FAQs

### *What will this supplement do for me?*

Soy is a nutritious food and a good source of high-quality, complete protein that appears to have beneficial effects on cholesterol, and possible activity protecting against various cancers and CVD. Soy isoflavones modestly reduce the frequency and severity of hot flushes in menopause. They have been shown to improve sleep quality amongst menopausal women with sleep disturbances.

### *When will it start to work?*

Clinical studies suggest the lipid-lowering effects of soy protein take between 6 and 12 weeks to appear. Reduction in hot flush frequency and severity may take up to 12 weeks and any positive effects on bone health take 6–12 months to be seen.

### *Are there any safety issues?*

Soy is generally considered safe when taken as a food source or protein substitute; however, soy isoflavone supplements should be taken with caution in pregnancy, and safety remains unclear in those with breast cancer or prostate cancer.

## St John's wort

S

**HISTORICAL NOTE** St John's wort (SJW) has been used medicinally since ancient Greek times when, it is believed, Dioscorides and Hippocrates used it to rid the body of evil spirits. Since the time of the Swiss physician Paracelsus (c. 1493–1541), it has been used to treat neuralgia, anxiety, neurosis and depression. Externally, it has also been used to treat wounds, bruises and shingles. The name 'St John's wort' is related to its yellow flowers, traditionally gathered for the feast of St John the Baptist, and the term 'wort' is the old English word for plant. SJW has enjoyed its greatest popularity in Europe and comprises 25% of all antidepressant prescriptions in Germany (Schradler 2000). In the past few decades, its popularity has grown in countries such as Australia and the United States.

### OTHER NAMES

Amber, balsana, devil's scourge, goatweed, hardhay, hartheu, herb de millepertuis, hierba de San Juan, hypericum, iperico, johanniskraut, klamath weed, konradskraut, millepertuis, rosin rose, sonnenwendkraut, St Jan's kraut, tipton weed, witch's herb

### BOTANICAL NAME/FAMILY

*Hypericum perforatum* (family Clusiaceae or Guttiferae)

### PLANT PARTS USED

Aerial parts, flowering tops

## CHEMICAL COMPONENTS

Naphthodianthrone (including hypericin and pseudohypericin). Flavonoids, mostly hyperoside, rutin, quercetin, isoquercitrin, quercetin and kaempferol, phenolics, including hyperforin, procyanidins, essential oil, sterols (beta-sitosterol), vitamins C and A, xanthenes and choline.

### **Clinical note — Pharmacologically important constituents**

It has generally been considered that most of the pharmacological activities of SJW are attributable to hypericin and the flavonoid constituent, hyperforin. Besides contributing to the antidepressant activity, hypericin is the primary constituent responsible for the photosensitivity reactions reported with high intakes. Hyperforin is also a major contributor to the herb's antidepressant activity (Butterweck et al 2003a, Mennini & Gobbi 2004) and considered the main constituent responsible for inducing the cytochrome P-glycoprotein (P-gp) and thereby producing drug interactions. Besides this, it demonstrates many other pharmacological effects, such as antibacterial, anti-inflammatory and anti-neoplastic activities. Components previously considered void of activity have also been identified as important for pharmacological activity. For example, both procyanidin B2 and hyperoside increase the oral bioavailability of hypericin by 58% and 34%, respectively, and therefore, its clinical effects (Butterweck et al 2003b). A report published in June 2003 demonstrated that an extract devoid of both hyperforin and hypericin still exhibited antidepressant activity (Butterweck et al 2003a). Other constituents with antidepressant activity were identified and include hyperoside, isoquercitrin and miquelianin, and the 3-O-galactoside, 3-O-glucoside and 3-O-glucuronide of quercetin.

Manufactured products will vary in the concentrations and proportions of the different plant constituents present because these are influenced by the plant's place of origin, its harvest time and drying, extraction processes and storage conditions. Hyperforin, in particular, can be present in variable concentrations because it is unstable in light, air and most organic solvents (Mennini & Gobbi 2004). This is extremely important to remember when comparing studies, as variations in chemical composition could be responsible for differences in results. It also provides a rationale for lack of interchangeability between brands.

## MAIN ACTIONS

SJW has demonstrated multiple mechanisms of action, due to the presence of multiple active constituents. Research has been undertaken to identify the key constituents responsible for each mechanism

of action. Often, the resulting activity is due to a combination of phytochemicals and cannot be ascribed to a single chemical entity.

### Antidepressant

Although SJW has been investigated extensively in scientific studies, there are still many questions about its pharmacology and mechanisms of action.

Collectively, the data show that SJW extract exerts significant pharmacological activity within several neurochemical systems believed to be implicated in the pathophysiology of depression. Recent investigations reveal that hyperforin and other constituents (e.g. adhyperforin, hypericins, flavanol glycosides) act synergistically through both pharmacodynamic and pharmacokinetic mechanisms to alleviate depression (Nahrstedt & Butterweck 2010). The synergistic antidepressive effects have been observed in vitro and in vivo (Fiebich et al 2011).

### Inhibits synaptic reuptake of several neurotransmitters

Preclinical animal studies have found that SJW inhibits the synaptic reuptake system for serotonin, noradrenaline and dopamine (Nathan 1999, Wonnemann et al 2001). Studies using specific isolated constituents have demonstrated potent uptake inhibition of gamma-aminobutyric acid (GABA) and L-glutamate in vivo (Bilia et al 2002, Chatterjee et al 1998). These effects appear to be non-competitive, dose-dependent and mediated via sodium channels (Roz & Rehavi 2004).

Studies with hyperforin have shown that it does not interact directly with uptake transporters but instead acts by reducing the pH gradient across the synaptic vesicle membrane, resulting in diffusion of uncharged monoamines out of the vesicular compartment into the cytoplasm. The increase in cytoplasmic concentration decreases the transmembrane gradient of the neurotransmitters, causing an 'apparent' inhibition of synaptosomal uptake by hyperforin. Additionally, hyperforin elevates intracellular sodium concentration, thereby inhibiting gradient-driven neurotransmitter reuptake (Beerhues 2006). This is a novel mechanism of action, which differs from conventional antidepressant drugs.

Although hyperforin is the main constituent responsible for these effects, tests now show that a number of others are also involved (Gobbi et al 2001), such as adhyperforin, which has demonstrated a strong inhibitory effect on neurotransmitter uptake, and the oligomeric procyanidin fraction, which has demonstrated weak to moderate effects (Wonnemann et al 2001).

### GABA receptor binding

SJW extracts have been shown to bind at GABA-A and -B receptors, to inhibit GABA reuptake, to evoke GABA release from synaptosomes and to exert an anxiolytic effect that is blocked by the benzodiazepine antagonist flumazenil (Perfumi et al 2002).

### Upregulation of serotonin receptors

SJW significantly upregulates both 5-HT<sub>1A</sub> and 5-HT<sub>2A</sub> receptors and has a significant affinity for opiate sigma receptors, which may contribute to the antidepressant effect (Teufel-Mayer & Gleitz 1997).

### Dopamine beta-hydroxylase inhibition

Studies on isolated constituents showed that hypericin and pseudohypericin can inhibit the enzyme dopamine beta-hydroxylase in vitro (Bilia et al 2002).

### Inhibition of catechol-O-methyltransferase

This has been demonstrated in test tube studies (Thiede & Walper 1994).

### Suppresses interleukin-6 (IL-6) synthesis

Various extracts from SJW produce a potent and dose-dependent inhibition of substance P-induced IL-6 synthesis (Fiebich et al 2001), which may also contribute to the herb's overall antidepressant effect.

### Monoamine oxidase (MAO) inhibition

Inhibition of MAO by hypericin demonstrated in vitro was believed to be the primary mode of action; however, this has not been confirmed in several subsequent studies that have shown only weak inhibitory activity at doses in excess of usual therapeutic levels (Di Carlo et al 2001).

### Anxiolytic

Several in vivo studies confirm the anxiolytic effects of SJW extract (Beijamini & Andreatini 2003, Jakovljevic et al 2000, Vandenbogaerde et al 2000). Activity at the GABA receptors and an increase in circulating GABA levels are likely to be involved. Whether the effect is clinically significant is unclear, as a recent systematic review concluded that there is insufficient evidence to conclude that SJW monotherapy is an effective anxiolytic treatment (Lakhan & Vieira 2010).

### Cognitive effects

SJW extracts and hyperforin improve cognitive function in experimental models (Kiewert et al 2004); however, clinical studies have been less convincing (Siepmann et al 2002, Timoshanko et al 2001). In vivo studies with hyperforin have found that it induces the release of acetylcholine from cholinergic terminals in the hippocampus and striatum, providing an explanation for the observed effects. Preventive administration of *Hypericum perforatum* (350 mg/kg orally) counteracted the working-memory impairments caused by repeated stress in male Wistar rats. The herb significantly improved hippocampus-dependent spatial working memory in comparison with control ( $P < 0.01$ ) and alleviated some other negative effects of stress on cognitive functions (Trofimiuk & Braszko 2008). Interestingly, a small trial ( $n = 20$ ) reported that smokers' cognitive function may benefit from taking SJW

(Remotiv, ZE117) while on nicotine replacement therapy (Nicabate CQ) (Camfield et al 2013).

### Neuroprotective

A 2010 review of neurobiological effects of hyperforin and its potential role in Alzheimer's disease indicates that it has several mechanisms which are of relevance, including the ability to disassemble amyloid-beta aggregates in vitro, decrease of astroglial and microglia activation, as well as improving spatial memory in vivo (Griffith et al 2010). A recent in vivo study confirmed that mainly hyperforin and quercetin appear to be involved in the neuroprotective action of SJW standardised extracts (Gómez Del Rio et al 2013).

### Anticonvulsant effects

A study in mice showed that SJW methanolic extract increased latency of seizure in the pretreated group (50 mg/kg) against seizure induced by picrotoxin. The higher dose of extract (200 mg/kg) significantly decreased the duration of seizure and death latency (Etemad et al 2011).

### Effects on alcohol and food intake

Several reports indicate comorbidity between depression and ethanol abuse and that depressive disorders and ethanol abuse may be associated with similar changes in the activity of central neurotransmitters (Markou et al 1998). In vivo studies using SJW in animal models of alcoholism have found that it does not alter food and water intake, or the pharmacokinetics of alcohol, but a reduction in ethanol intake occurs (Panocka et al 2000).

In a model of binge eating (brought upon by stress and food restrictions), treatment with 250 and 500 mg/kg of SJW dry extract decreased the binge-eating episode (Micioni Di Bonaventura et al 2012).

### Effects on morphine withdrawal syndrome

A study in morphine-dependent rats suggests that SJW extract is capable of reducing the symptoms of opiate withdrawal. Its effectiveness may be equivalent to clonidine in reducing the opiate withdrawal syndrome (Feily & Abbasi 2009).

### Anti-inflammatory and analgesic

SJW extract and several of its various isolated constituents have demonstrated effects on inflammation and pain pathways in different in vitro and animal models (Jakovljevic et al 2000, Raso et al 2002).

It potently inhibits binding to mu-, delta- and kappa-opioid receptors (Simmen et al 1998). In vivo tests also identify modulation of cyclooxygenase-2 (COX-2) expression for hypericum extract (Raso et al 2002). Studies with the isolated constituent hyperforin have shown that it potently inhibits COX-1 and 5-lipo-oxygenase in vitro (Albert et al 2002), and also demonstrates high effectiveness in vivo (Feist et al 2009).

A more recent study found that hyperforin inhibits microsomal prostaglandin E<sub>2</sub> synthase-1 and

suppresses prostaglandin E<sub>2</sub> formation in vivo (Koeberle et al 2011). Quercetin and other flavonoids contribute to the anti-inflammatory effect. Hyperoside (quercetin-3-O-galactoside) seems to exert its anti-inflammatory activity through the suppression of nuclear factor- $\kappa$ B activation, as detected in mouse peritoneal macrophages (Kim et al 2011).

A dried extract of SJW, as well as purified hyperforin and hypericin, induced a prolonged antinociception effect that persisted for 120 minutes after administration. The persistent thermal and chemical antinociception of SJW was mainly mediated by protein kinase C-inhibiting mechanisms (Galeotti et al 2010). Similarly, a single oral dose of a SJW dried extract (5 mg/kg orally) produced prolonged relief from pain hypersensitivity in vivo. Moreover, preventive SJW administration increased the latency to induction of hyperalgesia and reduced the duration of the painful symptomatology in a migraine model (Galeotti et al 2013a). Subsequently, hypericin was identified as a key component responsible for reversing nitric oxide-induced nociceptive hypersensitivity, whereas hyperforin and flavonoids were ineffective (Galeotti et al 2013b).

### Anticancer effects

Hypericin, the photoactive compound of *Hypericum perforatum*, is probably the most powerful photosensitiser found in nature (Kacerovska et al 2008). It has minimal toxicity but exhibits potent photo-damaging effects in the presence of light (Olivo et al 2006). It is known to generate a high yield of singlet oxygen and other reactive oxygen species that are associated with photo-oxidative cellular damage (Karioti & Bilia 2010). The application of photodynamic therapy (PDT) with hypericin for the treatment of cancers such as recurrent mesothelioma and skin cancer has been validated in clinical trials. It may also have potential as a photodynamic agent in the treatment of nasopharyngeal cancer according to in vitro and in vivo models (Kacerovska et al 2008).

Hyperforin also exhibits antineoplastic potential based on the sum of its anticarcinogenic, antiproliferant, proapoptotic, anti-invasive and antimetastatic effects (Medina et al 2006). Hyperforin has been shown to effectively decrease the proliferation rates of a number of mammalian cancer cell lines, induce apoptosis of tumour cells and inhibit angiogenesis both in vitro and in vivo. For example, under hyperforin treatment in vivo, the growth of Kaposi's sarcoma — a highly angiogenic tumour — is strongly inhibited, with the resultant tumours reduced in size and vascularisation as compared with controls. Hyperforin inhibits neutrophil and monocyte chemotaxis in vitro and angiogenesis in vivo induced by angiogenic chemokines (CXCL8 or CCL2) (Lorusso et al 2009).

Besides hypericin and hyperforin, polyphenolic procyanidin B2 has also demonstrated an inhibitory effect on the growth of leukaemia cells, brain glioblastoma cells and normal human astrocytes in vitro (Hostanska et al 2003). Further, the inhibitory

effects on leukaemic cell growth were synergistically strengthened when hypericin and hyperforin were tested together.

### Antiretroviral, antifungal and antibacterial

Alcoholic SJW extracts (methanolic/ethanolic) have more pronounced antibacterial activity than aqueous extracts (Saddiqe et al 2010). The key antibacterial compound isolated to date from SJW is hyperforin, which has a higher antibacterial activity against Gram-positive than Gram-negative bacteria. More recently, a study found that an SJW extract was effective at inhibiting five non-pathogenic *Mycobacterium* isolates and *Bacillus subtilis*, but not *Escherichia coli*. Hyperforin isolated from this extract was more effective than hypericin or pseudohypericin (Mortensen et al 2012). This supports an earlier paper which identified hyperforin as a key constituent demonstrating antibacterial activities (Medina et al 2006).

Hyperforin exhibits effective antibacterial activity against methicillin-resistant *Staphylococcus aureus* and other Gram-positive bacteria, but no growth-inhibitory effect on Gram-negative bacteria or *Candida albicans* (Schempp et al 1999).

In a recent animal study SJW reduced the lung index and viral titre of mice infected with influenza A virus, decreasing mortality and prolonging the mean survival time (Xiuying et al 2012).

Although in vitro and studies in animal models have identified antiretroviral activity for hypericin and pseudohypericin (Meruelo et al 1988), two clinical trials could not confirm these effects, even when larger doses of hypericin were administered (Gulick et al 1999, Jacobson et al 2001).

The mechanism involved is not known; however, it is suspected to involve direct inactivation of the virus or prevention of virus shedding, budding or assembly at the cell membrane (Meruelo et al 1988). The presence of light is an important requirement for antiretroviral activity to be demonstrated, as the effect appears to be photoactivated (Hudson et al 1993, Miskovsky 2002).

### Cardiovascular effects

New in vivo research revealed that SJW significantly lowered total cholesterol and low-density lipoprotein (LDL) cholesterol when tested in healthy rats. It significantly inhibited weight gain in high-fat-fed rats, and in fructose-fed rats, SJW normalised the dyslipidaemia induced by fructose feeding and improved the insulin sensitivity (Husain et al 2011a). The same authors showed that SJW significantly reduced elevated blood glucose levels in diabetic rats and exerted a significant anxiolytic effect in this test group (Husain et al 2011b). A significant decrease in blood glucose levels was also observed after 1 week's administrations of SJW extract (125 and 250 mg/kg) to streptozotocin-diabetic rats. It also improved their dysregulated metabolic parameters (Can et al 2011).

Hypolipidaemic activity and antiatherosclerotic effects were also seen in another study utilising

hypercholesterolaemic rabbits being treated with hydroalcoholic SJW extract (150 mg/kg). The effect appeared to be stronger than that of lovastatin (10 mg/kg) (Asgary et al 2012).

Previously, SJW extracts were identified as inhibitors of adipogenesis of 3T3-L1 cells and shown to inhibit insulin-sensitive glucose uptake in mature fat cells. The same authors subsequently found that SJW extract limits the differentiation of pre-adipocytes and significantly induces insulin resistance in mature fat cells. These effects were not mediated by hyperforin and hypericin (Richard et al 2012)

### Gastrointestinal effects

SJW exhibits antispasmodic activity, according to research conducted with an experimental animal model (Jakovljevic et al 2000), most likely mediated via GABA activity. Among the chemical constituents of SJW extract tested, hyperforin and, to a lesser extent, the flavonoids kaempferol and quercetin inhibited acetylcholine-induced contractions in an animal model (Capasso et al 2008). SJW has a direct inhibitory effect on smooth muscle and could also possibly modulate gastric neurotransmission. A more recent in vivo irritable bowel syndrome study showed that SJW extract diminished the recruitment of inflammatory cells and tumour necrosis factor- $\alpha$  following restraint stress not in a dose-dependent manner and inhibited small-bowel and colonic transit acceleration like loperamide, but had minimal effect on gastric emptying (Mozaffari et al 2011).

### OTHER ACTIONS

No clinically significant effect on platelet aggregation has been identified (Beckert et al 2007).

### Induction of CYP3A4 activity in the intestinal wall

Human studies have identified CYP3A4 and 2C19 induction effects for standard SJW extracts (e.g. LI 160), but no effects on CYP1A2, CYP2C9 or CYP2D6 (Durr et al 2000, Gurley et al 2008a, Jiang et al 2004, Wang et al 2001, 2004a). Human studies have failed to identify significant CYP3A4, 2D6, 2C9, 1A2 or 2C19 induction for low-hyperforin SJW extracts, such as ZE 117, using the appropriate probe drugs (Arold et al 2005, Madabushi et al 2006, Mueller et al 2004).

Hyperforin is a potent ligand for the pregnane X receptor, an orphan nuclear receptor that regulates expression of the CYP3A4 mono-oxygenase (Moore et al 2000). Although it is considered the chief constituent responsible for the pharmacokinetic interactions reported, there are other, less potent constituents in SJW, which also modulate cytochrome enzymes (Obach 2000).

Results from an open-label clinical study suggest that the effects of standard SJW (LI 160) on CYP3A4 enzymes may be biphasic, where the initial dose leads to a minor inhibition, followed by significant induction during long-term use (Rengelshausen et al 2005). Clinical studies indicate that CYP3A

activity returns progressively to the basal level approximately 1 week after cessation of SJW administration (Imai et al 2008).

### Increases levels of intestinal P-glycoprotein

SJW extract produced a 3.8-fold increase of intestinal P-gp expression in vivo (Durr et al 2000). Hyperforin has been identified as the key constituent responsible for P-gp induction effects (Tian et al 2005), although in vitro tests suggest other less potent constituents also exist, such as quercetin, hypericin, biapigenin and kaempferol (Patel et al 2004, Weber et al 2004).

Once again, low-hyperforin SJW extracts do not appear to significantly induce P-gp (Arold et al 2005, Madabushi et al 2006, Mueller et al 2004).

In vitro and in vivo tests further indicate that P-gp effects caused by standard SJW (LI 160) are biphasic, with an initial inhibitory effect followed by induction after longer exposure (Rengelshausen et al 2005, Wang et al 2004a).

### Decreases levels of P-glycoprotein at blood-brain barrier

Newer research shows that SJW extract and the constituents hyperforin, hypericin and quercetin decreased P-gp transport activity at the blood-brain barrier in a dose- and time-dependent manner. SJW extract and hyperforin directly inhibited P-gp activity, whereas hypericin and quercetin modulated transporter function through a mechanism involving protein kinase C (Ott et al 2010).

### CLINICAL USE

SJW is one of the most clinically tested herbal medicines available. As a result, we have an understanding of the key mechanisms of action, clinical effects, safety issues and also how it compares to standard pharmaceutical treatments. Its strong evidence base provides a good rationale for every clinician to consider its use where appropriate. Various SJW extracts have been tested in clinical trials. Some trials conducted with SJW used a 0.3% hypericin water and alcohol extract, known as LI 160. Most newer studies use different preparations, such as WS 5573 (standardised to hyperforin) or ZE 117 (a low-hyperforin concentration preparation).

### Depression

Overall, SJW preparations are mainly used for mood disorders in modern-day practice, although it demonstrates benefits for other indications. There is now strong evidence from several meta-analyses to conclude that SJW extract is an effective treatment in mild, moderate and major depressive disorder with efficacy comparable to tricyclic and selective serotonin reuptake inhibitor (SSRI) antidepressant drugs (Cipriani et al 2012, Linde et al 2005a, 2009, Nahas & Sheikh 2011, Sarris & Kavanagh 2009). Additionally, SJW is well tolerated and associated with fewer side effects than pharmaceutical antidepressants. There is also evidence indicating that it reduces relapse.

**Clinical note — The Hamilton Depression Scale (HDS)**

The HDS is an observer-rated scale that focuses mainly on somatic symptoms of depression. Although the original version included 21 items, a similar version using 17 items is more commonly used in clinical trials. Most studies using the HDS report the number of 'treatment responders' (patients achieving a score less than 10 and/or less than 50% of the baseline score) (Linde et al 2005a).

**Mild to moderate depression**

SJW has shown efficacy as a successful treatment for mild to moderate depression in numerous double-blind, placebo-controlled trials, confirmed by several meta-analyses and systematic reviews. Moreover, the clinical guidelines for the management of major depressive disorder in adults published by the Canadian Network for Mood and Anxiety Treatments (CANMAT) conclude that level 1 evidence supports SJW in mild to moderate depressive disorder (Ravindran et al 2009).

A 2005 Cochrane review analysed data from 37 double-blind, randomised studies ( $n = 4925$ ) that used monopreparations of SJW over a treatment period of at least 4 weeks (Linde et al 2005a). It concluded that SJW extracts were superior to placebo for improving symptoms and SJW produced effects similar to synthetic antidepressants (tricyclic antidepressants [TCAs] and SSRIs) in adults with mild to moderate depression. The same conclusion was found in a later systematic review (Sarris & Kavanagh 2009).

Kasper et al (2008a) reanalysed data from a subset of patients ( $n = 217$ ) suffering from an acute episode of mild depression from controlled trials testing SJW extract WS 5570 from the 2005 Cochrane review. The analysis shows that SJW extract WS 5570 has a meaningful beneficial effect during acute treatment of patients suffering from mild depression and leads to a substantial increase in the probability of remission. The studies tested three different doses — 600, 900 or 1200 mg/day — or placebo for 6 weeks. Patients receiving active treatment with WS 5570 experienced decreases in the HDS total score by an average of 10.8 (600 mg/day), 9.6 (900 mg/day), and 10.7 (1200 mg/day) points between the pre-treatment baseline value and the end of acute treatment, compared to 6.8 points in the placebo group. All differences were significant. The rates of responders were 73%, 64%, 71% and 37% for WS 5570 600 mg/day, 900 mg/day and 1200 mg/day and placebo, respectively.

Since then, a long-term, open, multicentre study testing 500 mg/day of SJW ZE117 extract over 52 weeks found that the herbal treatment produced a significant reduction in depression scores (HDS) and was associated with a lower side effect rate than for standard antidepressants, thereby confirming earlier results (Brattström 2009).

Melzer et al (2010) conducted a different type of trial in an attempt to see whether using SJW in a real practice setting, where patients were taking multiple medications and required individualised dosing, would still be effective in the treatment of depression. This open-label, German study ( $n = 1778$ , from 304 centres) utilised Helarium-425 capsules from Bionorica, Neumarkt, Germany, at different doses, individualised for the patient. The mean daily dose was  $822.5 \pm 205.4$  mg dry ethanolic *Hypericum* extract at admission (range 425–1700 mg) and  $754.4 \pm 231.1$  mg at the last visit. The most commonly prescribed dosage schedules were an intake twice or three times daily. Used in this way by outpatients, SJW treatment was effective as an antidepressant in the management of depression in daily practice and lower age and shorter duration of the disorder were associated with significantly better outcomes (Melzer et al 2010). The herbal drug was well tolerated, and no new or serious adverse drug reactions were identified. More specifically, the SJW treatment was an extract with 255–285 mg dry ethanolic extract per coated tablet, standardised to hypericin 0.3% and a hyperforin content of 2–3%, or Helarium-425 with 425 mg dry ethanolic extract per capsule (DER 3.5–6:1) or Helarium-425, which is standardised to hypericin 0.1–0.3% and has a hyperforin content of maximum 6%, flavonoid/rutoside minimum 6% in the extract.

**Major depression**

Although a 2005 Cochrane review stated that SJW shows only minimal benefits over placebo in major depression (Linde et al 2005a), an updated 2009 Cochrane systematic review has concluded that SJW extracts: (1) are superior to placebo in patients with major depression; (2) are similarly effective as standard antidepressants (SSRIs and TCAs); and (3) have fewer side effects than standard antidepressants (Linde et al 2009). A total of 29 randomised controlled trials (RCTs) were evaluated ( $n = 5489$ ), including 18 comparisons with placebo and 17 comparisons with synthetic standard antidepressants. The standard antidepressants used as active comparators were fluoxetine (six trials, dosage 20–40 mg), sertraline (four trials, 50–100 mg), imipramine (three trials, dosage 100–150 mg), citalopram (one trial, 20 mg), paroxetine (one trial, 20–40 mg), maprotiline (one trial, 75 mg) and amitriptyline (one trial, 75 mg). Most trials used a dose range 500–1200 mg/day of SJW.

More recently, another double-blind, placebo-controlled, randomised study was conducted which involved 100 patients with moderate severity of major depression and vegetative features of atypical depression (Mannel et al 2010). The SJW extract LI 160 (600 mg/day) given over 8 weeks was significantly superior to placebo for producing an antidepressant effect (HDS) and also improved hypersomnolence. In addition, the secondary outcome variables were significantly improved by SJW treatment. These were the depression subscore

of the Patient Health Questionnaire, the Clinical Global Impression (CGI), a patient's satisfaction scale and the Hamilton Anxiety Scale.

This result is clinically important as the effects of standard antidepressants over placebo are modest and, although SSRIs are better tolerated than older antidepressant drugs (such as monoamine oxidase inhibitors), side effects are still common.

### Comparative studies

#### *SJW vs SSRIs*

SJW is as effective as the newer generation of antidepressants but with fewer adverse events and better tolerability. The most recent Cochrane review found no significant differences between SJW and SSRIs in the proportion of people responding (12 RCTs) and active treatment with SJW resulted in significantly fewer drop-outs due to side effects compared with SSRIs (11 RCTs, 1769 people). There were no significant differences between groups in the reporting of adverse effects, although the result was of borderline significance (nine RCTs, 1641 people;  $P = 0.048$ ) (Cipriani et al 2011, Linde et al 2009). Similarly, a meta-analysis of SJW trials (13 controlled trials) in major depressive disorder found that SJW does not differ from SSRIs according to efficacy and adverse events. Once again, there were fewer drop-outs due to adverse events in the SJW group (Rahimi et al 2009).

A comparative analysis by Kasper et al (2010b) between paroxetine and SJW extract WS 5570 revealed a 10–38-fold higher adverse events rate for the synthetic comparator.

#### Citalopram

A double-blind study ( $n = 388$ ) found SJW extract (900 mg daily of extract STW3-VI) to be as effective as citalopram (20 mg daily) in moderate depression (Gastpar et al 2006). Both antidepressants were significantly more effective than placebo. Significantly more adverse events were documented in the citalopram group (53.2%) than for SJW (17.2%) or placebo (30%). In contrast, a subsequent three-arm RCT ( $n = 81$ ) found that neither SJW (810 mg/day, extract not further described) nor citalopram (20 mg/day) showed a statistically significant effect over placebo in the treatment of minor depression over a 12-week period. The authors state that both treatments were associated with a significant number of adverse effects during the treatment. However, the prevalence of adverse effects reported in the placebo arm was higher (91.3%) than in the SJW (84.6%) arm, confirming Gastpar's study (Rapaport et al 2011).

#### Sertraline

To study the long-term efficacy of SJW, a cohort of 124 participant 'responders' continued treatment after week 8, until week 26. They were randomly assigned SJW (900–1500 mg), sertraline (50–100 mg) or matching placebo during this extension phase. At week 26, the outcome was equivocal; although

both SJW and sertraline were still therapeutically effective, a pronounced 'placebo effect' impeded calling a significant result at week 26 (Sarris et al 2012a).

#### *SJW vs TCAs*

The most recent Cochrane review found no significant differences between SJW and TCAs in the proportion of people responding (five RCTs in total, of which three RCTs used imipramine, one RCT used amitriptyline and one RCT used maprotiline). Additionally, significantly fewer participants withdrew for any reason or due to side effects with SJW treatment compared to older antidepressants (three RCTs, imipramine; one RCT, amitriptyline; one RCT, maprotiline) and significantly fewer reported any adverse effects (Cipriani et al 2011, Linde et al 2009). Importantly, SJW is not associated with orthostatic hypotension, a common adverse effect associated with TCAs and related drugs, the older MAO inhibitors and serotonin-noradrenaline reuptake inhibitors (SNRIs) (Darowski et al 2009).

#### *SJW vs SSRI and SNRI and others (mirtazapine)*

A Cochrane review analysing citalopram vs other antidepressants for depression found that SJW was equally effective as citalopram, mirtazapine or venlafaxine. They also found that citalopram was associated with a higher rate of patients experiencing side effects than SJW (odds ratio 1.69, 95% confidence interval 1.01–2.83; one trial, 258 participants). It was shown that citalopram was associated with a higher rate of patients experiencing gastrointestinal problems or vertigo (Cipriani et al 2012).

#### **Clinical note — Which extracts are effective?**

Since the constituents of SJW extract differ between the individual manufacturers, the efficacy cannot be extrapolated from one extract to another. Three RCTs have favourably compared low-hyperforin extracts (ZE 117) to fluoxetine or imipramine, suggesting that the absence of hyperforin does not hinder the antidepressant effect (Friede et al 2001, Schrader 2000, Woelk 2000). In a subsequent review of trials included in the clinical studies above, WS 5572, LI 160, WS 5570 and ZE 117 SJW extracts have all shown significantly greater efficacy than placebo and similar efficacy and better tolerability than standard antidepressant drugs (Kasper et al 2010a).

S

#### **Paediatric use**

Results from a postmarketing surveillance study of 101 children under 12 years with mild to moderate depression have suggested that SJW may be an effective and well-tolerated treatment in this population (Hubner & Kirste 2001). The number of doctors rating effectiveness of treatment with SJW as 'good' or 'excellent' was 72% after 2 weeks, 97% after 4 weeks and 100% after 6 weeks and ratings

**Clinical note — Is SJW cost-effective?**

A recent study reports on using the Markov model to estimate the health and economic impacts of SJW versus antidepressants. Outcomes were treatment costs, quality-adjusted life years and net monetary benefits. SJW was shown to be a cost-effective alternative to generic antidepressants (Solomon et al 2011, 2013).

Similarly, a report commissioned by the National Institute of Complementary Medicine in Australia and undertaken by Access Economics concluded that, based on analyses of RCTs for SJW, it was found to be cost-effective and produced a cost saving compared to standard antidepressants for patients with mild to moderate depression (Access Economics 2010). More specifically, with treated mild and moderate depression estimated to affect 339,752 Australians in 2009, there could be around \$50 million per annum in potential savings from switching to SJW from standard antidepressants.

In the sensitivity analysis, SJW dominated standard antidepressants for mild to moderate depression because it is cheaper than standard antidepressants and fewer patients withdraw from SJW than from standard antidepressants. Even if the unit cost of SJW was the same as that of standard antidepressants, SJW would remain dominant due to the lower changeover rates compared to standard antidepressants.

by parents were similar. Although encouraging, it is difficult to interpret the clinical significance of the results, as there was no placebo group and the final evaluation included only 76% of the initial sample. A subsequent study by Findling and colleagues (2003) evaluated the use of SJW in 33 children aged 6–16 years in an open-label design for 8 weeks, also finding good results. The initial dose was 150 mg three times daily and could be titrated up to 300 mg three times daily. Using the Children's Depression Rating Scale, 76% of the patients clinically improved and 93% continued therapy at the end of the study.

An 8-week open pilot study was conducted with SJW (300 mg three times daily) in 26 adolescents with major depressive disorder (Simeon et al 2005). The subjects were aged 12–17 years (mean 14.8 years). Only 11 patients completed the study; 9 (82%) of them showed significant clinical improvement based on CGI change scores. Of the 15 patients (58%) who did not complete the study, 8 patients were non-compliant and 7 patients were discontinued because of persisting or worsening depression. The interpretation of these results is difficult due to a large drop-out rate.

**Preventing relapse of depression**

A double-blind, placebo-controlled, multicentre trial conducted by Kasper et al (2008b) evaluated

the efficacy and safety of hypericum extract WS 5570 in preventing relapse during 6 months' continuation treatment and 12 months' long-term maintenance treatment after recovery from an episode of recurrent depression. After 6 weeks of single-blind treatment with 3 × 300 mg/day WS 5570, patients with score ≤2 on item 'Improvement' of the CGI scale and an HDS total score decrease ≥50% versus baseline were randomised to 3 × 300 mg/day WS 5570 or placebo for 26 weeks. This provided a total of 426 patients in the next study phase. Treatment with WS 5570 showed more favourable HDS and Beck Depression Inventory time courses and greater overall improvement (CGI) than controls. In long-term maintenance treatment, a pronounced prophylactic effect of WS 5570 was observed in patients with an early onset of depression as well as in those with a high degree of chronicity. Adverse event rates under WS 5570 were comparable to placebo.

A reanalysis of data obtained from a total of 154 patients responders, in a multicentre RCT after 6 weeks of treatment for an episode of moderate depression with either 20 mg citalopram or 900 mg SJW extract STW 3-VI, showed that SJW extract STW 3-VI is more efficient in lowering the relapse and recurrence rates of responders, when compared to citalopram and placebo. In addition, duration of response was increased in the group treated with SJW extract STW 3-VI (Singer et al 2011).

**Postnatal depression**

A 2009 systematic review found no clinically important results about the effects of SJW in postnatal depression (Craig & Howard 2009).

**Obsessive-compulsive disorder (OCD)**

Treatment with a fixed dose of 450 mg of SJW containing 0.3% hypericin twice daily over 12 weeks improved the condition in 5 of 12 patients, according to an open study (Taylor & Kobak 2000). Two recent systematic reviews, however, concluded that controlled studies suggest that SJW is ineffective in treating OCD (Camfield et al 2011, Sarris et al 2012b).

**Autism**

SJW was only modestly effective in the short-term treatment of irritability in some patients with autistic disorder in an open pilot study of three male participants (Niederhofer 2009).

**Seasonal affective disorder (SAD)**

Wheatley (1999) found that people with mild to moderate SAD experienced significant improvements with anxiety, loss of libido and insomnia after 8 weeks' treatment with SJW. The test group receiving SJW extract (Kira 300 mg) three times daily plus light therapy experienced superior sleep compared with the group receiving SJW as stand-alone treatment.

**Clinical note — Relative safety of SJW compared with pharmaceutical antidepressants**

Much has been made of the known or suspected risks associated with the use of SJW, with far too little discussion focusing on the decisive question of its relative safety compared with pharmaceutical antidepressants. It has been estimated that approximately 1 in 30,000 people using SJW will experience an adverse reaction, including those attributed to drug interactions (Schulz 2006). An overview of 16 postmarketing surveillance studies involving different SJW preparations and 34,804 patients found that side effect incidence varied from 0 to 2.8% in short-term studies (4–6 weeks) and 3.4–5.7% in long-term studies (52 weeks) (Linde & Knuppel 2005). Gastrointestinal symptoms, sensitivity to light and other skin conditions and agitation were the most commonly reported side effects and were generally described as mild. The review found that serious side effects or interactions were not reported by any study. Taking this into account, the incidence of side effects to SJW is approximately 10-fold lower than for conventional antidepressants (SSRIs) (Schulz 2006). The most common adverse event among spontaneous reports is photosensitivity, which is estimated to occur in 1 in 300,000 treated cases. This can occur with a dose of 5–10 mg/day hypericin, which is 2–4-fold higher than the recommended dose. SJW has no significant effect on blood pressure or heart rate (Siepmann et al 2002), making it a safer choice than TCAs in patients with cardiovascular disease. It also lacks anticholinergic activity, so side effects such as dry mouth, urinary retention and blurred vision do not occur. In addition, the common side effects reported for SSRIs, such as anorexia, insomnia, sexual dysfunction, excessive sweating and visual disturbance, have not been reported for SJW. Similarly to all standard antidepressants, SJW can interact with other medicines and needs to be judiciously prescribed.

**Polyneuropathy**

Although SJW is sometimes used for nerve pain, a randomised, double-blind, crossover study of 54 patients identified a trend towards lower total pain score with SJW treatment, although none of the individual pain ratings was significantly changed (Sindrup et al 2001). The dose of SJW used provided 2.7 mg/day total hypericin and was taken over 5 weeks.

**Menopause: psychological and psychosomatic symptoms**

A 2013 meta-analysis has concluded that *Hypericum perforatum* L. extracts and its combination with other herbs were significantly superior to placebo in the treatment of menopause (Liua et al 2013).

Importantly, SJW treatment had fewer side effects than the placebo arms of the studies analysed.

It appears that its effects are seen after at least 8 weeks of treatment, according to a placebo-controlled study showing SJW was an effective treatment for the vasomotor symptoms of perimenopausal or postmenopausal women ( $n = 100$ ) (Abdali et al 2010). Other symptoms may also respond, as was seen in another study using SJW (160 mg effervescent tablet, Goldaru, three times a day), which significantly decreased psychomental changes, sleep disorders and vasomotor symptoms in 30 menopausal women throughout the third and the sixth week of the study (Fahami et al 2010). An early study not only confirmed that menopausal symptoms reduced or disappeared completely in the majority of women (76.4% by patient evaluation and 79.2% by doctor evaluation) but sexual wellbeing also improved in 80% of cases (Grube et al 1999). The study used 900 mg hypericum (Kira 300 mg three times daily) in the 12-week study.

A review of the evaluations given by women assessed in the VITamins And Lifestyle (VITAL) cohort ( $n = 35,016$ ), of whom  $n = 880$  had invasive breast cancer, found no risks associated with taking SJW for menopausal symptoms (Brasky et al 2010).

**IN COMBINATION****SJW and black cohosh**

A fixed combination of isopropanolic black cohosh (Remifemin; standardised to 1 mg triterpene glycosides) and ethanolic SJW (standardised to 0.25 mg total hypericin) was tested in 301 women with menopausal symptoms with pronounced psychological symptoms (Uebelhack et al 2006). The double-blind, randomised study found that 16 weeks of herbal treatment produced a significant 50% reduction in the Menopause Rating Scale score compared to 20% with placebo and a significant 42% reduction in the HDS score compared to only 13% in the placebo group.

A second study testing the effectiveness of combined SJW and black cohosh found that combination therapy was superior to stand-alone black cohosh therapy for the treatment of climacteric mood symptoms in general practice (Briese et al 2007). This was a prospective, controlled, open-label observational study which involved 6141 women attending 1287 outpatient gynaecologists in Germany.

A 2012 review similarly concluded that the combination of black cohosh and SJW showed an improvement of climacteric complaints in comparison to placebo, whereas most of the studies that compared black cohosh monotherapy with placebo did not show significant effects (Laakmann et al 2012).

**SJW and chaste tree**

The herbal combination of SJW and *Vitex agnus-castus* (chaste tree) was not found to be superior to placebo for the treatment of menopausal symptoms in an RCT with 93 women (van Die et al 2009a).

## Perimenopause

Symptomatic perimenopausal women aged 40–65 years who experience hot flushes (three or more per day) may experience significant improvements to menopause-specific quality of life using SJW extract (900 mg t.i.d.) according to a double-blind, placebo-controlled study (Al-Akoum et al 2009). After 3 months of treatment, herbal treatment was significantly better than placebo for menopause-specific quality of life and also provided significant improvements for self-reported sleep problems. No significant effects were seen at 6 weeks, indicating that the effects have slow onset.

### IN COMBINATION

#### SJW and chaste tree

It has been suggested that some of the symptoms typically attributed to menopause may be more related to premenstrual syndrome (PMS) than menopause, as perimenopausal women appear to be more prone to PMS-like symptoms, or at least to tolerate them less well. An RCT ( $n = 14$ , late perimenopausal women) conducted over 16 weeks found that the herbal combination was superior to placebo for total PMS-like scores ( $P = 0.02$ ), PMS-depression ( $P = 0.006$ ), and PMS-craving clusters ( $P = 0.027$ ) and produced a significant reduction in anxiety ( $P = 0.003$ ) and flushes ( $P = 0.002$ ) (van Die et al 2009b).

## Premenstrual syndrome

An early open study in patients with PMS found that a low dose of 300 mg SJW daily produced significant reductions in all outcome measures. The degree of improvement in overall PMS scores between baseline and the end of the trial was 51%, with over two-thirds experiencing at least a 50% decrease in symptom severity (Stevinson & Ernst 2000). Similarly, a 2009 systematic review concluded that SJW shows some benefit in PMS (Whelan et al 2009).

In a subsequent study Canning et al (2010) reported that SJW was more effective than placebo in the treatment of PMS. By measuring levels of serum sex hormones and inflammatory cytokines, they also excluded inflammatory or hormone regulation as a possible mechanism of action. Another subsequent RCT ( $n = 170$  women with PMS for at least 6 months) showed that those receiving SJW (tablets, standardised to 680 mg of hypericin per day) had significantly lower PMS scores compared with baseline and placebo. The biggest improvements in score occurred for crying (71%) and depression (52%) (Ghazanfarpour et al 2011).

## Attention-deficit hyperactive disorder (ADHD)

A double-blind RCT found that SJW (300 mg three times daily of *H. perforatum* standardised to 0.3% hypericin) was ineffective for the symptomatic treatment of ADHD in children (Weber et al 2008). The study involved 54 children aged 6–17 years who met *Diagnostic and Statistical Manual of Mental*

*Disorders* (Fourth Edition) criteria for ADHD by structured interview and was conducted over 8 weeks. Two subsequent reviews have also concluded that SJW is ineffective in ADHD (Rucklidge et al 2009, Sarris et al 2011).

## Nervous agitation in children

### IN COMBINATION

A multicentre, prospective observational study with 115 children aged between 6 and 12 years tested a herbal combination of SJW, valerian root and passionflower root dry extract for 4 weeks. According to the parents, a distinct improvement was observed in children who had attention problems, showed social withdrawal and/or were anxious/depressive. Based on the doctors' assessment, 82–94% of the affected children responded as they showed no or just mild symptoms at the end of the treatment period, an observation based on evaluated symptoms such as depression, school/examination anxieties, further anxieties, sleeping problems and different physical problems. Therapeutic success was not influenced by additional medication or therapies and treatment was well tolerated (Trompeter et al 2013).

## Smoking cessation

Preliminary evidence from experimental models suggested that SJW may be of use in reducing nicotine withdrawal signs, although more recent research indicates no effect on abstinence rates. In the study, SJW significantly and dose-dependently reduced the total nicotine abstinence score (Catania et al 2003). In contrast, a placebo-controlled blinded RCT ( $n = 143$ ) which tested 900 mg SJW or placebo tablets taken 2 weeks prior and 2 weeks after the quit day did not find that SJW increased absolute quit rates or affected withdrawal symptoms (Parsons et al 2009). Similarly, a placebo-controlled blinded RCT ( $n = 118$ ) which tested 300 mg SJW, 600 mg SJW or placebo tablets three times daily also did not find that SJW increased smoking abstinence rates (Sood et al 2010).

## Herpes infection

Based on its antiviral activity, SJW is also used clinically in the treatment of herpesvirus infections. One study of unknown design found that oral extract LI 160 (over a period of 3 months) reduced the frequency and severity of episodes of recurrent herpes labialis and herpes genitalis (Mannel et al 2000).

## Topical use

SJW extract is used in a variety of skin conditions based on effects such as increased skin hydration, reduced the transepidermal water loss and promoted keratinocyte differentiation. For further information on the underlying mechanisms of these effects, please refer to Casetti et al (2011).

## Atopic dermatitis

A cream containing SJW extract (standardised to 1.5% hyperforin) was shown to reduce the intensity

of eczematous lesions when used twice daily in a prospective, double-blind study (Schempp et al 2003). Beneficial effects were already observed at the first visit, which was on day 7. A review evaluating plants for their effects in skin diseases also concluded that SJW appears promising for atopic dermatitis (Reuter et al 2010).

### Treatment of acute and contused injuries

No controlled studies are available, but anti-inflammatory, analgesic and bactericidal activities provide a theoretical basis for its use.

Commission E approves the topical use of oily SJW preparations for this indication (Blumenthal et al 2000).

### Herpes simplex 1 and 2

#### IN COMBINATION

A single-use, topical formulation containing copper sulfate pentahydrate and SJW (Dynamiclear) was compared to topical 5% aciclovir cream in an RCT ( $n = 149$ ) for the treatment of herpes simplex virus type 1 and 2 lesions in adult patients. The SJW formulation was well tolerated and more effective in reducing burning, stinging, pain, erythema and vesiculation (Clewell et al 2012).

### Myalgia

Although no controlled studies are available, anti-inflammatory and analgesic activities provide a theoretical basis for its use in this condition.

Commission E approves the topical use of oily SJW preparations for this indication (Blumenthal et al 2000).

### First-degree burns

Although no controlled studies are available, anti-inflammatory, analgesic and bactericidal activities provide a theoretical basis for its use in this condition.

Commission E approves the topical use of oily SJW preparations for this indication (Blumenthal et al 2000).

### Plaque-type psoriasis

SJW ointment applied twice daily for 4 weeks may be effective in reducing psoriasis area severity index scores in mild plaque-type psoriasis (Najafizadeh et al 2012).

### Ultraviolet (UV)-protective effects

SJW cream significantly reduced UVB-induced erythema as opposed to the vehicle when tested on 20 volunteers in a randomised, double-blind, vehicle-controlled study (Meinke et al 2012).

### Caesarean section

A placebo-controlled study of 144 volunteers supports the use of SJW ointment (applied three times daily for 16 days) following caesarean section to promote wound healing, improve scar formation and reduce pain and pruritus (Samadi et al 2010).

### Diabetic foot

#### IN COMBINATION

A case report exists describing the successful use of an extract of SJW and neem oil (*Azadirachta indica*) for foot wounds with exposed bone in a patient with bilateral advanced diabetic ulcers (Labichella 2013).

### Venous ulcers

#### IN COMBINATION

The therapeutic effects of the ointment Herbadermal (extracts of garlic, SJW and calendula) was tested over a 7-week period in 25 patients with ulceration of the lower leg (no longer than 2 months or recurrent ulceration during the last 6 months). The percentage of epithelialisation was 99.1% without significant effects on the microbial flora (Kundaković et al 2012).

### Scalp wounds

#### IN COMBINATION

A retrospective, non-controlled analysis suggests that a mixture of SJW oil and neem oil (*Azadirachta indica*) is a therapy that is very simple to use, safe and potentially effective for the treatment of scalp wounds with exposed bone (Läuchli et al 2012).

### Photodynamic therapy

A prospective study aimed at investigating the efficacy of PDT with topical application of an extract of *H. perforatum* in actinic keratosis, basal cell carcinoma (BCC) and morbus Bowen (carcinoma in situ) was conducted with 34 patients (8 with actinic keratoses, 21 with BCC and 5 with Bowen's disease) (Kacerovska et al 2008). Hypericum extract was applied on the skin lesions under occlusion and followed by irradiation with 75 J/cm<sup>2</sup> of red light 2 hours later. The treatment was performed weekly for 6 weeks on average. The percentage of complete clinical response was 50% for actinic keratoses, 28% in patients with superficial BCC and 40% in patients with Bowen's disease. There was only a partial remission seen in patients with nodular BCCs. A complete disappearance of tumour cells was found in the histological preparation of 11% of patients with superficial BCCs and 80% in the patients with Bowen's disease. Unfortunately, the combined treatment was poorly tolerated, as all patients complained of burning and painful sensations during irradiation.

### OTHER USES

In practice, SJW is also used to treat fibrositis, nervous exhaustion, sciatica and gastrointestinal conditions, such as oesophagitis and peptic ulcers. Traditionally, SJW has been used for wound healing, as a diuretic, for melancholy, as pain relief, treatment for snake bites, for bedwetting in children, and in malaria and psychosis.

### DOSAGE RANGE

- Dried herb: 2–5 g/day.
- Liquid extract (1:2): 3–6 mL/day.

**Clinical note — PDT for tumour cells**

PDT involves the administration of a photosensitiser, which is taken up and stored within tumour cells, followed by light irradiation with a specific wavelength, giving rise to irreversible tissue destruction (Kacerovska et al 2008). It is aimed at destroying tumour cells without damaging the surrounding normal tissues (Agostinis et al 2002). This combination approach results in the production of cytotoxic oxygen singlets within the tumour that cause irreversible cellular damage and tumour destruction.

- Tincture (1:5): 7.5–15 mL/day.
- Standardised extract containing 1.0–2.7 mg total hypericin daily.
- It is advised that patients using SJW long-term should have their doses reduced slowly when discontinuing its use.

**External use**

- Oily macerate: Macerate flowering tops in olive oil for several weeks and stir often, then drain through a gauze. Store in a dark bottle out of direct light. Apply oil directly to the affected area. To promote extraction of flavonoids, store in a sunny area for 6 weeks (oil will turn red).

**According to clinical studies**

Doses are for dried herb or equivalent.

- Mild to moderate depression: adult — doses ranging from 350 to 1800 mg/day have been used; children (aged 6–12 years) — 200–400 mg/day in divided doses.
- Major depression: 500 mg–1800 mg/day in divided doses.
- OCD: 450 mg twice daily of an extract containing 0.3% hypericin.
- Menopausal symptoms: 900 mg/day in divided doses.
- PMS: 300 mg/day (standardised to 900 mcg hypericin).
- SAD: 900 mg/day in divided doses.

Several pharmaceutical-grade preparations of SJW are commercially available, typically extracted from dried aerial parts. LI 160, produced by Lichtwer Pharma, Berlin, Germany, is standardised to contain 0.3% hypericin derivatives and 1–4% hyperforin. It is normally sold as 300 mg capsules. Similarly, the STEI 300 extract, produced by Steiner Arzneimittel of Berlin, Germany, contains 0.2–0.3% hypericin and pseudohypericin and 2–3% hyperforin. Capsules contain 350 mg of extract.

The extracts WS 5570, WS 5572 and WS 5573 are produced by Dr Willmar Schwabe Pharmaceuticals, Karlsruhe, Germany. In contrast to the previously mentioned extracts WS 5570 and WS 5572 contain a higher hyperforin amount (5–6%), whereas WS 5573 contains only low hyperforin levels (0.5%).

WS 5570 is an 80% ethanolic extract of SJW with a plant-to-extract ratio of between 3:1 and 3:1–7:1. Tablets contain 300 or 600 mg of extract. The product WS 5572 has similar hyperforin and hypericin profiles to WS 5570, but has a plant-to-extract ratio of between 2.5:1 and 5:1.

In contrast, the hyperforin content of Ze 117 is only 0.2%, much lower than that of other products. Ze 117 is produced by Zeller, Switzerland. It is a 50% ethanolic extract with a herb-to-extract ratio of 4:1–7:1. The dosage of Ze 117 is 500 mg/day.

Helarium-425, produced by Bionorica, Neumarkt, Germany, contains 425 mg SJW 60% ethanolic extract with a plant-to-extract ratio of 3.5–6:1 (Kienow et al 2011).

**Clinical note — Mechanisms responsible for reported interactions**

Based on the herb's pharmacology, there are several mechanisms by which it may interact with drugs. Considering that SJW has significant serotonin reuptake inhibitor activity and significantly upregulates both 5-HT<sub>1A</sub> and 5-HT<sub>2A</sub> receptors, concomitant use of drugs that elevate serotonin levels, such as TCAs or SSRIs, may result in additive or synergistic effects and increase the risk of serotonergic syndrome. As the constituent hyperforin has a significant and selective induction effect on CYP3A4 and 2C19 activity (Durr et al 2000, Wang et al 2001) and induces the drug transporter P-gp, a number of pharmacokinetic interactions are possible with those drugs that are substrates for CYP3A4 or 2C19 and/or rely on P-gp transport. Refer to Chapter 8 for further information on interactions with herbs and natural supplements.

**ADVERSE REACTIONS**

It has been estimated that approximately 1 in 30,000 people using SJW will experience an adverse reaction, including those attributed to drug interactions (Schulz 2006). The incidence of side effects to SJW is approximately 10-fold lower than for conventional antidepressants (SSRIs). According to an overview of 16 postmarketing surveillance studies, gastrointestinal symptoms, sensitivity to light and other skin conditions and agitation were the most commonly reported side effects and were generally described as mild (Linde & Knuppel 2005). Recent reviews confirm earlier studies stating that adverse effects from SJW are infrequent and minor (Posadzki et al 2013).

**Photosensitivity (unlikely at therapeutic doses)**

The most common adverse event among spontaneous reports is photosensitivity, which is estimated to occur in 1 in 300,000 treated cases. This can occur with a dose of 5–10 mg/day hypericin, which is 2–4-fold higher than the recommended dose. Commission E has noted the possibility of

photosensitivity reactions, particularly in fair-skinned people.

### SIGNIFICANT INTERACTIONS

SJW is one of the few herbal medicines that has been subjected to controlled studies in order to determine the significance of its interaction with numerous drugs, which are mainly due to CYP450 enzyme induction and the induction of P-gp (Colalto 2010), and therefore mainly pharmacokinetic in nature (Tsai et al 2012). Although this can be reassuring, the clinical significance of many interactions is still unpredictable because of the variable chemical composition of products (Steinhoff 2012).

Hyperforin is a key mediator of SJW's antidepressive action and mainly responsible for the herb's drug interaction potential. It is a high-affinity ligand for human pregnane X receptor, an orphan nuclear receptor selectively expressed in the liver and intestine that mediates the induction of XME and efflux transporter gene transcription, resulting in decreased oral bioavailability, enhanced systemic clearance and reduced drug efficacy for many drugs.

Most SJW extracts are currently standardised to contain 3% hyperforin, yet several clinical studies have demonstrated that SJW extracts containing less than 1% hyperforin (e.g. ZE 117 extract) are both effective and less likely to produce clinically relevant pharmacokinetic herb-drug interactions (Arold et al 2005, Mai et al 2004, Mueller et al 2009).

Please also note that the enzyme induction may be unmasked after the withdrawal of a combination of SJW (a potent CYP3A inducer with a potent CYP3A inhibitor, e.g. ritonavir) leading to substantial drops in drug exposure of CYP3A substrates (e.g. midazolam). This may require substantial dose adjustments, particularly of orally administered drugs (Hafner et al 2010).

#### Alprazolam

Decreases serum levels of alprazolam via CYP induction. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

#### Amitriptyline

Although SJW decreases serum levels of amitriptyline via CYP induction in vivo (Johne et al 2002), theoretically it could also induce increases in serotonin availability, which has an opposite effect; the clinical outcome of these two interacting mechanisms is unknown — monitor for signs of changed drug effectiveness and adjust the dose if necessary or avoid concurrent use.

#### Antidepressants (SSRIs and SNRIs)

Increased risk of serotonin syndrome possible; however, increased antidepressant activity is also possible with appropriate doses — avoid concurrent use unless under medical supervision, so that doses may be altered appropriately.

#### Anticonvulsants

Phenobarbitone, phenytoin: SJW may increase drug metabolism, resulting in reduced drug efficacy — avoid concurrent use unless under medical supervision, so that doses may be altered appropriately.

#### Antineoplastic drugs

Irinotecan imatinib mesylate: plasma levels decreased (He et al 2010, Mathijssen et al 2002) (see Chapter 10 for more information on the safety of complementary medicines and cancer). Reduction of toxicity — the combination might be of benefit (Rahimi & Abdollahi 2012).

#### Atorvastatin

SJW reduces the efficacy of atorvastatin, so lipid-lowering effects are compromised, according to a clinical study which tested a product called Movina (containing 300 mg of *Hypericum perforatum*), taken as one tablet twice daily (Andren et al 2007).

#### Bupropion

SJW decreased, to a statistically significant extent, the plasma concentrations of bupropion, probably by increasing the clearance of bupropion — avoid (Lei et al 2010).

#### Cisplatin

Cisplatin-induced histological abnormality of the kidney was blocked by pretreatment with SJW in vivo (Shibayama et al 2007). Total and free cisplatin concentration in serum was not influenced by SJW treatment, suggesting that this may be a beneficial interaction under professional supervision.

#### Clopidogrel

SJW might represent a valid option to increase the antiplatelet effect of clopidogrel in non-responders and/or hyporesponders. For example, SJW increased platelet inhibition by enhancement of CYP3A4 metabolic activity for clopidogrel in hyporesponsive volunteers (Lau et al 2011), and a recent study showed that residual platelet reactivity improved with SJW during the first month post percutaneous coronary intervention (Trana et al 2013).

#### Cyclosporin

Decreases plasma levels of cyclosporin significantly within 3 days of concomitant use via CYP induction (Bauer et al 2003) — avoid concurrent use.

A pharmacokinetic study with kidney graft recipients suggests that the effect is not significant when low-hyperforin products are used (Madabushi et al 2006).

#### Digoxin

Decreases serum digoxin levels significantly within 10 days of concomitant use (Johne et al 1999), chiefly due to induction of the P-gp. The interaction between digoxin and SJW in humans has been confirmed more recently by Gurley et al (2008) and

is clinically significant — monitor patient for signs of reduced drug effectiveness and adjust the dose if necessary or avoid concurrent use.

### **Fexofenadine**

In rats, SJW (1 g/kg) enhanced the elimination of fexofenadine, an antihistamine and P-gp substrate, into the bile when given once daily for 14 days (Turkanovic et al 2009).

### **Finasteride**

SJW treatment for 2 weeks induced the metabolism of finasteride and caused a reduced plasma exposure of the drug (Lundahl et al 2009). A case report reported on an increased prostate-specific antigen value for a man who had started SJW 900 mg/day 10 weeks prior to the test and who was previously well controlled on finasteride (Lochner & Kirch 2011).

### **Gliclazide**

Treatment with SJW significantly increases the apparent clearance of gliclazide, which is independent of CYP2C9 genotype, according to a crossover clinical study (Xu et al 2008). People with diabetes receiving this combination should be closely monitored to evaluate possible signs of reduced efficacy.

### **HIV non-nucleoside transcriptase inhibitors**

Decreases serum levels — avoid concurrent use.

Etravirine — potential effect (Kakuda et al 2011)

Rilpivirine (Sharma & Saravolatz 2013).

### **HIV protease inhibitors**

Decreases serum levels — avoid concurrent use.

### **Indinavir**

Oral administration of either 150 or 300 mg/day SJW for 15 days significantly reduced indinavir plasma levels in rats. This interaction was attributable to the induction of indinavir metabolism by SJW (Ho et al 2009).

### **Ketamine**

SJW greatly decreased the exposure to oral S-ketamine in healthy volunteers. Although this decrease was not associated with significant changes in the analgesic or behavioural effects of ketamine in the present study, usual doses of S-ketamine may need adjustment if used concomitantly with SJW (Peltoniemi et al 2012) — use with caution.

### **Methadone**

Decreases serum levels via CYP induction — avoid concurrent use (Eich-Hochli et al 2003).

### **Methotrexate**

Coadministration of 300 and 150 mg/kg of SJW significantly increased the systemic exposure and toxicity of methotrexate (Yang et al 2012).

### **Midazolam**

Decreases serum levels of midazolam via CYP induction — monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

### **Nifedipine**

SJW was shown to induce nifedipine metabolism in vivo (Wang et al 2007) — monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

### **Non-steroidal anti-inflammatory drugs (etoricoxib)**

Decreases serum levels of the drug via CYP induction in vivo — avoid coadministration (Radwan et al 2012).

### **Omeprazole**

Decreases serum levels via CYP induction (Wang et al 2004b) — monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

### **Oral contraceptives**

Breakthrough bleeding has been reported, which can indicate decreased effectiveness of oral contraceptives. In 2003, a controlled study confirmed that standard doses of SJW cause an induction of ethinyl oestradiol–norethindrone metabolism, consistent with increased CYP3A activity (Hall et al 2003) — use this combination with caution.

In 2002, a pharmacokinetic study found no significant interaction between low-hyperforin SJW and low-dose oral contraceptives (Madabushi et al 2006). This has been confirmed in a further clinical study using an SJW extract (Ze 117) with low hyperforin content on the pharmacokinetics of ethinyl oestradiol and 3-ketodesogestrel (Will-Shahab et al 2009) — low-hyperforin extracts appear to be safe.

### **Oxycodone**

SJW greatly reduced the plasma concentrations of oral oxycodone — avoid (Nieminen et al 2010).

### **Pegylated interferon-alpha (peginterferon- $\alpha$ )**

The combination of peginterferon- $\alpha$  and SJW (taken for 6 weeks during 8 weeks' drug treatment) resulted in severe acute hepatitis in a 61-year-old woman. After 6 months of prednisone treatment, the liver function tests returned to baseline levels — avoid combination (Piccolo et al 2009).

### **Psoralen plus UVA therapy**

High-dose hypericin may increase sensitivity to UV radiation — caution is advised.

### Simvastatin

Decreases serum levels of simvastatin via CYP induction (Sugimoto et al 2001) — monitor for signs of reduced drug effectiveness and adjust the dose if necessary (no interaction is expected with pravastatin).

### Tacrolimus

Decreases serum levels of tacrolimus via CYP induction (Mai et al 2003) — avoid this combination.

### Verapamil

Decreases serum levels of verapamil via CYP induction — monitor for signs of reduced drug effectiveness and adjust the dose if necessary.

### Warfarin

Metabolism of warfarin is chiefly by CYP2C9, and a minor metabolic pathway is CYP3A4, so theoretically it may interact with SJW. A clinical study found no change to international normalised ratio (INR) or platelet aggregation (Jiang et al 2004), but there are case reports suggesting that SJW may lower the INR. Caution is advised — monitor INR.

### Zolpidem

Repeated administration of SJW decreases the plasma concentration of zolpidem, probably by enhancing CYP3A4 activity (Hojo et al 2011) — avoid.

### CONTRAINDICATIONS AND PRECAUTIONS

People with fair skin undergoing UV treatment or with conditions which would be adversely affected by high UV exposure should use high doses of SJW with caution.

A case study reported on the occurrence of radiation-induced optic neuropathy, which may have been the result of radiosensitisation by temozolomide, which could have been strengthened by the hypericin the patient was also taking (Schreiber et al 2010).

### People with cancer and undergoing treatment

Hypericum extract, by inducing both CYP3A4 and P-gp, can reduce the plasma concentrations of different antineoplastic agents such as imatinib, irinotecan and docetaxel, thus reducing the clinical efficacy of these drugs. Although these interactions are often predictable, the concomitant use of hypericum extract should be avoided in cancer patients taking interacting medications (Caraci et al 2011).

### PREGNANCY AND LACTATION USE

A systematic review of the literature for evidence on the use, safety and pharmacology of SJW focusing on issues pertaining to pregnancy found there is *in vitro* evidence from animal studies that SJW during pregnancy does not affect cognitive development nor cause long-term behavioural defects, but may lower offspring birth weight (Dugoua et al 2006). A prospective study investigated 54 SJW-exposed pregnancies and 108 pregnancies in the two comparator groups (the second group was taking other pharmacological therapy for depression and a third group of healthy women was not exposed to any known teratogens). The rates of major malformations were similar across the three groups, and were not different from the 3–5% risk expected in the general population. The live birth and prematurity rates were also not different among the three groups (Moretti et al 2009).

A recent study comparing the effects of 7.5 mg/kg fluoxetine and 100 mg/kg SJW showed that maternal exposure to fluoxetine but not SJW could interfere with reproductive parameters in adult male rats (Vieira et al 2013). However, encouragingly, safe doses in pregnant women have not yet been determined. In practice, SJW is not recommended in pregnancy.

SJW appears to be relatively safe in lactation (Dugoua et al 2006, Howland 2010). A systematic review, which reported the results of observational studies, found weak evidence that SJW use during lactation did not affect maternal milk production or infant weight. However, in a few cases, it may cause infant colic, drowsiness or lethargy (Linde et al 2005b). A more recent review identified three studies in which SJW was used by breastfeeding mothers (one case report, one open-label and one cohort study). No adverse effects were reported for mothers and infants for any of these studies (Budzynska et al 2012).

### PATIENTS' FAQs

#### *What will this herb do for me?*

SJW is an effective treatment for mild, moderate and severe depression and it reduces the risk of relapse. Its antidepressant effects are similar to pharmaceutical antidepressant drugs; however, it is better tolerated with fewer side effects. It may also be useful for PMS symptoms, in SAD and OCD and for menopausal and premenopausal women with psychological and psychosomatic symptoms. The oily preparations are also used topically to treat burns, injuries, allergic dermatitis and muscle pain.

#### *When will it start to work?*

It often starts to exert beneficial effects in depression within 2–4 weeks of continuous use; however, maximal effects in other conditions may take longer.

**Are there any safety issues?**

SJW is well tolerated and has far fewer side effects than pharmaceutical antidepressant drugs, but it can interact with a number of different medications. Patients with clinically diagnosed depression should be under the care of a healthcare professional.

**Practice points/Patient counselling**

- SJW contains numerous constituents with pharmacological activity, including antidepressant, analgesic, anti-inflammatory, antispasmodic, anxiolytic, antineoplastic, antiviral and bactericidal activities.
- The efficacy of SJW in the treatment of mild-to-moderate major depressive disorders is well established through numerous clinical studies. The most commonly studied extract is LI 160, although others have also been tested (e.g. WS 5573 [standardised to hyperforin], ZE 117 [a low-concentration hyperforin preparation], WS 550 and STW3-V1). Clinical effects are comparable to TCAs and SSRIs; it also reduces the incidence of depression relapse.
- With regard to safety, SJW is better tolerated than standard antidepressants (SSRIs and TCAs); however, it still needs to be prescribed judiciously to avoid interactions. Patients with clinically-diagnosed depression should be under the care of a healthcare professional.
- Low-hyperforin-containing SJW extracts do not have the same interaction potential as standard SJW extracts and may present a safer option for some individuals.
- Preliminary human studies have suggested a possible role in PMS, SAD, OCD and in menopausal and premenopausal women with psychological and psychosomatic symptoms.
- Oily preparations have been used topically to treat burns, acute and contused injuries, atopic dermatitis and myalgia.

## St Mary's thistle

**HISTORICAL NOTE** St Mary's thistle has a long history of traditional use since ancient times. Over the centuries, it has been touted as a remedy for snakebite, melancholy, liver conditions and promoting lactation. The name 'milk thistle' derives from its characteristic spiked leaves with white veins which, according to legend, were believed to carry the milk of the Virgin Mary.

**OTHER NAMES**

*Carduus marianus*, cardo blanco, cardo de burro, chandon marie, holy thistle, lady's milk, lady's thistle, Mariendistel, Marian thistle, Mary thistle, milk thistle, silybum, true thistle.

**BOTANICAL NAME/FAMILY**

*Silybum marianum* (family [Compositae] Asteraceae)

**PLANT PART USED**

Ripe seed

**CHEMICAL COMPONENTS**

Often silymarin is referred to as the active constituent of seeds from St Mary's thistle, but in fact it is a complex of at least seven flavonolignans, one flavonoid taxifolin and a bioflavonoid quercetin. The principal component of silymarin is silybin (more commonly referred to as silibinin), which makes up more than 50% of silymarin and is regarded as one of the most biologically active constituents (Jacobs et al 2002). Silibinin is not a single compound either, but rather a mixture of two diastereoisomers, silybin A and silybin B (Kroll et al 2007). Other flavonolignans include isosilybin, silychristin and silydianin, all of which exist as diastereoisomers. A new flavonolignan, silymandin, was discovered in St Mary's thistle preparations (MacKinnon et al 2007). St Mary's thistle seeds also contain a fixed oil comprising linoleic, oleic and palmitic acids, tocopherol and sterols, including cholesterol, campesterol, stigmasterol and sitosterol.

**MAIN ACTIONS**

Silymarin has confirmed antioxidant (Aghazadeh et al 2011, Gazák et al 2010, Morazzoni & Bombardelli 1995, Shaker et al 2010), antifibrotic (Hernandez-Gea & Friedman 2011, Trappoliere et al 2009, Tzeng et al 2013), anti-inflammatory (Aghazadeh et al 2011, El-Zayadi et al 2005, Morishima et al 2010, Polyak et al 2007), hepatoprotective (Ferenci et al 1989, Fraschini et al 2002, Lieber et al 2003), antihypercholesterolaemic (Krecman et al 1998), antihyperglycaemic (Velussi et al 1997), immunomodulatory (Polyak et al 2007) and antiviral (Ahmed-Belkacem et al 2010, Ferenci et al 2008, Neumann et al 2010, Polyak et al 2007) pharmacological actions in vitro, in vivo and in human studies.

**Hepatoprotective**

Hepatoprotection is defined as several non-mutually exclusive biological activities including antiviral, antioxidant, anti-inflammatory and immunomodulatory functions (Polyak et al 2013).

Silymarin and silybin exert some of these mechanisms and have hepatoprotective effects (Abenavoli et al 2010). In particular, *Silybum marianum* achieves many of its pharmacological actions via its antioxidant mechanisms.

Specifically, in regards to *Amanita phalloides* (death cap mushroom) poisoning cases, silibinin as Legalon

SIL appears to exert its hepatoprotective effects by competitive inhibition of amatoxin binding and uptake by hepatocytes (Jacobs et al 2002) and by the reduction of enterohepatic recirculation through the modulation of bile flow. Adjunct to these mechanisms, silibinin reduces the oxidative stress, consequent to necrotic cell death caused by amatoxin poisoning with anti-inflammatory and antifibrotic downstream effects. Silibinin also reduces damage through inhibition of TNF- $\alpha$  and helps recovery through the stimulation of protein synthesis for repair in damaged liver cells (Mengs et al 2012).

It has therefore been postulated that *Silybum marianum* protects the liver by preventing the uptake of toxins and viruses through the stabilisation of cell membranes, reducing the oxidative stress caused by the metabolism of toxins and reducing hepatic inflammation, fibrosis and aiding hepatic repair and regeneration (Polyak et al 2010).

The mechanisms of membrane stability have been researched in detail. Silymarin and silibinin alter the structure of hepatocyte cell membranes by being incorporated into the hydrophobic-hydrophilic interface of the microsomal bilayer (Parasassi et al 1984). Silibinin interacts with the surface rather than deeper regions of the bilayer, and therefore does not change significantly the biophysical properties of the deeper membrane regions (Wesolowska et al 2007). Additionally, inhibition of cyclic adenosine monophosphate (AMP)-dependent phosphodiesterase by silibinin has been shown in vitro, which results in increased cAMP and stabilisation of lysosomal membranes (Koch et al 1985).

**Toxin blockade**

Protection of liver cells has been demonstrated against the following substances in vitro or in vivo:

- Carbon tetrachloride-induced liver cirrhosis (Chrungoo et al 1997, Mourelle et al 1989, Muriel & Mourelle 1990, Tsai et al 2008).
- Ethanol (Das & Vasudevan 2006).
- Paracetamol-induced liver peroxidation (Chrungoo et al 1997, Muriel et al 1992).
- Cyclosporin (von Schonfeld et al 1997).
- Phenothiazine (Palasciano et al 1994).
- Butyrophenone (Palasciano et al 1994).
- Erythromycin (Davila et al 1989).
- Amitriptyline and nortriptyline (Davila et al 1989).
- Oestradiol (Morazzoni & Bombardelli 1995).
- *Amanita phalloides* (Floersheim 1976, Vogel et al 1984).
- Tacrine (Galisteo et al 2000).
- Iron overload (Choi 2012, Masini et al 2000, Pietrangelo et al 1995).
- Benzo(a)pyrene-induced lung cancer (Kiruthiga et al 2007).

**CHELATES IRON AND DECREASES IRON EXCESS**

*Silybum marianum* interacts with iron in a number of ways. Excess iron increases oxidative stress and

*Silybum marianum* exerts antioxidant activity thereby decreasing the pathological consequences of excessive oxidative stress. *Silybum marianum* acts indirectly to reduce iron-induced damage by protecting the mechanisms, such as the expression of hepcidin, that regulates iron uptake (Choi 2012) and directly chelating iron to reduce its absorption (Hutchinson et al 2010) and reactivity (Borsari et al 2001).

### Antioxidant

In vivo research suggests the key mechanisms of action responsible for the antioxidant activity of silymarin are:

- direct activity via redox reactions;
- indirect activity by inhibiting the activity of free radical producing enzymes; and
- indirect activity achieved by upregulating endogenous, antioxidant enzyme systems such as Nrf2 (Son et al 2008) and glutathione (Kim et al 2012, Lu et al 2010a).

In vivo research involving rats with induced-steatohepatitis found that treatment with *Silybum marianum* decreased the oxidative stress marker malondialdehyde (MDA) by 45%, while glutathione (GSH) was increased by 65% and TNF- $\alpha$  lowered by 47% all relative to the control group (Aghazadeh et al 2011).

### Anti-inflammatory

The anti-inflammatory activity of silymarin is due to several different mechanisms, such as antioxidant and membrane-stabilising effects, and inhibition of the production or release of inflammatory mediators, such as arachidonic acid metabolites. Inhibitory activity on lipo-oxygenase, cyclo-oxygenase (COX) and prostaglandin (PG) synthetase has been demonstrated in several in vitro assays and animal studies (Alarcon de la Lastra et al 1992, Dehmlow et al 1996, Fiebrich & Koch 1979, Rui et al 1990, Zhao et al 1999). Furthermore, silymarin inhibits NF-kappaB signalling and suppresses tumour necrosis factor (TNF)-alpha, nitric oxide synthase (iNOS) and interleukin (IL)-1 (Agarwal et al 2006, Kim et al 2012, Polyak et al 2007).

### Antifibrotic

Silymarin and silibinin demonstrate antifibrotic activity in a variety of preclinical models via multiple mechanisms of action.

Silymarin reduces markers for collagen accumulation in the liver and exerts antifibrotic activity, according to an animal model of liver fibrosis (Boigk et al 1997). Oral silibinin (25–50 microM) dose-dependently inhibited the transforming growth factor beta (TGF- $\beta$ )-induced de novo synthesis of pro-collagen I directly, by reducing platelet derived growth factor (PDGF)-induced cell proliferation, and indirectly, by de novo reduction of TGF- $\beta$ -induced synthesis of collagen type 1 in human hepatic stellate cells (Trappoliere et al 2009). This finding was confirmed in thioacetamide-induced hepatic fibrosis, where silibinin downregulated hepatic

MMP-2, MMP-13, TIMP-1, TIMP-2, AP-1, KLF6, TGF $\beta$ 1,  $\alpha$ SMA and COL- $\alpha$ 1 (Chen et al 2012).

A silibinin-phosphatidylcholine complex (silibinin 200 mg per kg) taken for five weeks caused an improvement in liver steatosis and inflammation and reduced the levels of plasma insulin and TNF- $\alpha$ . These effects were associated with a reduction in membrane lipid peroxidation, decreased free radical release and restoration of GSH levels (Haddad et al 2011).

Oral silymarin reduced steatohepatitis, raised nuclear translocation of nuclear factor erythroid 2-related factor 2 (Nrf2), and reduced tumour necrosis factor (TNF)- $\alpha$  mRNA expression in the liver in insulin-resistant rats, suggesting its antifibrotic effect is achieved through anti-inflammatory, antioxidant and hepatoprotective effects (Kim et al 2012).

### Antitumour effects

A variety of mechanisms attributed to silymarin show it has promise in the prevention and/or treatment of several different cancers.

Oxidative stress (OS) in chronic disease accelerates inflammation, fibrosis and necrosis, through damage to proteins, DNA, lipids, sensitising redox-regulated necrotic and inflammatory cell signalling pathways, affecting gene expression (Finkel & Holbrook 2000) and causing mitochondrial dysfunction and pathology (Kung et al 2011, Pias & Aw 2002, Pias et al 2003, Polyak et al 2007). Therefore it has been suggested that by ameliorating OS and inflammation, silymarin could theoretically have a role in reducing disease progression and cancer incidence (Ting et al 2013).

In vivo and in vitro research with silibinin has identified an ability to reduce proliferation and angiogenesis, and to promote cell cycle arrest and apoptosis (Agarwal et al 2013, Deep & Agarwal 2010, Kauntz et al 2012b, Li et al 2010, Zeng et al 2011). Recent in vitro studies have shown that silibinin also possesses strong anti-invasive and antimetastatic efficacy (Agarwal et al 2013, Deep & Agarwal 2010).

At this stage, most studies investigating mechanisms of action and effects in cancer have been conducted in vivo and in vitro, whereas human trials are limited (Li et al 2010). There have also been preclinical trials in humans to investigate suitable doses, treatment safety and improvements in bioavailability with phytosome-based preparations (Flaig et al 2010).

Silibinin has been shown to regulate multiple cellular proliferative pathways in cancer cells, including receptor tyrosine kinases, androgen receptor, STATs, NF- $\kappa$ B, cell cycle regulatory and apoptotic signalling pathways in vivo and in vitro (Li et al 2010). In prostate cancer, in mice, silymarin treatment down-regulates androgen receptor, epidermal growth factor receptor, and nuclear factor- $\kappa$ B mediated signalling and induces cell cycle arrest (Deep & Agarwal 2007). Kim et al (2009) showed in in vitro studies that silibinin can prevent the degradation of

certain proteins in breast cancer. By studying the effects of silibinin on matrix metalloproteinases (MMPs), whose abnormal expression is associated with carcinoma and vascular endothelial growth factor (VEGF) which is expressed by malignant and non-malignant cells, they propose that this constituent is a possible candidate for the therapy of tumour metastasis and angiogenesis. The action responsible appears to be inhibition of 12-*O*-tetradecanoyl phorbol-13-acetate (TPA)-induced MMP and VEGF expression in breast cancer cells (Kim et al 2009).

In colon carcinogenesis, in rats, silibinin shifted the disturbed balance between cell renewal and cell death through potent proapoptotic, anti-inflammatory and multi-targeted effects at the molecular level. The study concluded that the effective reduction of pre-neoplastic lesions by silibinin supports its use as a natural agent for colon cancer chemoprevention (Kauntz et al 2012a).

### Brain, neuroprotective activity

Silymarin has been shown to reduce sepsis-induced lung and brain injury, partially through its antioxidant effects, inhibition of neutrophil infiltration and regulation of inflammatory mediator release (Nencini et al 2007, Toklu et al 2008). Additionally, pre-treatment with silymarin, but not silibinin, dose-dependently reduced cerebral ischaemic/reperfusion induced brain infarction by 16–40% and improved neurological deficits in rats through antioxidant and anti-inflammatory mechanisms (Hou et al 2010). Another study in rats pre-treated with silymarin found it slowed neuronal injury in focal cerebral ischaemia and enabled functional recovery close to the baseline. Similar to previous studies, the authors suggest that the neuroprotective potential of silymarin is mediated through its antioxidative and anti-apoptotic properties (Raza et al 2011).

According to an in vitro study, silibinin may have potential as both a preventive and an active treatment for Alzheimer's disease as it reduced the formation of amyloid plaque and also protected cells from amyloid plaque-induced oxidative stress in a dose-dependent manner (Yin et al 2011).

### Nephroprotective effect

In vitro experiments with kidney cells damaged by paracetamol, cisplatin or vincristin demonstrate that administration of silibinin before or after the chemical-induced injury can lessen or avoid the nephrotoxic effects (Sonnenbichler et al 1999). Animal studies have confirmed the nephroprotective effect for cisplatin-induced injury (Karimi et al 2005). In one study, the effects of cisplatin on glomerular and proximal tubular function as well as proximal tubular morphology were totally or partly ameliorated by silibinin (Gaedeke et al 1996). In an in vivo study, silymarin significantly decreased gentamicin-induced nephrotoxicity when used as a single agent and when used in combination with vitamin E in comparison to the placebo group. Serum creatinine concentrations, but not urea concentrations, were significantly lower (Varzi et al 2007).

### Gastroprotective effect

St Mary's thistle extract produces a dose-dependent antiulcerogenic activity against indomethacin-induced ulcers, which can be histologically confirmed, according to research with test animals (Khayyal et al 2001). This is associated with reduced acid output, increased mucin secretion, increased PGE<sub>2</sub> release and decreased leukotriene release. Experiments with silymarin have found it to be effective in the prevention of gastric ulceration induced by cold-restraint stress in rats (Alarcon de la Lastra et al 1992) and postischaemic gastric mucosal injury (Alarcon de la Lastra et al 1995).

### IN COMBINATION

A herbal formulation known as STW 5, containing extracts of milk thistle fruit and eight other herbs (bitter candy tuft, lemon balm leaf, chamomile flower, caraway fruit, peppermint leaf, licorice root, angelica root and greater celandine) produced antiulcerogenic activity against indomethacin-induced gastric ulcers in rats as well as antisecretory and cytoprotective activities (Khayyal et al 2001). In addition, it was shown that STW 5 lowered the gastric acidity as effectively as commercial antacid preparations (i.e. Rennie, Talcid, Maaloxan), prevented secondary hyperacidity more effectively and, additionally, inhibited serum gastrin levels in rats (Khayyal et al 2006).

### Antidiabetic effect

In type 2 diabetes (T2DM) amyloid deposits contribute to the dysfunction of  $\beta$ -cells and the loss of  $\beta$ -cell mass in T2DM patients. In vitro silibinin reduces the formation of amyloid deposits and enhances the viability of pancreatic  $\beta$  cells (Cheng et al 2012).

In vivo research showed that silibinin exerts pronounced effects on liver carbohydrate metabolism. The metabolic pathways that contribute to glycaemia maintenance, i.e. gluconeogenesis in the fasted condition and glycogenolysis and glycolysis in the fed condition, were both reduced by silibinin corroborating the role of the liver in the antihyperglycaemic effect of silibinin (Colturato et al 2012).

### Antiviral effect

*Silybum marianum*, particularly silymarin and intravenous silibinin, block hepatitis C virus (HCV) infection and proliferation in vitro by blocking viral fusion, viral entry, viral RNA and protein synthesis, and virus transmission (Ahmed-Belkacem et al 2010, Blaising & Pecheur 2013, McClure et al 2012, Morishima et al 2010, Polyak et al 2007, 2010, 2013, Wagoner et al 2010, 2011). This mechanism would also apply to other viruses such as vesicular stomatitis virus, reovirus, and the influenza virus (McClure et al 2012). Guedj et al (2012) confirmed in vivo that intravenous silibinin may block both viral infection and viral production/release dose-dependently.

Intravenous silibinin reduced HCV RNA in previous non-responders to pegylated interferon and ribavirin in a clinical study (Ferenci et al 2008) and

prevented HCV RNA re-infection after liver transplantation (Beinhardt et al 2011, Marino et al 2013, Neumann et al 2010). Intravenous silibinin has also been found to inhibit HIV in human cell lines (McClure et al 2012), previously confirmed in a HCV/HIV co-infected patient (Payer et al 2010).

### Mast-cell stabilisation

Silibinin has shown mast-cell stabilisation activity in vivo (Lecomte 1975), which was confirmed some years later and found to be dose-dependent (Fantozzi et al 1986).

### Asthma

Allergic asthma is a chronic inflammatory disease regulated by coordination of T-helper2 (Th2) type cytokines and inflammatory signal molecules. Previously, silymarin has been shown to exert protective effects in the early phase of asthma, most likely due to its influence on histamine release (Breschi et al 2002). More recently, research with an animal model of asthma showed that pretreatment with silibinin prevented the development of airway hyperresponsiveness, significantly inhibited airway inflammatory cell recruitment and peribronchiolar inflammation and reduced the production of various cytokines in bronchoalveolar fluid (Choi et al 2012).

### Cytochromes

#### Effects on Phase I CYP450

There has been extensive investigation into the effects of various St Mary's thistle preparations on various cytochromes. Human studies with standard St Mary's thistle preparations have identified no clinically significant effect on cytochromes CYP 1A2, 2D6, 3A4 whereas 2C9 appears most vulnerable to inhibition (Gurley et al 2012, Hackett et al 2013, Hermann & von Richter 2012). The lack of effect may be due to poor bioavailability (Goey et al 2013). If this is the case, then preparations with greater bioavailability still require testing to confirm that clinically significant drug interactions are absent. Additionally, the use of isolated silymarin and silibinin preparations could produce different results (Loguercio & Festi 2011).

Tests with an animal model suggest inhibition of CYP 1A1 however human studies have not confirmed the findings (Kiruthiga et al 2013).

#### Effects on phase II conjugation pathways

Phytochemicals such as silymarin can increase levels of Nrf2 either by stimulating its release or inhibiting its proteolytic breakdown. Activated Nrf2 translocates into the nucleus where it interacts with small MAF family proteins bound to the antioxidant response element (ARE), allowing transcription of target genes including those that regulate antioxidant and phase II enzymes (Kim et al 2012, Son et al 2008).

An in vitro study on cardiomyocytes with a product called Protandim (*Bacopa monniera*, *Silybum marianum*, *Withania somnifera*, *Camellia sinensis* and *Curcuma longa*) resulted in nuclear accumulation of

Nrf2, upregulation of key endogenous phase II antioxidant enzymes, and Nrf2-dependent protection of cardiomyocytes from apoptosis after an oxidative stress (Reuland et al 2012).

### P-glycoprotein

No clinically significant effects are seen for St Mary's thistle preparations and P-gp (Gurley et al 2006a, 2006b, Hermann & von Richter 2012), despite an earlier in vitro study which identified that silymarin inhibited P-glycoprotein (P-gp) ATPase activity in such a way as to suggest direct interaction with P-gp substrate binding (Zhang & Morris 2003).

## OTHER ACTIONS

### Cholesterol lowering

Cholesterol reduction has been demonstrated for silymarin in three studies of rats fed a highcholesterol diet (Krecman et al 1998, Shaker et al 2010, Sobolova et al 2006).

Although the mechanism of action is unknown, it has been suggested that inhibition of HMG-CoA reductase (Skottova & Krecman 1998a) and inhibition of cholesterol absorption from dietary sources (Sobolova et al 2006) are involved. Considering that the herb also contains phyosterols, these too may play a role in cholesterol reduction.

## CLINICAL USE

In practice, St Mary's thistle is commonly used for treating digestive disorders and any indication whereby improved liver function or liver protection may be a benefit. Milk thistle fruits have a positive European Scientific Cooperative on Phytotherapy (ESCOP) monograph for the following therapeutic indications: toxic liver damage; supportive treatment in patients with chronic inflammatory liver conditions and hepatic cirrhosis (ESCOP 2009).

### Dyspepsia

St Mary's thistle is commonly used to treat dyspeptic complaints, such as loss of appetite, poor digestion and upper gastrointestinal discomfort. Animal studies have identified a dose-dependent increase in bile flow and bile salt secretion for silymarin, achieved by stimulating the synthesis of bile salts (Crocenzi et al 2000). Silymarin has been found to impact on bile salt synthesis, bile secretion, biotransformation of cholestatic compounds and changes in transported expression and activity (Crocenzi & Roma 2006).

Commission E approves the use of crude milk thistle preparations for dyspeptic complaints (Blumenthal et al 2000).

### Toxic liver damage

#### Mushroom poisoning (*Amanita phalloides*)

One of the best-documented uses of milk thistle is in the treatment of poisoning by the mushroom *Amanita phalloides*. Nausea, vomiting, abdominal cramps and severe diarrhoea usually occur 8–12 hours after ingestion, with extensive hepatic necrosis

occurring 1–2 days later. A mortality rate of 20–30% has been observed but can be as high as 50% in children under 10 years of age (Floersheim et al 1982).

Since intervention studies would be unethical, a review of case reports and studied mechanisms of action are used as evidence to support its use.

A review of 154 cases of *Amanita phalloides* poisoning in Germany (1983–1992) showed a mortality rate of 15.2% in non-silibinin treated cases ( $n = 38$ ) compared to 8.3% in patients treated with silibinin ( $n = 116$ ) (Saller et al 2008). A more recent review of nearly 1500 documented cases concluded that the overall mortality in patients treated with Legalon SIL is less than 10% in comparison to more than 20% when using penicillin or a combination of silibinin and penicillin. Mengs et al (2012) recommend a daily dose of 20 mg silibinin/kg via continuous infusion over 24 hours, following a single loading dose of 5 mg silibinin/kg and to start treatment as soon as possible.

At the Poison Information Centre, Vienna, Austria; if silibinin is administered within 48 hours of poisoning, only mild to moderate liver injury is observed ( $n = 18$ ) (Hruby et al 1983). After 48 hours, if left untreated, severe liver damage, coagulation disorders and coma are likely to occur. Hruby administered four divided doses of silibinin intravenously, each dose consisting of 20–50 mg/kg body weight/day; the dose varied depending on the severity of intoxication (Hruby et al 1983).

Silymarin protects against the *Amanita phalloides* toxins,  $\alpha$ -amanita and phalloidin, by inhibiting the toxins binding to cell receptors by competitive inhibition of hepatocyte-specific OATP2 transporters; their uptake and interaction with cell components; binding with nuclear receptors and inhibiting protein synthesis and cell repair (Ferenci et al 1989, Hackett et al 2013). As silymarin reduces the uptake of toxins into cells, the earlier it is administered after exposure, the better the protective effects (Hruby et al 1983, Mengs et al 2012).

#### **Clinical note — Hepatic fibrosis**

Hepatic fibrosis is a pathological wound-healing process that occurs when the liver is injured chronically, such as in chronic alcohol abuse. The oxidative metabolite of ethanol, acetaldehyde, often in conjunction with viral or metabolic liver disease, is implicated as the major cause for liver fibrogenesis, which ultimately leads to cirrhosis (Schuppan et al 1995). Antifibrotic and antiviral interventions, which interrupt the continuous process of wound healing in the liver, are being investigated as strategies to prevent or reverse liver cirrhosis (Poynard et al 2009).

#### **Environmental toxins and drugs**

In animals, milk thistle reduces acute liver injury caused by paracetamol (Ali et al 2001, Muriel et al 1992), carbon tetrachloride (Favari & Perez-Alvarez 1997, Letteron et al 1990), radiation (Hakova & Misurova 1996, Kropacova et al 1998), iron overload (Masini et al 2000, Pietrangelo et al 1995), phenylhydrazine (Valenzuela & Guerra 1985) and D-galactosamine (Tyutyulkova et al 1981, 1983).

One randomised, double-blind study involving 222 patients showed that silymarin improves the tolerability of tacrine without altering the drug's cognitive effects (Allain et al 1999). Two other clinical trials have documented the effectiveness of silymarin in improving or preventing hepatotoxicity from chronic administration of phenothiazines or butyrophenone.

#### **Supportive treatment in chronic liver diseases**

Milk thistle fruits have a positive European Scientific Cooperative on Phytotherapy (ESCOP) monograph for supportive treatment in patients with chronic inflammatory liver conditions and hepatic cirrhosis (ESCOP 2009).

Numerous clinical trials have been conducted with St Mary's thistle preparations in various chronic liver diseases. The most studied treatments are Legalon (Madaus Corporation, Cologne, Germany) and silipide (Inverni Della Beffa Research and Development Laboratories, Milan, Italy), designed to improve oral absorption of silymarin.

A 1998 clinical review of St Mary's thistle concluded that it may be effective in improving the clinical courses of both acute and chronic viral, drug-induced, toxin-induced and alcoholic hepatitis (Flora et al 1998). A systematic review of efficacy for St Mary's thistle in chronic liver diseases stated that data are still too limited to detect a substantial benefit on mortality or recommend the herb in liver disease (Jacobs et al 2002).

Twelve clinical studies were located in which researchers have attempted to clarify the role of St Mary's thistle in the treatment of various liver diseases (Angulo et al 2000, Benda et al 1980, Buzzelli et al 1993, Ferenci et al 1989, Loguercio et al 2007, Lucena et al 2002, Magliulo et al 1978, Par et al 2000, Pares et al 1998, Salmi & Sarna 1982, Trinchet et al 1989, Velussi et al 1997). Much of the research focuses on the different forms of hepatitis and alcoholic liver cirrhosis with doses ranging from 100 to 300 mg three times daily, usually given in a standardised extract of 70–80% silymarin. Overall, results have been mixed, with nine trials showing generally positive results and three negative, suggesting that milk thistle is effective in only some forms of liver disease.

#### **Alcoholic liver disease**

A 2005 Cochrane review of 13 randomised clinical trials and a 2007 Cochrane review of 18 randomised clinical trials assessed milk thistle in 915 and 1088 patients, respectively, looking at its effect in

alcoholic and/or hepatitis B or C virus liver diseases (Rambaldi et al 2005, 2007). The authors stated in both reviews that the methodological quality of the trials was low and that milk thistle versus placebo or no intervention had no significant effect on complications of liver disease or liver histology, and that milk thistle was not associated with a significantly increased risk of adverse events.

In comparison to the 2005 review, which concluded that liver-related mortality was significantly reduced by milk thistle in patients with alcoholic liver disease, the 2007 review found that liver-related mortality was significantly reduced by milk thistle in all trials, but not in high-quality trials (Rambaldi et al 2005, 2007).

A review of 36 papers concluded that silymarin may have a role in the treatment of liver cirrhosis, especially alcoholic cirrhosis. In five trials of patients with liver cirrhosis ( $n = 602$ ), a significant but small (7%) reduction of liver-related mortality (not corrected for study duration) was attained with silymarin (Saller et al 2001). These findings were confirmed in a recent meta-analysis by the same author (Saller et al 2008).

#### Acute viral hepatitis

Several studies have investigated the use of milk thistle in this disease, reporting beneficial effects on serological outcomes (Bode et al 1977, Magliulo et al 1978, Tkacz & Dworniak 1983). However, these early studies were not clearly blinded.

More recently, a randomised, double-blind, placebo-controlled clinical trial involving 105 subjects with acute hepatitis (hepatitis A, B, C and E) patients tested a commercial St Mary's thistle product (Legalon 140 mg three times daily) taken for four weeks. The silymarin group had faster resolution of symptoms related to biliary retention, dark urine ( $P = 0.013$ ), jaundice ( $P = 0.02$ ) and scleral icterus ( $P = 0.043$ ). However, the primary outcome measure of normalisation of bilirubin and hepatic enzymes did not differ between the herbal and placebo groups (El-Kamary et al 2009).

#### Hepatitis C infection

A 2003 systematic review of medicinal herbs for HCV infection concluded that compared with placebo, none of the herbs showed effects on HCV RNA or liver enzymes, except for the constituent silybin, which showed a significant reduction of serum aspartate aminotransferase (AST) and gamma-glutamyltranspeptidase levels in one trial (Liu et al 2003).

In a 4-week randomised, controlled clinical trial ( $n = 34$ ) using 160 mg of milk thistle three times a day, AST, alanine aminotransferase (ALT) and viral load values decreased from baseline levels after 4 weeks although the effect was not significant. In comparison, values for ALT and viral load showed a significant increase in the control group over the same period. When treatment and control groups were then compared, a significant difference was

observed for ALT and AST, but not for viral load (Torres et al 2004). Similarly, a 2005 review concluded that silymarin decreases serum AST and ALT levels, but does not seem to affect viral load or liver histology (Mayer et al 2005).

A randomised, double-blind, placebo-controlled, crossover study ( $n = 24$ ) where subjects received 12 weeks treatment with 600 or 1200 mg milk thistle daily, viral load, ALT levels and quality of life scores (short-form (SF)-36) were not significantly different to placebo (Gordon et al 2006).

As part of the hepatitis C Antiviral Long-Term Treatment Against Cirrhosis (HALT-C) trial ( $n = 1145$  participants), involving people with advanced chronic hepatitis C, non-responders to prior antiviral therapy continued taking pegylated interferon treatment with the addition of oral silymarin therapy; however, no changes to ALT and viral load were observed with adjunctive herbal treatment. Silymarin therapy did significantly lower liver-related symptoms and improved QOL parameters such as fatigue, nausea, liver pain, anorexia, muscle and joint pain, as well as general health (Seeff et al 2008).

Non-responders to pegylated interferon and ribavirin were treated with increasing doses of intravenous (IV) silibinin (Legalon, SIL; Madaus) (Ferenci et al 2008). A dose-dependent reduction of HCV RNA was achieved. Patients were given 15 or 20 mg/kg/day IV silibinin for 14 days, and 280 mg oral silymarin three times per day combined with pegylated interferon and ribavirin therapy from day 8. At week 12, 50% (7/14) previous non-responders had undetectable HCV RNA (Ferenci et al 2008). Despite the small numbers and lack of a control group, this was the first time that silibinin (intravenously) had shown a direct anti-HCV activity in chronic hepatitis C patients (Ferenci et al 2008). It identifies a new pharmacological action for silibinin in humans and provides useful information about effective doses of intravenous silibinin and oral silymarin. It is of clinical significance, because adding pegylated interferon and ribavirin to intravenous silibinin showed greater efficacy than silibinin or pegylated interferon and ribavirin alone, suggesting a synergistic effect.

A review found no evidence for a beneficial effect of oral silymarin on the progression of viral hepatitis, especially hepatitis C (Saller et al 2008). Negative results were also obtained in a 2012 double-blind placebo-controlled trial testing oral Legalon (420 mg or 700 mg three times a day) in people with chronic hepatitis C (CHC). The study of 154 CHC patients found treatment with silymarin for 24 weeks produced no significant change in serum ALT levels during or after the trial, compared to placebo. Additionally, other markers of advanced liver disease such as serum bilirubin, albumin and platelet counts were the same (Fried et al 2012).

The recent use of intravenous silibinin prevented HCV RNA re-infection after orthotopic liver transplantation (Neumann et al 2010). Neumann and

colleagues (2010) started silibinin infusions (1400 mg daily for 14 days) administered eight hours after orthotopic liver transplantation, when HCV RNA levels measured 182 IU/mL. Three days later HCV RNA became undetectable (<15 IU/mL) and remained so 168 days later (Neumann et al 2010).

#### IN COMBINATION

More recently, a randomised, double-blind, placebo-controlled trial of 118 chronic hepatitis C participants showed that treatment with silymarin (720 mg silybin per day) and 12 vitamin and phytochemical based antioxidants achieved a higher rate of ALT normalisation compared to placebo ( $P = 0.02$ ) or silymarin ( $P = 0.003$ ) at Week 24. There was also a significant improvement in overall mental wellbeing (mental component summary scale) in the active treatment group (Salmond et al 2010).

A review concluded that silymarin 'is reasonable' to be employed as an adjunct therapy for alcoholic and grade Child A liver cirrhosis (Saller et al 2008).

#### Non-alcoholic fatty liver disease (NAFLD)

A phase III, double-blind clinical trial assessing the effects of silybin plus phosphatidylcholine on patients with nonalcoholic fatty liver disease showed positive outcomes over the 12-month treatment program. Patients were given Realsil, which is comprised of 94 mg silymarin, 194 mg phosphatidylcholine and 89.28 mg vitamin E acetate 50%. The study showed that there was substantial normalisation in ALT, AST and glutamyl-transpeptidase levels over the trial period. Blood glucose was 31% lower in the treatment group compared to placebo suggesting positive improvements in insulin resistance. Liver histology improvement was also noted via ultrasound (lobular inflammation, ballooning and fibrosis). In all measurements the active treatment group outperformed controls. It is suspected that the herb's antioxidant activity is chiefly responsible for the beneficial effects observed (Loguercio et al 2012).

#### IN COMBINATION

In 2013, another study was published testing silymarin (twice daily) in NAFLD producing positive results. The open study involved 72 patients who were on a restricted diet for 3 months and a food supplement containing vitamin E, L-glutathione, L-cysteine, L-methionine and *Silybum marianum* (Epaclin 3.5 g) taken twice a day. This treatment regimen reduced the biochemical, inflammatory and ultrasonic indices of hepatic steatosis and some parameters indicative of early stage of atherosclerosis (Cacciapuoti et al 2013). In particular, Steato test significantly ( $P < 0.001$ ) reduced from baseline ( $0.71 \pm 0.07$ ) to the end of treatment ( $0.40 \pm 0.05$ ), ALT serum levels ( $P < 0.01$ ) fell from a mean level of  $109.48 \pm 4.4$  to  $75.12 \pm 3.3$  U/L and AST recorded at baseline ( $72.39 \pm 8.4$  U/L) also significantly reduced ( $P < 0.05$ ) after silymarin and diet ( $48.65 \pm 3.2$  U/L) (Cacciapuoti et al 2013).

#### Clinical note — What is NAFLD?

Non-alcoholic fatty liver disease is the most common silent liver disease worldwide. It is characterised by fat accumulation in the liver (steatosis) and alterations in liver biochemical tests in people who do not consume high amounts of alcohol. Importantly, there are no obvious symptoms of disease. It has been estimated that the prevalence of NAFLD in Western countries is 20–30%. Obesity, type 2 diabetes and hyperlipidaemia are often associated with NAFLD (Cacciapuoti et al 2013).

#### Diabetes

Silymarin has also been investigated in people with type 2 diabetes both with and without cirrhosis. Velussi et al (1997) investigated whether long-term treatment with silymarin is effective in reducing lipoperoxidation and insulin resistance in diabetic patients with cirrhosis. The 6-month open trial found that silymarin treatment had several benefits. After the first month's treatment, fasting glucose levels showed a progressive and significant decline that, interestingly, did not lead to an increase in the frequency of hypoglycaemic episodes. Other observations revealed decreased glucosuria and levels of glycosylated haemoglobin also decreased significantly, indicating an overall improvement in glucose control. The dose used was 600 mg/day silymarin.

A 4-month randomised, double-blind, placebo-controlled trial in 51 type 2 diabetes patients receiving silymarin (200 mg three times daily) as an adjunct treatment to their conventional therapy showed a significant decrease in HbA<sub>1c</sub>, fasting blood glucose, total cholesterol, LDL and triglyceride levels compared with placebo as well as with values at the beginning of the study in each group (Huseini et al 2006). Another randomised, double-blind, placebo-controlled trial of 4 months' duration involving 59 subjects with type 2 diabetes compared treatment with 200 mg silymarin/day plus 10 mg glibenclamide to placebo plus glibenclamide vs glibenclamide alone. The silymarin group had significant reductions in both fasting and postprandial glucose levels, HbA<sub>1c</sub> and BMI compared to the placebo (Hussain 2007). A meta-analysis found the pooled mean difference (in the above two studies) in HbA<sub>1c</sub> and fasting glucose were  $-1.92\%$  ( $P = 0.008$ ) and  $-38.05$  mg/dL ( $P < 0.009$ ) in silymarin plus conventional treatment vs placebo plus conventional treatment (Suksomboon et al 2011). This meta-analysis concluded that treatment with *Silybum marianum* may improve glycaemic control in T2DM and called for further high quality studies to better elucidate the effects of these herbs on glycaemic control (Suksomboon et al 2011).

#### OTHER USES

Traditionally, the seeds have been used to treat jaundice, hepatitis, haemorrhoids and psoriasis, as a

tonic for nursing mothers, and as a general 'liver-cleansing' agent.

### Haemochromatosis

St Mary's thistle may have benefits in this condition, based on its mechanisms of action. Hutchinson et al suggested that silybin could chelate iron in the neutral pH of the duodenum and reduce the absorption of iron postprandially which they demonstrated in a crossover study with 10 people with haemochromatosis. Consumption of 140 mg of silybin with a meal resulted in a reduction in the postprandial increase in serum iron (AUC  $\pm$  SE) compared with water (silybin 1726.6  $\pm$  346.8 vs water 2988.8  $\pm$  167;  $P < 0.05$ ) and tea (silybin 1726.6  $\pm$  346.8 vs tea 2099.3  $\pm$  223.3;  $P < 0.05$ ) (Hutchinson et al 2010).

### Hypercholesterolaemia

In clinical practice, it is not unusual to find treatment with St Mary's thistle at the higher end of the dose range results in cholesterol-lowering effects. Several in vivo studies confirm that St Mary's thistle increases LDL cholesterol clearance and raises HDL cholesterol levels; however, only one clinical trial is available to determine whether the effect is clinically significant (Krecman et al 1998, Skottova & Krecman 1998b, Somogyi et al 1989). An open trial involving 14 subjects with type 2 hyperlipidaemia found that treatment with silymarin (420 mg/day) slightly reduced total cholesterol and HDL cholesterol levels (Somogyi et al 1989).

### Cancer prevention and treatment

In the past two decades, silybin has demonstrated remarkable anti-cancer as well as cancer chemopreventive efficacy in preclinical cell culture and animal models of several cancer models including skin, breast, lung, bladder (Zeng et al 2011), colon, prostate, lung and kidney carcinomas (Deep & Agarwal 2010, Niture et al 2014). Silybin has also been tested in human phase I–II pilot clinical trials, where it was reported to be well tolerated and showed plasma and target-tissue bioavailability, though limited (Agarwal et al 2013, Flaig et al 2007, 2010).

Topical application of silymarin provided significant protection against different stages of UVB-induced skin carcinogenesis in mouse skin tumorigenesis models (Ahmad et al 1998, Lahiri-Chatterjee et al 1999).

A randomised, double-blind, placebo-controlled study of 37 men, 2–3 months after radical prostatectomy were randomised to receive 570 mg of silymarin and 240 mcg selenium ( $n = 19$ ) or placebo ( $n = 18$ ) daily for 6 months. The combination of silymarin and selenium significantly reduced two markers of lipid metabolism associated with prostate cancer (PCa) progression, LDL and total cholesterol which suggests that silymarin and selenium may be effective in reducing PCa progression (Vidlar et al 2010).

### Chemotherapy support

Whether silymarin is a useful treatment to prevent organ toxicity due to chemotherapy remains to be tested. Based on its anti-inflammatory, antioxidant and hepatoprotective mechanisms, it could prove useful (Comelli et al 2007, Greenlee et al 2007). In a case of hepatotoxicity during chemotherapy which did not resolve with supportive care, there was an immediate response to milk thistle at 280 mg twice daily (McBride et al 2012).

Besides lowering toxicity, silybin strongly sensitises human prostate carcinoma cells to doxorubicin, cisplatin, carboplatin, and mitoxantrone-induced growth inhibition and apoptotic death. Similar synergistic effects of silybin with doxorubicin and cisplatin have also been reported in various other cancer cell lines (Agarwal et al 2013, Greenlee et al 2007). Further research is warranted to determine its role in practice and identify any safety issues.

### Obsessive compulsive disorder

In a pilot randomised, double-blind trial of 35 adults with obsessive compulsive disorder (OCD) designed to compare the efficacy of silymarin to fluoxetine, both interventions provided equal and highly significant reductions on Yale-Brown Scale for OCD (Y-BOCS) ( $P = 0.0001$ ). Patients were randomly assigned to receive either capsules of the *Silybum marianum* (600 mg/day taken in 200 mg capsules 3 times a day) or fluoxetine (30 mg/day taken in 10 mg capsules three times a day). There was also no significant difference between the two groups in terms of observed side effects (Sayyah et al 2010). Camfield suggests this effect is achieved through silybin's inhibition of monoamine oxidase activity (Mazzio et al 1998) which increases serotonin levels in the cortex (Osuchowski et al 2004) and was shown to ameliorate decreases in dopamine and serotonin in the prefrontal cortex and hippocampus associated with methamphetamine abuse (Camfield et al 2011, Lu et al 2010b).

#### Clinical note — Cisplatin

Cisplatin is one of the most active cytotoxic agents in the treatment of testicular cancer, head and neck, gastrointestinal, cervical, lung and bladder cancer. However, its clinical use is associated with side effects, such as severe nausea, ototoxicity, neurotoxicity and nephrotoxicity (Giacomelli et al 2002).

### Pharmacokinetics of silymarin

Silymarin has low solubility in water and has poor oral bioavailability, similar to other flavonolignans, and undergoes rapid excretion (Loguercio & Festi 2011). Following oral administration, silymarin undergoes phase I and phase II metabolism, especially phase II conjugation reactions, forming chiefly monoglucuronides detectable in human plasma and

in urine two hours after ingestion (Calani et al 2012). It undergoes multiple conjugation reactions and is primarily excreted into bile and urine (Pradhan & Girish 2006, Venkataramanan et al 2006, Wen et al 2008, Wu et al 2009).

A pharmacokinetic dosing study identified that oral doses of between 140 mg and 560 mg of silymarin resulted in increases in plasma silibinin A and silibinin B only whereas a higher dose of 700 mg silymarin resulted in six silymarin flavonolignans being detected in the plasma (Hawke et al 2010).

Due to its poor water solubility, research has been undertaken to find methods of improving silymarin bioavailability. This includes creating different preparations of more soluble derivatives of silybin creating silymarin nanoparticles, using a semisolid dispersion system and phytosomes of phosphatidylcholine as emulsifying agents (Filburn et al 2007, Hsu et al 2012, Hussein et al 2012, Loguercio & Festi 2011).

Efforts to improve silymarin bioavailability are important to obtain better clinical outcomes. For example, poor bioavailability with oral silymarin is correlated with liver inflammation (Hawke et al 2010, Loguercio & Festi 2011, Schriber et al 2008). This supports the results and comments from the HALT-C trial (Freedman et al 2011). Ferenci's study (Ferenci et al 1989) and *A. phalloides* poisoning (Hruby et al 1983) showed that early administration of more bioavailable silymarin has better hepatoprotective activity.

To overcome oral bioavailability issues, intravenous silibinin has also been investigated. This method of use has recently been applied to patients with chronic hepatitis C, successfully clearing hepatitis C virus (HCV) infection in some patients even in monotherapy (Esser-Nobis et al 2013) and has also been successfully used to treat amatoxin poisoning (Mengs et al 2012).

## DOSAGE RANGE

Studies show that the dose; route of administration; treatment duration; patient's diagnosed condition and any comorbidities; the inflammatory stage in the disease process (Loguercio & Festi 2011) and the genotype of the virus in HCV (Huber et al 2005) all impact the efficacy of silymarin treatment in liver disease. In summary:

- To show benefits in hepatic necroinflammation: 450 mg/day silymarin for 12 months achieved ALT normalisation in 15% of the CHC patients in a randomised study (El-Zayadi et al 2005);
- To improve liver histology: 420 mg/day silymarin for 41 months (mean) is required in alcoholic cirrhosis (Child-Pugh A, 5–7) (Fehér et al 1989, Ferenci et al 1989);
- To elicit antioxidant effects: 600 mg/day silymarin for 12 months reduced malondialdehyde in diabetic cirrhosis (Velussi et al 1997); and
- To elicit direct anti-HCV activity: 1400 mg/day intravenous silibinin administered for 14 days is

needed (Biermer et al 2010, Ferenci et al 2008, Neumann et al 2010).

In most clinical trials the effective daily doses of silymarin range from 420 to 600 mg (Saller et al 2008). To obtain a midpoint of 500 mg of silymarin from a 1:1 herbal extract, assuming 1 mL of herbal extract contains 25 mg of silymarin, then 20 mL/day of the *Silybum marianum* extract is required. This is a higher level than is normally recommended in clinical practice.

- Liquid extract (1:1): 4–9 mL/day (Mills & Bone 2000).
- Silybin-phytosome: 13 g daily (Flaig et al 2007).

## TOXICITY

### Extremely low

Hawke et al (2010) showed that oral doses up to 2100 mg oral silymarin were non-toxic. Toxicity studies in rats and mice have shown that silymarin, even at daily doses as high as 2500–5000 mg/kg, produced no adverse toxic effects (Madaus 1989). In a 12-month study in rats and dogs given up to 2500 mg/day, no signs of toxicity were seen. Milk thistle products with a standardised content of silymarin (70–80%) were found to be safe for up to 41 months of usage (Francine 2005). Safety was further confirmed after comprehensive in vitro studies concluded that interference or hepatotoxicity of the dry extract from *S. marianum* at the recommended maximum daily dose of four Hepar-Pasc tablets, equivalent to 210 mg silibinin, is unlikely, and is to be considered safe (Doehmer et al 2011).

## ADVERSE REACTIONS

Milk thistle is considered safe and well-tolerated when taken within the recommended dose range (Post-White et al 2007). A review of studies involving more than 7000 participants identified three cases of serious adverse reactions (two anaphylaxis and one gastroenteritis symptoms) (Jacobs et al 2002). In one clinical trial, patients with colorectal adenocarcinoma who received silybin (silybin with phosphatidylcholine) at dosages of 360, 720 or 1440 mg daily for 7 days found the administration of silybin to be safe (Hoh et al 2006). Another clinical trial ( $n = 13$ ) reported hyperbilirubinaemia in 9/13 patients and increased ALT in 1/13 patients using silybin-phytosome (Flaig et al 2007), whereas all other trials reported only rare adverse events (Gordon et al 2006, Rainone 2005, Torres et al 2004), mostly gastrointestinal symptoms, even for intravenously administered silymarin (Ferenci et al 2008). Reviews concluded that silymarin has an excellent safety profile (Dryden et al 2006, Rainone 2005, Sagar 2007).

Overall, adverse effect frequency was the same as for placebo and had a low frequency, ranging from 2% to 12% in controlled trials. In practice, loose bowels and gastrointestinal symptoms have been reported.

## SIGNIFICANT INTERACTIONS

In vitro studies using a standardised dry extract from *Silybum marianum* (Hepar-Pasc) state that according to FDA regulations, drug–drug interactions are possible for CYP2C8 and CYP2C9 but not likely, and are remote for CYP2C19, CYP2D6, and CYP3A4 (Doehmer et al 2011, Kiruthiga et al 2013). Although in vitro and some animal studies (Kiruthiga et al 2013) show possible drug interactions with silymarin these are not replicated in clinical interactions (Hackett et al 2013). A prospective human study of standard milk thistle extracts (non-phytosome) concluded that on the basis of current clinical data, the drug interaction risk for milk thistle products is minimal (Gurley et al 2012).

### Cisplatin

Preliminary research has shown this combination may reduce toxic effects, yet enhance antitumour activity — theoretically adjunctive use may be beneficial when used under professional supervision however further research is required to confirm benefits (Agarwal et al 2013, Greenlee et al 2007).

### Doxorubicin

Silymarin reduces cardiotoxicity and possibly chemosensitises resistant cells to anthracyclines — theoretically adjunctive use may be beneficial when used under professional supervision (Agarwal et al 2013, Greenlee et al 2007).

### Hepatotoxic substances

General hepatoprotective effects reported for silymarin — adjunctive use may be beneficial when used under professional supervision.

## CONTRAINDICATIONS AND PRECAUTIONS

Contraindicated in people with known allergy to the Asteraceae (Compositae) family of plants. One case of exacerbation of haemochromatosis due to ingestion of milk thistle has been reported (Whittington 2007); however, the association between herbal intake and outcome reported is unlikely (Kidd 2008).

## PREGNANCY USE

An in vivo study concluded that silibinin was safe when used by pre-eclamptic pregnant women (Giorgi et al 2012). A review of four studies found no evidence of adverse effects in mothers and their offspring for silymarin when used by pregnant women with intrahepatic cholestasis, alcoholic and non-alcoholic liver cirrhosis, chronic and acute viral hepatitis, drug-induced liver toxicity, fatty degeneration of the liver (Hess 2013).

## PATIENTS' FAQs

### What will this herb do for me?

St Mary's thistle may improve digestion, particularly of fatty foods, and afford protection against the toxic effects of a number of drugs and environmental poisons. It is also used as supportive treatment in chronic liver diseases and high-cholesterol states.

### When will it start to work?

This varies, depending on the indication.

### Are there any safety issues?

St Mary's thistle is considered a very safe and well-tolerated herb. The most common side effects relate to gastrointestinal symptoms such as loose bowels.

### Practice points/Patient counselling

- St Mary's thistle has hepatoprotective activity and has been shown to reduce the hepatotoxic effects of a variety of environmental toxins and medicines, such as paracetamol, erythromycin, carbon tetrachloride and death cap mushrooms (*Amanita phalloides* poisoning).
- It has direct and indirect antioxidant activities, accelerates the regeneration of hepatocytes after liver damage, has significant gastroprotective and nephroprotective activities, anti-inflammatory and antihistamine activities, and anti-tumour effects according to in vitro and animal studies.
- Numerous clinical studies have investigated its effects in a variety of liver diseases, many producing promising results however it's still too early to suggest the herb is used as routine treatment in chronic liver diseases. An individualised approach is best.
- In clinical practice, it is used to treat dyspepsia, toxic liver damage, as supportive therapy in chronic liver diseases and hypercholesterolaemia.
- Preliminary evidence suggests a possible role as adjunctive therapy with cisplatin and as a skin cancer preventive agent when applied topically.
- Dose and route of administration of silymarin preparations are important considerations in management of liver disease.

## Stinging nettle

**HISTORICAL NOTE** Stinging nettle has been used since ancient times, with Dioscorides and Galen in ancient Greece reporting diuretic and laxative effects for nettle leaf. Roman troops were thought to flail themselves with the stinging nettle to keep warm. It is also widely used for gynaecological complaints by North American Indians and in Ayurvedic medicine in India (Blumenthal et al 2000). The Latin root of *urtica* is *uro*, meaning 'I burn', indicative of the small stings caused by the hairs on the leaves of nettle when contact is made with the skin.

### OTHER NAMES

Common nettle, brennessel, brennesselkraut, brennesselwurzel, urtica ortie, great stinging nettle, haarnesselkraut, haarnesselwurzel, ortica, ortie, otriga.

### BOTANICAL NAME/FAMILY

*Urtica dioica* (family Urticaceae)

### PLANT PARTS USED

Aerial parts and root

### CHEMICAL COMPONENTS

Constituents found within the leaf include vitamins A and C, B group, K, beta-carotene, calcium and potassium, phosphorus, chlorophyll, magnesium and tannins, flavonoids, sterols and amines (US Department of Agriculture 2003). Various constituents' levels will vary with the age of the plants at harvest time, the season of harvest and the cut used. For example, beta-carotene is more concentrated in older plants. Iron and manganese content are higher in the leaves of young plants whereas nickel and lead are the lowest in older plants. There is a seasonal variation in the concentration of tannin and chlorophyll in the plant. The leaves contain a higher concentration of calcium and magnesium than the roots but are not affected by the age of the plant (Upton 2013).

Constituents found chiefly in the root include polysaccharides, lectins, lignans, fatty acids, terpenes and coumarin (Ernst et al 2001).

### MAIN ACTIONS

#### Anti-inflammatory and analgesic

In vitro studies have identified anti-inflammatory activity for *Urtica* extract (Obertreis et al 1996a, 1996b, Riehemann et al 1999). The mechanism of action has not been fully elucidated, but test tube studies have demonstrated inhibitory effects on NF-kappaB activation and partial inhibitory effects on cyclo oxygenase and 5-lipoxygenase-derived reactions. Additionally, isolated phenolic acid from nettle has been shown to inhibit leukotriene B<sub>4</sub> synthesis in a concentration-dependent manner in vitro.

Although extensive investigation has not been conducted in humans to confirm anti-inflammatory mechanisms, one study of 20 volunteers showed that oral ingestion of 1.34 g nettle extract for 3 weeks significantly decreased lipopolysaccharide-stimulated tumour necrosis factor-alpha (TNF-alpha) and interleukin-1 beta (IL-1-beta) when tested ex vivo but had no effects on cytokine levels (Teucher et al 1996).

In vitro data have shown that nettle leaf extract (IDS 30) reduces the induction of primary T-cell responses and TNF-alpha in T-cell-mediated diseases such as rheumatoid arthritis (Broer & Behnke 2002). Faecal IL-1-beta and TNF-alpha concentrations were significantly reduced in mice with induced Crohn's disease treated with IDS 30 (Konrad et al 2005). Mice treated with nettle extract

displayed fewer histological changes and general disease symptoms. The authors conclude that the effect may be due to a decrease in TH1 response and may constitute a new treatment option for prolonging remission in inflammatory bowel disease.

A recent study investigating different stinging nettle preparations for anti-inflammatory activity found lipophilic extracts had stronger activity than the traditional tinctures (water, methanol, ethanol), thereby suggesting clinical effects may be more likely with these forms (Johnson et al 2013).

### Hypotensive and diuretic

When administered intravenously to test animals, *Urtica* extract exerts an acute hypotensive action accompanied by diuretic and natriuretic effects (Tahri et al 2000). It is uncertain whether the same effects are seen with oral administration.

A review of in vitro and in vivo studies concluded that the hypotensive action of *U. dioica* is due in part to negative inotropic activity and a vasodilatory effect (Testai et al 2002).

### Antihyperglycaemic

A 33% reduction in blood glucose was noted in rats administered 250 mg/kg of nettle leaf extract orally, 30 minutes before glucose loading (Bnouham et al 2003). Nettle was shown to decrease glucose absorption in the small intestine of rats under anaesthesia; however, administration of 500 mg/kg failed to modify blood glucose levels in alloxan-induced diabetic rats.

A six-fold increase in blood insulin levels occurred after intravenous administration of a nettle leaf fraction in streptozotocin-diabetic rats, with a corresponding drop in blood sugar levels as compared to control (Farzami et al 2003). Details of the isolated fraction were not given.

### Antiproliferative effects on prostate cells

Nettle extract has shown antiproliferative effects on prostate cells; however, the exact mechanism of action has not been fully elucidated (Lichius & Muth 1997, Lichius et al 1999). Results from several in vitro studies suggest that a combination of mechanisms is responsible. It seems likely that sex hormone binding globulin (SHBG), aromatase, epidermal growth factor and prostate steroid membrane receptors are involved in the antiprostatic effect, but less likely that 5- $\alpha$ -reductase or androgen receptors are involved (Chrubasik et al 2007).

### Prostate cancer

One study found that a methanolic extract of stinging nettle roots slows the progression of prostate cancer in both an in vivo model and an in vitro system (Konrad et al 2000). One study involving 20 males with prostatic adenoma found that treatment for 7 days with nettle produced a significant drop in zinc level, thought to be a result of altering zinc-testosterone metabolism and diminishing zinc secretion in adenomatous tissue (Romics & Bach 1991).

### Antiviral

A lectin extracted from nettle had inhibitory effects against HIV-1, HIV-2, human cytomegalovirus, respiratory syncytial virus and influenza A virus in vitro (Balzarini et al 1992).

### Antioxidant

Nettle has shown potent antioxidant activity in a range of in vitro tests (Gulcin et al 2004): 50, 100 and 250 microgram inhibited peroxidation of linoleic acid by 39%, 66% and 98%, respectively, as compared to 30% inhibition demonstrated by 60 microgram/mL of alpha-tocopherol.

In the same study, nettle was shown to scavenge free radicals, hydrogen peroxide and superoxide anion radicals and to chelate heavy metals. Ozen and Korkmaz (2003) reported that constituents from nettle can regulate glutathione reductase, glutathione peroxidase, superoxide dismutase and catalase in vivo.

The fixed oil of nettle has demonstrated strong antioxidant activity in mice treated with carbon tetrachloride, by decreasing lipid peroxidation and increasing antioxidant status (Kanter et al 2003). Nettle extract is significantly effective in preventing fibrosis in liver tissue from carbon tetrachloride damage in vivo (Turkdogan et al 2003). Dried nettle added to the diet of rats decreased cerebral free radicals after forced-swim tests (Toldy et al 2005).

Antioxidant activity has also been demonstrated in humans. An alcoholic extract of stinging nettle was tested for effects on oxidative stress in 50 volunteers with type 2 diabetes. The test dose of 100 mg kg<sup>-1</sup> of nettle extract of body weight taken for 8 weeks resulted in a significant increase in Total Antioxidant Capacity (TAC) and superoxide dismutase (SOD) compared to the control group ( $P < 0.05$ ) (Namazi et al 2012).

### Hepatoprotective

Treatment with stinging nettle effectively protected against aflatoxin-induced hepatotoxicity, as evidenced by decreased aspartate aminotransferase (AST), alanine aminotransferase (ALT) and gamma glutamyl transpeptidase (GGT) levels, and hepatic lipid peroxidation and elevated the antioxidants' levels in an animal model (Yener et al 2009). These findings were confirmed by histological observation. One mechanism proposed to account for this observation is nettle-maintained antioxidant enzyme activity (superoxide dismutase, catalase and glutathione reductase) which protected against hepatotoxic effects induced by aflatoxin. Comparisons between groups revealed the untreated animals experienced a significant decrease in antioxidant enzyme activity, whereas no significant changes were seen with co-administration of nettle treatment.

### CLINICAL USE

Different parts of the nettle herb have been used for different indications, notably the whole herb and the root. More recently, fresh, freeze-dried leaves

have also been used. Some evidence comes from traditional usage; however, most recent research efforts have investigated various nettle preparations in urological and rheumatological conditions.

### Arthritic conditions

Traditionally, nettle herb and leaf have been used to treat painful joint diseases, but scientific investigation has only just begun to determine whether there is a demonstrable benefit with its use.

One randomised, double-blind crossover study involving 27 patients with osteoarthritic pain at the base of the thumb or index finger compared topical applications of stinging nettle leaf with placebo, used daily for 1 week. After a 5-week washout period, treatments were then reversed. Nettle application used for 1 week showed reduction in pain and disability and produced significantly superior results to placebo (Randall et al 2000). An open study of 17 patients reporting beneficial effects with the nettle sting of *U. dioica* showed that a transient urticarial rash can be associated with topical use (Randall et al 1999). It is suspected that a counterirritant effect is chiefly responsible.

Most recently, a randomised, controlled, single-blind pilot study of 42 adults with knee pain and taking NSAIDs or analgesics (presumed osteoarthritis) investigated the feasibility of conducting research to determine the effect of the sting of *Urtica dioica*, for chronic knee pain (Randall et al 2008). Patients were instructed to apply a specific number of nettle (*Urtica dioica*) leaves to the affected area, or placebo intervention with *Urtica galeopsifolia* daily for 1 week. The effect of *U. dioica* did not appear to be superior to the control treatment; however, the authors suggested several possible interpretations of this negative result. Importantly, during the study it was found that the choice of placebo was poor as *Urtica galeopsifolia* had a stinging irritant effect similar to stinging nettle. Next, there was the possibility of inadequate treatment as researchers found it difficult to supply well-grown nettles in late season, and not all patients used as many leaves as recommended. Finally, the study may have been underpowered to detect a statistical difference between groups.

A large, multi-centre, post-marketing surveillance review including 8955 patients (5953 females, 2920 males) suffering from osteoarthritis ( $n = 7935$ ) or rheumatoid arthritis ( $n = 1550$ ) also investigated the effects of 1340 mg of stinging nettle extract (IDS23) over 3 weeks as mono- or co-treatment (Ramm & Hansen 1997 as reported in Upton 2013). Fifty per cent of the patients were pretreated with NSAIDs (82% diclofenac), while 8% received other treatments.

Treatment with IDS23 resulted in 5% improvement in pain at rest, 45% improvement in pain during movement and 38% improvement in physical impairment. In 38% of the patients NSAID consumption was reduced by 50% whereas for 28% of patients there was no change to NSAID requirements and in 8% additional NSAIDs were necessary.

There was no difference in the score improvement (rest, movement, physical impairment) between patients pretreated with NSAIDs and those not pretreated.

There was a low incidence (1.2%) of adverse effects reported during treatment, which mainly consisted of gastrointestinal discomfort.

### Nettle, fish oils and vitamin E

In combination, treatment of fish oils, vitamin E and *Urtica dioica* (concentrations not stated) was compared to placebo in a double-blind, randomised study of 81 volunteers with OA of the knee or hip (Jacquet et al 2009). The treatment product known as Phytalgic was taken for 3 months. The active treatment group had a significantly-reduced requirement for analgesics and NSAIDs compared to controls and significantly-different WOMAC scores indicating symptomatic benefits. While these results are promising, the role of the stinging nettle ingredient is unknown and concerns have been raised about detection bias.

Clearly, further clinical research is required to clarify the effectiveness of *Urtica dioica* in musculoskeletal conditions.

Commission E approved stinging nettle as supportive therapy for rheumatic ailments when used internally or applied externally (Blumenthal et al 2000).

### Benign prostatic hyperplasia (BPH)

Clinical trials have used many different nettle extracts in liquid or oral dose forms utilising root preparations. The Bazoton products (Kanoldt) have been most commonly investigated; however, there has also been some investigation with extracts including *Urtica* plus (Osterholz/Schwarzpharma), *Urtica* APS (Zyma/Novartis), Prostatin (Abbott), Prostaherb (Cesra), and Prosta Truw (Truw).

According to a 2007 systematic review, at least 40,000 men with BPH have been treated with various nettle root preparations in 34 clinical studies (Chrubasik et al 2007). Twenty-four studies were open and uncontrolled, two studies were open and controlled and six were randomised controlled studies. All studies evaluated methanolic nettle root extracts. Overall, available evidence indicates that methanolic nettle extracts are effective in BPH. Most studies report decreased residual urine volume, increased maximal urinary flow and improvements in symptom scores compared to placebo. Significant improvements in prostate size have also been reported in some open trials (ESCOP 1996–97). Further randomised studies are required to determine the significance and magnitude of these effects. Commission E approved the use of *Urtica* root for difficulty in urination in BPH stages 1 and 2 (Blumenthal et al 2000).

### IN COMBINATION

In practice, nettle root preparations are often prescribed in combination with other herbal medicines, such as saw

palmetto or pygeum. Several clinical trials have investigated combination products which are more reflective of practice, overall producing positive results.

### Nettle and pygeum

In one study, 134 patients with BPH were randomly assigned an *Urtica* and *Pygeum* preparation (300 mg *Urtica dioica* root extract combined with 25 mg *Pygeum africanum* bark extract) or a preparation containing half that dose under double-blind test conditions for 8 weeks. Both treatments significantly increased urine flow, and reduced residual urine and nocturia after 28 days, whereas after 56 days further significant decreases were found in residual urine (half-dose group) and in nocturia (both groups) (Krzeski et al 1993).

### Nettle and saw palmetto extract

In 1995, an open, prospective, multicentre observational study involving 419 specialist urological practices investigated the efficacy and tolerability of a saw palmetto and nettle combination in 2080 patients with BPH (Schneider et al 1995). Herbal treatment was seen to improve pathological findings and obstructive and irritative symptoms. Both efficacy and tolerability were assessed by doctors as very good or good and most patients reported an improvement in general quality of life (QOL) and reduction in symptoms of BPH.

A randomised, multicentre double-blind study involving 543 patients with early stage BPH found that a combination of nettle and saw palmetto extract was as effective as finasteride at increasing maximum urinary flow and improving International Prostate Symptom Scores (IPSS) after 24 weeks' treatment, which continued to improve by week 48 (Sokeland 2000). Improvement in QOL scores was similarly observed with both treatments, regardless of prostate size. Overall, the two treatments only differed in regard to adverse reaction incidence, with the herbal combination much better tolerated (Sokeland & Albrecht 1997). A 2003 review concluded that a combination of nettle and saw palmetto is safe and effective for the treatment of lower urinary tract symptoms associated with BPH, comparable to the alpha-blocker tamsulosin (Bondarenko et al 2003).

A randomised, placebo-controlled, double-blind, multicentre trial in 2005 further demonstrated the effectiveness of saw palmetto fruit (160 mg) and nettle root (120 mg) for lower urinary tract symptoms due to prostate enlargement (Lopatkin et al 2005): 257 men aged 50 years or more were randomised to take either two capsules of the study medication (320 mg saw palmetto and 240 mg nettle root) daily or placebo for 24 weeks. Men on the treatment experienced a 35% reduction in symptoms — most notably intermittency, hesitancy, urgency and nocturia — compared to 24% for placebo. At the end of the 24-week period, an open trial was conducted for an additional 24 weeks and all men were given the herbal medicine.

Those previously taking placebo reported significant improvements when switched to the study medication.

### Allergic rhinitis

A double-blind randomised study showed that a freeze-dried preparation of nettles improved global assessments of allergic rhinitis after 1 week's therapy (Mittman 1990).

### Nutritional tonic

Due to the presence of a range of vitamins and minerals, including iron, the stinging nettle herb is used as a nutritional tonic and to increase energy. It is used as a steamed green vegetable, pureed ingredient in soup or as a tea.

An open study involving 10 healthy women drinking 1 L of strained stinging nettle tea for 12 days found significant increase in vitamin B<sub>12</sub> blood levels, an increase in red cell folate and iron binding capacity. There was no noted change in ferritin levels. The tea was made from 15 g of herb in 1 L of boiling water, cooled for 4 to 8 hours before consumption (Burgess & Baillie 1999).

### OTHER USES

Stinging nettle has also been used in various preparations for diarrhoea, dysentery and diseases of the colon, internal bleeding, chronic skin eruptions such as eczema and discharges.

#### Practice points/Patient counselling

- Preliminary research has demonstrated anti-inflammatory, analgesic and antiviral activities for nettle.
- Several test tube studies have shown that it reduces prostate cell proliferation and slows the progression of prostate cancer in both an in vivo model and an in vitro system.
- The aerial parts are most commonly used to relieve symptoms of arthritis, whereas the root is used for BPH symptom relief.
- There is evidence that stinging nettle extracts provide significant symptom relief in BPH and some studies indicate a possible reduction in prostate size. In practice, nettle root preparations are often prescribed in combination with other herbal medicines, such as saw palmetto or pygeum.
- Application of nettle leaf for 1 week reduced pain and disability in osteoarthritis according to one double-blind study; however, larger studies have not been performed to confirm the effects.
- One double-blind study found that nettle reduced symptoms of allergic rhinitis.
- Studies using nettle root in combination with saw palmetto or pygeum have shown positive results in BPH.

## DOSAGE RANGE

### Leaf

- Dry extract: 0.6–2.1 g/day in divided doses; or
- Liquid extract (1:2): 15–40 mL/week.
- Tincture (1:5, 25% ethanol): 6 mL up to 3 times daily.
- Freeze-dried powder : 300–600 mg up to 3 times daily.

### Root

4–9 mL daily of 1:2 liquid extract, although Commission E recommend 4–6 g/day cut root for symptoms of BPH, doses up to 18 g/day have been used ([www.phytotherapies.org](http://www.phytotherapies.org) June 2003).

## TOXICITY

Insufficient reliable evidence is available.

## ADVERSE REACTIONS

One report states that gastrointestinal discomfort, allergic reactions, urticaria, pruritus, oedema and decreased urine volume are possible with oral use ([Ernst et al 2001](#)).

Clinical studies in BPH with herbal combinations containing nettle have found that only 0.72–3.7% experience mild adverse effects.

### Clinical note — What causes the sting?

A frequent cause of contact urticaria is skin exposure to the stinging nettle. The urticaria is accompanied by a stinging sensation lasting longer than 30 minutes. The hairs of the leaves of the stinging nettle plant *Urtica dioica* contain acetylcholine histamine, 5-hydroxytryptamine (serotonin) and small amounts of leukotrienes B<sub>4</sub> and C<sub>4</sub> ([Czarnetzki et al 1990](#)). It is recommended to wear rubber or plastic gloves when handling and processing dried or fresh material to avoid irritation due to direct contact. Much of the irritating contents of the stinging hairs are dissipated upon extraction, drying and cooking, but not all. This means skin irritation can still occur when handling properly dried material ([Upton 2013](#)).

## SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

### Diuretic medicines

Potentiated effects are theoretically possible — observe patients taking this combination.

### Antihypertensive medicines

Additive effects are theoretically possible — observe patients taking antihypertensives concurrently.

## Finasteride

Additive effects are theoretically possible, although the interaction may be beneficial.

### CONTRAINDICATIONS AND PRECAUTIONS

People with known sensitivities or allergies to stinging nettle should use this herb cautiously.

The leaves have a powerful topical counter-irritant effect and can cause blistering and wheal and flare. People handling or processing dried or fresh material should wear rubber or plastic gloves to avoid irritation due to direct contact with skin. Irritation can still occur with properly dried materials ([Upton 2013](#)).

### PREGNANCY USE

Use of nettle during pregnancy is contraindicated because of its effects on hormones ([WHO 2003](#)). It is suggested to be used with caution in the first trimester ([Upton 2013](#)).

## PATIENTS' FAQs

### What will this herb do for me?

Nettle leaf may reduce pain in osteoarthritis when applied topically for 1 week, whereas oral preparations of nettle root in combination with saw palmetto or pygeum reduce symptoms of BPH. Internal preparations may also reduce symptoms of allergic rhinitis, according to one human study.

### When will it start to work?

Topical applications of the leaf in osteoarthritis have been shown to work after 1 week, whereas benefits in BPH require at least 28 days' treatment.

### Are there any safety issues to be concerned about?

Local application of nettle can be irritating and cause contact urticaria, but preparations taken internally seem generally well tolerated.

## Taurine

### BACKGROUND AND RELEVANT PHARMACOKINETICS

Taurine occurs as one of the most abundant free amino acids in a wide variety of animal tissues; it is mostly absent from plants (Bouckennooghe et al 2006). In humans and other mammals, the highest taurine concentrations are found in heart, retina, spleen and bone marrow (Timbrell et al 1995). Blood cells such as platelets and leucocytes are also very rich in taurine.

Traditionally taurine has been regarded as an end product of methionine metabolism. Other pathways for taurine biosynthesis exist but they have not been

fully characterised and in mammals the cysteine sulfinic pathway seems to be the major pathway (Brosnan & Brosnan 2006).

There is marked variation in taurine biosynthesis in different organs and it is species- and age-dependent. The activity of cysteine sulfinic acid decarboxylase, a key enzyme in the biosynthesis of taurine from cysteine (Lambert 2004), is low in the liver and brain of human fetuses, infants and adults. The extent to which taurine can be synthesised by humans is unknown at present.

Taurine does not undergo any major metabolic biotransformation, although a small amount is

deaminated to isethionic acid. As taurine is metabolically inert, free taurine is readily excreted in the urine. The kidney is the major organ involved in regulating taurine levels (Chesney et al 1985, Rozen & Scriver 1982) and excess dietary taurine is excreted in the urine (Sturman 1988).

A small amount of taurine is also degraded by intestinal bacteria to sulfate, which is absorbed from the intestine and excreted in urine. The high tissue taurine levels in both mature and newborn animals have led to much speculation about possible roles of taurine in brain, retina, heart and skeletal muscle (Grimble 2006).

## CHEMICAL COMPONENTS

2-Aminoethanesulfonic acid

## FOOD SOURCES

Taurine does not need to be supplied in the human diet as it can be derived indirectly from dietary precursors. Dietary taurine is found preformed in considerable quantities in meat, fish and seafood (Roe & Weston 1965). Daily intake of preformed taurine can be 40–400 mg/day (Hayes & Trautwein 1994, Rana & Sanders 1986). Taurine can become a conditionally essential nutrient when there are limited dietary and precursor amino acid supplies, biosynthetic enzymes or their cofactors are deficient, or there is excessive loss, such as in conditions characterised by digestive malabsorption (e.g. cystic fibrosis).

## DEFICIENCY SIGNS AND SYMPTOMS

### Deficiency

Taurine deficiency is associated with cardiomyopathy, renal dysfunction, developmental abnormalities, pancreatic  $\beta$ -cell malfunction and severe damage to retinal neurons (Ripps & Shen 2012). Children receiving parenteral nutrition without supplemental taurine develop low taurine plasma levels and neuronal (especially retinal) dysfunction, which can be counteracted by taurine supplementation (Geggel et al 1985).

This was previously detected as degeneration of the retina in taurine-deficient cats (Knopf et al 1978). The animals showed growth retardation and developed retina degeneration that eventually led to blindness. The retina degeneration could be prevented or reversed by the addition of preformed taurine to the diet, but not by feeding methionine or cysteine.

Taurine deficiency has been reported in parenteral nutrition as taurine is not routinely added to parenteral formulations (Lloyd & Gabe 2007).

Taurine deficiency can present in infants with cholestatic disease and this can be prevented by parenteral supplementary taurine; extensive gastrointestinal surgery can also result in taurine deficiency due to increased loss of bile acids (Lloyd & Gabe 2007, Schneider et al 2006). It has also been found that people with cystic fibrosis frequently have taurine deficiency due to bile acid malabsorption. Low levels have also been found in people with heart failure.

## MAIN ACTIONS

Taurine is one of the most abundant amino acids in the brain, retina, muscle tissue and organs throughout the body, although it is not incorporated into proteins (Ripps & Shen 2012). Many studies report that taurine is involved in a wide variety of biological processes, although the exact mechanisms of action are usually not well defined. The evidence that taurine is essential to human nutrition remains unclear: dietary taurine has been shown to play an important part in maintaining body taurine pools.

Taurine has been proposed to have numerous roles, such as a membrane stabiliser, a substrate for the formation of bile salts, a neurotransmitter/neuromodulator, an intracellular osmolyte involved in cell volume regulation and an antioxidant, and may have a number of other roles, including immunomodulation and growth modulator (Bouckennooghe et al 2006, Huxtable 1992, 1996, Ripps & Shen 2012).

### Eye function and health

All ocular tissues contain taurine, which is critical for photoreceptor development in the retina and acts as a cytoprotectant against stress-related neuronal damage and other pathological conditions. Supplementation can inhibit light-induced lipid peroxidation, and thereby protect isolated rod outer segments from photic damage (Ripps & Shen 2012).

### Bile acid conjugation

Despite extensive studies on the proposed functions of taurine, the only well-defined role for taurine is conjugation with bile acids. Taurine is preferentially conjugated with bile acids in the liver, forming predominantly taurocholic acid, prior to excretion in the bile (Bouckennooghe et al 2006). Bile acids have an important role in the emulsification of dietary fat. The regulation of cholesterol and bile acid homeostasis is mediated by CYP7A1, which has become a biomarker for cholesterol metabolism (Chen et al 2012).

## OTHER ACTIONS

Taurine has many of the same characteristics as neurotransmitters, but evidence of a taurine-specific receptor has yet to be identified (Ripps & Shen 2012). Animal studies indicate that taurine supplementation may result in lower plasma lipid levels (Murakami et al 2002) and improve insulin sensitivity (Anuradha & Balakrishnan 1999, Nakaya et al 2000).

The compound taurine chloramine (Tau-Cl) is reported to act as an antioxidant; it is produced when hypochlorous acid, produced in the 'oxidant burst' of stimulated neutrophils and monocytes, interacts with taurine (Grimble 2006). Studies report that Tau-Cl downregulates the production of pro-inflammatory mediators and also has antibacterial properties (Schuller-Levis & Park 2004).

### Cell membrane stabilisation

Taurine reportedly acts as a modulator of membrane excitability in the central nervous system by

inhibiting the release of other neurotransmitters and decreasing mitochondrial release of calcium (Grimble 2006, Muramatsu et al 1978).

### Osmoregulation

It has been suggested that taurine plays an important role in osmoregulation due to its biophysical and biochemical properties (Huxtable 1992); however, this characteristic may be significant in some species and not in others.

### Calcium modulation

Taurine is a modulator of intra- and extracellular calcium levels and is able both to increase  $\text{Ca}^{2+}$  availability and to resist  $\text{Ca}^{2+}$  overload, depending on the circumstances (Bradford & Allen 1996).

### Xenobiotic conjugation

Taurine can conjugate with xenobiotics, and animal studies indicate that this is to a varying degree, being dependent on the animal species (Nakashima et al 1982).

### Neuroprotective

Taurine has been shown to prevent mitochondrial dysfunction in neurons and to protect against endoplasmic reticulum stress associated with neurological disorders (Kumari et al 2013).

## CLINICAL USE

### Deficiency: treatment and prevention

Taurine deficiency has not been significantly investigated in humans, so the information is generally derived from *in vitro* and animal studies. Taurine deficiency may be reflected by low plasma levels and these can be normalised by supplementary taurine.

### Growth and development

Findings from animal studies have shown that maternal diet supplemented with taurine during late gestation resulted in higher fetal plasma taurine levels and the offspring had increased postnatal growth, although the mechanism for this has not been elucidated (Hultman et al 2007).

Adult humans have a low activity of hepatic cysteine sulfinic acid decarboxylase and infants, especially premature infants, possess even lower enzyme activity. It has therefore been suggested that infants and particularly premature infants may have a greater requirement for preformed taurine than adults (Sturman 1975).

A systemic review by Verner et al (2009) assessed the effect of supplemental taurine versus no supplementation on the growth and development of preterm or low-birth-weight infants who were fed via enteral and parenteral nutrition. The authors identified nine small studies in which supplemental taurine was given with formula milk via enteral feeding in eight studies and supplemental taurine via parenteral nutrition in one study. Meta-analyses of

these randomised or quasi-randomised controlled trials showed that supplemental taurine did not result in improved outcomes. However, the infants in these studies were clinically stable and the majority were greater than 30 weeks' gestational age at birth, and it may be that taurine requirements are different among infants who are ill or in other subgroups.

### Cardiovascular disease (CVD)

Various studies have indicated reduced CVD risk from supplementary taurine intake alone or in combination with omega-3 polyunsaturated fatty acids (PUFA) (Militante & Lombardini 2004, Mizushima et al 1997). Studies by Yamori et al (2001, 2006) found that urinary taurine excretion was the most significant single factor to correlate inversely with ischaemic heart disease (IHD) mortality and they also highlighted the benefits of combined taurine and omega-3 fatty acids with respect to IHD mortality.

Elvevoll et al (2008) studied hypolipidaemic and antiatherogenic effects of taurine and omega-3 fatty acids in 75 healthy adults in a 7-week double-blind and parallel intervention trial where one group received omega-3 PUFA, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) (1.1 g EPA + DHA/day) and the second group received both omega-3 and taurine (425 mg/day). The results of this study demonstrated the beneficial effect of omega-3 combined with taurine, producing significant reductions in total cholesterol, low-density lipoprotein cholesterol and apolipoprotein (apo) B in the omega-3 + taurine group compared to the omega-3 group alone.

Taurine supplementation has also been reported to have a beneficial effect on plasma homocysteine levels in a study of 22 healthy middle-aged women aged  $40.3 \pm 4.7$  years (range 33–54 years) who were provided with 3 g taurine per day for 4 weeks; the levels of plasma homocysteine and serum thiobarbituric acid reaction products were significantly decreased (Ahn 2009). In contrast, a recent prospective case-control study nested in the New York University Women's Health Study of 223 cases of coronary heart disease (1986–2006) and age and menopausal status-matched controls (median age 58 years at baseline) found no association between serum taurine levels and coronary heart disease risk (Wójcik et al 2013).

### Hypertension

In a randomised controlled study of 31 borderline hypertensive adults and normal adults, 6 g taurine was given daily for 7 days; although the normal subjects did not experience any effects, the intervention group experienced a significant decrease in blood pressure and serum catecholamines (Fujita et al 1987).

In another randomised controlled trial of 11 healthy adult males taking 6 g taurine/day in the presence of a high-fat, high-cholesterol diet for 3 weeks, there was no change in blood pressure but there was a significant increase in very-low-density

lipoproteins and triglycerides (Mizushima et al 1996).

### Heart failure

Patients suffering from CHF have suboptimal taurine levels together with impaired myocardial energy production, myocyte calcium overload, and increased oxidative stress. Taurine plays an important role in the prevention of these conditions, so it is reasonable to suspect that supplemental taurine could have a beneficial role in HF management. Several small studies confirm it is a promising treatment, but further research is required. Oral taurine supplementation (2 g twice daily) improves left ventricular function in people with heart failure (New York Heart Association [NYHA] class II-IV). The study of 24 patients found that treatment was effective in 19 of the 24 patients after 4–8 weeks of active treatment. In addition, 13 of the 15 patients designated as NYHA functional class III or IV before receiving taurine could be designated as class II after they completed the study (Azuma et al 1983).

Following this, a double-blind, randomised, crossover study was performed with 14 patients with congestive heart failure receiving standard care also receiving taurine or placebo for 4 weeks (Azuma et al 1985). Compared with placebo, taurine significantly improved the NYHA functional class ( $P < 0.02$ ), pulmonary crackles ( $P < 0.02$ ) and chest film abnormalities ( $P < 0.01$ ). Pre-ejection period (corrected for heart rate) decreased from  $148 \pm 14$  ms before taurine treatment to  $137 \pm 12$  ms after taurine ( $P < 0.001$ ), and the quotient pre-ejection period/left ventricular ejection time decreased from  $47 \pm 9$  to  $42 \pm 8\%$  ( $P < 0.001$ ).

In a 1992 study, oral taurine (3 g/day) was found to be more effective than low-dose coenzyme Q10 (30 mg/day) for improving systolic left ventricular function after 6 weeks in a double-blind study of 17 patients with congestive heart failure secondary to ischaemic or idiopathic dilated cardiomyopathy, whose ejection fraction assessed by echocardiography was less than 50% (Azuma et al 1992).

In a randomised, single-blind, placebo-controlled clinical study involving 29 patients with heart failure, oral taurine supplementation of 500 mg three times a day taken for 2 weeks significantly improved exercise performance compared to placebo (Beyranvand et al 2011). Taurine supplementation resulted in increased exercise time, metabolic equivalents and exercise distance.

### Obesity

In a small randomised controlled trial, 15 healthy overweight adults were treated with 3 g taurine/day for 7 weeks, resulting in a significant decrease in serum triglycerides, although there was no change in high-density lipoprotein cholesterol or fasting glucose (Zhang et al 2004a). In a somewhat larger study of 30 overweight or obese non-diabetic young subjects, taurine supplementation (3 g/day; 1 g  $\times$  3 times/day) over a 7-week period resulted in a

beneficial effect on lipid metabolism and a decrease in body weight (Zhang et al 2004b).

### Diabetes

In animal studies taurine appears to exert a positive effect on insulin resistance and the complications of diabetes mellitus, including retinopathy, nephropathy, neuropathy, atherosclerosis and cardiomyopathy, independently of hypoglycaemic effect in several animal models (Ito et al 2012). However, human studies do not altogether support a role for taurine in the management of diabetes. Numerous studies have reported mixed findings regarding the effectiveness of taurine supplementation. Most studies have been small-scale with insufficient numbers of patients, and the mechanisms of reported beneficial effects remain to be elucidated. A study of 22 patients with type 2 diabetes mellitus (T2DM) who were treated with 3 g taurine/day for 4 months found no effect on glycated haemoglobin A<sub>1c</sub> or fasting glucose (Chauncey et al 2003). Likewise, a double-blinded, randomised, crossover study of 20 non-diabetic subjects who were overweight first-degree relatives of T2DM patients received a daily supplementation of 1.5 g taurine or placebo; the results of this study showed that taurine supplement did not exert any effect on blood lipid levels or insulin secretion or sensitivity in subjects with both genetic and some non-genetic factors predisposing them to T2DM (Bröns et al 2004). Similarly, Spohr et al (2005) showed that taurine supplementation had no effect on platelet aggregation in 20 healthy men with a predisposition to T2DM. A study by Franconi et al (1995) looking at 1.5 g/day of taurine supplementation for 90 days in 39 patients with insulin-dependent diabetes mellitus, with healthy age- and sex-matched subjects, found that taurine reduced platelet aggregation in patients with diabetes whereas aggregation was not affected in the controls. In a recent randomised, double-blind, crossover study, Moloney et al (2010) reported that taurine supplementation was beneficial regarding early detectable endothelial dysfunction in young men with type 1 diabetes: male patients (under 30 years of age) with type 1 diabetes and no evidence of macrovascular or microvascular disease were provided with 1.5 g/day taurine (500 mg three times daily) for 14 days. Taurine supplementation was reported to reverse the augmentation index, a marker of arterial stiffness, and restored conduit vessel dysfunction.

### Epilepsy

Several studies have investigated the role of taurine supplementation in the management of seizure disorders, overall producing inconsistent results. In some studies, patients with severe intractable epilepsy were administered taurine either orally or intravenously, varying in both duration and dose (from 200 mg/day and up to 21 g/day), making comparisons difficult. Additionally, most studies were uncontrolled and flawed with regard to methodology, thereby hindering accurate interpretation

(Fariello et al 1985). Some studies reported a reduction in seizure frequency (Takahashi & Nakane 1978), whereas others did not observe any benefit (Mantovani & DeVivo 1979).

The optimal dose of taurine supplementation in the management of epilepsy may be in the range of 100–500 mg/day, with a study by Gaby (2007) noting loss of antiseizure activity in some patients when the dose was increased to above 1.5 g/day. According to this study, beneficial effects are relatively short-lasting and are not maintained beyond a few weeks of treatment. Additional studies are required to clarify the role of taurine supplementation in practice.

### Liver disease

Taurine supplementation has been reported to ameliorate liver injury and improve liver function. In a small study of 24 patients with chronic hepatitis, 12 patients (average age 58 years; range 46–75 years) were given 2 g taurine three times a day for 3 months, and then treatment was stopped for 1 month and 12 patients (control group; an average of 58 years; 41–78 years) were given a placebo without taurine for 4 months. Taurine supplementation resulted in a significant decrease ( $P < 0.05$ ) in the activities of alanine aminotransferase and aspartate aminotransferase and likewise thiobarbituric acid reaction product values were also significantly affected (Hu et al 2008).

### Exercise and sport

A number of small studies have reported that taurine supplementation may be useful for exercise performance and/or reducing muscle soreness and damage; however further research is required before a definitive conclusion can be made. It is most likely for this reason that it is included in many 'energy' and 'sports' drinks.

In a randomised, double-blind, crossover study, taurine supplementation was reported to significantly improve exercise performance of eight well-trained competitive male middle-distance runners (age  $19.9 \pm 1.2$  years). Active treatment consisted of 1000 mg taurine taken 2 hours prior to a simulated 3-km time trial on a treadmill and resulted in significant differences in the overall 3-km time trial performance ( $P = 0.013$ ) (Balshaw et al 2013). A recent randomised study of 21 male participants (mean age  $21 \pm 6$  years;  $n = 11$  taurine group and  $n = 10$  placebo group) reported that 14 days of taurine supplementation resulted in less muscle damage and better performance after eccentric exercise (three sets until exhaustion, with eccentric exercise of the elbow flexors on the Scott bench, 80% one repetition maximum) (da Silva et al 2014).

In contrast, in a double-blind study, Rutherford et al (2010) found no effect of a smaller acute dose of taurine (1.66 g) on endurance time trial performance and whole-body metabolism in well-trained cyclists. Supplementation of taurine 1 hour before 90 minutes of submaximal cycling followed by an ~25-minute time trial was not effective in improving

performance. The differences in the effects of taurine on exercise performance across studies may be due to methodological differences, including factors such as size of the taurine dose, ingestion timing and varying exercise protocols.

Taurine has been shown to attenuate delayed-onset muscle soreness and muscle damage induced by high-intensity exercise in 36 untrained male volunteers. The combination of 2.0 g taurine and 3.2 g branched-chain amino acids three times a day for 2 weeks prior to and 4 days after elbow flexion eccentric exercise was superior to single or placebo supplementation (Ra et al 2013).

### Practice points/Patient counselling

- Taurine can be readily obtained by eating meat, fish and seafood.
- Most people are able to produce taurine naturally; however, young infants are limited in their ability to produce taurine and obtain their dietary taurine from either breast milk or supplemented milk formulas.
- Plasma taurine levels can be low in some illnesses and conditions (such as sepsis) and can be restored with supplementary taurine.
- At present there is no evidence to prove the benefit of taking taurine during breastfeeding.
- Traditionally taurine has been used in CVD, hypertension and hyperlipidaemia. Several small studies indicate that there may be significant benefits for people with congestive heart failure.
- 'Energy' soft drinks may contain taurine as well as caffeine, although the potential interactions between these two ingredients have not been determined.

### DOSAGE RANGE

Taurine is administered orally, usually in divided doses; adult dosage is generally 500 mg to 3 g daily and paediatric dosage 250 mg to 1 g daily, and these are dependent on the size and age of the child.

There appear to be very few health concerns regarding taurine supplementation, although safety has been of interest recently because of the high intakes that can be easily consumed from some sports drinks (Munro & Renwick 2006).

### TOXICITY

In a risk assessment by Shao and Hathcock (2008), the following recommendations have been made: no observed adverse effect level and lowest observed adverse effect level  $>10$  g taurine/day; observed safe level 3 g/day; upper level for supplements: 3 g/day.

### ADVERSE REACTIONS

Taurine administration appears to be safe, even at higher doses. Children should be monitored for any adverse side effects and supplementation ceased if any adverse effects develop.

At dosages of 2 g/day, patients with psoriasis experienced intense temporary itching (Kendler

1989); dosages of 1.5 g taurine/day caused nausea, headache, dizziness and gait disturbances in some epileptic patients (Van Gelder et al 1975). Recently a case was reported of a 33-year-old female who experienced anaphylaxis due to taurine-containing drinks. The response was due to ingestion of synthetic taurine, as confirmed by an oral challenge test. In contrast the patient had no signs or symptoms of an adverse reaction after ingesting 1500 mg natural taurine (Lee et al 2013).

## SIGNIFICANT INTERACTIONS

Controlled studies are not available and at present there are no known drug interactions with taurine.

### CONTRAINDICATIONS AND PRECAUTIONS

High doses of taurine (10 g/day for 6 months) have been taken without any major side effects (Durelli et al 1983); the longest duration recorded has been 1 year (Colombo et al 1988). Many commercially-available energy drinks contain substantial amounts of supplementary taurine (1000 mg/L) and, as there is very little information about the effects of these doses, the young, people who are immunocompromised, pregnant and nursing mothers should consult a relevant health professional before excessive intake. People with psoriasis and epilepsy should avoid high intakes of taurine.

### PREGNANCY USE

At present there is no evidence to prove the benefit of taking supplementary taurine during pregnancy.

## PATIENTS' FAQs

### *What will this supplement do for me?*

Decreased plasma levels can be normalised by taurine supplementation. There is some evidence that taurine may be a useful treatment in CVD and heart failure and possibly enhance physical exercise performance.

### *When will it start to work?*

Plasma taurine levels can increase within a week of taking supplementary taurine.

### *Are there any safety issues?*

Generally taurine supplementation has a good safety profile.
