DEDICATION

This book is dedicated to the memory of Mary Frances Picciano, Ph.D., former Senior Nutrition Research Scientist at the Office of Dietary Supplements, National Institutes of Health. Her interest, foresight, and willingness to have the Office of Dietary Supplements support a partnership with the American Herbal Products Association and the University of Massachusetts made this work possible.

PREFACE TO THE FIRST EDITION

Increased attention on herbal products, both in the marketplace and in the legislative arena, has created a need for wider public access to data regarding the safety of botanicals. The passage of the Dietary Supplement Health and Education Act in October, 1994, furthered the need for such information, as this law authorizes the use of cautionary labeling for dietary supplements, including those that contain herbs.

The American Herbal Products Association (AHPA), through its Standards Committee, convened a special SubCommittee (hereinafter "the Committee") to address this need. The Committee members identified considerable safety data in varied texts and journals and discovered that some attempts to classify herbs had been undertaken in several other countries. No comprehensive compilation or review of this data for botanical ingredients sold in the North American marketplace, however, was available in a useful format.

The goal of the present work is to find a rational platform for the evaluation of herb safety, neither assuming that all natural substances are inherently safe, as some popular references suggest, nor blindly accepting reports of toxicity from uncritical sources. In undertaking this task, the Editors met with information that presented significant challenges. Many authors utilize unreferenced data, perpetuate historical inaccuracies or display inherent biases against the use of botanicals. Also, contemporary reviews of the toxicity of many herbs are not available. Nonetheless, the Editors are confident that the body of information presented here is largely accurate. It is our sincere hope that readers of this work will find it to be a valuable reference and will address all useful criticisms to our attention.

In sponsoring this effort, the American Herbal Products Association (AHPA) addresses the common interest of industry, the public, and regulatory agencies in assuring safe access to a wide range of herbs and herbal products. This document provides accurate data to guide manufacturers and consumers in safe utilization of herbal products. As the most broadly established trade association in the herbal marketplace, AHPA has, by supporting and sponsoring the creation of this work, furthered the herb industry's leadership role in promoting the responsible use of herbs.

PREFACE

This second edition of AHPA's *Botanical Safety Handbook* represents a significant modification from the first edition, published in 1997. At the same time, the second edition reflects the continued commitment of the American Herbal Products Association (AHPA) to provide accurate information about the safe use of herbs in a practical and accessible format.

The original edition classified botanical ingredients in four safety classifications to differentiate those that can be safely consumed when used appropriately from those for which some contraindication or other restriction is known, as well as those that should be used only under the guidance of a qualified expert. A handful of entries in that edition were also placed in a separate class if the editors had insufficient data for classification. The revised edition largely retains this safety classification system, except that if the review process did not provide enough information to make a knowledgeable decision on any specific herb, that species was removed from the text.

The present edition also includes a separate classification system to address what is known about the potential for an herb to interact with any drugs. Each of the herbs listed here is identified in one of three interaction classes to differentiate between those for which no clinically relevant interactions are expected and those for which clinically relevant interactions are biologically plausible or are, in fact, known to occur.

Botanical products continue to be broadly used throughout the world. In the United States, most herbs are sold in loose form or as tablets, capsules, or tinctures, and regulated as dietary supplements (this product class also includes vitamins, minerals, amino acids, and numerous other ingredients). Many herbs are also common flavorings for foods, or are used in teas. In addition, a handful of herbs provide active ingredients in non-prescription drugs. The U.S. marketplace for herbal products in the supplement category has increased significantly in the years since publication of the first edition, and the retail value of this product category grew from $3 billion in 1996 (Muth et al. 1999) to $5 billion in 2010 (Anon. 2011).

An even more significant change in the past 15 years has been the emergence of the Internet and online scientific databases as tools for accessing scientific information. The first edition of this book relied almost entirely on secondary references (i.e., books and other summaries of traditional or scientific information), and the editors of that document used their personal collections of such texts to compile the information needed to make safety determinations for the plants addressed in it. On the other hand, the process for compiling information for this second edition, as described in the introduction, involved a much more thorough review of primary references (i.e., published research papers, case reports, and other original literature). Thus, while the first edition included just 280 references to evaluate the over 500 plants addressed therein, this revision cites 301 references just in its treatment of St. John's wort herb (*Hypericum perforatum*), ginkgo leaf and seed (*Ginkgo biloba*), and garlic bulb (*Allium sativum*).

Any attempt to provide a summary of safety information on botanicals will encounter certain prejudices and inaccuracies in the published record. One such prejudice, often repeated in reviews of herbal medicines and dietary supplements, is the view that consumers have been led to believe the myth that "anything natural is safe" (Barnes 2003; Dasgupta and Bernard 2006). While one survey of consumer attitudes in Canada found that 7 percent of respondents completely agree that there is no risk associated with products made with natural ingredients (Anon. 2005), there are no published analyses of consumer beliefs that indicate that there is broad acceptance of any such assumption.

It is, however, true that many of the plants that enjoy broad culinary and traditional therapeutic usage are generally safe. We can safely season our food with any number of herbs to make a meal more flavorful. We can appreciate a delicious cup of peppermint leaf or rose hips tea, or safely take an herbal supplement containing dandelion root, saw palmetto berries, or any number of other herbs. Although allergies and individual reactions have been recorded for a few herbs that are widely used in foods and supplements, such individual concerns are also seen with many other foods, and do not diminish the safety profile of the many herbs that are widely regarded as safe.

On the other hand, and as everyone knows, there are any number of plants that are highly toxic, even deadly. Every savvy North American hiker knows to stay away from poison ivy (*Toxicodendron* spp.) when walking in the woods. The death sentence imposed on Socrates by an Athenian jury 2,400 years ago was carried out with a fatal dose of poison hemlock (*Conium maculatum*). The poison curare, a blend of several equatorial rain forest plants (e.g., species of *Chondrodendron*, *Curarea* and *Strychnos*) is used by some South American hunter cultures to make their arrows more deadly (Schultes and Raffauf 1990). And in

the "concrete jungle" of Los Angeles, two young boys died in 2000 from ingesting a few leaves of the ubiquitous oleander (*Nerium oleander*) (Garrison 2000). Federal law and good common sense, however, prevent the use of any such highly toxic plants in products that are readily available to consumers.

The revised edition of the *American Herbal Products Association's Botanical Safety Handbook* fills the need for a reference that neither promulgates the myth that all herbs are always safe, since they are "natural," nor accepts without review every case report or conceptual theory that draws an unsubstantiated or illogical conclusion of harm from an herb or herbal product. In assembling this revision, significant effort has gone into sorting out references that are factual from those that are inaccurate. Texts that communicate that all natural substances are inherently safe would not have been included here, though in fact no such documents were encountered. More effort was needed to avoid blind acceptance of reports that purport to identify herbal safety concerns with unreferenced statements or incomplete records of specific herbal preparations, which are unfortunately quite common, even in peer-reviewed scientific journals. Such references may nonetheless be included in this text to provide readers with a complete record, though efforts were made to highlight any perceived flaws.

Even as the consumer market for herbal supplement products expands and scientific information becomes more accessible, the goals of the second edition of the AHPA's *Botanical Safety Handbook* are essentially the same as those of the original edition. Companies that market herbal products are bound by federal regulations to disclose known safety concerns that may result from a product's use. Health care providers, especially those lacking in training or experience in the use of herbs, are in need of accurate data if they are to provide guidance to their patients who use herbs. And consumers of herbs and herbal products need readily understandable information to assist them in making safe and appropriate health care choices. AHPA's *Botanical Safety Handbook, 2nd edition* is designed to provide the information needed by each of these audiences.

It should be recognized, however, that this reference is not an herbal user's guide. Numerous excellent references exist that provide information on the uses and benefits of herbs. Readers of the present document are advised to seek out these references, or to consult with experts qualified by training and experience, for advice on when and how to use herbs for their health benefits.

The editors are confident that the body of information presented in this second edition of the AHPA *Botanical Safety Handbook* is largely accurate, and hope that readers of this work will find it to be a valuable reference. Useful criticisms will nonetheless be welcome, and should be addressed to the attention of the editors.

ACKNOWLEDGMENTS

Appreciation was expressed in the first edition of the *Botanical Safety Handbook* to three individuals who were essential to AHPA's decision to take on the task of creating this document. This appreciation is restated now to Daniel Gagnon, for his vision and persistence; to John Hallagan, for the encouragement borne of his own experience; and to the late William Appler, for so clearly seeing the value of this text when it was just an idea.

The members of this edition's Expert Advisory Council met together on a regular basis for nearly five years, all on their own time, and without any financial compensation. The expertise and experience embodied in these individuals are unsurpassed, and without them the work could not have proceeded beyond a collection of references, as it was through their efforts that these references were evaluated and organized into the present text. Biographies of each of these individuals follow.

Additional specific guidance was occasionally solicited from a number of other experts, and thanks are due to Dennis Awang, Dan Bensky, Paul Bergner, Mary Bove, Eric Brand, Josef Brinckmann, Francis Brinker, Chanchal Cabrera, Todd Caldecott, John Chen, Sigrun Chrubasik, Emily Cohen, Cynthia Copple, Amanda McQuade Crawford, De-Qiang Dou, Lana Dvorkin-Camiel, Andrew Ellis, Thomas Avery Garran, Christopher Hobbs, David Hoffmann, Prashanti de Jager, K.P. Khalsa, Vasant Lad, Reinhard Länger, Wilson Lau, Phyllis Light, Russell Molyneux, Vikram Naharwar, Robert Newman, Xie Peishan, Sebastian Pole, Bill Schoenbart, Atreya Smith, Ed Smith, James Snow, Alan Tillotson, Jonathan Treasure, Nancy Turner, Donnie Yance, Eric Yarnell, and Yifang Zhang.

Thanks are also due to the generations of herbalists and scientists around the world whose research and experience have provided the basis for our understanding of the safety of medicinal plants. Their work and publications have created a significant foundation for our understanding of the safety of the botanicals reviewed in the present text.

Appreciation is also due to Joseph Betz, Ph.D. and the late Mary Frances Picciano, Ph.D. of the Office of Dietary Supplements (ODS) at the National Institutes of Health. Dr. Betz shared his ideas on the makeup of the Expert Advisory Council and on the importance of addressing the potential for an herb to modify the effect of a drug taken concomitantly, commonly referred to as an herb–drug interaction (a topic that was outside of the scope of the first edition). Dr. Picciano facilitated ODS's significant financial support of the revision process and ensured that the planned revision met high academic and scientific standards.

A number of research assistants helped to acquire and manage the thousands of documents reviewed in this project. A work of this scope would not have been possible without the enthusiastic assistance of Jamie Blair, Brittney Laramee, Annie Winkler, Ryan Rogan, Rye Zemelsky, Kathleen Broadhurst, Jennifer Kehoe, Margo Voskanian, Jennifer Hast, and Abigail Haines. Thanks are also due to Constance Parks and Bill Schoenbart for their detailed reading and editing of the manuscript.

FINANCIAL SUPPORT

This work was made possible with financial support from the Office of Dietary Supplements at the National Institutes of Health, and in-kind contributions by the Medicinal Plants Program at the University of Massachusetts, Amherst.

Financial contributions to support this effort were also made by numerous AHPA member companies and individuals identified as follows.

EDITORS

Zoë Gardner, M.S., Ph.D.(c)
Research & Development Manager, Traditional Medicinals

Fascinated by the connection between people and plants, Zoë Gardner has been studying, researching, and teaching on the production, conservation, quality, safety, and appropriate use of medicinal plants since 1998. After completing her undergraduate degree in environmental studies at the Audubon Expedition Institute, Zoë helped to establish the Medicinal Plant Program at the University of Massachusetts, earning her master's degree there in plant & soil sciences. More recently, Zoë joined the Research & Development Department at Traditional Medicinals, a leading producer of botanical dietary supplements. A self-proclaimed "herb nerd," Zoë is currently completing her Ph.D. on medicinal plant quality and safety.

Michael McGuffin
President, American Herbal Products Association

Michael McGuffin has been active in the herbal industry since 1975, having owned and managed both retail and manufacturing businesses in this field. He is the managing editor of *Botanical Safety Handbook, 1st edition* (1997) and of *Herbs of Commerce, 2nd edition* (2000). He serves on the boards of the American Herbal Pharmacopoeia and United Plant Savers; on the Advisory Board of the USC School of Pharmacy Regulatory Science Program; and as chair of the U.S. Technical Advisory Group for ISO/TC 249, the International Organization for Standardization's Technical Committee on Traditional Chinese Medicine (provisional title). Michael maintains active involvement with regulatory agencies, and served on FDA's Food Advisory Committee Working Group on Good Manufacturing Practices for Dietary Supplements (1998–1999), FDA's Food Advisory Committee's Dietary Supplements Subcommittee (2003–2005), and California's Office of Environmental Health Hazard Analysis Food Warning Workgroup (2008–2010).

EXPERT ADVISORY COUNCIL

Roy Upton, RH (AHG), DAyu
Executive Director, American Herbal Pharmacopoeia

Roy Upton has been trained in traditional Ayurvedic, Chinese and Western herbal traditions, has studied Native American and Caribbean ethnobotanical traditions, and is a professional member of the American Herbalists Guild. He is the executive director and editor of the *American Herbal Pharmacopoeia* and a member of the Standards Committee of the American Herbal Products Association and advisory committees for the American Botanical Council, AOAC International, and NSF International. Along with being an author and lecturer, Roy was co-founder and past president of the American Herbalists Guild and is the herbalist and director of the California-based herbal company Planetary Herbals.

Soaring Bear, Ph.D.
Technical Information Specialist (Ret.), National Library of Medicine

Dr. Soaring Bear has been collecting herbal data, with a focus on toxicology, since the early 1970s. He earned a B.S. in biochemistry with honors and a Ph.D. in pharmacology from the University of Arizona. His doctoral research on structure–activity relationships and chemical interactions provides him with a unique perspective on bioactivity of herbs. He created herbmed.org and edited over ten thousand quick summaries and links into Medline. His work at the National Library of Medicine in the Medical Subject Headings (MeSH) section included significant revisions of the herbal, alternative medicine, and chemistry sections of MeSH, which improves the quality of millions of searches done every day on the pubmed.gov database.

David Winston, RH (AHG)
President, Herbalist & Alchemist

David Winston is an herbalist and ethnobotanist with over 40 years of training in Cherokee, Chinese, and Western/Eclectic herbal traditions. David is a founding/professional member of the American Herbalists Guild and has been in clinical practice for over 33 years. He is an herbal consultant to many physicians and other healthcare professionals throughout the U.S. and Canada. David is also the president of Herbalist & Alchemist, Inc. and founder and director of David Winston's Center for Herbal Studies and the Herbal Therapeutics Research Library. He is the author of numerous texts on herbal medicine, is an internationally known lecturer, and teaches frequently at medical schools, symposia, and herb conferences.

Daniel Gagnon, M.S., RH (AHG)
President, Herbs, Etc.

Daniel Gagnon, owner of Herbs, Etc., has been a practicing herbalist since 1976. Daniel has studied medical herbalism, pharmacognosy, and related subjects at the Santa Fe College of Natural Medicine, the College of Santa Fe, and the University of New Mexico. He received his B.S. in herbal medicine from the North American College of Botanical Medicine and his M.S. in herbal medicine from the Scottish School of Herbal Medicine. Daniel was a faculty member of the North American College of Botanical Medicine for over 10 years and currently serves as an herbal consultant to healthcare providers. He is the author of several books on herbal medicine.

Aviva Jill Romm, M.D.
Director, Integrative Medicine for Women and Children

Before becoming a physician, Dr. Aviva Romm was a recognized expert in midwifery, women's health, and women's and pediatric botanical medicine, and she practiced as a homebirth midwife and herbalist for over 20 years. A graduate of the Yale School of Medicine, she completed her internship in internal medicine (Yale) and her residency in family medicine (Tufts). She was the president of the American Herbalists Guild, the founder and director of Herbal Medicine for Women, a distance learning program, and is the medical director for the American Herbal Pharmacopoeia. Dr. Romm has been active in establishing standards for botanical medicine practice and education in the United States, and is the author of numerous texts on botanical medicine, pregnancy, and children's health.

Tieraona Low Dog, M.D.
Director of the Fellowship, Arizona Center for Integrative Medicine, University of Arizona College of Medicine

Dr. Tieraona Low Dog's extensive career in natural medicine began more than 25 years ago. A graduate of the University of New Mexico School of Medicine, Tieraona has served as president of the American Herbalists Guild and is currently the Director of the Fellowship at the Arizona Center for Integrative Medicine at the University of Arizona School of Medicine. She has been involved in national health policy and regulatory issues, serving previously on the White House Commission of Complementary and Alternative Medicine and as a member of the Advisory Council for the National Center for Complementary and Alternative Medicine, and is currently chair of the U.S. Pharmacopeia Dietary Supplements and Botanicals Expert Committee.

Mary Hardy, M.D.
Medical Director, UCLA Center for Integrative Oncology

Dr. Mary Hardy is an integrative medicine physician who received her Doctor of Medicine degree from Louisiana State University School of Medicine and studied medical ethics at Harvard Divinity School and Loma Linda University. She has studied with herbal practitioners in the United States and Europe and visited traditional healers in Peru, Kenya, South Africa, Morocco and China. She is the complementary and alternative medicine expert for a number of research projects conducted by the Southern California Evidence-Based Practice Center at the RAND Corporation, co-chairperson of the Clinical Practice Committee of the Academic Consortium of Integrative Medicine, and associate director of the UCLA Botanical Research Center, funded by the National Institutes of Health.

Lyle Craker, Ph.D.
Professor, Medicinal Plant Program, University of Massachusetts Amherst

Dr. Lyle Craker has been a researcher in the field of medicinal plants for over 30 years. With a Ph.D. in agronomy from the University of Minnesota, he is founding and past editor of the *Journal of Herbs, Spices, and Medicinal Plants*, founding and current executive editor of the *Journal of Medicinally Active Plants*, past chairman of the International Society for Horticultural Science (ISHS) Section on Medicinal and Aromatic Plants, organizer of the Herb, Spice, & Medicinal Plant Working Group within the American Society for Horticultural Science (ASHS), and an organizing member of the International Council on Medicinal and Aromatic Plants and the American Council for Medicinally Active Plants. He is an advisory board member of the American Botanical Council and serves on the board of the AHPA Foundation for Education and Research on Botanicals.

INTRODUCTION

The second edition of AHPA's *Botanical Safety Handbook* provides information on a number of safety factors that may affect an individual's decision to ingest any of the herbal* substances listed in this work. The information was prepared through a process that involved identification of relevant publications on each botanical, as well as a review by experts qualified by training and experience in the traditional and therapeutic use of herbs and herbal products.

Each of the botanical ingredients† included in this text is classified into one or more Safety Class, and also into an Interaction Class, details of which are described below. These classifications, as well as a synopsis of pertinent information from reviewed references, are presented in a Quick Reference Summary, which provides basic data needed to understand safety issues associated with each botanical. This summary is followed by a section titled Review Details in which more in-depth information is presented when available. Thorough descriptions of the templates and contents of each of these sections are provided later in this introduction.

DETERMINATION OF HERB SAFETY

In developing this document, the voices and experience of various organizations and individuals were considered. A primary source of guidance and inspiration for the first edition of this text was the work of the World Health Organization (WHO). In 1991, WHO's Programme on Traditional Medicines presented Guidelines for the Assessment of Herbal Medicines at the Sixth International Conference of Drug Regulatory Authorities. These guidelines, which were subsequently reviewed and adopted by WHO, propose that the safety of herbal medicine be assessed according to the following principle:

> *…that if the product has been traditionally used without demonstrated harm, no specific restrictive regulatory action should be undertaken unless new evidence demands a revised risk-benefit assessment. (WHO 1991)*

The editors of the first edition adopted this principle from the WHO Guidelines and this view has been maintained for the compilation of the present work.

In his classic text, *The Problem of Poisonous Plants*, J.M. Kingsbury provides further direction by calling attention to the fact that there are many instances in which a plant contains a measurable amount of a toxic substance, though the plant may be poisonous only if consumed in excessive quantities. He notes:

> *In order for a plant to be functionally poisonous, it must not only contain a toxic secondary compound, but also possess effective means of presenting that compound to an animal in sufficient concentrations, and the compound must be capable of overcoming whatever physiological or biochemical defenses the animal may possess against it. Thus the presence of a known poison principle, even in toxicologically significant amounts, in a plant does not automatically mean that either man or a given species of animal will ever be effectively poisoned by the plant. (Kingsbury 1979)*

In examining the relevance of Kingsbury's position, it is of interest to revisit the means by which concerns for the safety of herbs arise. Toxicity studies are often conducted by feeding abnormally high quantities of an herb or isolated constituent of an herb to laboratory animals. For example, Bensky and Gamble report in their monograph on mulberry leaves that "long-term use of 250 times the normal human dose in mice produced both liver and kidney damage" (Bensky and Gamble 1986). Data based on excessive consumption have little relevance to the practical use of herbal supplements, and such findings are clearly not pertinent to normal human consumption patterns. In addition, information is sometimes available that identifies an LD_{50} for an herb, herbal preparation, or isolated compound (i.e., the "lethal dose" at which 50 percent of test animals are killed by the studied substance), but often fails to specify the concentration or form of the specific material used. Such incomplete data cannot be accurately applied to safety evaluations of human consumption.

Significant toxicity data exist for isolated constituents of a wide variety of commonly available foods, as well as herbs. Potatoes, as a member of the Solanaceae family, contain trace amounts of the toxic glycoalkaloid solanine, especially in green parts of the potato tuber (Turner and Szczawinski 1991). Although the symptoms of solanine poisoning are serious, potatoes themselves are generally considered to be a safe food. While consumption of

* The terms "herbal" and "botanical" are used interchangeably throughout this work.

† Or occasionally, groups of ingredients. Examples are listings for more than one plant part from a specific taxa, when the safety concerns for these are not different, or groups of two or more species within a genus, when these have common safety profiles.

as little as five grams of nutmeg can cause marked hallucinations (Sangalli and Chiang 2000), no safety concerns prevent us from enjoying a sprinkle of this characteristic flavor on our holiday eggnog. Similarly, no safety concern is associated with a candy flavored with peppermint oil, though as many as 26 toxins are reported to have been observed in the plant (Duke 1989). Safety concerns for herbal products need not be extrapolated from constituent profiles with any more alarm than is appropriate for foods.

In following the principles espoused by WHO and incorporating the ideas delineated by Kingsbury, it is imperative that herb safety be assessed according to the intended use of the substance within the historical context of its use. In establishing safety classifications, this work has intentionally refrained from automatically applying information on the toxicity of isolated constituents or considering excessive or irresponsible consumption patterns. The decision to place an herb in a restrictive safety class was made only if the use of the herb in a normal dosage range is documented as presenting a safety concern, or if the amount of a harmful or potentially harmful constituent obtainable from the crude plant is of sufficient quantity to be problematic.

ADDRESSING POTENTIAL DRUG INTERACTIONS

The issue of herb–drug interactions was specifically excluded from the first edition of this work, since at that time very little accurate information had been developed on this subject. In the years since then, this topic has been much more prominently studied. Some early publications on the subject were largely speculative, but researchers have now begun to develop scientifically based data that have measured actual effects of several herbs on the metabolism of selected drugs or on drug-metabolizing enzymes. At the same time, emerging research on many specific botanicals has confirmed that no drug interactions should be expected with these herbs.

Drug interactions are generally divided into two categories: pharmacodynamic interactions, in which the physiological effects of drugs or botanicals interact (including additive and opposing effects), and pharmacokinetic interactions, in which an interaction affects a drug's absorption, metabolism, or excretion, and changes the amount and duration of a drug's bioavailability (see CYP450 and P-gp interactions profile in Appendix 3). While pharmacodynamic interactions are generally predictable based on the pharmacological effects of drugs and botanicals, pharmacokinetic interactions, until identified through testing or well-documented case reports, generally cannot be predicted.

This work focuses primarily on pharmacokinetic interactions, although a small number of pharmacodynamic interactions are also listed, especially when such interactions may have significant health consequences (e.g., additive effects on heart medications or antiplatelet drugs). In pharmacokinetic herb–drug interactions, the severity of an interaction is generally based on the toxicity of the drug being used or the consequences if the therapeutic dose is not achieved. When herbs are used with drugs that have a narrow therapeutic window (i.e., small difference between the effective dose and the toxic dose, such as with digoxin, warfarin, lithium, cyclosporine, phenytoin, and theophylline), supervision by a qualified healthcare practitioner is strongly advised.

Both pharmacodynamic and pharmacokinetic interactions may have positive effects, such as increasing the efficacy or bioavailability of drugs or botanicals. Such positive therapeutic interactions are not covered in this text, unless the interaction also poses a safety concern.

SELECTION OF THE EXPERT ADVISORY COUNCIL

Methods and considerations for safety evaluations that are outlined in the U.S. Institute of Medicine's (IOM) *Framework for Evaluating the Safety of Dietary Supplements* provided guidance in the literature collection and review processes that went into the creation of this text (IOM 2005). This IOM document also highlights the importance of using experts from a number of fields related to dietary supplements. Consistent with this advice, an advisory panel of qualified experts was assembled at the outset of this project. All members were selected for their extensive knowledge and experience in areas such as medicine, clinical herbalism, pharmacology, biochemistry, or traditional herbal medicine systems (e.g., traditional Chinese medicine or Ayurvedic medicine). When knowledge of a particular topic or botanical was not found in the Expert Advisory Council, the experience and opinions of outside experts were solicited.

LITERATURE REVIEW METHODS

Systematic literature searches were conducted in several electronic databases from January 2007 to May 2010, using search terms developed in cooperation with a technical information specialist from the National Library of Medicine, as follows:

- PubMed ([Latin name] OR [standardized common name]) AND (adverse effects OR adverse reaction OR safety OR tolerability OR drug interactions OR herb–drug interactions OR poisoning OR toxic OR toxicity OR toxicology OR drug toxicity OR teratogen* OR contraindicat* OR cytochrome OR p450 OR pregnancy OR lactation OR breast feeding OR breast milk OR pharmacodynamics OR "[MeSH term]/adverse effects" OR "[MeSH term]/toxicity" OR (Case Reports[ptyp]))
- EMBASE and Biological Abstracts ([Latin name] OR [standardized common name]) AND (adverse drug reaction OR safety OR tolerability OR drug tolerability OR herb drug interaction OR drug interaction OR drug contraindication AND contraindication OR poisoning OR intoxication OR drug toxicity OR toxic OR toxicity OR toxicology OR teratogen OR teratogenic OR teratogenicity OR cytochrome OR pregnancy OR lactation)
- TOXNET ([Latin name] OR [standardized common name]) AND (teratogen* OR adverse effects OR safety OR tolerability OR drug interactions OR poisoning OR toxicity OR cytochrome OR contraindications OR pregnancy OR lactation) NOT PubMed

Literature selected from these searches for review included meta-analyses, systematic reviews, other reviews, clinical trials, human, animal and *in vitro* pharmacological studies related to safety (including drug interaction studies), toxicity studies including reproductive and developmental toxicity studies, epidemiological studies, and ethnobotanical surveys. Articles on combination products and homeopathic products were generally excluded. No language restrictions were imposed, so publications in other languages were included whenever possible, but the review focused on English language publications.

Besides this extensive literature review, numerous other publications were consulted. These consisted primarily of authoritative references on the traditional use of herbal medicines, and also included regulatory documents, ethnobotanical records, pharmacopoeial texts, and writings on toxicology, food ingredients, and other relevant topics.

Literature was identified, obtained, and summarized by the research editor. Full literature summaries were presented to the Expert Advisory Council and other experts as needed, for review and assignment of safety and interaction ratings, contraindications, and precautions. Ratings were assigned by the Expert Advisory Council bearing in mind the history of use of the botanical under review.

No formal assessment of the validity of each reference was undertaken in this process, although the levels of evidence afforded by different types of publications (i.e., case report vs. randomized, placebo-controlled double-blind study) were actively considered during the review process. In addition, it was observed that some identified publications were of limited value, especially those that lack sufficient detail about the specific herbal preparation addressed, and case reports that postulate a causal relationship between a specific herbal ingredient and a reported adverse effect, without consideration for confounding factors such as patient history or concomitant drug use. Some such references were nonetheless retained, though the editors attempted to call attention to their perceived flaws.

Additional articles in scientific journals that were published subsequent to the 2007 to 2010 review were also considered for several entries during the editing stages that followed the process described above.

THE REVIEW PROCESS AND CLASSIFICATION

The herbal ingredients included in this edition are very nearly the same as those included the first edition, published in 1997. Some other herbs were added in order to include ingredients that have become more prominent in the U.S. marketplace in the interim. A few herbs addressed in the first edition are not included here, usually because no relevant contemporary publications were found and evidence from historical sources was lacking or insufficient.

Classifications are included for each part of the plant* identified in an entry, and are for dried plant material, unless otherwise stated. Classifications address only the identified part of the herb in its whole, cut, or powdered form, as a raw material or as an ingredient in a finished product (tablets, capsules, teas, etc.); or as a decoction, tincture, or extract prepared from that plant part by a traditional process. Concentrated extracts, extracts with added compounds, or compounds isolated from botanicals may be expected to have different physiological effects and safety and interaction considerations than the source

* Plant parts identified as "herb" consist of the leaf and stem of the identified plant, and this term is generally used only for nonwoody plants. A plant part identified as "above-ground parts" means all of the plant above the ground, so it generally includes not only leaf and stem, but also flowers, fruits, and seeds, depending on the state of maturity of the plant at the time of harvest. All other plant parts (e.g., bark, leaf, root) are each identified with the generally used botanical term.

botanical, and classifications should not be extrapolated to other such ingredients without additional review.

Classifications are generally based on data that are associated with use of the specific herb and in the quantities generally consumed for a health-promoting or therapeutic effect. Any cautions may therefore be somewhat overstated for an herb that appears in the market in a smaller amount as part of a combination product, or for herbs that are used as flavorings in less than therapeutic quantities.

Each herb is placed in two classes based on all of the information included, along with the experience of the Expert Advisory Council. The first is the **Safety Class**, which evaluates the safety of a particular herb. The second is the **Interaction Class**, which provides information on what is currently known about the potential for an herb to alter the effect of prescription or non-prescription drugs when the herb and drug are used concomitantly. Central to the appropriate application of this document is the understanding that classifications are based on an assumption of rational, informed use of herbs and herbal products.

Classes are defined below, and are followed by bullet points which list criteria and considerations for inclusion in each particular class.

SAFETY CLASSES

Class 1. Herbs that can be safely consumed when used appropriately.

- History of safe traditional use
- No case reports of significant adverse events with high probability of causality
- No significant adverse events in clinical trials
- No identified concerns for use during pregnancy or lactation
- No innately toxic constituents
- Toxicity associated with excessive use is not a basis for exclusion from this class
- Minor or self-limiting side effects are not bases for exclusion from this class

Class 2.[*] Herbs for which the following use restrictions apply, unless otherwise directed by an expert qualified in the use of the described substance:

2a: For external use only

- Toxicity demonstrated with crude preparation taken orally at traditional dose
- Adverse event data in humans with probability of causality of toxicity (e.g., hepatotoxicity, nephrotoxicity, neurotoxicity) associated with oral use

2b: Not to be used during pregnancy

- Traditional use contraindicates
- Traditional use as an abortifacient or uterine stimulant
- Relevant adverse event data in humans exist and have probability of causality
- Data in animals suggesting teratogenicity or other adverse effects on the fetus or mother, with reasonable application to humans
- For plants with common food uses, standard dose is in excess of typical food amounts

2c: Not to be used while nursing

- Traditional use contraindicates
- Relevant adverse event data in humans exists and has probability of causality
- Potential hepatotoxicity or neurotoxicity
- Bioavailability of constituents of concern in breast milk has been demonstrated

2d: Other specific use restrictions as noted

- Information exists that use may be unsafe for specific populations
- Dosage level outside of a standard range known to cause adverse effects

Class 3. Herbs to be used only under the supervision of a qualified expert. The following labeling is recommended for Class 3 herbs: "To be used only under the supervision of an expert qualified in the appropriate use of this substance." Labeling must include proper use information: dosage, contraindications, potential adverse effects and drug interactions, and any other relevant information related to the safe use of the substance.

- Narrow therapeutic range
- Identified safety concerns in many populations

Interaction classes

Class A. Herbs for which no clinically relevant interactions are expected

- No case reports of suspected interactions with probability of causality
- No clinically relevant interactions in human pharmacological studies, if any

Class B. Herbs for which clinically relevant interactions are biologically plausible

- Human or animal pharmacological study data suggest potential for clinically relevant interaction.

[*] Herbs placed in any of the subparts of Class 2 may also be placed in other of these subparts.

- Multiple case reports have suggested a potential interaction concern.
- Cell culture or biochemical assays establish a basis for biologically plausible mechanism of interaction.

Class C. Herbs for which clinically relevant interactions are known to occur

- Human pharmacological study has demonstrated interaction with a specific drug or supplement.
- Human pharmacological study has demonstrated clinically relevant effects on drug metabolizing enzymes or drug transporter proteins.
- Case reports of suspected interactions have a probability of causality.

Limitations of Scope

This work specifically excludes the following data, conditions, and related products:

- Excessive consumption. Safety and interaction classifications given here are for normally consumed amounts, and cannot be assumed to have relevance for any quantity. Also, any concerns that are significant only in excessive or immoderate use are not relevant to assignation of classifications, though these may be referred to in an Editors' Note.
- Safety or toxicity concerns based on isolated constituents. As is the case with many common foods, some herbs are known to contain constituents that, in isolation, exhibit toxicity. Data based solely on constituents are not considered relevant to safety classification except in those cases where such compounds are known to accumulate, or where consumption patterns are sufficient to provide cause for health concerns. The presence of a constituent has been identified in a Notice if knowledge of the constituent is relevant to the safe use of an herb.
- Toxicity data based solely upon intravenous or intraperitoneal administration. The majority of herbal products consumed by the public are taken orally and with adequate dosage instructions. The physiological effects of injectable preparations are not relevant to oral consumption. Information associated with other forms of administration was reviewed but was not considered as a sole basis for classifications, and classifications should be assumed to address oral administration, unless otherwise stated.
- Traditional Chinese and Ayurvedic contraindications. In Chinese and Ayurvedic therapeutic traditions, most herbs have contraindications based on an individual's constitutional strengths and weaknesses, seasons, climate, and other factors that can only be understood in the context of the specific tradition. These traditional concerns have not been included in the text unless they can also be interpreted in a modern biomedical context, such as contraindication in pregnancy.
- Gastrointestinal disturbances. Reports of nausea or emesis from excessive doses, or occasional and/or minor gastrointestinal disturbances, have been noted but have not been considered in establishing safety classification, unless frequency or severity of such reactions warrants consideration.
- Idiosyncratic reactions. Any plant substance, whether used as food or medicine, has the potential to stimulate a negative response in unpredictably sensitive individuals. Safety classifications do not take into account such idiosyncratic responses, unless there is evidence to suggest that such an idiosyncratic reaction may be predictable.
- Allergic reactions. Certain plants in the Asteraceae, Apiaceae, and other plant families possess a relatively high degree of allergenicity, and specific mention of this is provided in the text for certain plants, such as feverfew herb (*Tanacetum parthenium*) and *Echinacea* spp. flowering tops. A plant's allergic potential, however, is not generally considered a basis for restrictive safety classification. Persons with a known allergy to ragweeds are nonetheless advised to observe caution in the consumption of all plants of the Asteraceae family, especially flowering parts.
- Contact dermatitis. The primary focus of this work is on herbal products for oral ingestion. Except in cases where there is a history of external therapeutic use, coupled with a record of associated dermatitis (e.g., mustard plasters), such concerns are beyond the scope of this document.
- Well-known toxic plants with known safety concerns that are not broadly traded. Many of the plants which are listed in standard toxicological texts as highly poisonous are not included in this document. Although isolates and constituents of some of these might be included in prescription drugs, they are not found in products which are otherwise accessible in a retail setting. Among the plants excluded are *Adonis vernalis*,

Claviceps purpurea, *Chondrodendron tomentosum*, *Colchicum autumnale*, *Conium maculatum*, *Croton tiglium*, *Datura* spp., *Gelsemium sempervirens*, *Hyoscyamus niger*, *Nicotiana* spp., *Rauwolfia* spp., *Stramonium* spp., *Strophanthus kombe*, and *Strychnos nux-vomica*.

- Homeopathic herbal preparations. Homeopathic products are classified as over-the-counter or prescription drugs and are regulated under the *Homeopathic Pharmacopoeia of the United States*. Safety concerns that arise for an herb in crude form may not apply to homeopathic preparations of the same herb, and this document does not address herbal products in homeopathic forms.
- Essential oils. Essential oils are concentrations of specific volatile compounds. While many essential oils have a well-documented history of safe use by appropriately skilled persons, they often present toxicological concerns that are absent or moderate in the crude plant materials from which the oil is derived. Except for a small number of essential oils that have a history of internal use, the classification of essential oils is beyond the scope of this document.
- Herbal products to which chemically defined active substances, including chemically defined isolated constituents of an herb, have been added. Safety of such products should be determined by manufacturers and marketers prior to market introduction.
- Environmental factors, additives, or contaminants. Classifications do not consider potential adulteration of botanical materials, although known adulterations that present health risks may be listed in an Editors' Note. Safety concerns of this sort must be addressed by the manufacturing practices of suppliers and manufacturers, who are responsible for assuring that herbal products are not contaminated or adulterated.

ORGANIZATION OF DATA

Listings are alphabetically arranged by Latin name. More than one species of a genus are combined into a single listing in those cases where two or more species are used interchangeably, or where the issues relevant to safe use are the same or nearly the same for related species. Some herbs supply more than one useful part. These parts are listed and classified together only in those cases where the safety issues of all parts are sufficiently similar; otherwise, separate listings are included for each plant part.

Following the Latin name is the botanical family name. In instances where synonymous Latin names may be encountered in relevant references, one or more of these may be listed as a Synonym (**Syn).**

It is not unusual for a plant to have many common names, a fact which can confound the understanding of an herb's uses and potential safety concerns. AHPA published *Herbs of Commerce, 2nd edition* (McGuffin et al. 2000) to address this concern by assigning a single common or usual name to each herb, denoted in each listing in the current text as its standardized common name (**SCN**). Additional familiar common names are listed as other common names (**OCN**), though this field is generally not intended to be exhaustive. Ayurvedic names (**AN**) and pinyin names (**PN**) for botanical ingredients commonly used in Ayurvedic or traditional Chinese medicine are also included; note that Ayurvedic names tend to identify the plant itself, while pinyin names usually identify a specific plant part. With occasional exceptions, nomenclature in this work is derived from *Herbs of Commerce, 2nd edition*.

Following the plant's names is the **Part** of the plant for which the safety and interactions classifications that follow are made. Occasional specific information is included for those herbs that require special processing.

The remainder of each listing is divided into two sections, the **Quick Reference Summary**, which provides a concise, clinically relevant summary of the scientific information and traditional knowledge on the safety of each species or set of species, and the **Review Details** section, which provides details on the information presented in the summary.

Each entry's **Quick Reference Summary** includes the following elements. Each of the fields printed below in bold are always included, and state "None known" in the absence of any information relevant to the entry. All other fields are optional, and are included only for those entries for which information in the described area is relevant.

- Safety Class: Each entry is assigned one or more of the Safety Classes described earlier in this introduction.
- Interaction Class: Each herb is also assigned an Interaction Class as described previously.
- Contraindications: Any situations, conditions, or populations in which the botanical should not be used are listed here.
- Other Precautions: Special considerations for use are identified in this field. These may include, for example, common idiosyncratic effects (e.g., allergic reactions), adverse effects that may be undesirable but are not typically dangerous, or other conditions that require some specific caution, as stated.
- Drug and Supplement Interactions: This section gives details on known or suspected interactions in order to provide further information on any possible or probable interactions noted in an Interaction Class B or C. Note, however, that possible interactions that have low levels of evidence, or drugs for which a lack of interactions has been demonstrated, are generally listed under Pharmacological Considerations.
- Standard Dose: Quantitative dosage information is included here only for those plants listing a recommendation that excessive dosage be avoided. The dose is usually given in the quantity and form for direct consumption or for preparation as a tea or decoction and is based on the herb in its dried (dehydrated) form, unless otherwise stated. Equivalent dosage in the form of tinctures and extracts must be calculated based on the concentration of such extracts on a dry weight basis. Standard Dose should not be taken to be the equivalent of a dosage limitation. Rather, this dosage should be seen as related to the concept of "serving size." Although Standard Dose may be relevant to the determination of appropriate dosage limits, a thorough examination of other specific factors would be required prior to setting such levels.
- Notice: Certain plant constituents, such as caffeine or pyrrolizidine alkaloids, and herbs with known physiological actions, such as emetics and nervous system stimulants, may present safety considerations in numerous species. Rather than address such concerns in detail for each individual species, a Notice identifies these constituents

or actions and directs the reader to a thorough discussion of each such subject in Appendix 1, 2, or 3.

- Editors' Notes. Supplemental information relevant to the safe use of an herb, such as specific labeling recommendations, information regarding preparation, content of a chemical compound of potential concern, exceptions to use restrictions, possible adulteration, and other information are all included in this section, if required. Some discussion of the details, quality, or applicability of cited references may also be included here.
- Adverse Events and Side Effects. Recorded adverse changes in health, including any abnormal signs or symptoms, that have been reported to have occurred in association with the use of a particular herb are listed at this field. Side effects are defined as predictable effects of an herb that are not the principal effect for which the herb was taken (e.g., some people experience heartburn after ingestion of ginger). Adverse events, which include any health-related event associated with the use of a product that is perceived as harmful to the user, may or may not be related to an herb that was being taken at the time of an event. While some adverse events temporally associated with usage may be attributable to the herb consumed (e.g., nausea, vomiting, and central nervous system disturbances with overdose of raw *Ginkgo biloba* seed), many adverse events identified in case reports are not likely to be related to the associated herb. Sufficient detail is often lacking in case reports to determine whether a particular herb was likely the cause of any adverse event, and a case report cannot be considered to be in and of itself evidence that the reported adverse event was caused by the identified herb. All case reports in this text refer to human cases, unless they are listed under animal studies or otherwise specified.
- Pharmacological Considerations. If the physiological effects or other pharmacological activity of an herb may be relevant to the safe use of that herb, this information is reported here. Preference is given to data from human and animal use, although in vitro data that may be relevant to clinical use is also listed here. Low-level evidence for potential drug interactions is also typically included here.
- Pregnancy and Lactation. As available, information on the safety of herbs during pregnancy or while nursing is provided in this field. For a number of the Class 1 herbs, substantial data or traditional use suggests that these may be safely used in pregnancy and lactation. For other botanicals, less data and clinical experience are available regarding their use in pregnancy or lactation. The absence of formal data and clinical experience regarding the use of a botanical in pregnancy or lactation, in and of itself, was not justification to contraindicate the botanical in these conditions. In such cases, the editors and Expert Advisory Council have used their best judgment in conjunction with the available literature to make the most appropriate determination. The following statement is included in those entries for which data and clinical experience for the botanical were lacking or less robust than desired:

No information on the safety of this herb in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

The **Review Details** section for each entry is divided into five primary fields, each of which has its own organization. The reader will observe considerable redundancy when reading an herb's Quick Reference Summary and its Review Details sections together, as each of these is designed to be complete in itself. Thus, while the Quick Reference Summary provides enough information to understand an herb's safety and interaction profile, the Review Details section provides a more in-depth discussion of the data that was reviewed for the entry.

Some of the specific elements of this section are always present (again shown in bold font below) and when there is no relevant information known for a specific entry, that fact is affirmatively stated (e.g., "No clinical trials of drug or supplement interactions were identified."). All other elements are optional, and are again included only for those entries where information in the described area is relevant to the listing.

I. Drug and Supplement Interactions
   - Clinical trials of drug or supplement interactions
   - Case reports of suspected drug or supplement interactions
   - Animal trials of drug or supplement interactions

II. Adverse Events
   - Adverse events reported in clinical trials
   - Case reports of adverse events

III. Pharmacology and Pharmacokinetics
   - Human pharmacological studies
   - Animal pharmacological studies
   - In vitro pharmacological studies

IV. Pregnancy and Lactation
V. Toxicity Studies
- Acute toxicity
- Short-term toxicity
- Subchronic toxicity
- Chronic toxicity
- Genotoxicity
- Cytotoxicity

Each entry closes with a listing of the **Literature Cited** for that particular entry.

DISCLAIMER

The editors and the Expert Advisory Council of the *Botanical Safety Handbook* have endeavored to ensure that the information contained in this document accurately represents contemporary knowledge on the safe use of herbal ingredients. In developing this work, particular care was given to identifying references that provide accurate information, and efforts were made to present a balanced view of all available scientific information.

The safe oral consumption of any substance can depend to a great deal on the health of an individual consumer, as well as to the quantity of the substance consumed. In addition, idiosyncratic or allergic reactions are often unpredictable. Any person who consumes an herb listed in this reference based on its classifications does so at his or her own risk, and should consult a healthcare provider in the event of an adverse response.

There is no obligation at this time for AHPA members to adopt the specific information contained here in their product labeling. Rather, this document is presented as a guideline, providing data to assist member and nonmember manufacturers in developing labels that fully inform consumers. Verification of all data and classifications for the purpose of label development is the responsibility of the manufacturer.

Abies balsamea (L.) Mill.

Pinaceae

SCN: balsam fir
OCN: American silver fir

Part: bark, needles, sap, wood

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of balsam fir in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An ethanol extract of an unidentified part of balsam fir demonstrated in vitro mechanism-based inhibition of the drug metabolizing isoenzyme CYP3A4 (Tam et al. 2011).

IV. Pregnancy and Lactation

No information on the safety of balsam fir during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Literature Cited

Tam, T.W., R. Liu, J.T . Arnason, A. Krantis, W .A. Staines, P .S. Haddad, and B.C. Foster. 2011. Cree antidiabetic plant extracts display mechanism-based inactivation of CYP3A4. *Can. J. Physiol. Pharmacol.* 89(1):13-23.

A

Achillea millefolium L. — Asteraceae

SCN: yarrow
OCN: milfoil

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as feverfew, chamomile, or *Echinacea* species) should exercise caution with yarrow, as allergic cross-reactivity is common to Asteraceae plants (Hausen 1996; Paulsen et al. 1993).

Drug and Supplement Interactions

None known.

Notice

Thujone (trace amounts) (Bradley 1992); *see* Appendix 1.

Editors' Notes

Use of yarrow as a food additive in the United States is subject to a limitation that the finished food or beverage is thujone-free (CFR 2011). Dietary ingredients for use in dietary supplements, however, are specifically excluded from the federal food additive definition (U.S.C. 2010).

Thujone is present in yarrow only in trace amounts (Leung and Foster 1996). Some concerns regarding the safety of thujone have been based on the effects of absinthe, an alcoholic beverage that historically contained thujone. Recent research, however, indicates that the alcohol content, rather than the thujone content, of absinthe was responsible for the reported adverse effects (Lachenmeier et al. 2006, 2008).

Adverse Events and Side Effects

Cases of contact allergy to yarrow plants have been reported, and allergic cross-reactivity to plants in the Asteraceae family has been documented (Davies and Kersey 1986; Guin and Skidmore 1987; Hausen 1996; Paulsen et al. 1993).

Pharmacological Considerations

In vitro studies with yarrow have reported inhibition of some CYP enzymes (Scott et al. 2006), increase in bile flow (Benedek et al. 2006), and estrogenic activity (Innocenti et al. 2007). One animal study showed some adverse effects on sperm at high doses (1.2 g/kg daily) but not at lower doses (Dalsenter et al. 2004).

Pregnancy and Lactation

Information on the safety of yarrow during pregnancy and lactation is limited. One animal study showed a decrease in fetal weight in offspring of rats administered high (2.8 g/kg) doses of yarrow, but no adverse effects were seen at lower doses (Boswell-Ruys et al. 2003).

No information on the safety of yarrow during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Cases of contact allergy to yarrow have been documented (Davies and Kersey 1986; Guin and Skidmore 1987) and are believed to be caused primarily by the sesquiterpene lactone α-peroxyachifolid (Hausen et al. 1991).

In patch testing of Asteraceae-sensitive individuals, approximately 1.5% of 3800 test subjects were sensitive to yarrow (Hausen 1996). Similarly, patch testing of 686 subjects revealed 32 with sensitivity to several species of Asteraceae plants, including yarrow (Paulsen et al. 1993).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No adverse effects on the male reproductive system were observed in male rats orally administered up to 600 mg/kg daily of an aqueous yarrow extract for 90 days. An increase in the percentage of abnormal sperm was observed in rats treated with 1.2 g/kg daily (Dalsenter et al. 2004).

In Vitro Pharmacological Studies

Inhibition of CYP450 isoenzymes CYP2C19, CYP19, and CYP3A4 by a methanolic extract of yarrow was observed in vitro (Scott et al. 2006).

A dose-dependent increase in bile flow was observed in isolated perfused rat livers treated with a polar fraction of yarrow (Benedek et al. 2006).

A methanol and water extract of yarrow demonstrated estrogenic activity in estrogen receptor-positive human breast cancer cells (MCF-7). Activation of estrogen receptors α and β was seen (Innocenti et al. 2007).

IV. Pregnancy and Lactation

A decrease in fetal weight was observed in offspring of rats administered 2.8 g/kg daily of an ethanolic extract of yarrow on gestational days 8 to 15, but no effects on fetuses were seen when yarrow was administered on GD 1 to 8. No changes in pre-implantation or post-implantation loss were observed (Boswell-Ruys et al. 2003).

No information on the safety of yarrow during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of both orally and subcutaneously administered yarrow extract (2% in propylene glycol and water) in mice is 1 g/kg (Provital 1998).

Chronic Toxicity

No signs of toxicity were observed in rats administered up to 1.2 g/kg daily of a yarrow aqueous extract for 90 days (Cavalcanti et al. 2006).

Genotoxicity

A weakly genotoxic effect of a yarrow aqueous extract was reported in *Drosophila melanogaster* (Graf et al. 1994).

A

Achyranthes bidentata Blume — Amaranthaceae

SCN: achyranthes
PN: *niu xi* (root)
OCN: ox knee
Part: root

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Not for use in excessive menstruation (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Notice

Uterine stimulant (Bensky et al. 2004; Chen and Chen 2004); *see* Appendix 2.

Editors' Note

Multiple species are traded under the name *niu xi*, and all are contraindicated in pregnancy (Bensky et al. 2004).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that achyranthes should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004). Dilation of the cervical os was observed in association with achyranthes use in women who had abortions (Chen and Chen 2004). Animal studies of achyranthes have indicated anti-implantation, antifertility, and uterine stimulating activity (Che 1988; Chen and Chen 2004; Zhu and Che 1987).

No information on the safety of achyranthes during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In mice intraperitoneally administered polysaccharides from achyranthes at doses of 50, 100, or 200 mg/kg daily for 15 days, the 50 mg/kg dose inhibited the growth of introduced lung cancer tumors while the 200 mg/kg dose increased tumor growth. Tumor growth in mice administered 100 mg/kg was equivalent to that of the untreated control group (Jin et al. 2007).

Also see Pregnancy and Lactation for this entry.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Dilation of the cervical os was observed in association with achyranthes use in women who had abortions (Chen and Chen 2004).

A benzene extract of achyranthes saponins orally administered to mice at doses of 50 or 80 mg/kg reduced female fertility and implantation. The chloroform extract administered at doses of 80 or 120 mg/kg reduced fertility but did not affect implantation (Che 1988).

A dose-dependent decrease in fertility was observed in mice orally administered achyranthes saponins at doses of 125 to 1000 mg/kg (ED_{50} was 218 mg/kg). Implantation was prevented in mice orally administered 500 mg/kg of achyranthes saponins 5 days after mating, although no such activity was observed in rats administered 500 mg/kg. No

abortifacient activity was observed in rats orally administered 2 g /kg daily achyranthes saponins on days 14 to 19 after mating (Zhu and Che 1987).

Administration of achyranthes to mated female mice at doses of 250 to 500 mg/kg for 20 days resulted in a decrease in fertility and increased risk of miscarriage (Chen and Chen 2004).

Studies in rabbits and rats indicated that achyranthes stimulates uterine contractions (dose and route of administration not specified in English language translation) (Chen and Chen 2004).

No information on the safety of achyranthes during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered combination of the compounds ecdysterone and inoteosterone in mice is 9 g /kg (Chen and Chen 2004).

Short-Term Toxicity

No abnormalities in blood parameters, liver, or kidneys were observed in mice orally administered an achyranthes decoction at a dose of 60 g/kg daily for 30 days (Chen and Chen 2004).

Aconitum carmichaelii Debeaux — Ranunculaceae

SCN: Sichuan aconite
PN: *chuan wu* (prepared main root); *fu zi* (prepared lateral root)

OCN: Japanese aconite
Part: prepared main and lateral root

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004; Bisset 1981; Chan 2009; Fitzpatrick et al. 1994; Lin et al. 2004).

The unprepared root should never be taken internally (Bensky et al. 2004).

Other Precautions

References on traditional Chinese medicine indicate that alcohol should not be consumed with Sichuan aconite, as the absorption of the toxic constituents of Sichuan aconite will be greatly enhanced (Bensky et al. 2004; Chen and Chen 2004).

Drug and Supplement Interactions

Extreme caution is advised for use of Sichuan aconite in combination with antiarrhythmic medications (Chen and Chen 2004).

Editors' Notes

Both prepared and unprepared Sichuan aconite are available commercially. Sichuan aconite contains aconitine, a toxic alkaloid that affects the heart and the central nervous system (Bensky et al. 2004). Due to aconitine content, the unprepared root is highly toxic and is the primary herb associated with serious adverse events in traditional Chinese medicine hospitals in Hong Kong (Chan 2002; Chan et al. 1994a, 1994c; Poon et al. 2006). Processing of Sichuan aconite root greatly reduces the content of aconitine (Chen and Chen 2004). The prepared root, that has been processed to reduce toxicity, is the subject of this entry.

Sichuan aconite may be prepared in several ways, the most common of which is to cook the herb at boiling temperature for several hours. Such processing reduced the toxicity of Sichuan aconite to between 1/2000 and 1/4000 of the toxicity of the unprocessed herb (Chen and Chen 2004). Heat processing at temperatures above 120°C for 50 minutes decreased the diester alkaloids, such as mesaconitine, aconitine, and hypaconitine, and increased monoester alkaloids, such as benzoylmesaconine, benzoylaconine, and benzoylhypaconine, whereas heating to 105°C preserved the diester alkaloids (Taki et al. 1998).

A text on traditional Chinese medicine notes that while prepared Sichuan aconite is recognized to be toxic, if the appropriate dosage of the prepared root is combined with other appropriate ingredients such as ginger and licorice, and the patient is carefully instructed on the method of proper decoction, little likelihood of toxicity exists (Bensky et al. 2004).

Other species of *Aconitum* are also in trade (Bensky et al. 2004), and all should be considered class 3.

Adverse Events and Side Effects

Cases of aconite poisoning have been reported; some have been fatal. Characteristic symptoms of poisoning include nausea, vomiting, generalized paresthesia (numbness), irregular heartbeat, and cold extremities (Bisset 1981; Fitzpatrick et al. 1994).

A review of case reports of poisoning from various species of aconite indicated that the risk of poisoning is higher with inadequately processed aconite root, improperly prepared extracts (i.e., patients not boiling root as long as directed when making decoctions), large doses, and alcohol-based extracts (Lin et al. 2004).

Pharmacological Considerations

See Adverse Events and Side Effects above.

Pregnancy and Lactation

Traditional Chinese medicine texts contraindicate the use of prepared Sichuan aconite in pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of prepared Sichuan aconite during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Aconite poisoning has been reported to occur after mistaken use of the unprepared herb, inappropriate preparation, or overdose. Poisoning may affect the nervous system (dizziness, blurred vision, mydriasis, loss of vision, and numbness of mouth, limbs, or whole body), digestive system (severe nausea and vomiting), and circulatory system (palpitations, low blood pressure, cold extremities, chest pain, bradycardia, sinus tachycardia, ventricular ectopics, ventricular arrhythmias, and junctional rhythm) (Bisset 1981; Chan 2009; Fitzpatrick et al. 1994).

Toxic effects are caused by the alkaloid aconitine (Fu et al. 2006; Lin et al. 2004). Aconitine and other alkaloids activate the sodium channel and have widespread effects on the excitable membranes of cardiac, neural, and muscle tissues. Muscarinic activation also causes hypotension and bradyarrhythmias (Chang and But 1986).

A number of cases of aconite poisoning have been reported, most with typical clinical symptoms of aconite poisoning; some cases were fatal (But et al. 1994; Chan 2002; Chan et al. 1993, 1994a, 1994b, 1994c; Fatovich 1992; Fujita et al. 2007; Kolev et al. 1996; Lowe et al. 2005; Smith et al. 2005; Tai et al. 1992a, 1992b). Severe poisoning has been reported after consumption of as little as 0.2 mg of the compound aconitine or decoctions prepared from a Chinese herbal prescription containing 6 g of prepared Sichuan aconite (But et al. 1994). The toxic dose range is reported to be between 15 and 60 g of dried root prepared as a decoction, and is dependent on the time of harvest, method of preparation, and length of decocting time (Bensky et al. 2004).

A review of case reports of poisoning from various species of aconite indicated that the risk of poisoning is higher with inadequately processed aconite root, improperly prepared extracts (i.e., patients not boiling root as long as directed when making decoctions), large doses, and alcohol-based extracts (Lin et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies of prepared Sichuan aconite were identified.

Animal Pharmacological Studies

A dose-dependent decrease in plasma glucose levels was seen in diabetic rats orally administered up to 50 mg/kg prepared Sichuan aconite. The plasma glucose-lowering effect was eliminated by blockage of μ-opioid receptors (Liou et al. 2006).

In mice orally administered 1 mg/kg daily of the compound aconitine, various types of arrhythmias were observed including ventricular fibrillation, ventricular tachycardia, and bundle branch block. The arrhythmias occurred within 30 minutes of administration of aconitine,

and persisted after 90 min. The concentration of aconitine in organs and blood gradually decreased after repeated administration, such that on day 22 of the study, transient ventricular tachycardia and bundle branch block were rarely observed. Twenty percent of mice died in the first 2 days of the study, presumably due to aconitine poisoning (Wada et al. 2005).

A decrease in urine taurine and trimethylamine *N*-oxide (TMAO) and increase in urine citrate, 2-oxoglutarate, succinate, and hippurate were observed in rats administered an aqueous extract of prepared Sichuan aconite at a dose of 18, 36, or 88 g/kg daily for 14 days (Li et al. 2008).

In Vitro Pharmacological Studies

A study in rat liver microsomes suggested that the compound aconitine may be metabolized by CYP3A and CYP1A1/2 (Cao et al. 2001).

IV. Pregnancy and Lactation

Traditional Chinese medicine texts indicate that prepared Sichuan aconite is contraindicated in pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No malformations were found in fetuses of rats treated with doses up to 10.3 g/kg prepared Sichuan aconite, although the body weight and food consumption were reduced in the pregnant rats. Fetuses of rats administered 8.3 g/kg of *Aconitum kusnezoffii* had a reduction in body length and breastbone calcification (Xiao et al. 2005). The dosage form and route of administration used in this study was not specified in the English language abstract but is likely to have been a decoction administered orally (Xiao et al. 2005).

In rat embryos treated with the compound aconitine at doses of 0, 1, 2.5, 5, or 10 µg/ml, with or without S9 mix, embryonic growth and development were adversely affected at the concentration of 2.5 µg/ml aconitine without S9 mix. Effects included reduced crown-rump length and head length, decreased number of somites, and lower morphologic score. When the concentration of aconitine was increased to 5 µg/ml, severe dysmorphogenesis effects were observed, including cardiac defects, irregular somites, and brain malformation (Xiao et al. 2007).

No information on the safety of prepared Sichuan aconite during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of prepared Sichuan aconite is 161 g/kg from oral administration and 3.5 g/kg from intravenous administration (Chen and Chen 2004). The LD_{50} of unprepared Sichuan aconite in mice is 5.49 g/kg from oral administration and 0.49 g/kg from intravenous administration (Chen and Chen 2004). The LD_{50} of orally administered Sichuan aconite root is approximately 10 g/kg in rats and over 10 g/kg in mice (Minematsu et al. 1996).

The lethal human dose of the compound aconitine is reported as 3 to 6 mg (Frohne and Pfänder 1983).

Short-Term Toxicity

In mice intraperitoneally administered a decoction of Sichuan aconite or *Aconitum kusnezoffi*, at doses of 40, 200, or 400 mg/kg, no changes in liver or kidney parameters were seen at a dose of 40 mg/kg, while at doses of 200 or 400, high serum levels of lactate dehydrogenase were observed along with histological changes in the liver and kidney, but no significant changes in heart or gonads were seen (Chan et al. 1995).

Myelo-optic neuropathy was observed in rabbits intraperitoneally administered a tincture of *Aconitum* spp. containing 0.6 mg/kg total alkaloids (Suk et al. 1994).

In rats orally administered prepared Sichuan aconite daily for 5 weeks, the nontoxic level was estimated to be over 2.5 g/kg daily (Minematsu et al. 1996).

Acorus calamus L. — Acoraceae

SCN: calamus
AN: *vacha*
OCN: acorus; sweet calamus; sweetflag

Part: rhizome of the asarone-containing triploid or tetraploid varieties

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Chadha 1988; De Smet 1985; Leung and Foster 1996; Martindale and Reynolds 1996; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Alkenylbenzenes (β-asarone and α-asarone) (usually 1.1–2.6%; up to 8.0%) (Hanson et al. 2005; Kumar et al. 2000; Motley 1994; Oprean et al. 1998; Subramanian et al. 2004; Widmer et al. 2005); *see* Appendix 1.

Editors' Notes

Calamus grows wild in India, China, Europe, and North America, and the chemical composition of the plant material

varies according to origin. The essential oil of plants from India contains up to 75% β-asarone (*see* Alkenylbenzenes in Appendix 1), while the oil of calamus from Japan and eastern Russia contains 10–40%, oil from European plants contains approximately 13%, and that from North America contains almost no β-asarone (Keller and Stahl 1982, 1983; Raina et al. 2003; Stahl and Keller 1981; Subramanian et al. 2008). Since varieties of calamus may not be well differentiated in commerce, the caution stated for the Asian and European varieties should be considered relevant to any sample that is not positively identified as the North American variety.

Animal and in vitro studies have indicated that the compound β-asarone has carcinogenic, mutagenic, and chromosome-damaging properties (Abel 1987; Balachandran et al. 1991; FAO/WHO 1981; Goggelmann and Schimmer 1983; Habermann 1971; Hasheminejad and Caldwell 1994).

All varieties of calamus are prohibited in foods in the United States (CFR 2011).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

A reference text on traditional Chinese medicine indicated that overdose and long-term use of calamus should be avoided (Bensky et al. 2004).

Pregnancy and Lactation

A study with calamus essential oil in chicken eggs showed no adverse effects on embryo development (Yabiku et al. 1979). No other information on the safety of calamus in pregnancy or lactation was identified.

While this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Extracts of calamus have been shown to potentiate pentobarbitone-induced sleeping time (Dandiya et al. 1959; Hazra et al. 2007; Panchal et al. 1989).

II. Adverse Events

Case Reports of Adverse Events

A 19-year-old man experienced diaphoresis, persistent vomiting, and mild leukocytosis after ingesting an 8-inch-long calamus rhizome (Vargas et al. 1998).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

An ethanolic extract of calamus demonstrated immunomodulatory potential by inhibiting proliferation of mitogen- and antigen-stimulated human peripheral blood mononuclear cells. The extract inhibited growth of several mouse and human cell lines (Mehrotra et al. 2003).

Animal studies have indicated that calamus has a depressant effect on the central nervous system (Agarwal et al. 1956; Dandiya et al. 1958, 1959; Dandiya and Cullumbine 1959; Dasgupta et al. 1977).

In Vitro Pharmacological Studies

Negative ionotropic and chronotropic effects were observed in frog heart preparations treated with concentrations of 100 µg/ml of an alcohol extract of calamus (Panchal et al. 1989).

IV. Pregnancy and Lactation

No teratogenic effects were observed in chicken eggs injected with calamus essential oil at doses of 0.12, 0.60, 3.00, 15.00, or 75.00 mg/egg (Yabiku et al. 1979). Similarly, no teratogenic effects were observed in chicken eggs injected with α-asarone at doses up to 4 mg/egg. In eggs injected with β-asarone, 43% of embryos survived a dose of 0.04 mg/egg, while none survived a dose of 4 mg/egg (Yabiku et al. 1979).

No information on the safety of calamus in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered calamus oil in rats was 0.77 g/kg for oil from Jammu (~75% β-asarone) (Jenner et al. 1964), 4.3 g/kg for oil from Kashmir (~5% β-asarone) (WHO 1981), and 3.5 g/kg for oil from Europe (~5% β-asarone) (WHO 1981).

The LD_{50} of intraperitoneally administered European calamus oil in mice was 1.1 g/kg for oil containing β-asarone and 1.7 g/kg for oil with no β-asarone (Yabiku et al. 1979). In rats, the intraperitoneal LD_{50} of the essential oil was 299 mg/kg (Yabiku et al. 1979). The LD_{50} of intraperitoneally administered β-asarone in mice was 0.184 g/kg (Yabiku et al. 1979).

Chronic Toxicity

In rats fed diets containing 0, 500, 1000, 2500, or 5000 ppm (0, 0.05, 0.1, 0.25, and 0.5%) Jammu calamus essential oil (~75% β-asarone) daily for 2 years, all of the 5000 ppm group died within 45 weeks, all of the 2500 ppm group died within 68 weeks, and all of the 1000 ppm group died within 104 weeks. Gross abnormalities were observed, including liver damage, fluid in the pleural and or peritoneal cavity, and tumorous masses in the intestines. Cardiac atrophy was observed in both test and control animals but was more severe in test animals (Taylor 1967, 1981).

In rats fed diets containing 0.1, 0.5, 1.0, or 2.0% European calamus essential oil (~5% β-asarone) daily for 2 years, leiomyosarcomas, hepatocellular adenomas, and hepatocellular adenocarcinomas were observed at the 1 and 2% dose levels. Other dose-dependent adverse effects on the livers were observed, with effects at the 0.1% dose being similar to those in the controls, or slightly increased. Dose-dependent changes observed in the heart included myocardial atrophy, fibrosis, fatty degeneration, and fatty infiltration (Taylor 1981).

In rats fed diets containing 0, 400, 800, or 2000 ppm (0, 0.04, 0.08, or 0.2%) β-asarone for 2 years, none of the animals receiving 2000 ppm β-asarone survived more than 84 weeks, and mortality was increased at the 800 ppm dose. Gross pathological changes were observed and included serous fluid in the abdominal and pleural cavities, liver and kidney changes, and tumorous masses in the intestinal tract. Occurrence of tumors was dose-related. Changes in the heart included myocardial atrophy, fibrosis, thrombosis, fatty degeneration, and fatty infiltration (Taylor 1981).

Genotoxicity

No mutagenic activity of a calamus extract was observed in *Salmonella typhimurium* strains TA97a, TA100, TA102, and TA104. Dose-dependent antimutagenic activity was observed at concentrations of 25 to 100 µg/plate (Aqil et al. 2008).

The compound *cis*-asarone has shown mutagenic activity in vitro (Goggelmann and Schimmer 1983), although this activity has been characterized as weak in comparison with other mutagenic/carcinogenic natural substances (Wichtl 2004).

No mutagenic activity of β-asarone was observed in *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537, or TA1538 at concentrations of 2 to 200 µg/plate with metabolic activation. Tests without metabolic activation were not completed (Hsia et al. 1979).

No mutagenic activity of α-asarone was observed in the Ames test with *Salmonella typhimurium* at concentrations of up to 5000 ppm with or without activation. In a related study, β-asarone was not mutagenic at 50 ppm, but did show mutagenic activity at a concentration of 5000 ppm with activation (Yabiku et al. 1979).

Cytotoxicity

An ethanol extract of calamus demonstrated cytotoxic activity in a brine shrimp lethality test (Padmaja et al. 2002).

Acorus calamus L.

Acoraceae

SCN: calamus
AN: *vacha*

OCN: acorus; sweet calamus; sweetflag
Part: rhizome of the diploid asarone-free variety

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Calamus grows wild in India, China, Europe, and North America, and the phytochemical profile of the plant material varies according to origin. The essential oil of plants from India contains up to 75% β-asarone (*see* Alkenylbenzenes in Appendix 1), while the oil of calamus from Japan and eastern Russia contains 10–40%, oil from European plants contains

approximately 13%, and that from North America contains almost no β-asarone (Keller and Stahl 1982, 1983; Raina et al. 2003; Stahl and Keller 1981; Subramanian et al. 2008). Since varieties of calamus may not be well differentiated in commerce, the caution stated for the Asian and European varieties should be considered relevant to any sample that is not positively identified as the North American variety.

All varieties of calamus are prohibited in foods in the United States (CFR 2011).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

A reference text on traditional Chinese medicine indicated that overdose and long-term use of calamus should be avoided (Bensky et al. 2004).

Pregnancy and Lactation

A study in chicken eggs showed no teratogenic activity of calamus essential oil (Yabiku et al. 1979). No other information on the safety of calamus in pregnancy or lactation was identified.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Extracts of calamus have been shown to potentiate pentobarbitone-induced sleeping time (Dandiya et al. 1959; Hazra et al. 2007; Panchal et al. 1989).

II. Adverse Events

Case Reports of Adverse Events

A 19-year-old man experienced diaphoresis, persistent vomiting, and mild leukocytosis after ingesting an 8-inch-long calamus rhizome (variety unspecified) (Vargas et al. 1998).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

An ethanolic extract of calamus demonstrated immunomodulatory potential by inhibiting proliferation of mitogen- and antigen-stimulated human peripheral blood mononuclear cells. The extract inhibited growth of several mouse and human cell lines (Mehrotra et al. 2003).

Animal studies have indicated that calamus has a depressant effect on the central nervous system (Agarwal et al. 1977; Dandiya et al. 1958, 1959; Dandiya and Cullumbine 1959; Dasgupta et al. 1977).

In Vitro Pharmacological Studies

Negative ionotropic and chronotropic effects were observed in frog heart preparations treated with concentrations of 100 µg/ml of an alcohol extract of calamus (Panchal et al. 1989).

IV. Pregnancy and Lactation

No teratogenic effects were observed in chicken eggs injected with calamus essential oil at doses of 0.12, 0.60, 3.00, 15.00, or 75.00 mg/egg (Yabiku et al. 1979).

No other information on the safety of calamus in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered calamus oil from Europe in mice was 1.1 g/kg for oil containing β-asarone, and 1.7 g/kg for oil with no β-asarone (Yabiku et al. 1979).

Genotoxicity

No mutagenic activity of a calamus extract was observed in *Salmonella* strains TA97a, TA100, TA102, and TA104. Dose-dependent antimutagenic activity was observed at concentrations of 25–100 µg/plate (Aqil et al. 2008).

Cytotoxicity

An ethanol extract of calamus demonstrated cytotoxic activity in a brine shrimp lethality test (Padmaja et al. 2002).

Acorus gramineus Sol. ex Aiton — Acoraceae

SCN: grass-leaf sweetflag
Syn: *Acorus tatarinowii* Schott
PN: *shi chang pu* (rhizome)

OCN: grass-leaf calamus
Part: rhizome

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Notice

Alkenylbenzenes (β-asarone and α-asarone, 0.08–0.8%) (Chang and But 1986; Chen and Chen 2004; Cho et al. 2002; Sugimoto et al. 1997a, 1997b). (See Appendix 1.)

Editors' Notes

Different varieties of grass-leaf sweetflag and material of different geographical origin have varying levels of β-asarone (*see* Alkenylbenzenes in Appendix 1) (Bensky et al. 2004; Sugimoto et al. 1997b). Plant material with low β-asarone is strongly preferred, while material high in β-asarone should be used only when absolutely necessary, only for acute conditions, and only for short periods (Bensky et al. 2004).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Increases in pentobarbital-induced sleeping time have been observed in mice after oral administration or aroma inhalation of grass-leaf sweetflag (Koo et al. 2003; Liao et al. 1998).

Pregnancy and Lactation

A study in chicken eggs showed no teratogenic activity of compounds from grass-leaf sweetflag (Yabiku et al. 1979). No other information on the safety of grass-leaf sweetflag in pregnancy or lactation was identified.

While this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

A dose-dependent increase in pentobarbital-induced sleeping time was observed in mice orally administered an aqueous extract of 0.5 to 5.0 g/kg of grass-leaf sweetflag (Liao et al. 1998).

Inhalation of the aroma of grass-leaf sweetflag also prolonged the pentobarbital-induced sleeping time in mice (Koo et al. 2003).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A dose-dependent decrease in locomotor activity was observed in mice orally administered an aqueous extract of 0.5 to 5.0 g/kg of grass-leaf sweetflag (Liao et al. 1998).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No teratogenic effects were observed in chicken eggs injected with α-asarone at doses up to 4 mg/egg. In eggs injected with β-asarone, 43% of embryos survived a dose of 0.04 mg/egg, while none survived a dose of 4 mg/egg (Yabiku 1980).

No information on the safety of grass-leaf sweetflag in lactation was identified.

V. Toxicity Studies

Also see entry for *Acorus calamus* rhizome of the asarone-containing triploid or tetraploid varieties for more information on the toxicity of β-asarone.

Acute Toxicity

The LD_{50} of intraperitoneally administered aqueous extract of grass-leaf sweetflag in mice was 53 g/kg (Chen and Chen 2004). The LD_{50} of intraperitoneally administered α-asarone in mice was 339 mg/kg. Toxic effects included seizures, convulsions, and slowed respiration (Chen and Chen 2004).

SCN: Chinese cimicifuga
Syn: *Cimicifuga heracleifolia* Kom.
PN: *sheng ma* (rhizome)
OCN: large-leaf bugbane
Part: rhizome

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

A typical therapeutic use of Chinese cimicifuga is in the initial stages of measles or measles with incomplete eruptions. Use after full eruption of measles is not recommended (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

A reference text on traditional Chinese medicine notes that overdose (standard dose listed as decoction of 3–9 g) of Chinese cimicifuga may cause headaches, dizziness, vomiting, tremors, gastroenteritis, and pathogenic erections (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Chinese cimicifuga in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdoses of Chinese cimicifuga (standard dose listed as decoction of 3–9 g) may cause nausea, vomiting, and gastroenteritis. High doses have been noted to cause headache, tremors, tetanic contraction of limbs, lassitude, vertigo, and abnormal erections. Extreme overdoses may result in hypotension, dyspnea, delirium, and respiratory arrest (Bensky et al. 2004; Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

The compound isoferulic acid, isolated from Chinese cimicifuga, has been shown to lower plasma glucose in diabetic rats in a dose-dependent manner with effects on plasma glucose observed at doses of 5 mg/kg (intravenous) and higher (Liu et al. 1999).

In Vitro Pharmacological Studies

An extract of Chinese cimicifuga demonstrated antibacterial activity in Gram-positive and Gram-negative bacteria (Moskalenko 1986).

IV. Pregnancy and Lactation

No information on the safety of Chinese cimicifuga in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a methanolic extract of Chinese cimicifuga orally administered to mice could not be determined at doses up to 10 g/kg. The LD_{50} of the same extract administered intraperitoneally to mice was 8.5 g/kg (Shibata et al. 1975).

Actaea racemosa L. — Ranunculaceae

SCN: black cohosh
Syn: *Cimicifuga racemosa* (L.) Nutt.

OCN: black bugbane; black snakeroot; rheumatism weed
Part: rhizome

Quick Reference Summary

Safety Class: 2B
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Analyses of black cohosh products associated with liver toxicity in Canada found that several products were not black cohosh but instead a closely related species (Painter et al. 2010). An analysis of products on the American market indicated that 3 of 11 products tested contained Asian species of *Actaea* in place of or in addition to *Actaea racemosa* (Jiang et al. 2006).

Adverse Events and Side Effects

Broad attention has been paid to case reports of hepatotoxicity in persons taking black cohosh. An assessment by the European Medicines Agency (EMEA) of 7 published and 42 unpublished cases of hepatotoxicity reported in persons taking black cohosh products concluded, "Overall, all discussed cases of literature and pharmacovigilance reports are poorly documented" but nevertheless found three "possible" and two "probable" cases (EMEA 2006). Based on some of the same and also additional case reports of hepatotoxicity, Britain's Medicines and Healthcare Products Regulatory Agency and the Australian Therapeutic Goods Administration require cautionary labels on products containing black cohosh (MHRA 2006; TGA 2006). The U.S. Pharmacopoeia has also recommended cautionary labeling (Mahady et al. 2008). Prior to the emergence of these case reports, reviews of clinical trials and other safety data have indicated that black cohosh is generally safe (Huntley and Ernst 2003; Low Dog et al. 2003).

A review of 69 published and unpublished case reports of black cohosh-associated hepatotoxicity indicated that there was an excluded, unlikely, unrelated, or unassessable causality for black cohosh in 68 of 69 cases and "little, if any, supportive evidence for a significant hepatotoxic risk of black cohosh" (Teschke et al. 2009). Although one animal study on black cohosh rhizome has identified a biologically plausible mechanism of hepatotoxicity at high dose levels (Lüde et al. 2007), no changes in liver enzyme levels have been observed in several human studies (Bai et al. 2007; Nasr and Nafeh 2009; Osmers et al. 2005; van Breemen et al. 2009). Healthcare practitioners and consumers should be aware of the possible association between products containing black cohosh and hepatotoxicity.

Occasional gastrointestinal discomfort has been reported to occur with black cohosh use (Bradley 1992).

Pharmacological Considerations

While preclinical human, animal, and in vitro studies gave mixed results on the estrogenic activity of black cohosh,

6- and 12-month human clinical trials indicated a lack of estrogenic effects (Huntley 2004; Liske et al. 2002; Mahady 2003, 2005; Raus et al. 2006; Reed et al. 2008).

Pregnancy and Lactation

Black cohosh has been contraindicated by some references for use during pregnancy due to the reported emmenagogic effect (Brinker 2001; Dugoua et al. 2006). Contemporary herbal practitioners, however, have not observed this effect and have used black cohosh early in pregnancy to prevent miscarriage (Upton 2002).

In this work, the contraindication for use in pregnancy is based on concerns regarding the recent cases of hepatotoxicity reported in association with black cohosh use, as the implications of these case reports and possible mechanisms of hepatotoxicity have yet to be fully understood.

Black cohosh is traditionally used late in pregnancy, in or around labor as a partus preparator (Ellingwood 1919; Felter 1891; Felter and Lloyd 1898; McFarlin et al. 1999; Scudder 1903).

While one reference (Dugoua et al. 2006) noted low-level evidence suggesting potential hormonal activity of black cohosh could be a cause for concern during lactation, further studies indicated a lack of estrogenic activity of black cohosh (*see* Human pharmacological studies).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

A trial of single doses of digoxin (0.4 mg) before and after 14 days of black cohosh administration (40 mg/day) indicated no interaction between black cohosh and digoxin (Gurley et al. 2006).

Black cohosh (1090 mg, twice daily for 28 days) was shown to inhibit CYP 2D6 in a nonclinically significant manner (Gurley et al. 2005).

Case Reports of Suspected Drug or Supplement Interactions

No cases of suspected drug interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a systematic review of clinical trials, published case reports and pharmacovigilance reporting center data, Huntley and Ernst (2003) concluded that black cohosh is generally safe. If products are taken for a limited amount of time, the risk of adverse events is slight and the events are usually mild and transient, with gastrointestinal upset and rashes being the most common events reported. The reviewers noted that some serious adverse events have been reported, including hepatic and circulatory conditions, but due to limited information on cases, causality could not be determined (Huntley and Ernst 2003).

Similarly, a review of human clinical trials (including over 2800 participants), postmarketing surveillance, and uncontrolled case reports on black cohosh indicated a low incidence (5.4%) of adverse events in persons taking black cohosh. Of the adverse events reported, 97% were minor and the severe events were attributed to causes other than black cohosh use (Low Dog et al. 2003).

Case Reports of Adverse Events

As of October 2009, a total of 83 cases of liver toxicity associated with black cohosh use had been reported to drug monitoring agencies and or published in the literature (Mahady et al. 2009). Using rating scales that generally include categories of "unassessable, unlikely, possible, probable, or highly probable," critical analyses of these case reports conclude that most cases are "unlikely" or "possible" in relation to black cohosh, while only two cases have been categorized as "probable" and none as "highly probable." Reviewers noted that lack of detail in most of the cases made causality assessment difficult (EMEA 2006; Mahady et al. 2008; Teschke and Schwarzenboeck 2009). Synopses of the published case reports are as follows.

A case of autoimmune hepatitis was reported in a 57-year-old woman with a history of polymyositis, diabetes, high blood pressure, and obstructive sleep apnea. Medications being taken were labetalol, fosinopril, verapramil, metformin, insulin, aspirin, and aminosalicylic acid. The woman had been taking black cohosh (product and dose unspecified) for approximately 1 week (Cohen et al. 2004).

Fulminant liver failure was reported in a 50-year-old woman who had been taking 500 mg black cohosh daily for 5 months (Levitsky et al. 2005a). The initial case report did not include any listed comedications or significant medical history, although in a published erratum, the physicians indicated that the patient had been consuming alcohol on a regular basis and was taking the drug valaciclovir at the time of the original incident (Levitsky et al. 2005b).

Fulminant liver failure was reported in a 54-year-old woman who had been taking 1000 mg of an unspecified black cohosh product daily for 8 months. The woman had a history of fibromyalgia, osteoarthritis, depression, and hypothyroidism and was also taking fluoxetine, propoxyphene, acetaminophen, and levothyroxine (Lynch et al. 2006).

Acute hepatitis was reported in a 47-year-old woman who had been taking 40 mg of an *isopropanol* extract of black cohosh daily for 6 days (Whiting et al. 2002).

Hepatitis was reported in a 50-year-old woman with a history of gallstones, gastroesophageal *reflux* disease, and anxiety who took 40 mg of black cohosh (product unspecified) daily for 2 weeks along with lansoprazole (Nisbet and O'Connor 2007).

Acute liver failure was reported in a 41-year-old woman who had been taking black cohosh for 2 weeks; the dose and product used were not specified. In this case, the woman developed giant cell hepatitis that increased in severity after cessation of black cohosh (Dunbar and Solga 2007).

Elevated liver enzymes were reported in a 50-year-old woman with a history of chronic fatigue and high blood pressure. The woman had been taking black cohosh, although the dose, duration, and product used were not specified (Joy et al. 2008).

Elevated liver enzymes were reported in a 51-year-old woman with a history of gallstones, fatty liver, and asthma who had been taking black cohosh for 2 months. The black cohosh dose and product used were not specified (Joy et al. 2008).

Liver failure was reported in a 51-year-old woman who had been taking 20 mg of black cohosh intermittently for 3 years, with titration according to her menopausal symptoms. The woman had a history of obesity, gastric bypass surgery, and alcoholism (Chow et al. 2008).

Liver injury was reported in a 42-year-old woman with a history of hypothyroidism who had been taking black cohosh (product and dose not specified) for 6 months along with levothyroxine. Liver enzyme levels remained elevated for several months after cessation of black cohosh (Guzman et al. 2009).

Elevated liver enzymes were reported in a 53-year-old woman with a history of irritable bowel syndrome. Medications included dicyclomine and nonsteroidal anti-inflammatory drugs as needed and a product containing black cohosh and soy protein (dose, duration, and product used not specified) (Guzman et al. 2009).

Chronic hepatitis was reported in a 58-year-old woman with a history of high blood pressure, hypothyroidism, diabetes, and high cholesterol. The woman had been taking 80 mg of black cohosh extract daily for 1 year along with irbesartan, levothyroxin, simvastatin, and insulin. The liver injury was initially thought to be induced by simvastatin, although discontinuation of simvastatin did not result in a reduction of liver enzyme levels (Pierard et al. 2009).

Cutaneous vasculitis was reported in two patients taking 80 mg black cohosh daily for 2–4 months (one woman was taking a product that contained black cohosh and "other vitamin, mineral, and herbal supplements"). The vasculitis resolved after treatment and cessation of black cohosh. No other medications or significant medical history were reported in either patient, and both patients declined a rechallenge (Ingraffea et al. 2007).

A renal transplant rejection occurred 16 years post-transplant in a woman taking black cohosh, alfalfa (*Medicago sativa*), azathioprine, and cyclosporine. The woman had undergone treatment for breast cancer several months prior to the incident (Light and Light 2003).

Other adverse events associated with black cohosh use include a case of asthenia (Minciullo et al. 2006) and a case of an erythematous rash (Meyer et al. 2007), each in women who had been taking black cohosh for 1 year.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Human clinical trials have indicated a lack of estrogenic effects of black cohosh. In a clinical trial of 400 postmenopausal women, administration of 40 mg of black cohosh extract daily for 1 year did not produce any endometrial hyperplasia or other adverse endometrial outcomes, and no change in endometrial thickness was observed (Raus et al. 2006). Likewise, in a clinical trial of peri- and postmenopausal women, 24 weeks of black cohosh (39 or 127 mg/day) administration did not produce any changes in vaginal cytology and no systemic estrogenic effects were observed (Liske et al. 2002).

No changes in vaginal cytology profiles, vaginal dryness, menstrual cyclicity, or hormone profiles were observed in women ages 45 to 55 orally administered 160 mg black cohosh daily for 12 months (Reed et al. 2008).

No estrogenic activity was observed in postmenopausal women orally administered 80 mg black cohosh daily for 12 weeks. Measures of estrogenicity included estrogenic markers in serum, pS2 levels, and cellular morphology in nipple aspirate fluid (Ruhlen et al. 2007).

No changes in mammographic breast density, breast cell proliferation, or endometrial thickness were observed in postmenopausal women who consumed 40 mg daily of isopropanolic extract of black cohosh for 6 months (Hirschberg et al. 2007).

In a retrospective cohort study of breast cancer survivors, a delay in breast cancer recurrence was observed in women using black cohosh, as compared to women not taking black cohosh (Zepelin et al. 2007).

In postmenopausal women taking 40 mg black cohosh extract daily for 4 months, no changes in total hepatic blood flow, bilirubin, γ-glutamyltransferase, alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, serum albumin, or prothrombin time and concentration were observed (Nasr and Nafeh 2009). No changes in liver enzyme levels were observed in other studies with women taking 40 mg black cohosh daily for 3 or 4 months, or in women given single doses up to 128 mg (Bai et al. 2007; Osmers et al. 2005; van Breemen et al. 2009).

A human study with the compound 23-epi-26-deoxyactein , administered at doses of 1.4, 2.8, or 5.6 mg, indicated that no phase I or phase II metabolites of this compound were found. Based on the lack of metabolites, 23-epi-26-deoxyactein is believed to not be metabolized by cytochrome

P450 enzymes and thus is unlikely to be a source of interactions caused by competition for CYP enzymes (van Breemen et al. 2010).

Animal Pharmacological Studies

Reviews examining the estrogenic effects of black cohosh have indicated that data from animal studies is mixed but currently leans toward lack of estrogenic activity (Huntley 2004; Mahady 2003, 2005). Reviewers have noted that older studies tend to demonstrate estrogenic effects while new studies demonstrate a lack of estrogenicity. Increased uterine weight and decreased luteinizing hormone (LH) levels are indications of estrogenic activity (Upton 2002).

Studies in rats and mice (typically ovariectomized animals) have indicated increased uterine weight and or decreased luteinizing hormone (LH) levels in animals administered black cohosh (Düker et al. 1991; Eagon et al. 1999; Foldes 1959; Gizicky 1944; Jarry and Harnischfeger 1985; Jarry et al. 1985). Other studies have shown no increase in uterine weight (Einer-Jensen et al. 1996; Kretzschmar et al. 2005). In rats, black cohosh reduced bone mineral density loss with no effect on uterine weight or gene expression, suggesting that black cohosh is an organ-specific selective estrogen receptor modulator (Seidlova-Wuttke et al. 2003).

In rats orally administered up to 600 mg of a black cohosh extract or up to 40 mg of a lipophilic fraction of black cohosh extract, no uterotrophic activity was observed (Bolle et al. 2007).

In mice genetically predisposed to breast cancer that were fed diets containing black cohosh at a level equivalent to a human 40 mg daily dose, no differences were detected in the incidence or onset of mammary tumors. In tumor-bearing mice, an increase in the incidence of lung metastases was observed in animals on the same black cohosh-containing diet (Davis et al. 2008).

In rats with estrogen-dependent mammary tumors, treatment with black cohosh did not stimulate cancerous growths (Freudenstein et al. 2002). Likewise, in rats with endometrial cancer treated with black cohosh alone or with tamoxifen, animals in both the black cohosh and black cohosh plus tamoxifen treatment groups had fewer metastases and smaller tumor mass than the untreated control animals (Nisslein and Freudenstein 2004).

In Vitro Pharmacological Studies

Reviews examining the estrogenic effects of black cohosh have indicated that data from in vitro studies is mixed but leans toward lack of estrogenic activity (Huntley 2004; Mahady 2003, 2005). The authors noted that older studies tend to demonstrate estrogenic effects while new studies demonstrate a lack of estrogenicity.

In vitro experiments have examined effects of black cohosh on proliferation of various cancer cell lines, mostly on estrogen receptor-positive breast cancer lines. A number of studies have shown that black cohosh did not cause cell proliferation and in some cases even inhibited proliferation (Bodinet and Freudenstien 2002; Dixon Shanies and Shaikh 1999; Einbond et al. 2007, 2008; Freudenstein and Bodinet 1999; Gaube et al. 2007; Hostanska et al. 2004; Lupu et al. 2003; Nesselhut et al. 1993; Rice et al. 2007; Zava et al. 1998), while others have indicated a proliferative effect (Harnischfeger and Cillien 1996; Liu et al. 2001a; Lohning et al. 2000). Similarly, studies examining the binding of black cohosh to estrogen receptors have shown no binding (Düker et al. 1991; Eagon et al. 1996; Harnischfeger and Cillien 1996; Liu et al. 2001b; Zava et al. 1998; Zierau et al. 2002), while others have shown binding (Jarry et al. 1985, 1999, 2003; Liu et al. 2001a).

In mouse mammary tumor cells, treatment with black cohosh increased the cytotoxicity of doxorubicin and docetaxel and decreased the cytotoxicity of cisplatin, but did not alter the effects of radiation or 4-hydroperoxycyclophosphamide (an analog of cyclophosphamide that is active in cell culture) (Rockwell et al. 2005).

In human liver cancer cells (HepG2), an ethanol extract of black cohosh impaired mitochondrial β-oxidation at a concentration of 10 µg/ml and demonstrated cytotoxic activity at a concentration of 75 µg/ml (Lüde et al. 2007).

In estrogen receptor-positive breast cancer cells (MCF-7), black cohosh alone did not show any stimulatory effect on cell growth, while a dose-dependent inhibition of estrogen proliferative effect with black cohosh was noted. A combination of black cohosh with increasing tamoxifen concentrations further inhibited breast cancer cell growth (Al-Akoum et al. 2007).

Black cohosh was shown to be a partial agonist of the µ-opiate receptor in hamster ovary cells expressing human opiate receptors (Rhyu et al. 2006).

IV. Pregnancy and Lactation

Limited scientific information is available on the use of black cohosh during pregnancy and labor. Traditional use indicates black cohosh as a partus preparator (Upton 2002).

Reviewing the available literature, Dugoua et al. (2006) concluded that low-level evidence showed concerns for use during pregnancy due to labor inducing effects, hormonal effects, emmenagogue properties, and anovulatory effects (Dugoua et al. 2006). Those authors noted that low-level evidence suggested that potential hormonal activity of black cohosh could be a cause for concern during breast-feeding. Human studies conducted since that review was completed have indicated a lack of estrogenic activity of black cohosh (*see* Human pharmacological studies).

One reference (Dugoua et al. 2006) noted low-level evidence suggesting potential hormonal activity of black cohosh could be a cause for concern during lactation, while other studies indicated a lack of estrogenic activity of black cohosh (*see* Human pharmacological studies).

Review Details

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound acteina was greater than 500 mg/kg in mice after intraperitoneal administration, was 1000 mg/kg in rats after oral administration, and was 70 mg/kg in rabbits after intravenous administration. Toxic doses of acteina could not be determined in rabbits administered the compound orally or subcutaneously (Genazzani and Sorrentino 1962).

Short-Term Toxicity

In a study of an ethanolic extract of black cohosh administered by gavage to rats in daily doses from 1 to 1000 mg/kg for 21 days, some dose-dependent changes in liver cell mitochondria were observed beginning at the 10 mg/kg dose. At 10 mg/kg, a slight amount of mitochondrial swelling and an enlargement of bile canaliculi was observed. At the 100 or 300 mg/kg dose, more distinct mitochondrial swelling and alterations in mitochondrial morphology such as vacuoles in the matrix was observed. At 1000 mg/kg, effects included microvesicular steatosis of the hepatocytes, and glycogen depletion (Lüde et al. 2007).

No changes in liver morphology or hepatic function indices were observed in rats orally administered 300 mg/kg of black cohosh extract daily for 30 days (Mazzanti et al. 2008).

Chronic Toxicity

In rats administered black cohosh extract up to 5000 mg/kg/day, slight and reversible increases in some organ weights were noted in animals administered the highest doses, but no toxic effects were noted at any of the dose levels (Korn 1991).

Genotoxicity

No evidence of mutagenicity was demonstrated in the Ames test (Beuscher 1996; Boblitz et al. 2000; Schaper and Brümmer 1990).

OCN: ladybells
Adenophora triphylla (Thunb. ex Murray) A. DC.
SCN: adenophora
Syn: *Adenophora tetraphylla* Fisch.
PN: *nan sha shen* (root)
OCN: ladybells
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to adenophora have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of adenophora in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Inappropriate use of adenophora may cause headaches, weakness, apathy, aversion to cold, distended abdomen, vomiting, or delayed menstruation (Bensky et al. 2004).

Allergic reactions to adenophora, including drug rash and asthma, have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Methanol and ethanol extracts of adenophora exhibited weak estrogenic effects in recombinant yeast system assays (Kang et al. 2006; Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the use of adenophora during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (List and Hörhammer 1973; Taylor 2005).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

"Large" doses may be emetic (Chadha 1988; List and Hörhammer 1973).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Maidenhair fern has traditionally been used to promote menstruation (Taylor 2005). Use in pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of maidenhair fern during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

Aesculus hippocastanum L.

Hippocastanaceae

SCN: horse chestnut

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Systematic reviews and meta-analyses of clinical trials with horse chestnut indicate that horse chestnut is generally well tolerated with few associated adverse events (Pittler and Ernst 2006; Siebert et al. 2002). Mild adverse events reported in clinical trials were gastrointestinal complaints, dizziness, nausea, headache, and itching (Pittler and Ernst 2006).

Allergic reactions, including anaphylactic reactions, to horse chestnut have been reported (Jaspersen-Schib et al. 1996; Sirtori 2001).

Cases of kidney and liver damage have been reported in association with injections of purified extracts of horse chestnut (Grasso and Corvaglia 1976; Hellberg et al. 1975; Klose and Pistor 1976; Takegoshi et al. 1986; Voigt and Junger 1978). No such reactions have been reported or are expected with oral use of horse chestnut (Mills and Bone 2005).

Pharmacological Considerations

In vitro studies examining the effects of horse chestnut on the drug-metabolizing isoenzymes CYP3A4, CYP1A2, CYP2D6, CYP2E1, and CYP2C19, and P-glycoprotein (P-gp) drug efflux transporters showed some effects on these isoenzymes and transporters, but none were thought to be clinically relevant (Brandin et al. 2007; Hellum et al. 2007, 2009; Hellum and Nilsen 2007, 2008).

Pregnancy and Lactation

No adverse effects on fetal development were reported in several clinical studies on the use of horse chestnut extract in pregnant women (Alter 1973; Steiner 1990; Steiner and Hillemanns 1986, 1990). In animal studies, decreased fetal weight was observed in rabbits orally administered high doses (300 mg/kg) of horse chestnut. No adverse effects were observed at the same dose in rats or lower doses (100 mg/kg) in rats or rabbits (Liehn et al. 1972).

No information on the safety of horse chestnut during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of double-blind, controlled studies of horse chestnut indicated that 14 of the identified studies reported on adverse events. Of the 14, 4 reported that there were no treatment-related adverse events in the horse chestnut groups. In 6 studies, gastrointestinal complaints, dizziness, nausea, headache, and pruritus were reported with a frequency ranging from 1 to 36% of treated patients. The remaining 4 studies reported that horse chestnut treatments were well tolerated. The review characterized adverse events in the horse chestnut groups as mild and infrequent (Pittler and Ernst 2006).

A meta-analysis of randomized controlled trials (totaling 1051 patients) and large-scale observational studies (totaling 10,725 patients) of horse chestnut extract indicated that no serious adverse events were reported in the trials and studies and that treatment with horse chestnut extract did not significantly increase mild adverse events (Siebert et al. 2002).

Case Reports of Adverse Events

Cases of acute renal failure have been reported in children who were intravenously administered injections of 0.5 mg/kg (approximately 2 to 3 times the recommended dose) of aescin (a mixture of saponins from horse chestnut) for an

average of 4 days. The cases were primarily seen in children ages 2 to 10 and were observed after 3 to 4 days of normal renal function. The overall mortality rate was 10.7% (Grasso and Corvaglia 1976; Hellberg et al. 1975; Klose and Pistor 1976; Voigt and Junger 1978). Commenting on these cases, a text on the use of drugs in patients with renal insufficiency notes that the cases involved patients administered either the standard dose or overdose, and that some were also taking other drugs. Also, most of the patients were polytraumatic after accidents or had undergone severe surgery, conditions that alone may lead to acute renal failure (Seyffart 1991). Aescin may cause hemolysis after injection, and the liberated hemoglobin can deposit in the kidneys, leading to renal failure. Such effects are not expected with oral use of horse chestnut (Mills and Bone 2005).

Hepatic injury was reported in a 37-year-old man who had received a single intramuscular injection of 65 mg of a standardized horse chestnut extract prior to surgery. Liver tests performed 17 days after injection revealed moderate elevation of total bilirubin, ALP, GGTP and mild eosinophilia. The lymphocyte stimulation test was positive, and the liver biopsy demonstrated marked cholestasis with zonal necrosis in the centrilobular areas but showed little or no changes in the portal tracts (Takegoshi et al. 1986).

Allergic reactions, including anaphylactic reactions, to horse chestnut have been reported (Jaspersen-Schib et al. 1996; Sirtori 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In trials assessing the renal effects of intravenously administered aescin (a mixture of saponins from horse chestnut; 10 to 25 mg daily for 3 to 10 days), no impairment of renal function was observed in patients with healthy kidneys, and no worsening of function was observed in patients with renal impairment (Ascher 1977; Bastian and Valilensieck 1976; Sirtori 2001; Wilhelm and Feldmeier 1975).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of the drug-metabolizing isoenzyme CYP3A4 and the P-gp drug efflux transporters was observed in cDNA baculovirus-expressed CYP3A4 and Caco-2 cells treated with horse chestnut extract. The effects were less than that of St. John's wort (Hellum and Nilsen 2008). Some inhibition of CYP2D6 was observed in cDNA baculovirus-expressed CYP2D6, although the activity was not considered to be clinically relevant (Hellum and Nilsen 2007).

General inhibitory potential of the drug-metabolizing isoenzymes CYP1A2, CYP2D6, and CYP3A4 were observed in primary human hepatocytes treated with an extract of horse chestnut. The activity was less than that of other botanicals considered to have clinically relevant CYP interactions (Hellum et al. 2007).

A twofold induction of the drug-metabolizing isoenzyme CYP1A2 was observed in human colon cancer cells (LS180) treated with horse chestnut extract. No effects on CYP3A4 or the transporter protein MDR1 were observed (Brandin et al. 2007).

No significant effects of horse chestnut extract were observed in the drug-metabolizing isoenzymes CYP2C19 and CYP2E1 in cultured human hepatocytes (Hellum et al. 2009).

IV. Pregnancy and Lactation

Several clinical studies on the use of horse chestnut extract in pregnant women have been completed. Dosages were 480 to 600 mg daily (standardized to 100 mg aescin) for 2 to 4 weeks. In these studies, no adverse effects on fetal development were reported (Alter 1973; Steiner 1990; Steiner and Hillemanns 1986; Steiner and Hillemanns 1990).

No teratogenic effects were observed in the offspring of rats orally administered 100 or 300 mg/kg or rabbits orally administered 100 mg/kg horse chestnut extract during pregnancy. In rabbits administered 300 mg/kg, a significant reduction in the weight of fetuses was observed (Liehn et al. 1972). No teratogenic or embryotoxic effects of horse chestnut extract were observed in rats intravenously administered 9 or 30 mg/kg on days 6 to 15 of pregnancy, or rabbits administered the same doses on days 6 to 18 of pregnancy (Liehn et al. 1972).

No information on the safety of horse chestnut during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered horse chestnut extract is 990 mg/kg in mice, 2150 mg/kg in rats, 1120 mg/kg in guinea pigs, 1530 mg/kg in rabbits, 10,700 mg/kg in hamsters, and 10,600 mg/kg in chicks (Liehn et al. 1972; Williams and Olsen 1984). In dogs, no oral LD_{50} could be determined, as dogs vomited the test substance at doses over 130 mg/kg (Liehn et al. 1972). The LD_{50} of intravenously administered horse chestnut extract is 138 mg/kg in mice, 165 mg/kg in rats, 465 mg/kg in guinea pigs, and 180 mg/kg in rabbits. The LD_{50} of intraperitoneally administered horse chestnut in mice was 342 mg/kg (Liehn et al. 1972).

Subchronic Toxicity

In rats intravenously administered 9, 30, or 90 mg/kg horse chestnut extract daily for 8 weeks, no adverse effects were reported at the 9 mg/kg dose. At the 90 mg/kg dose, 8 of the 30 test animals died during the first several days, although the rest of the animals in that treatment group developed normal body weights (Liehn et al. 1972).

No toxic effects or organ damage were observed in dogs orally administered 20, 40, or 80 mg/kg (8 times the human dose) or rats orally administered 100, 200, or 400 mg/kg (40 times the human dose) of horse chestnut extract 5 days per week for 34 weeks (Liehn et al. 1972).

Genotoxicity

In the Ames test for mutagenicity, horse chestnut extract was weakly mutagenic with metabolic activation by S9 but showed no mutagenicity without activation. Fluid extracts of horse chestnut showed no mutagenic activity without activation, and weak mutagenic activity with activation (Schimmer et al. 1994). The authors of this study indicated that the mutagenic effects were likely due to the compound quercetin, and quercetin is not considered to have clinically relevant mutagenic activity in humans (Harwood et al. 2007).

A

Aframomum melegueta K. Schum. — Zingiberaceae

SCN: grains-of-paradise (seed)
Syn: *Amomum melegueta* Roscoe
AN: *brihadela*

OCN: Guinea grains (seed); melegueta pepper (seed)
Part: fruit, seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Contains piperine (Githens 1948); *see* Appendix 3.

Editors' Note

Concerns for this herb are based on the relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

In one human study, consumption of single doses of 350 mg of grains-of-paradise seed led to temporary ocular changes (Igwe et al. 1999).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of grains-of-paradise in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Ingestion of 350 mg of grains-of-paradise seed by healthy males increased the near point of convergence in the eyes by 17% and reduced the amplitude of ocular accommodation by 9.2% without affecting pupil size or visual acuity. The increased near point of convergence leads to doubling of vision while the reduction or loss of accommodation leads to blurring of vision, with these effects synergizing to transiently impair vision. The authors indicated that traditional practice of long-term, excessive consumption of grains-of-paradise may contribute to premature presbyopia that is common among the Igbo peoples of eastern Nigeria (Igwe et al. 1999).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of grains-of-paradise during pregnancy or lactation was identified.

V. Toxicity Studies

The LD_{50} of intraperitoneally administered grains-of-paradise ethanol extract in mice was 2.1 g/kg (Okoli et al. 2007).

SCN: buchu
Syn: *Barosma serratifolia* (Curtis) Willd.
OCN: long buchu
Part: leaf

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bradley 1992; Collins and Graven 1996; Kaiser et al. 1975).

Other Precautions

Use with caution in persons with kidney inflammation (McGuffin et al. 1997).

Drug and Supplement Interactions

None known.

Notice

Diuretic (Felter and Lloyd 1898; Moolla and Viljoen 2008; Remington and Wood 1918). (See Appendix 2.)

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Buchu contains the compound pulegone (2.4–4.5% of *A. betulina* essential oil and 31.6–73.2% of *A. crenulata* essential oil) (Collins and Graven 1996; Kaiser et al. 1975). Pulegone is considered to be the primary compound in European pennyroyal (*Mentha pulegium*) responsible for the abortifacient activity of this plant (Anderson et al. 1996). Although no reports of abortifacient activity of buchu were identified, use of buchu during pregnancy is not recommended.

No information on the safety of buchu during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Buchu contains the compound pulegone (2.4–4.5% of *A. betulina* essential oil and 31.6–73.2% of *A. crenulata* essential oil) (Collins and Graven 1996; Kaiser et al. 1975). Pulegone is considered to be the primary compound in European pennyroyal (*Mentha pulegium*) responsible for the abortifacient activity of that plant (Anderson et al. 1996). Although no reports of abortifacient activity of buchu were identified, use of buchu during pregnancy is not recommended.

No information on the safety of buchu during lactation was identified.

V. Toxicity Studies

Cytotoxicity

At concentrations up to 100 µg/ml, no cytotoxic activity of the essential oil of buchu species (*A. betulina* and *A. crenulata*) was observed in the MTT cellular viability assay (Viljoen et al. 2006).

Albizia julibrissin Durazz. — Fabaceae

SCN: silk tree
PN: *he huan pi* (bark)

OCN: mimosa tree
Part: bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that silk tree bark should be used with caution in pregnancy (Bensky et al. 2004; Chen and Chen 2004). One text indicates that silk tree bark stimulates uterine contractions (Chen and Chen 2004).

No information on the safety of silk tree bark during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound julibrin II (4′-*O*-methylpyridoxine) was found to induce arrhythmias in isolated frog hearts. Other related compounds also isolated from silk tree did not induce arrhythmias (Higuchi et al. 1992). The compound 4′-*O*-methylpyridoxine is also found in ginkgo seed and is believed to be the compound associated with seizures reported after excessive consumption of ginkgo seed. The seizures are thought to be due to vitamin B_6 deficiency, which can be caused by 4′-*O*-methylpyridoxine (van Beek and Montoro 2009; Wada et al. 1985). No cases of seizures have been reported in association with traditional use of silk tree.

IV. Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that silk tree bark should be used with caution in pregnancy (Bensky et al. 2004; Chen and Chen 2004) and indicate that silk tree bark stimulates uterine contractions (Chen and Chen 2004).

No information on the safety of silk tree bark during lactation was identified.

V. Toxicity Studies

Silk tree bark contains the compound 4′-*O*-methylpyridoxine, a compound that can cause vitamin B_6 deficiency symptoms and is believed to be responsible for the toxic effects (seizures and gastrointestinal symptoms) of ginkgo seed consumption (see *Ginkgo biloba* seed entry) (Mooney et al. 2009; Wada et al. 1985). No toxic effects of silk tree bark have been reported in association with use in traditional Chinese medicine (Bensky et al. 2004; Chen and Chen 2004).

Cytotoxicity

Saponin fractions of silk tree exhibited cytotoxic activity in vitro (Ikeda et al. 1997).

V. Toxicity Studies

Genotoxicity

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA100, some mutagenic activity of an ethanol extract of lady's mantle was observed in TA98 but not in TA100. Mutagenic activity in this and other plant extracts tested in the study was consistent with quercetin levels in the plants and the mutagenic activity was attributed to the quercetin (Schimmer et al. 1988). Reviews of quercetin have indicated that although mutagenic effects have been observed in vitro, such effects are not seen in vivo (Harwood et al. 2007).

Aletris farinosa L. — Liliaceae

SCN: aletris
OCN: blazing star; colic root; star grass; true unicorn

Part: rhizome, root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

One early animal study indicates a uterine depressant effect of aletris and reports that aletris may antagonize the oxytocin-stimulating effects of the pituitary gland (Butler and Costello 1944). There is no evidence to suggest this would

result in a clinically relevant interaction with oxytocin administration during labor.

No information on the safety of aletris during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

A hydroalcoholic extract of aletris showed minimal binding to human breast cancer cells rich in estrogen (MCF-7) or progesterone (T47D) receptors (Zava et al. 1998).

IV. Pregnancy and Lactation

A fluid extract of aletris exhibited depressant activity on the uterus of anesthetized cats, and in isolated rat uteri. An antagonistic effect against the stimulating action of the oxytocic principle of the posterior lobe of the pituitary was also observed (Butler and Costello 1944).

No information on the safety of aletris during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Literature Cited

Butler, C.L., and C.H. Costello. 1944. Pharmacological studies. I. *Aletris farinosa*. *J. Am. Pharm. Assoc.* 33:177-183.

Alisma plantago-aquatica L. ssp. *orientale* (Sam.) Sam. — Alismataceae

SCN: Asian water plantain
Syn: *Alisma orientale* (Sam.) Juz.
PN: *ze xie* (rhizome)

OCN: alisma
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Prolonged use may cause gastrointestinal irritation or disturb electrolyte balance (Bensky et al. 2004).

Drug and Supplement Interactions

None known.

Notice

Diuretic (Bensky et al. 2004; Chen and Chen 2004; Zhu 1998); *see* Appendix 2.

Adverse Events and Side Effects

Long-term use or overdose of Asian water plantain can disturb electrolyte balance (Bensky et al. 2004).

Nausea, vomiting, abdominal pain, diarrhea, and disturbance of liver function have been reported in association with Asian water plantain use (Bensky et al. 2004).

Allergic skin rash after exposure to Asian water plantain has been reported (Bensky et al. 2004).

Pharmacological Considerations

One in vitro study has indicated that Asian water plantain may inhibit the drug-transporting protein P-glycoprotein (Fong et al. 2007).

Pregnancy and Lactation

No information on the safety of Asian water plantain in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Long-term use or overdose of Asian water plantain can disturb the electrolyte balance and may cause hematuria and, in severe cases, acidosis (Bensky et al. 2004).

Nausea, vomiting, abdominal pain, diarrhea, and disturbance of liver function were reported in association with Asian water plantain use (Bensky et al. 2004).

Allergic skin rash after exposure to Asian water plantain was reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In multidrug-resistant cancer cells, extracts of Asian water plantain showed a s ynergistic growth inhibitory effect with cancer drugs that are P-glycoprotein (P-gp) substrates including actinomycin D, puromycin, paclitaxel, vinblastine, and doxorubicin. The authors of the study concluded that Asian water plantain may contain components that are effective inhibitors of P-gp (Fong et al. 2007).

IV. Pregnancy and Lactation

No information on the safety of alisma in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intravenously injected alcohol extract of Asian water plantain in rats was 0.98 g/kg and 1.27 g/kg after intraperitoneal injection (Chen and Chen 2004).

Subchronic Toxicity

No adverse effects on internal organs were observed in rats orally administered an extract of Asian water plantain at doses of 1 or 2 g/kg daily for 3 months (Chen and Chen 2004).

Alkanna tinctoria (L.) Tausch

Boraginaceae

SCN: alkanet

Part: root

Quick Reference Summary

Safety Class: 2a, 2b, 2c
Interaction Class: A

Contraindications

For external use only (Roeder et al. 1984).

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Roeder et al. 1984).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Pyrrolizidine alkaloids (Roeder et al. 1984); *see* Appendix 1.

Editors' Notes

The American Herbal Products Association has established a trade requirement (AHPA 2011) that all products with botanical ingredients that contain toxic pyrrolizidine alkaloids, including alkanet, are not offered for sale for internal use and display the following cautionary label: "For external use only. Do not apply to broken or abraded skin. Do not use when nursing."

Alkanet contains unsaturated pyrrolizidine alkaloids, although the concentrations of alkaloids in various parts of the plant are not known (Roeder et al. 1984).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of alkanet in pregnancy or lactation was identified in the scientific or traditional literature. Based on the presence of pyrrolizidine alkaloids, alkanet should not be used in pregnancy or lactation.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of alkanet in pregnancy or lactation was identified. Based on the presence of pyrrolizidine alkaloids, alkanet should not be used in pregnancy or lactation.

V. Toxicity Studies

Subchronic Toxicity

No toxic effects were observed in mice fed a diet containing 1% of the compound alkannin daily for 15 weeks. The compound was not detected in abdominal fat or in urine of the treated animals (Majláthová 1971).

Genotoxicity

No mutagenic activity of the compound alkannin was observed in *Salmonella typhimurium* strains TA98 or TA1535 with or without metabolic activation (Papageorgiou 1978).

Literature Cited

Allium sativum L. — Liliaceae

SCN: garlic
AN: *lashuna*; *rasona*

PN: *da suan* (bulb)
Part: bulb

Quick Reference Summary

Safety Class: 1
Interaction Class: C

Contraindications

None known.

Other Precautions

Use of two or more grams of garlic daily in persons with coagulation disorders should be under the supervision of a qualified healthcare professional (Bordia et al. 1996; Kiesewetter et al. 1993a; Kiesewetter et al. 1993b; Steiner and Li 2001).

Patients undergoing surgery are advised to stop consuming garlic seven days before surgery (Bordia et al. 1996; Kiesewetter et al. 1993a; Kiesewetter et al. 1993b; Steiner and Li 2001).

Persons with acute or chronic stomach inflammation should use caution when taking raw or minimally processed garlic products (De Smet 1992; Felter and Lloyd 1898; Nelson et al. 2006). Persons with acid-reflux should avoid garlic due to the reported relaxing effects on the lower esophageal sphincter of aromatic compounds (Brinker 2001).

External applications of raw garlic may cause skin irritation, contact dermatitis, or chemical burn (Friedman et al. 2006).

Drug and Supplement Interactions

Doses equivalent to two or more grams daily of fresh garlic may reduce plasma levels of saquinavir (Piscitelli et al. 2002).

Also see Pharmacological Considerations for this entry.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

In a systematic review of garlic clinical trials, adverse effects included "smelly" breath and body odor. Other effects, noted as possible but not proven, included flatulence, esophageal and abdominal pain, small intestinal obstruction, dermatitis, rhinitis, asthma, and bleeding (Mulrow et al. 2000). Garlic may cause gastrointestinal disturbance in sensitive individuals (Bradley 1992; De Smet 1992; Felter and Lloyd 1898; Nelson et al. 2006).

Several cases of abnormal bleeding have been reported in association with garlic use (Burnham 1995; Carden et al. 2002; German et al. 1995; Rose et al. 1990).

Allergic reactions to garlic, including anaphylactic reactions, have been reported (Perez-Pimiento et al. 1999). Topical exposure to raw garlic is recognized to cause various types of allergic and non-allergic skin irritation in sensitive individuals (Jappe et al. 1999).

Pharmacological Considerations

Persons taking heparin, clopidogrel, or aspirin, and doses equivalent to two or more grams daily of fresh garlic should be monitored for abnormal bleeding (Bordia et al. 1996; Kiesewetter et al. 1993a; Kiesewetter et al. 1993b; Steiner and Li 2001). Human studies have shown no additive effects of garlic and warfarin on platelet aggregation (Abdul et al. 2008; Macan et al. 2006).

Human studies have shown varying effects of garlic preparations on platelet aggregation, with some studies showing no effects and others showing inhibition of aggregation (Beckert et al. 2007; Bordia et al. 1996; Kiesewetter et al. 1993a; Kiesewetter et al. 1993b; Scharbert et al. 2007; Steiner and Li 2001).

In human studies, garlic oil has been shown to inhibit the drug metabolizing isoenzyme CYP2E1 (Gurley et al. 2002; Gurley et al. 2005).

Pregnancy and Lactation

No maternal or fetal adverse events were observed in one human study of garlic use during the third trimester of pregnancy (Ziaei et al. 2001).

Ingestion of garlic by nursing mothers has been shown to change the odor of human breast milk (Mennella and Beauchamp 1991), in some cases leading to increased nursing

(Mennella and Beauchamp 1991; Mennella and Beauchamp 1993). As with some commonly consumed vegetables, such as broccoli and cabbage, garlic consumption by nursing mothers has been associated with colic in some breastfeeding infants (Lust et al. 1996).

One text on Ayurvedic medicine contraindicates garlic in pregnancy (Chadha 1988); however, the long history of use as a food has established that consumption of garlic in reasonable quantities is generally safe, though caution may be indicated in children.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Coadministration of 3.6 g saquinavir and 2.4 g garlic daily for 20 days resulted in a decrease in plasma levels of saquinavir (Piscitelli et al. 2002).

No changes in INR (a standardized scale used to report the results of blood coagulation tests), platelet aggregation, clotting factor activity, or plasma levels of warfarin, were observed in healthy volunteers orally administered two garlic tablets (each the equivalent of 2 g fresh garlic) daily for two weeks (Abdul et al. 2008).

In patients on warfarin therapy, supplementation with 10 ml daily of aged garlic extract did not require adjustments in warfarin dose. No significant changes in hematological parameters, including INR, platelet count, and incidences of hemorrhages, were observed (Macan et al. 2006).

Single doses of acetaminophen (1 g) administered during three months supplementation of aged garlic extract (equivalent to 6 cloves/day) showed that peak plasma concentrations of acetaminophen and acetaminophen metabolites were increased and renal clearance was decreased by garlic coadministration (Gwilt et al. 1994).

No effects on ritonavir (400 mg, single dose) were observed after ingestion of 10 mg garlic extract (equivalent to 1 g of fresh garlic) daily for four days (Gallicano et al. 2003).

In renal transplant patients on cyclosporine therapy, ingestion of one clove of garlic daily did not affect cyclosporine levels (Jabbari et al. 2005).

In breast cancer patients undergoing treatment with docetaxel (30 mg/m^2/week), coadministration with 1200 mg garlic daily did not significantly affect docetaxel pharmacokinetics (Cox et al. 2006).

Case Reports of Suspected Drug or Supplement Interactions

Two cases of increased international normalized ratio (INR) (a standardized scale used to report the results of blood coagulation tests) and clotting time have been reported in persons taking garlic and the anticoagulant, warfarin (doses unspecified) (Sunter 1991).

A case of decreased INR was reported in an 82-year-old man taking garlic (600 mg daily) and the anticoagulant, fluindione (Pathak et al. 2003).

A case of platelet dysfunction in an 87-year-old patient was reported after chronic consumption of approximately 2 g daily of garlic cloves (De Smet 1993).

Two cases of gastrointestinal toxicity were reported in patients taking garlic and the protease inhibitor, ritonavir (Laroche et al. 1999).

Animal Trials of Drug or Supplement Interactions

In rabbits, single doses of the antibiotic isoniazid (30 mg/kg) before and after 14 days supplementation with an aqueous garlic extract significantly decreased the bioavailability of isoniazid with no change in rate of elimination (Dhamija et al. 2006). An identical study completed with the antibiotic rifampicin (24 mg/kg) indicated no change in rifampicin bioavailability (Dhamija et al. 2006).

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a systematic review of garlic clinical trials, adverse effects included "smelly" breath and body odor. Other effects, noted as possible but not proven, included flatulence, esophageal and abdominal pain, small intestinal obstruction, dermatitis, rhinitis, asthma, and bleeding (Mulrow et al. 2000).

Case Reports of Adverse Events

Several cases of abnormal bleeding have been reported in association with garlic ingestion. These cases include spinal epidural hematoma with platelet dysfunction (Rose et al. 1990), post-operative bleeding (Burnham 1995; German et al. 1995) and a periorbital hematoma (Carden et al. 2002).

Allergic reactions to garlic, including anaphylactic reactions, have been reported (Perez-Pimiento et al. 1999). Topical exposure to raw garlic has caused irritant, allergic and protein contact dermatitis, contact urticaria, induction of pemphigus (blisters) and combinations thereof (Jappe et al. 1999).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In patients with stage II peripheral arterial occlusive disease, 800 mg garlic daily for 12 weeks was found to reduce spontaneous thrombocyte aggregation and plasma viscosity (Kiesewetter et al. 1993b).

In patients with cerebrovascular risk factors and constantly increased platelet aggregation, administration of 800 mg garlic daily for four weeks resulted in inhibition of circulating platelet aggregates and of spontaneous platelet aggregation. No significant changes were observed in the placebo group (Kiesewetter et al. 1993a).

In blood samples from patients with coronary artery disease who were administered garlic oil, inhibition of

chemically induced platelet aggregation was observed. Administration of different single doses indicated a lack of dose-dependent effect on platelet aggregation after acute administration, while lower doses administered long-term had anti-platelet activity (Bordia et al. 1996).

In blood samples taken from healthy volunteers orally administered 2.4, 4.8, or 7.2 g aged garlic extract daily for six weeks, platelet aggregation induced by ADP was slowed only at the highest dose level. When aggregation was induced by collagen, the middle and high doses had a slower rate than the low dose, while for epinepherine-induced aggregation, the low and middle doses were more effective in reducing aggregation than the high dose (Steiner and Li 2001).

In healthy volunteers orally administered garlic capsules at the manufacturer's recommended dose (amount not specified) daily for two weeks, no effects on platelet function or other hematological parameters were observed, including prothrombin time, partial thromboplastin time, thrombin time, bleeding time, the collagen/epinephrine assay, or the collagen/adenosine diphosphate assay. Aspirin was used as a positive control and markedly inhibited platelet function (Beckert et al. 2007).

In healthy volunteers fed 4.2 g raw garlic in food as either a single dose or a daily dose for one week, platelet function was not impaired by the single or repeated doses (Scharbert et al. 2007).

In blood samples taken from healthy volunteers orally administered 5 ml of aged garlic extract daily for 13 weeks, inhibition of the rate of ADP-induced aggregation was observed. Plasma levels of thromboxane B_2 and 6-ketoprostaglandin $F_{1\alpha}$ were unchanged (Rahman 2007).

Garlic oil (1500 mg/day for 28 days) has been shown to cause a significant inhibition of CYP2E1 activity in humans (Gurley et al. 2002; Gurley et al. 2005). No effects of garlic on CYP3A4, CYP1A2, or CYP2D6 have been observed (Gurley et al. 2002; Gurley et al. 2005; Markowitz et al. 2003).

Animal Pharmacological Studies

In rats orally administered 5 or 50 mg/kg diallyl trisulfide-rich garlic oil, prolongation of bleeding time and thrombin time and enhanced anticoagulation factor activity were observed. At 50 mg/kg, garlic oil increased plasma fibrinogen concentration and affected the levels of several hematological parameters such as erythrocyte count, hemoglobin, and platelets (Chan et al. 2007).

In rats administered 1 g/kg odorless garlic extract daily for two weeks, activation of the coagulation system in animals with induced thrombosis was suppressed in the garlic group, as evaluated by prothrombin time and activated partial thromboplastin time (Fukao et al. 2007).

In Vitro Pharmacological Studies

Studies available but omitted due to availability of human data.

IV. Pregnancy and Lactation

In a study of garlic in pregnant women, garlic intake of 800 mg daily for 8 weeks in the third trimester of pregnancy produced no adverse effects on infants or mothers, aside from "odor due to garlic" reported in 34% of mothers taking garlic (Ziaei et al. 2001).

Ingestion of garlic by nursing mothers has been shown to change the odor of human breast milk (Mennella and Beauchamp 1991). In studies of infant breastfeeding from nursing mothers who had taken a single dose of 1.5 grams of garlic, sulfur-containing volatile compounds were transmitted to breast milk. Infant nursing behavior on this milk ranged from unchanged to a significantly greater amount of time attached to the nipple (Mennella and Beauchamp 1991; Mennella and Beauchamp 1993).

As with some commonly consumed vegetables, such as broccoli and cabbage (Lust et al. 1996), garlic consumption by nursing mothers has been associated with colic in some breastfeeding infants, although no colic was reported in the studies detailed above (Mennella and Beauchamp 1991; Mennella and Beauchamp 1993).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered garlic extract in male rats was 30 ml/kg; female rats survived this dose of garlic (Nakagawa et al. 1984). Male and female rats survived doses of 30 ml/kg garlic administered orally or subcutaneously (Nakagawa et al. 1984).

Short-Term Toxicity

In rats intraperitoneally administered 500 mg/kg garlic extract for four weeks, changes in lung and liver tissue were observed. Side effects of garlic treatment included soft feces, dehydration and increase of white and red blood cells (Alnaqeeb et al. 1996).

In rats orally administered 5 ml/kg of fresh garlic juice daily for 21 days, serious stomach injury occurred along with swelling of the liver, hypertrophy of the adrenal glands and spleen, and changes in red blood cell count (Nakagawa et al. 1980).

Raw garlic powder administered by gavage (direct feeding tube) into dog stomachs caused severe damage of gastrointestinal mucosa. Boiled garlic powder administered in the same manner caused reddening of the stomach mucosa, while aged garlic extract did not cause any adverse effects (Hoshino et al. 2001).

Rats administered 1, 2.5 or 5 g/kg of fresh garlic showed a significant deterioration in liver function after one week of garlic ingestion. Lower doses of 0.1 and 0.25 g/kg did not produce any adverse effects (Rana et al. 2006).

Subchronic Toxicity

In rats administered 2000 mg/kg daily of garlic extract five times weekly for 6 months, no adverse effects were observed (Sumiyoshi et al. 1984). In mice administered 100 mg/kg daily of garlic extract for three months, heart, liver, and spleen weights were slightly reduced as compared to control (al-Bekairi et al. 1990).

Genotoxicity

In the Ames test for mutagenicity, no mutagenic effects were shown for garlic tincture. Garlic juice, however, in the absence of metabolic activation, induced significant levels of chromosomal damage (Schimmer et al. 1994).

Aloe spp. — Liliaceae

Aloe ferox Mill.
SCN: cape aloe

Aloe perryi Baker
SCN: Perry's aloe
OCN: Socotrine aloe; Zanzibar aloe

Aloe vera (L.) Burm. f.
SCN: aloe vera
Syn: *Aloe barbadensis* Mill.
AN: *ghrita kumari*; *kanyasara* (dried juice of leaf)
PN: *lu hui* (dried concentrated juice of leaf)
OCN: aloe; Barbados aloe; Curaçao aloe
Part: dried juice from the pericyclic region of the leaf (commonly called aloe latex)

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Aloe latex should not be used in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004; Mills and Bone 2005).

Internal use of aloe latex is contraindicated in persons with the following conditions: intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (i.e., appendicitis, colitis, Crohn's disease, irritable bowel syndrome) (Bensky et al. 2004; Bradley 1992; Chadha 1988; Roth et al. 1984; Weiss and Meuss 2001; Wichtl 2004); melanosis coli; hemorrhoids (Bradley 1992; Felter and Lloyd 1898; List and Hörhammer 1973; Roth et al. 1984); liver disease; kidney dysfunction (Wichtl 2004); and severe dehydration (with water and electrolyte depletion).

Aloe latex should not be used during menstruation (Wichtl 2004) or in children less than 12 years of age (Bradley 1992; De Smet 1993).

Not for use in excess of 8 days (Bensky et al. 2004; Bradley 1992; Chadha 1988; De Smet 1993; Felter and Lloyd 1898; Leung and Foster 1996; Martindale and Reynolds 1996; Roth et al. 1984; Weiss and Meuss 2001; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations below.

Notice

Stimulant laxative (Bensky et al. 2004; Bradley 1992; Chadha 1988; De Smet 1993; Felter and Lloyd 1898; Leung and Foster 1996; Martindale and Reynolds 1996; Weiss and Meuss 2001; Wichtl 2004; Williamson 2003); *see* Appendix 2.

Standard Dose

50–300 mg in a single dose at bedtime (Bradley 1992; Williamson 2003).

Editors' Notes

Aloe latex is prepared by drying the bitter yellow juice from the pericyclic region of the leaf and is a distinct product from aloe vera gel. The latex contains the laxative compound aloin, whereas the gel (*see* next entry) does not (Leung and Foster 1996).

The American Herbal Products Association has established a trade requirement (AHPA 2011) that products containing this herb in sufficient quantity to warrant such labeling bear the following label statement:

> NOTICE: Do not use this product if you have abdominal pain or diarrhea. Consult a health care provider prior to use if you are pregnant or nursing. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use.

Aloe latex is generally considered to be obsolete as a laxative, as it is a less desirable agent for laxation than other available substances (Hoover 1970; Martindale and Reynolds 1996).

Adverse Events and Side Effects

Adverse effects due to long-term use include electrolyte depletion, potassium depletion, damage to the colon, kidney malfunction, and heart palpitations (Wichtl 2004). In some epidemiological studies, long-term use of stimulant laxatives has been associated with colorectal cancer (Siegers 1992; Siegers et al. 1993), while other epidemiological studies have shown no correlation with cancer (Wald 2003).

Two cases of acute hepatitis have been reported in persons taking 500 mg of an extract of *Aloe vera* in tablet or capsule form for three to four weeks. No additional information on the preparation of the aloe ingredient was identified in either case (Kanat et al. 2006; Rabe et al. 2005).

Overdose (stated at as little as 1.0 g per day for several days) can cause colonic perforation and bleeding diarrhea, as well as kidney damage, and, according to one reference, death (Bradley 1992; Leung and Foster 1996; List and Hörhammer 1973; Martindale and Reynolds 1996; Wichtl 2004; Williamson 2003).

Pharmacological Considerations

Concomitant use of aloe latex is cautioned with antiarrhythmic drugs and botanicals containing cardiac glycosides, as long-term use of aloe latex as a laxative can cause potassium loss, leading to increased toxicity of these drugs and botanicals (Brinker 2001; De Smet 1993).

Concomitant internal use of aloe latex is cautioned with thiazide diuretics, corticosteroids, and licorice, and long-term use of aloe latex as a laxative may increase the potassium loss induced by these drugs and botanicals (Brinker 2001).

Use of stimulant laxatives, such as aloe latex, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

Oral use of aloe latex is contraindicated during pregnancy in traditional Chinese medicine (Bensky et al. 2004; Chen and Chen 2004). While most stimulant laxatives have traditionally been contraindicated in pregnancy due to concerns regarding stimulation of the uterus, a number of stimulant laxatives, including aloe latex, have shown a lack of adverse effects on pregnancy or the fetus when used according to the recommended dosage schedule (De Smet 1993; ESCOP 2003). Thus, these laxatives are now considered appropriate for use during pregnancy (De Smet 1993; ESCOP 2003; Prather 2004). Due to the potential genotoxicity of certain anthraquinones, however, it is recommended that use of certain anthranoid laxatives, including aloe latex, be avoided in the first trimester of pregnancy or used under professional supervision (ESCOP 2003).

Limited animal studies have provided mixed results on use of aloe latex in pregnancy, with one study showing no adverse effects and another showing some fetal abnormalities (ESCOP 2003; Nath et al. 1992).

Use of aloe latex while trying to become pregnant is best avoided (Mills and Bone 2005).

Use during lactation is cautioned (Bensky et al. 2004). Eclectic physicians traditionally administered aloe latex to breast-feeding mothers to produce a laxative effect in the nursing child (Felter and Lloyd 1898), although more recent publications indicate that laxative effects have not been observed in breast-feeding infants after maternal ingestion of other anthraquinone laxatives (Committee on Drugs 2001; Faber and Strenge-Hesse 1988; Tyson et al. 1937).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Use of stimulant laxatives may reduce the gastrointestinal transit time and thus absorption of orally administered drugs (Brinker 2001; Mills and Bone 2005).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Adverse events reported in association with aloe latex ingestion include nausea, vomiting, nose bleeds, abdominal pain, diarrhea, bloody stool, hematuria, albuminuria, and, after long-term administration, colitis (Bensky et al. 2004).

Two cases of acute hepatitis have been reported in persons taking *Aloe vera* internally (500 mg daily) for 3 to 4 weeks. No additional information on the preparation of the aloe ingredient was identified in either case (Kanat et al. 2006; Rabe et al. 2005).

Overdose of products containing aloe latex (stated at as little as 1.0 g per day for several days) can cause colonic perforation and bleeding diarrhea, as well as kidney damage, and, according to one reference, death (Bradley 1992; Leung and Foster 1996; List and Hörhammer 1973; Martindale and Reynolds 1996; Wichtl 2004; Williamson 2003).

One case of kidney failure was reported in a 47-year-old man with a history of hypertension and abdominal pain who had taken three doses of a traditional remedy believed to be *Aloe ferox* for constipation (Luyckx et al. 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Retrospective and prospective epidemiological studies of anthranoid-containing laxatives have correlated long-term use of these laxatives with colorectal cancer (Siegers 1992; Siegers et al. 1993). A review of chronic use of stimulant laxatives concluded that while stimulant laxatives can cause structural damage to surface cells in the colon, no causal relationship between laxative use and colorectal cancer could be established (Wald 2003).

Animal Pharmacological Studies

Animal pharmacological studies were identified but omitted due to availability of human data.

In Vitro Pharmacological Studies

In vitro pharmacological studies were identified but omitted due to availability of human data.

IV. Pregnancy and Lactation

Aloe latex extract (up to 1000 mg/kg) administered to pregnant rats did not demonstrate any embryotoxic, fetotoxic, or teratogenic activity (ESCOP 2003). Some fetal abnormalities were noted in fetuses of pregnant albino rats fed an extract of ground aloe vera leaf on days 0 through 9 of gestation (Nath et al. 1992).

Oral use of aloe latex is traditionally contraindicated during pregnancy (Bensky et al. 2004; Chen and Chen 2004), as side effects of stimulant laxatives, such as aloe latex, are reported to include induction of uterine contractions (De Smet 1993). Use during lactation is cautioned (Bensky et al. 2004; Brinker 2001).

Eclectic physicians traditionally administered aloe latex to breast-feeding mothers to produce a laxative effect in the nursing child (Felter and Lloyd 1898), although more recent publications indicate that laxative effects have not been observed in breast-feeding infants after maternal ingestion of other anthraquinone laxatives such as senna and cascara sagrada (Committee on Drugs 2001; Faber and Strenge-Hesse 1988; Tyson et al. 1937).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered aloe vera extract (0.50% total solids; 43.70% alcohol) in mice has been reported at 120 mg/kg (Lagarto Parra et al. 2001). This LD_{50} value is questionable, as oral administration of single doses of 0.5, 1, or 3 g/kg of aloe vera showed no signs of toxicity at either the 0.5 or 1 g/kg dose. At the 3 g/kg dose, a decrease in nervous system activity was noted (Shah et al. 1989).

Subchronic Toxicity

In rats fed whole leaf powder of aloe (species unspecified) at doses of 2, 4, or 8 g/kg daily for 90 days, some incidences of pigmentation of various organs was observed (Zhou et al. 2003).

Genotoxicity

Aqueous extracts of cape aloe (5 to 100 mg/ml) gave mixed results for mutagenicity, with mutagenicity reported for tests in the *Bacillus subtilis* rec-assay but no mutagenicity shown in *Salmonella* strains TA98 or TA100 (Morimoto et al. 1982).

Some genotoxicity but no cytotoxicity was noted for aloe vera pulp in a bacterial transformation assay with the pulp added to *E. coli* and exposed to UV light (Paes-Leme et al. 2005).

Aloe vera (L.) Burm. f. — Liliaceae

SCN: aloe vera
Syn: *Aloe barbadensis* Mill.
OCN: aloe; Barbados aloe; Curaçao aloe

Part: mucilaginous leaf gel from parenchymatous leaf cells (commonly called aloe vera inner leaf; often referred to as aloe vera gel)

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

Other drugs should be taken 1 hour prior to consumption of aloe vera leaf gel or several hours after consumption, as

it may slow the absorption of orally administered drugs (Brinker 1997).

Notice

Mucilages (~30%) (Roboz and Haagen-Smit 1948); *see* Appendix 3.

Editors' Note

Aloe vera leaf gel is commonly consumed in quantity as a cleansing juice preparation. It does not act as a strong cathartic like the dried juice from the pericyclic region of the leaf (*see* previous entry), which is a distinct product that contains the laxative compound aloin (Leung and Foster 1996).

Adverse Events and Side Effects

Reviews of topical use of aloe vera leaf gel have indicated that topical use is generally very well tolerated with few adverse effects (Vogler and Ernst 1999). Contact dermatitis has been reported after topical application of aloe vera leaf gel on some individuals (Ferreira et al. 2007; Hogan 1988; Hunter and Frumkin 1991).

Two cases of Henoch-Schönlein purpura (a disease that involves purple spots on the skin, joint pain, and gastrointestinal and kidney problems) have been reported in persons taking aloe vera leaf juice or extract (Cao et al. 2005; Cholongitas et al. 2005).

Pharmacological Considerations

Use on surgical wounds has been cautioned as wounds being healed by second intention (left open to heal from the base outward) treated with aloe vera leaf gel have been observed to have increased healing time in one study (Schmidt and Greenspoon 1991), although other studies have indicated beneficial effects of aloe vera leaf gel or extract on wound healing or psoriasis (Fulton 1990; Syed et al. 1996).

Pregnancy and Lactation

Among five animal studies of aloe vera leaf gel in pregnancy, one study showed some effects in preventing pregnancy, while four studies showed no effects on pregnancy (Kamboj and Dhawan 1982).

No information on the safety of aloe vera leaf gel during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Mass bleeding during surgery was reported in a patient administered the anesthetic sevoflurane (0.5–1.2%) who had been taking an aloe vera product for 2 weeks prior to surgery (4 tablets daily). The physicians reporting this case indicated that sevoflurane is known to reduce platelet aggregation and that approximately 1% of patients in sevoflurane clinical trials experience hemorrhages, and also stated that the patient did not know if the aloe preparation was a fresh herb product, a dehydrated ingredient, or an extract (Lee et al. 2004). The physicians also referenced a study that indicated significant inhibition of prostaglandin synthesis in rats administered aloe vera leaf gel extracts (Vazquez et al. 1996).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of 10 controlled clinical trials of topical or oral use of aloe vera leaf gel (or in one case of an extract, not further described) indicated no withdrawals due to adverse effects of aloe vera. Adverse effects reported included burning after topical application, contact dermatitis, and mild itching. Adverse effects were noted as reversible, and aloe vera was characterized as very well tolerated (Vogler and Ernst 1999).

Case Reports of Adverse Events

Cases of contact dermatitis have been reported after topical applications of aloe vera leaf gel (Ferreira et al. 2007; Hogan 1988; Hunter and Frumkin 1991). A case of hypersensitivity to aloe was reported in a woman who had used aloe vera orally (3 teaspoons daily) and topically (Morrow et al. 1980).

Two cases of Henoch–Schönlein purpura (a disease that involves purple spots on the skin, joint pain, gastrointestinal problems, and glomerulonephritis) have been reported in individuals that were using aloe. One patient had taken "some juice extracted from four to five leaflets of *Aloe vera*" (he had taken the same remedy several months prior with no reaction) 24 hours prior to developing a rash, abdominal pain followed by rapid deterioration of renal function and abnormal levels of serum creatinine (Cholongitas et al. 2005). The second patient had taken "extracts of *Aloe vera*" (parts consumed and dose consumed unspecified) for approximately 1 week. He developed general edema and palpable purpura that eventually resolved (Cao et al. 2005).

One case of thyroid dysfunction was reported in a woman who had used aloe vera plant juice orally (10 ml daily) and topically (Pigatto and Guzzi 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Several clinical trials have studied the effects of topical applications of aloe on healing of various types of wounds and skin conditions. A speeded healing time was observed in patients treated with aloe after dermabrasion (a surgical scraping of the skin) therapy for acne (Fulton 1990) and for healing in psoriasis patients (Syed et al. 1996). A slowed healing time was observed in postsurgical complicated wounds treated topically with aloe (Schmidt and Greenspoon 1991). In allergic patch testing of 700 patients, no reactions to a concentrated (10×) aloe vera leaf gel were observed (Reider et al. 2005).

Animal Pharmacological Studies

Animal pharmacological studies were identified but omitted due to availability of human data.

In Vitro Pharmacological Studies

In vitro pharmacological studies were identified but omitted due to availability of human data.

IV. Pregnancy and Lactation

A review of published and unpublished Indian research on plants for fertility regulation indicated that, in one study, aloe vera leaf extracts (100 to 500 mg/kg daily) administered to female rats on postcoital days 1 through 7 had some activity in preventing pregnancy. Contrarily, four similar studies indicated no effect on pregnancy (Kamboj and Dhawan 1982).

No information on the safety of aloe vera leaf gel during lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

No clinical signs of toxicity, mortality, or other adverse events were observed in rats orally administered 2 ml aloe vera leaf in water daily for 14 days (MDS 2000).

Subchronic Toxicity

No significant adverse effects were noted when technical grade acemannan (a polysaccharide fraction of aloe gel) was administered orally to rats for 14 days as 5% of the diet and for 6 months at up to 2000 mg/kg daily and to beagle dogs for 90 days at up to 1500 mg/kg daily (Fogelman et al. 1992).

No changes in organ weights or body weight were reported in male mice fed 100 mg/kg daily aloe vera extract for 90 days. Degeneration of sex organs was reported in 20% of mice (Shah et al. 1989).

Chronic Toxicity

No harmful effects were reported in rats that ingested aloe vera leaf powder as 1% of their diet from 42 days old until natural death (Ikeno et al. 2002).

Genotoxicity

Some genotoxicity but no cytotoxicity was noted for aloe vera leaf pulp in a bacterial transformation assay with the pulp added to *E. coli* and exposed to UV light (Paes-Leme et al. 2005).

Aloysia citriodora Palau

Verbenaceae

SCN: lemon verbena
Syn: *Aloysia triphylla* (L'Hér.) Britton; *Lippia citriodora* Kunth, nom. illeg.

OCN: verbena
Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of lemon verbena in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

A hexane extract of lemon verbena was observed to have an antagonistic effect on the activity of the β-receptor in rat hearts (Vargas Solis 2000).

IV. Pregnancy and Lactation

No information on the safety of lemon verbena in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LC_{50} of lemon balm essential oil in the brine shrimp lethality assay was 1279 µg/ml (Oliva et al. 2007).

Genotoxicity

Antigenotoxic activity of aqueous extracts of lemon verbena was observed in the comet assay in mice (Zamorano-Ponce et al. 2004; Zamorano-Ponce et al. 2006).

Alpinia galanga (L.) Sw. — Zingiberaceae

SCN: greater galangal
Syn: *Maranta galanga* L.
AN: *kulanjana*
PN: *da gao liang jiang*
OCN: galanga; Java galanga; Siamese galanga
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Although use of this species as a food additive in the U.S. is limited to its function as a flavoring substance in alcoholic beverages (CFR 2011a), the related *A. officinarum* is identified in the same reference as generally recognized as safe as a spice or flavoring (CFR 2011b). Also, dietary ingredients for use in dietary supplements are specifically excluded from the federal food additive definition (U.S.C. 2010).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of greater galangal in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis, confirmed by patch testing (both fresh and dried greater galangal), was reported after topical application of greater galangal (Hong and Chang 2006).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in blood glucose levels was observed in healthy rabbits but not in diabetic rabbits administered methanol or aqueous extracts or powdered rhizome of greater galangal (Akhtar et al. 2002).

A

In Vitro Pharmacological Studies

Inhibition of platelet-activating factor binding to rabbit platelets was observed after treatment with greater galangal (Jantan et al. 2005).

Inhibition of the drug metabolizing isoenzymes CYP2D6 and CYP3A4 were observed in human liver microsomes treated with methanol extracts of greater galangal (Subehan et al. 2006; Usia et al. 2006).

IV. Pregnancy and Lactation

No information on the safety of greater galangal in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No significant mortality was observed in mice orally administered single doses of up to 3 g/kg of an ethanol extract of greater galangal (Qureshi et al. 1992).

The LD_{50} of an ethanol extract of greater galangal in the brine shrimp lethality assay was 109 µg/ml (Khattak et al. 2005).

Subchronic Toxicity

An increase in red blood cell count but no changes in organ weights and no signs of toxicity were observed in mice orally administered 100 mg/kg of an ethanol extract of greater galangal daily for 90 days (Qureshi et al. 1992).

Genotoxicity

Single-strand breaks in DNA were observed in human fibroblast, mammary tumor, and lung adenocarcinoma cell lines treated with an aqueous extract of greater galangal. Breaks were observed after exposure to greater galangal at concentrations of 100 µg/ml or more (Muangnoi et al. 2007).

Cytotoxicity

Cytotoxic effects were observed in human fibroblast, mammary tumor, and lung adenocarcinoma cell lines treated with an aqueous or methanol and dichloromethane extract of greater galangal (Muangnoi et al. 2007; Nam et al. 2005).

Althaea officinalis L. — Malvaceae

SCN: marshmallow
OCN: althaea; althea

Part: flower, leaf, root

Quick Reference Summary

Safety Class: 1

Interaction Class: A

Contraindications
None known.

Other Precautions
Should be taken with at least 250 ml (8 oz.) of liquid.

Drug and Supplement Interactions
Other drugs should be taken 1 hour prior to consumption of marshmallow or several hours after consumption, as marshmallow may slow the absorption of orally administered drugs (Brinker 2001; De Smet 1993; Mills and Bone 2005).

Notice
Mucilages (~10%) (Evans 2002); *see* Appendix 3.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of marshmallow in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Andrographis paniculata (Burm. f.) Nees — Acanthaceae

SCN: andrographis
AN: *bhunimba*; *mahatikta*
PN: *chuan xin lian* (herb)

OCN: creat; green chiretta; Indian chiretta
Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (But 1988; Chang and But 1986; Chen and Chen 2004; Zoha et al. 1989).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Chang and But 1986; Chen and Chen 2004); *see* Appendix 2.

Adverse Events and Side Effects

A systematic review of human studies of andrographis concluded that "short-term therapy is associated with an encouraging safety profile, although adverse events have been demonstrated at higher doses" (Coon and Ernst 2004).

Large oral doses are reported to cause gastric discomfort and loss of appetite (Chang and But 1986). Allergic reactions, including an anaphylactic reaction, to andrographis have been reported (Coon and Ernst 2004).

Pharmacological Considerations

Animal studies have demonstrated that andrographis may modify glucose regulation; thus diabetic persons using insulin or oral hypoglycemic drugs should continue to monitor glucose levels during andrographis use (Borhanuddin et al. 1994; Husen et al. 2004; Zhang and Tan 2000).

Results of animal studies on the effects of andrographis on female and male fertility and embryo implantation are conflicting. Some studies indicated that high doses of andrographis prevented implantation and caused abortion (But 1988; Zhang and Tan 1997), while other studies with similar doses showed no adverse effects on female fertility or pregnancy (Shamsuzzoha et al. 1978, 1979). Results of studies of andrographis or the compound andrographolide on male animals vary from no observed effects on fertility in two studies, one with andrographis and the other with andrographolide (Burgos et al. 1997; Sattayasai et al. 2010), to a reduction in sperm counts and lack of sperm motility in a third study using andrographolide (Akbarsha and Murugaian 2000). Thus, until further evidence is available, the use of andrographis by women or men attempting to conceive is cautioned.

Pregnancy and Lactation

Information on the safety of andrographis during pregnancy is limited. Conflicting results on effects on fertility and pregnancy have been reported in animal studies, with some studies indicating no adverse effects on fertility in mice (Dhammaupakorn and Chaichantipyuth 1989; Shamsuzzoha et al. 1978, 1979) and other studies indicating antifertility or abortifacient activity (Chen and Chen 2004; But 1988; Zoha et al. 1989).

No information on the safety of andrographis during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Also see Pharmacological Considerations for this entry.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

A prolongation of pentobarbitone-induced sleeping time was observed in mice intraperitoneally administered 100 to 300 mg/kg of an andrographis extract (Mandal et al. 2001).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of human studies of andrographis concluded that "short-term therapy is associated with an encouraging safety profile, although adverse events have been demonstrated at higher doses" (Coon and Ernst 2004). The study utilizing the higher doses was a phase I trial of the compound andrographolide in HIV-positive and normal volunteers. The study was terminated early due to a large number of adverse events. The doses used in this trial, 5 or 10 mg/kg daily of andrographolide, were 6 to 12 times higher than doses used in other studies. Adverse events included allergic reaction (one anaphylactic reaction), fatigue, headache, rash, diarrhea, nausea, decreased taste, dry tongue, reduced libido, reduced short-term memory, eyes sensitive to light, decreased memory, dizziness, heartburn, tender lymph nodes, and lymphadenopathy. There was no placebo group in the study (Calabrese et al. 2000). Urticaria was reported in 2 of 60 subjects in a trial of standardized andrographis extract (Melchoir et al. 1996). Several additional human studies either reported no adverse events or did not provide information on adverse events (Coon and Ernst 2004).

Case Reports of Adverse Events

As of June 2003, no adverse events in persons taking andrographis had been reported to any national drug safety monitoring agencies including those in the United Kingdom, Germany, and Austria (Coon and Ernst 2004). One case of anaphylactic shock and two cases of anaphylactic reactions had been reported to the World Health Organization. All cases were from Sweden, and no details on the case reports were available in the published literature (Coon and Ernst 2004). Data obtained from manufacturers of andrographis products indicated that one company had received five reports of allergic reactions to products that contained andrographis (Coon and Ernst 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No testicular toxicity was observed in male rats orally administered a standardized extract of andrographis at doses up to 1000 mg/kg daily for 60 days (Burgos et al. 1997). A decrease in sperm counts and lack of motility in spermatozoa were observed in 3-month-old male rats orally administered 25 or 50 mg/kg of the compound andrographolide daily for 48 days (Akbarsha and Murugaian 2000). Conversely, no significant changes in sperm morphology and motility were observed in male mice orally administered 50 mg/kg of the compound andrographolide daily for up to eight weeks. After four weeks of treatment, an increase in serum testosterone levels was observed as compared to control. Male mice receiving andrographis mounted females more quickly and with greater frequency than untreated males (Sattayasai et al. 2010). Reductions in alkaline phosphatase activity and total protein were observed in the reproductive organs of male rats orally administered an andrographis powder suspension at a dose of 10 or 20 mg per animal daily for 24 or 48 days (Akbarsha and Manivannan 1993). Reduced libido was observed in male mice fed a diet supplemented with 0.75% andrographis stem powder for up to 4 weeks (Shamsuzzoha et al. 1979).

Inhibition of fasting serum glucose levels and glucose tolerance test levels was observed in diabetic rats orally administered an ethanolic extract of andrographis at doses of 100, 200, or 400 mg/kg (Zhang and Tan 2000). Prevention of hyperglycemia but no effects on adrenaline-induced hyperglycemia were observed in rabbits orally administered 10 mg/kg of an aqueous extract of andrographis (Borhanuddin et al. 1994). Similarly, a significant reduction in blood glucose levels was observed in hyperglycemic rats orally administered an aqueous extract of andrographis. The hyperglycemic effect was enhanced when the freeze-dried extract was used (Husen et al. 2004).

No significant changes in CYP450 enzymes were observed in rats administered 1 g/kg andrographis extract or 10 mg/kg of the compound andrographolide, each in single doses (Choudhury et al. 1987).

Dose-dependent choleretic action of the compound andrographolide was observed in rats and guinea pigs administered doses of 1.5 to 12 mg/kg (Shukla et al. 1992).

In Vitro Pharmacological Studies

In human platelets, the compound andrographolide inhibited platelet-activating-factor-induced aggregation in a dose-dependent manner (Amroyan et al. 1999). In mouse platelets, a standardized aqueous extract of andrographis, and the compounds andrographolide and 14-deoxy-11,12-didehydroandrographolide inhibited thrombin-induced platelet aggregation in a dose-dependent manner (Thisoda et al. 2006).

Methanolic and ethanolic extracts of andrographis inhibited CYP3A4 and CYP2D6 in vitro (Subehan et al. 2006; Usia et al. 2006). The compound andrographolide induced CYP1A1 and CYP1A2 but had no effect on CYP1B1 in vitro (Jaruchotikamol et al. 2007).

The compound bisandrographolide A has been shown to activate transient receptor potential V4 (TRPV4) with an EC_{50} (half maximal effective concentration) of 790 to 950 nM (Smith et al. 2006).

IV. Pregnancy and Lactation

After administration of 2 g/kg daily as part of the diet for 6 weeks, no pregnancies occurred in fertile female mice when the females were mated with male mice (not administered andrographis) known to be fertile (Zoha et al. 1989).

No antifertility effects were observed in mice administered powdered andrographis leaf or root as 1% of the diet (~2 g/kg daily) for 14 days prior to mating, and 21 days during mating (Shamsuzzoha et al. 1978). Similarly, no antifertility effects were observed in female mice administered andrographis stem powder for 28 days prior to mating (Shamsuzzoha et al. 1979).

Intraperitoneal administration of an aqueous extract of whole andrographis plants (dose not specified in English language abstract) prevented implantation in mice and caused abortion in mice during the first, second, and third trimesters of pregnancy (But 1988; Chen and Chen 2004).

In rats orally administered 200, 600, or 2000 mg/kg (30 to 300 times higher than the standard human dose) of an andrographis extract for days 0–19 of pregnancy, no change in progesterone levels and no progesterone-mediated pregnancy termination were observed (Panossian et al. 1999).

No teratogenicity or toxicity was observed in pregnant mice orally administered 200 or 400 mg/kg andrographis leaf powder suspension on alternate days for 4 weeks (Dhammaupakorn and Chaichantipyuth 1989).

A

No information on the safety of andrographis during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally or subcutaneously administered alcoholic extract of andrographis in mice could not be determined at doses up to 15 g/kg (Sithisomwongse et al. 1989). The LD_{50} of an intraperitoneally administered alcoholic extract was 14.98 g/kg (Sithisomwongse et al. 1989).

The LD_{50} of an aqueous-methanolic andrographis whole plant extract intraperitoneally administered in mice could not be determined at doses up to 1 g/kg (Nakannishi et al. 1965).

The LD_{50} of the compound andrographolide orally administered in mice could not be determined at doses up to 40 g/kg (Chang and But 1986).

Anemarrhena asphodeloides Bunge

Liliaceae

SCN: anemarrhena
PN: *zhi mu* (rhizome)

Part: rhizome

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with diarrhea (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that anemarrhena may modify glucose regulation; thus diabetic persons using insulin or oral hypoglycemic drugs should continue to monitor glucose levels during anemarrhena use (Chen and Chen 2004; Jia et al. 2003; Miura et al. 2001; Nakashima et al. 1993; Takahashi et al. 1985).

Pregnancy and Lactation

No information on the safety of anemarrhena in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Aqueous extracts of anemarrhena have been shown to dose-dependently lower glucose levels in diabetic mice (Miura et al. 2001; Nakashima et al. 1993; Takahashi et al. 1985).

In Vitro Pharmacological Studies

Steroidal saponins isolated from anemarrhena inhibited platelet aggregation and activated partial thromboplastin time in human blood (Zhang et al. 1999). Another saponin inhibited PAF-induced platelet aggregation in rabbit blood (Dong and Han 1991).

An ethanol extract of anemarrhena stimulated insulin secretion in the islets of pancreases isolated from normal and diabetic rats at concentrations of 3.3 mM (normal) and 16.7 mM (diabetic) (Hoa et al. 2004).

IV. Pregnancy and Lactation

No information on the safety of anemarrhena in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

In rabbits intravenously administered an extract (solvent type not specified in English language translation), a dose of 7 ml led to respiratory failure and death, while a dose of 1 to 3 ml caused difficulty breathing, and a dose of 0.5 ml showed no adverse effects (Chen and Chen 2004).

Anemopsis californica (Nutt.) Hook. & Arn. Saururaceae

SCN: yerba mansa

Part: rhizome, root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of yerba mansa in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Aqueous and ethanol extracts of yerba mansa inhibited the growth of human breast cancer cells (MCF-7/AZ, estrogen receptor positive) in a concentration-dependent manner and had no effect on the growth of colon cancer cells (HCT8/E11) (Daniels et al. 2006).

IV. Pregnancy and Lactation

No information on the safety of yerba mansa in pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Literature Cited

Daniels, A.L., S. Van Slambrouck, R.K. Lee, et al. 2006. Effects of extracts from two Native American plants on proliferation of human breast and colon cancer cell lines in vitr o. *Oncol. Rep.* 15(5):1327-1331.

Anethum graveolens L. — Apiaceae

SCN: dill
Syn: *Peucedanum graveolens* (L.) Benth. & Hook. f.

AN: *shatapushpa*
Part: fruit (commonly known as "seed"), herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Mahran et al. 1991); *see* Appendix 2.

Adverse Events and Side Effects

Allergic reactions to dill, confirmed by patch testing, have been reported (Monteseirin et al. 2003; Monteseirin et al. 2002).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of dill in pregnancy was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant women, safety has not been conclusively established.

Dill seed has been traditionally been used to promote milk production in nursing women (Jain et al. 2004; Mahran et al. 1992).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis to dill, confirmed by patch testing, has been reported (Monteseirin et al. 2002, 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A decrease in serum glucose and insulin levels was observed in rats with corticosteroid-induced diabetes orally administered 100 mg/kg of dill leaf extract daily for 15 days (Panda 2008).

In female rats orally administered 0.045 or 0.45 g/kg of an aqueous extract of dill seed or 0.5 or 5 mg/kg of an ethanol extract of dill seed daily for 10 days, a significant increase was observed in the duration of the estrus cycle, the diestrus phase, and the progesterone concentration in the high-dose groups of both extracts. The stereological study did not reveal any significant changes in the volumes of ovaries, or primary, secondary, or graafian follicles (Monsefi et al. 2006).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of dill in pregnancy was identified. While this review did not identify any concerns for pregnant women, safety has not been conclusively established.

Dill seed has traditionally been used in India to promote milk production in nursing women (Jain et al. 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered dill seed extracts in mice was 3.04 g/kg for the aqueous extract and 6.89 g/kg for the ethanolic extract (Hosseinzadeh et al. 2002).

The LD_{50} of dill seed oil in rats was 4.6 g/kg (Opdyke and Letizia 1982).

Guinea pigs intravenously administered 35 mg/kg of dill seed essential oil experienced anaphylactic shock and died. The same oil intravenously administered to cats at doses of 5 to 10 mg/kg resulted in lowered blood pressure and increased respiratory volume (Shipochliev 1968).

Genotoxicity

Dose-dependent induction of chromosomal aberrations and sister chromatid exchanges were observed in human lymphocytes treated with dill leaf or seed essential oil. No significant effects of dill seed essential oil were observed in the *Drosophila melanogaster* somatic mutation and recombination test (SMART) in vivo (Lazutka et al. 2001).

No genotoxic effects were observed in bone marrow cells of mice administered 1 g /kg dill seed essential oil daily (duration of dosing not specified in English language abstract). The seed oil protected against the genotoxic activity of benzo[*a*]pyrene (Morkunas 2002).

Cytotoxicity

Cytotoxic effects of dill seed and leaf essential oils were observed in human lymphocytes (Lazutka et al. 2001).

Angelica dahurica (Fisch. ex Hoffm.) Benth. & Hook. f. ex Franch. & Sav. Apiaceae

SCN: fragrant angelica
PN: *bai zhi* (root)

OCN: Dahurian angelica
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Other species of *Angelica* are commonly traded as *bai zhi* (Bensky et al. 2004; Chang and But 1986).

Adverse Events and Side Effects

Topical allergic reactions and dermatitis caused by contact with the fresh herb have been reported (Bensky et al. 2004). Although furanocoumarin compounds, such as those present in fragrant angelica, have photosensitizing effects (a heightened response of the skin to sunlight or other ultraviolet light) after contact with skin, no cases of photosensitivity due to oral ingestion of fragrant angelica are known (Bensky et al. 2004); such a reaction is theoretically possible.

Pharmacological Considerations

An animal study indicated that fragrant angelica inhibited the drug-metabolizing isoenzymes CYP2C, CYP3A, CYP2D1, and CYP2C9 (Ishihara et al. 2000). The relevance of this information to human use is not known.

Pregnancy and Lactation

No information on the safety of fragrant angelica in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Coumarins isolated from fragrant angelica administered orally to rats in single doses of 25, 50, or 100 mg/kg increased the duration of hypnosis induced by pentobarbital sodium. The 100 mg/kg dose also prolonged the latent period and shortened the duration of hypnosis induced by barbital sodium (Liu et al. 2006).

II. Adverse Events

Case Reports of Adverse Events

Large doses (30–60 g) of fragrant angelica may cause slowed heart rate, increased blood pressure, increased depth of respiration, nausea, vomiting, dizziness, difficulty breathing, sweating, or numbness of the limbs (Bensky et al. 2004; Chen and Chen 2004). Cases of gross overdose have been associated with seizures and convulsions (Chen and Chen 2004).

Although several sources indicate that persons ingesting fragrant angelica should limit exposure to the sun, due to the furanocoumarin content of the herb, no cases of photosensitivity associated with oral ingestion are known (Bensky et al. 2004). Topical allergic reactions and dermatitis caused by contact with the fresh herb have been reported (Bensky et al. 2004). Two cases of phytophotodermatitis associated with accidental skin contact with a multi-herb decoction including fragrant angelica have been reported (Zhang and Zhu 2011).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Inhibition of the drug-metabolizing isoenzymes CYP2C, CYP3A, and CYP2D1 was observed in rats orally administered a single dose of 1 g/kg of fragrant angelica. At the same dose level, fragrant angelica prolonged the half-life and reduced the clearance of intravenously administered tolbutamide (a CYP2C9 substrate) (Ishihara et al. 2000).

The furanocoumarin compound phellopterin was shown to be a partial agonist of the central benzodiazepine receptors. Two other naturally occurring furanocoumarins, byakangelicol and imperatorin, exhibited significantly less potent binding activity to the benzodiazepine site of the rat brain GABA-A receptor (Dekermendjian et al. 1996).

In Vitro Pharmacological Studies

Infusions of fragrant angelica inhibited the drug-metabolizing isoenzyme CYP3A4. Activity varied according to horticultural variety, and the infusions were significantly more active than the 40% ethanol extract of the different products (Guo et al. 2001).

Of 11 furanocoumarin compounds isolated from fragrant angelica, 2 showed strong abilities to induce alkaline phosphatase with EC_{50} values of 1.1 and 0.8 µg/ml, respectively, whereas the other 9 furanocoumarins were weakly or only slightly active (Piao et al. 2006).

Fragrant angelica inhibited melanogenesis in B16 melanoma cells (Cho et al. 2006).

Of eight furanocoumarin compounds isolated from fragrant angelica, one strongly inhibited (IC_{50} of 0.36 µ*M*) binding of diazepam to central nervous system benzodiazepine receptors, while other structurally similar compounds had minimal effect on receptor binding (Bergendorff et al. 1997).

IV. Pregnancy and Lactation

No information on the safety of fragrant angelica in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered decoction of fragrant angelica in mice was 53.82 g/kg (Chen and Chen 2004).

Angelica pubescens Maxim. — Apiaceae

SCN: pubescent angelica
PN: *du huo* (root)

Part: root

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Avoid prolonged exposure to sunlight (Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Photosensitizing (Chang and But 1986; Chen and Chen 2004); *see* Appendix 2.

Editors' Note

Other species of *Angelica* and plants of other genera are commonly traded as *du huo.*

Adverse Events and Side Effects

Gastric discomfort, nausea, vomiting, dizziness, headache, and numb tongue have been reported in association with pubescent angelica use, although detailed information on these cases is lacking (Bensky et al. 2004).

Pharmacological Considerations

Overdoses (standard therapeutic dose is 3–9 g as a decoction) of pubescent angelica have been associated with increased sensitivity to sunlight (Chen and Chen 2004).

Pregnancy and Lactation

No information on the safety of pubescent angelica in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

During the use of pubescent angelica in the treatment of bronchitis, adverse events of gastric discomfort, nausea, vomiting, dizziness, headache, and numb tongue have been reported. Details on these reports are lacking (Bensky et al. 2004).

Overdose of pubescent angelica has been associated with increased photosensitivity (Chen and Chen 2004). Overdose of the dried root or "large" doses (standard therapeutic dose is 3–9 g as a decoction) of the fresh root of pubescent angelica have been reported to cause rapid breathing, agitation, hallucinations, delirium, tetanic spasms, and, in severe cases, death. Details on these cases, including doses used and relevant medical history, are lacking (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound osthole, isolated from pubescent angelica, inhibited platelet aggregation and ATP release induced by ADP, arachidonic acid, PAF, collagen, ionophore A23187, and thrombin in washed rabbit platelets. It showed a weak activity in platelet-rich plasma (Ko et al. 1989).

IV. Pregnancy and Lactation

No information on the safety of pubescent angelica in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound xanthotoxin intramuscularly administered in rats is 160 mg/kg, while that of bergapten is 945 mg/kg (Chen and Chen 2004).

Angelica sinensis (Oliv.) Diels

Apiaceae

SCN: dong quai
Syn: *Angelica polymorpha* Maxim. var. *sinensis* Oliv.
PN: *dang gui shen* (root body); *dang gui tou* (root head); *dang gui wei* (root tail)

OCN: Chinese angelica; tang kuei
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: C

Contraindications

None known.

Other Precautions

Patients undergoing surgery are advised to stop use of dong quai 7 days before surgery due to reported inhibition of platelet aggregation (Li and Yang 1982; Tu and Huang 1984; Yan et al. 1987).

Drug and Supplement Interactions

Human case reports and an animal study have indicated a possible interaction between warfarin and dong quai (Ellis and Stephens 1999; Lo et al. 1995; Page and Lawrence 1999).

Adverse Events and Side Effects

Adverse events reported in persons taking dong quai include aggravation of endometriosis, severe bleeding of gums (high doses for many months), overstimulation of menstrual cycle, increased or excessive menstrual flow, edema and breast tenderness, headaches, increased irritability, gynecomastia, and occupational asthma (Goh and Loh 2001; Lee et al. 2001; Upton 2003). A causal association between these adverse events and dong quai was not determined in any of the cases. No significant adverse events are reported in the traditional Chinese medicine literature (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

Inhibition of platelet aggregation by dong quai extract has been observed in human and animal studies (Dong et al. 2004; Li and Yang 1982; Tu and Huang 1984; Yan et al. 1987).

Although conflicting results on the estrogenicity of dong quai have been reported in animal and in vitro studies (Circosta et al. 2006; Dixon-Shanies and Shaikh 1999; Lau et al. 2005), a human study of dong quai in menopausal women demonstrated no estrogenic activity (Hirata et al. 1997), and a binding and transcription study showed no activity of dong quai in estrogen receptors ERα or ERβ (Amato et al. 2002).

Induction of drug-metabolizing enzymes CYP2D6 and CYP3A was observed in rats administered dong quai extracts (Tang et al. 2006).

Pregnancy and Lactation

Limited information on the safety of dong quai during pregnancy or lactation is available. Both a stimulating and relaxing effect on the uterus have been reported for constituents of dong quai in vitro (Zhu 1998). In traditional Chinese medicine practices, dong quai is used in combination with other herbs at various stages of pregnancy (Upton 2003). In the West, dong quai is commonly used as a single herb; some texts contraindicate dong quai during pregnancy (Brinker 2001; Mills and Bone 2005), but no contraindication during pregnancy is noted in either of the Chinese herbal references cited in this work (Bensky et al. 2004; Chen and Chen 2004).

Cases of rashes and high blood pressure during lactation have been reported (Nambiar et al. 1999; Upton 2003).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

A woman taking warfarin, digoxin, and furosemide had an increased INR (a standardized scale used to report the results of blood coagulation tests; increased INR indicates slowed blood clotting) after having taken one or two tablets (565 mg each) daily of dong quai. The woman's INR returned to the normal range after cessation of dong quai (Page and Lawrence 1999). Increased INR and bleeding were reported in a woman taking warfarin and dong quai (dose, duration, and product unspecified) (Ellis and Stephens 1999).

Animal Trials of Drug or Supplement Interactions

In rabbits orally administered 4 g/kg daily dong quai and subcutaneously administered warfarin, an increase in prothrombin time was observed in a steady-state model of warfarin administration, whereas in a single-dose model, no significant changes in prothrombin time were observed. Dong quai alone did not produce any changes in prothrombin time (Lo et al. 1995).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of the available traditional and scientific data indicated that dong quai is a very safe herb with a low probability of side effects (Upton 2003).

Case Reports of Adverse Events

A case of gynecomastia was reported in a man who had taken dong quai capsules (dose unspecified) daily for 1 month. The man was on long-term treatment with phenytoin and folate. The gynecomastia resolved completely several months after cessation of the dong quai (Goh and Loh 2001). Several case reports have indicated an association of phenytoin use with gynecomastia (Ikeda et al. 1998; Monson and Scott 1987; Rossi et al. 1983).

Results of a survey of members of the American Herbalists Guild indicated that adverse events observed during the use of dong quai included aggravation of endometriosis, overstimulation of menstrual cycle, increased or excessive menstrual flow, edema and breast tenderness, headaches (sometimes severe), increased irritability, and severe bleeding gums (high doses for many months) (Upton 2003).

A case of occupational asthma was reported in a pharmacist who had worked in an herb shop processing herbal materials. The patient had a positive response to dong quai ("Angelica radix," species unspecified) in a skin prick test,

and bronchoprovocation tests showed an early asthmatic response to dong quai extract (Lee et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In patients with ulcerative colitis, intravenous administration of 40 ml daily of dong quai extract inhibited platelet activation (Dong et al. 2004). Intravenous administration of 200 ml daily of a 25% solution of dong quai for 20 days to patients with acute ischemic stroke resulted in decreases in a number of hematological parameters including platelet adhesion rate, platelet electrophoresis time, and whole blood adhesion, and an increase in prothrombin time (Tu and Huang 1984). A reduction in whole blood viscosity was observed for approximately 3 hours in people orally administered a dong quai extract (Terasawa et al. 1985).

In a human study of dong quai in menopausal women, involving administration of 4.5 g daily of dong quai for 24 weeks, no changes in serum hormone levels, vaginal cytology, or endometrial thickness were observed, indicating a lack of estrogenic effects (Hirata et al. 1997).

Animal Pharmacological Studies

In rats administered 3 g/kg dong quai aqueous or ethanolic extracts, both extracts significantly induced the drug-metabolizing isoenzymes CYP2D6 and CYP3A (Tang et al. 2006).

Injection of 1 g /ml dong quai prevented platelet aggregation and erythrocyte stasis in alveolar capillaries induced by the injection of measles vaccine (Yan et al. 1987). Administration of two doses of 6 or 8 ml each (1.5 hours between doses) of an aqueous extract of dong quai to fasting rats resulted in a decrease in time to thrombus formation and an increase in prothrombin time (Li and Yang 1982).

No increase in uterine weight was observed in ovariectomized mice orally administered 500 µl daily of an ethanolic extract of dong quai for 4 days (Amato et al. 2002). In ovariectomized rats administered 100 or 300 mg/kg daily of a dried ethanolic extract of dong quai or 1 µg/rat estradiol, a significant increase in uterine weight was observed in rats administered dong quai, but the increase was significantly less than that observed in rats administered estradiol. Mean luteinizing hormone levels were reduced in rats treated with dong quai, and no changes were observed in follicle-stimulating hormone levels. These results suggest an estrogenic effect of dong quai (Circosta et al. 2006).

In Vitro Pharmacological Studies

In a study of a dong quai ethanolic extract on MCF-7 (ER positive) human breast cancer cells, dong quai induced the growth of MCF-7 cells by 16-fold over that of untreated control cells. In a transient gene expression assay system, dong quai failed to show transactivation of either estrogen receptor ERα or ERβ cDNA (Amato et al. 2002). An aqueous extract of dong quai dose-dependently stimulated the proliferation of MCF-7 and BT-20 (ER negative) breast cancer cells (Lau et al. 2005). An extract of dong quai inhibited growth of T-47D (ER positive) and MCF-7 human breast cancer cells (Dixon-Shanies and Shaikh 1999).

IV. Pregnancy and Lactation

A survey of 593 pregnant women in Hong Kong indicated that 12% had used "Chinese angelica" during their pregnancy. This was the second most popular herb for use during pregnancy in the survey. No data on maternal or infant health was collected in the survey (Ong et al. 2005).

Subcutaneous administration of 0.1 to 0.4 ml daily of an aqueous dong quai extract to mice for 5 days did not affect fertility or show any teratogenic effects (Matsui et al. 1967).

Dong quai essential oil applied to isolated uteri produced a relaxant effect while the nonvolatile fractions produced a stimulant effect, potentiating uterine contraction (Zhu 1998).

Three unpublished cases of rashes have been reported in breast-feeding newborn infants whose mothers were taking dong quai (dose, duration, and preparation unreported) (Upton 2003).

A breast-feeding woman and her 3-week-old infant developed high blood pressure after the woman consumed an unspecified amount of dong quai prepared in a soup. Blood pressure of both the woman and her infant returned to normal 48 hours after cessation of dong quai (Nambiar et al. 1999).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered dong quai concentrated extract (8:1 to 16:1) in rats is 100 g/kg (Zschocke et al. 1998); of intravenously administered aqueous extract in mice is 100 g/kg (Wei 1987); and of orally administered 50% ethanol extract in mice is over 40 g/kg (Yang and Chen 1992). The LD_{50} of 4:1 concentrated extract of dong quai in rats is 100 g/kg (route of administration unspecified) (Zhu 1987). No toxic effects of dong quai extract were observed in rats or mice after single doses of 6 g/kg (Tanaka et al. 1983).

The LD_{50} of intravenously administered ferulic acid in mice is reported to be 856.6 mg/kg (Ozaki and Ma 1990); of intraperitoneally administered ligustilide in mice is approximately 410 mg/kg (Xie and Tao 1985), and of orally administered 3-*n*-butylidene phthalide in rats is 2.45 g/kg (Opdyke 1979).

In a review of the toxicology literature on dong quai, intravenous injection of the volatile fraction of dong quai was reported to cause kidney degeneration (Mei et al. 1991).

Short-Term Toxicity

After 21 days of oral administration of 1.5 or 3 g/kg dong quai extract daily to rats, increases in serum free cholesterol levels and kidney CYP450 enzymes were observed (Tanaka et al. 1983).

Genotoxicity

No genotoxic effects of dong quai were observed in a salmonella genotoxicity assay (NTP 2008).

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Felter and Lloyd 1898).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Felter and Lloyd 1898; Puri 1971); *see* Appendix 2.

Adverse Events and Side Effects

Although furanocoumarin compounds, such as those present in angelica or purple angelica, have photosensitizing effects (a heightened response of the skin to sunlight or other ultraviolet light) after contact with the skin, and some sources indicate that persons taking angelica or purple angelica should avoid prolonged exposure to sunlight (Blumenthal et al. 1998; Williamson 2003), no cases of phototoxicity associated with internal use of angelica or purple angelica were identified in the literature, although such a reaction is theoretically possible.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Angelica and purple angelica have traditionally been used as emmenagogues (Felter and Lloyd 1898; Puri 1971). Based on this, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of angelica in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No sensitization reactions were observed after 1% angelica root or seed oil in petroleum was applied to volunteers in a 48 hour closed patch test (Opdyke 1979).

Animal Pharmacological Studies

Among seven plants generally recognized to cause phytophotodermatitis, angelica had the highest concentration of coumarin compounds on the interior surface of the leaf. The concentration was greater than that of *Psoralea bituminosa*, although *P. bituminosa* had the highest concentration of coumarin on the leaf surface, as compared to other species (Zobel and Brown 1991).

A mild reaction was observed in rabbits topically treated with 500 mg of angelica seed essential oil (Opdyke 1974).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Among other uses, angelica has traditionally been used as an emmenagogue (Felter and Lloyd 1898).

No information on the safety of angelica during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered angelica root essential oil in rats is 11.16 g/kg (Skramlik 1959), and in mice is 2.2 g/kg (Opdyke 1975).

The dermal LD_{50} for angelica root essential oil in rabbits could not be determined at doses up to 5 g/kg (Opdyke 1975).

Genotoxicity

No genotoxic effects of angelica were observed in the micronucleus test in mouse bone marrow and peripheral blood cells (Salikhova et al. 1993). Antimutagenic activity of an alcohol extract of angelica was observed in the micronucleus test in murine bone marrow cells (Salikhova et al. 1993; Salikhova and Poroshenko 1995).

Anthriscus cerefolium (L.) Hoffm. — Apiaceae

SCN: chervil
OCN: garden chervil

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chadha 1988; List and Hörhammer 1973).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (List and Hörhammer 1973; Remington and Wood 1918); *see* Appendix 2.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Based on traditional use as an emmenagogue (Chadha 1988; List and Hörhammer 1973; Remington and Wood 1918), two herbal reference texts indicate that chervil should not be used during pregnancy (Chadha 1988; List and Hörhammer 1973). No other information on the use of chervil during pregnancy was identified.

No information on the use of chervil during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Based on traditional use as an emmenagogue (Chadha 1988; List and Hörhammer 1973; Remington and Wood 1918), two herbal reference texts indicate that chervil should not be used during pregnancy (Chadha 1988; List and Hörhammer 1973). No other information on the use of chervil during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Apium graveolens L. — Apiaceae

SCN: celery
OCN: wild celery

Part: fruit (commonly known as "seed")

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bradley 1992).

Other Precautions

Celery seed should be used with caution by individuals with inflammation of the kidneys or a history of irritation of the kidneys (Bradley 1992; Wichtl 2004).

Drug and Supplement Interactions

None known.

Notice

Photosensitizing (Ahluwalia et al. 1988; Garg et al. 1978, 1979; Schimmer 1983); *see* Appendix 2.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Allergic reactions, including anaphylactic reactions, to celery have been reported (Ballmer-Weber et al. 2000; Barg et al. 2008; Darsow et al. 2004; Luttkopf et al. 2000; Pauli et al. 1988; Vilke 2002).

Phototoxicity has been reported, primarily in persons handling fresh plants or ingesting large quantities of celery root followed by exposure to high-intensity UV radiation (UV therapy or tanning salon) (Birmingham et al. 1961; Jeanmougin et al. 2005; Ljunggren 1990; Schimmer 1983). No reports of phototoxicity in association with seed ingestion were identified. Furanocoumarin compounds present in celery seed, stem, and leaf are responsible for the phototoxicity (Beattie et al. 2007; Beier et al. 1983; Birmingham et al. 1961; Schimmer 1983).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No adverse effects of celery seed essential oil on fertility were observed in two animal studies (Garg et al. 1970; Sharma et al. 1983). Apiol, a compound found in celery essential oil, has been reported to have abortifacient activity (Kochmann 1931; van Itallie et al. 1932; Wichtl 2004).

No information on the safety of celery seed during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Anaphylactic reactions to celery have been reported, including two cases of food-dependent, exercise-induced anaphylaxis after ingestion of celery (Barg et al. 2008; Vilke 2002). One case of anaphylactic reaction to the drug oseltamivir (Tamiflu) occurred in a patient with celery-carrot-mugwort-spice syndrome (Hirschfeld et al. 2008).

Allergic reactions to celery have been confirmed in double-blind studies and by patch testing (Ballmer-Weber et al. 2000; Darsow et al. 2004; Ermertcan et al. 2007; Luttkopf et al. 2000; Pauli et al. 1988).

Phototoxicicity was reported in a woman who consumed large amounts of celery root prior to visiting a suntan parlor (Ljunggren 1990). A similar reaction was reported in a patient undergoing photochemotherapy (UVA) treatment (Jeanmougin et al. 2005).

Cases of mild to severe photodermatitis have been reported in persons handling fresh celery plants (Beier et al. 1983; Birmingham et al. 1961; Finkelstein et al. 1994; Seligman et al. 1987).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Birch-celery syndrome has been described, with individuals sensitized to birch (*Betula* spp.) pollen or mugwort (*Artemisia vulgaris*) pollen frequently displaying type I allergic symptoms after ingestion of celery (Breiteneder et al. 1995; Luttkopf et al. 2000).

No phototoxic reactions were observed in healthy volunteers administered 200 g raw or cooked celery stem or parsnip followed by exposure to UVA light (Beattie et al. 2007).

Animal Pharmacological Studies

In female rats administered 200 mg/kg of an ethanol extract of celery seed daily for 10 days, a lengthening of the estrus phase was observed, while administration for 20 or 30 days resulted in a decrease in other menstrual phases (Barethia 2008).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No effects on implantation were observed in rats orally administered 100 mg/kg of petroleum ether, alcoholic, or aqueous extracts of celery on days 1 to 7 of pregnancy (Garg et al. 1970). No adverse effects on fertility were reported in rats orally administered 250 mg/kg of an ethanol extract of celery daily on days 1 to 7 of pregnancy (Sharma et al. 1983).

Uterine stimulant activity of celery (plant part not specified in English language translation) has been reported (Kreitmair 1936).

No information on the safety of celery seed during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered celery seed essential oil in rats could not be determined at doses up to 5 g/kg (Opdyke 1974). The dermal LD_{50} of celery seed essential oil applied to the skin in rabbits could not be determined at doses up to 5 g/kg (Opdyke 1974).

A

Apocynum spp.

Apocynaceae

Apocynum androsaemifolium L.
SCN: spreading dogbane
OCN: common dogbane

***Apocynum cannabinum* L.**
SCN: Indian hemp
OCN: Canada hemp; hemp dogbane
Part: root

Quick Reference Summary

Safety Class: 3
Interaction Class: B

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Felter and Lloyd 1898; Wood and LaWall 1926).

Other Precautions

None known.

Drug and Supplement Interactions

Based on the presence of cardiac glycosides in spreading dogbane and Indian hemp, caution should be used in patients taking cardiac medications (Genkina et al. 1974; Grundmann and Gerlach 1967; Lee et al. 1972).

Notice

Emetic (Felter and Lloyd 1898; Wood and LaWall 1926); *see* Appendix 2.

Diuretic (Felter and Lloyd 1898; Wood and LaWall 1926); *see* Appendix 2.

Adverse Events and Side Effects

May cause irritation of the gastrointestinal tract, nausea, vomiting, and increased perspiration (Felter and Lloyd 1898; Wood and LaWall 1926).

Pharmacological Considerations

Medical texts from the late 1800s and early 1900s indicate that use of spreading dogbane almost invariably produces nausea or vomiting (sometimes copious), copious perspiration, diuretic activity, and "acts powerfully upon the heart, slowing its action and raising arterial tension" (Felter and Lloyd 1898; Graham 1909; Wood and LaWall 1926).

Pregnancy and Lactation

No information on the safety of spreading dogbane and Indian hemp in pregnancy or lactation was identified in the scientific or traditional literature. Based on the pharmacological activity, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Slowing of heart rate and increased urination were observed in cats, dogs, and frogs treated with varying doses of spreading dogbane (Graham 1909; Wood and LaWall 1926).

In Vitro Pharmacological Studies

Slowing of heart rate was observed in excised rabbit hearts treated with varying doses of spreading dogbane (Graham 1909).

IV. Pregnancy and Lactation

No information on the safety of spreading dogbane or Indian hemp in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a tincture of spreading dogbane administered intravenously to frogs is 5.1 ml/kg (Graham 1909).

Cytotoxicity

Fractions of a water-alcohol extract of spreading dogbane exhibited cytotoxic activity in human nasopharynx carcinoma cells (Kupchan et al. 1964).

Arctium lappa L. — Asteraceae

SCN: burdock
PN: *niu bang zi* (fruit)

OCN: *gobo*; *goboshi*; great burdock
Part: root, seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

An anaphylactic reaction to burdock root has been reported (Sasaki et al. 2003). Several cases of contact dermatitis have been reported after topical applications of burdock root plasters (Rodriguez et al. 1995).

Cases of atropine poisoning have been reported in persons that took adulterated burdock root products (Bryson et al. 1978; Fletcher and Cantwell 1978; Gandolfo and Accascina 1953; Rhoads et al. 1984). Atropine is not a known constituent of burdock (Leung and Foster 1996; Mills and Bone 2005).

Pharmacological Considerations

None known.

Pregnancy and Lactation

One animal study indicated no adverse effects of burdock on fetal development (Matsui et al. 1967). No other information on the safety of this herb in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Several cases of atropine poisoning have been reported in persons consuming tea labeled as burdock root (Bryson et al. 1978; Fletcher and Cantwell 1978; Gandolfo and Accascina 1953; Rhoads et al. 1984). Atropine is not a known constituent of burdock; its presence was a result of contamination (Leung and Foster 1996; Mills and Bone 2005).

An anaphylactic reaction to cooked burdock root has been reported. The patient tested positively to skin prick tests with raw and boiled burdock root, and raw and boiled carrot (Sasaki et al. 2003). Allergic contact dermatitis has been reported in three patients who topically applied burdock root plasters. All three patients tested positively in closed but not open patch tests, and none reported allergies

to other Asteraceae family plants. A positive patch test for nickel was reported in one patient. Tests with a sesquiterpene lactone mix were not completed (Rodriguez et al. 1995).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Some earlier reviews indicated a hypoglycemic effect of burdock root (Bever and Zahnd 1979; Farnsworth and Segelman 1971).

No adverse effects on fertility were seen in mice subcutaneously administered 0.05 to 0.2 ml of an aqueous burdock extract (part unspecified) twice daily for 5 days (Matsui et al. 1967).

In Vitro Pharmacological Studies

An extract of burdock root weakly inhibited the CYP isoenzymes CYP3A4, CYP19, and CYP2C19 (Scott et al. 2006).

An aqueous extract of burdock seed inhibited platelet-activating factor binding at a concentration of 200 µg/ml (Iwakami et al. 1992).

IV. Pregnancy and Lactation

No teratogenic effects were seen in offspring of pregnant mice subcutaneously administered 0.05 to 0.2 ml of an aqueous burdock extract (part unspecified) twice daily for 5 days (Matsui et al. 1967).

No information on the safety of burdock root or seed during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered alcohol extract of burdock root in rats is 700 mg/kg (Sharma et al. 1978).

Subchronic Toxicity

No toxic effects were observed in rats fed burdock root as 30% of the diet for 4 months (Hirono et al. 1978).

Arctostaphylos uva-ursi (L.) Spreng.

Ericaceae

SCN: uva-ursi
OCN: bearberry; kinnickinick

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (6.0–27.5%, usually around 10%) (Leung and Foster 1996; Wichtl 2004); *see* Appendix 1.

Editors' Notes

Although some herbal reference texts indicate that uva-ursi is contraindicated in kidney disorders (Bradley 1992; ESCOP 2003), a recent review of the literature found no evidence to support this contraindication (Upton et al. 2008). Some evidence of kidney damage has been observed in rats chronically administered the compound hydroquinone, which may have been the basis for contraindication in kidney disorders (Hoffman-Bohm and Simon 1992; Kari et al. 1992; Shibata et al. 1991). The kidney damage was seen primarily in aged male rats, a population that is predisposed to kidney damage (DeCaprio 1999; McGregor 2007).

One herbal reference text notes that "hydroquinone appears to be nontoxic with the administration of uva-ursi leaf tea, however hydroquinone must remain in suspicion with regard to having mutagenic and possibly carcinogenic effects" (Wichtl 2004). Reviews of the compound hydroquinone indicate that although genotoxic effects were observed in vitro and in animal tests using intraperitoneal or subcutaneous administration, such effects were generally not seen in animals orally administered the compound (DeCaprio 1999; McGregor 2007).

Uva-ursi contains arbutin and other hydroquinone glucosides, present at up to 12% of the dried leaf (Hegnauer 1966). The exposure to hydroquinone, however, depends on multiple factors including concentration in the leaf, concentration in the extract or other dosage form, and the absorption and distribution of hydroquinone in the body, which have yet to be fully investigated (Upton et al. 2008).

Adverse Events and Side Effects

A case of maculopathy was reported after long-term consumption of uva-ursi (Wang and Del Priore 2004).

Ingestion of uva-ursi has been reported to change urine to a brown-green color due to hydroquinone metabolites (Upton et al. 2008).

Pharmacological Considerations

Although several herbal reference texts indicate that concomitant use of uva-ursi and medications that can acidify the urine may result in a decrease in efficacy of uva-ursi with acidic urine or in conjunction with remedies that produce acidic urine (Blumenthal et al. 1998; Bradley 1992; ESCOP 2003; Weiss and Meuss 2001), a review of uva-ursi indicated that this concern appears to be theoretical, with no data available to support such an interaction (Upton et al. 2008).

Pregnancy and Lactation

No studies on the safety of uva-ursi in pregnancy were identified. A number of reproductive toxicity studies have been completed on the compounds arbutin and hydroquinone. The no-observed-effect level (NOEL) for arbutin in rats was 100 mg/kg daily (Itabashi et al. 1988). The NOEL for hydroquinone in rats was 100 mg/kg daily (Murphy et al. 1992). In rabbits, the NOEL for maternal toxicity of hydroquinone was 25 mg/kg, while the developmental toxicity NOEL was 75 mg/kg (Murphy et al. 1992).

In a two-generation reproductive toxicity study, no significant changes in rat pup development were observed (Blacker et al. 1993).

No information on the safety of uva-ursi during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of drug or supplement interactions were identified. Several reference texts indicate that concomitant use of uva-ursi with medications that can acidify the urine may result in a decrease of effectiveness of uva-ursi (Bradley 1992; ESCOP 2003; Weiss and Meuss 2001). The acidity of cranberry, another botanical commonly use to treat urinary tract infections, is often cited as a reason to avoid taking cranberry and uva-ursi together. Studies on the ability of cranberry to acidify the urine generally indicate that any such effects are mild or nonexistent (Upton 2002).

Animal Trials of Drug or Supplement Interactions

Studies of uva-ursi in rats, mice, and rabbits have indicated that uva-ursi may potentiate the anti-inflammatory effects of dexamethasone, prednisolone, and indomethacin (Matsuda et al. 1990, 1991, 1992).

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse effects or abnormal values in hematology or urinalysis were reported in men or women administered 300

or 500 mg daily of purified hydroquinone for 3 to 5 months (Carlson and Brewer 1953).

Case Reports of Adverse Events

A case of bull's-eye maculopathy was reported in a 56-year-old woman who had been taking uva-ursi tea "regularly" (dose and frequency not reported) for 3 years. The woman reported a decrease in visual acuity in the third year. The reporting authors noted that hydroquinone compounds are known inhibitors of tyrosine kinase and thus melanin synthesis, and that decreased melanin in the eye might account for the maculopathy (Wang and Del Priore 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No adverse effects were observed in healthy volunteers administered uva-ursi standardized extract or gastric juice-resistant tablet containing the same extract (Paper et al. 1993).

No adverse event data were reported in studies of urinary arbutin levels in persons taking uva-ursi (Quintus et al. 2005; Siegers et al. 1997).

Animal Pharmacological Studies

Some extracts of uva-ursi may have inhibitory effects on melanin synthesis, melasma, and other abnormal pigmentations in animals (Maeda and Fukuda 1996; Matsuda et al. 1992, 1996; Ortiz et al. 1999).

In Vitro Pharmacological Studies

Aqueous and methanolic extracts of uva-ursi inhibited the drug-metabolizing CYP isoenzymes CYP3A5, CYP3A7, CYP3A4, and CYP2C19; the aqueous extract also inhibited CYP19. For all isoenzymes, the aqueous extract had a stronger inhibitory effect than the methanolic extract (Chauhan et al. 2007).

Induction of MDR1 and the drug-metabolizing isoenzymes CYP1A2 and CYP3A4 was observed in vitro in human colon carcinoma cells (Brandin et al. 2007). Conversely, inhibition of CYP3A4 and CYP2C19 by ethanol extracts of uva-ursi was observed in a high-throughput screening assay (Scott et al. 2006).

Uva-ursi potentiated the effects of β-lactam antibiotics against methicillin-resistant *Staphylococcus aureus* (Shimizu et al. 2001).

IV. Pregnancy and Lactation

In pregnant rats subcutaneously administered 100 or 400 mg/kg daily of the compound arbutin, no signs of toxicity in parent animals or fetal toxicity were observed. The maximal no-observed-effect level (NOEL) dose was 100 mg/kg per day (equivalent to a human dose of ~7000 mg) (Itabashi et al. 1988).

In a two-generation reproductive toxicity study in rats, the compound hydroquinone was administered daily at doses up to 150 mg/kg 10 weeks prior to cohabitation, during cohabitation, and until scheduled termination, and no adverse effects were observed on feed consumption, survival, or reproductive parameters for the first or second generation (F0 or F1) parental animals. Mild, transient tremors were observed shortly after dosing at 150 mg/kg/day in several F0 and F1 animals and in a single F0 male at 50 mg/kg/day (Blacker et al. 1993).

In pregnant rats orally administered hydroquinone up to 300 mg/kg daily on days 6 to 15 of pregnancy, no changes in fertility, pregnancy outcomes, or fetal development were observed except that a slightly reduced fetal weight was seen at the highest dose level (Krasavage et al. 1992). In pregnant rats orally administered up to 300 mg/kg of the compound hydroquinone daily on days 6 to 15 of pregnancy, the NOEL for both maternal and developmental toxicity was 100 mg/kg, whereas 300 mg/kg was the no-observable-adverse-effect level (NOAEL) (Murphy et al. 1992).

In rabbits orally administered up to 150 mg/kg of the compound hydroquinone on days 6 to 15 of pregnancy, the NOEL for maternal toxicity was 25 mg/kg daily, and for developmental toxicity was 75 mg/kg daily. Under the conditions of this study, hydroquinone at 150 mg/kg/day produced minimal developmental alterations in the presence of maternal toxicity (Murphy et al. 1992).

No effects of uva-ursi on isolated rat or guinea pig uteruses were observed after application of 1 to 2 mg of crude drug per square centimeter (Shipochliev 1981).

No information on the safety of uva-ursi during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered hydroquinone is 200 mg/kg in rabbits, 80 mg/kg in cats, and could not be determined at doses up to 375 mg/kg in rats (Clayton and Clayton 1991; Topping et al. 2007). In rats, doses between 285 and 375 mg/kg caused animals to exhibit minor to moderate tremors and minor convulsions within the first hour after dosing (Topping et al. 2007). The LD_{50} of subcutaneously administered hydroquinone in mice is 160 mg/kg (Clayton and Clayton 1991). Based on these values, the LD_{50} of the compound hydroquinone in humans can be estimated at a mean of 21 g, suggesting that the potential for toxicity associated with typical doses of uva-ursi is low (Upton et al. 2008).

Subchronic Toxicity

In rats orally administered the compound hydroquinone 5 days a week for 13 weeks at doses of 0 to 200 mg/kg daily, doses of 64 or 200 mg/kg hydroquinone resulted in acutely observable behavioral effects including tremors and reduced activity. Oral doses of 64 mg/kg or more of hydroquinone resulted in acute neurobehavioral effects indicative of CNS stimulation; however, subchronic exposure to dose levels

that produced repetitive CNS stimulation by hydroquinone did not result in an exacerbation of acute stimulatory effects over time nor morphological changes in the CNS or PNS or nephrotoxicity. Nephrotoxic effects observed in other studies in Fischer 344 rats after hydroquinone exposure were not observed in this study with Sprague-Dawley rats (Topping et al. 2007).

Chronic Toxicity

Several chronic toxicity studies of the compound hydroquinone in rats have shown nephropathy after long-term dietary or other oral exposure, with male rats being significantly more affected than female rats (Hoffman-Bohm and Simon 1992; Kari et al. 1992; Shibata et al. 1991). Reviews of the toxicology of hydroquinone note that chronic progressive nephropathy is characteristic of aged male rats (DeCaprio 1999; McGregor 2007).

A chronic toxicity test of hydroquinone in mice and rats indicated some adverse effects after long-term administration as 0.8% of the diet for 2 years. In the hydroquinone group, renal tubular hyperplasia occurred in 100% of male rats, 30% of male mice, and 7% of female rats; adenomas occurred in 47% of male rats and 10% of male mice (Shibata et al. 1991).

After chronic exposure to hydroquinone, nephropathy occurred in 80% of male rats, 27% of female rats, and not at all in mice. Mice developed squamous cell hyperplasia in the stomach; 67% of male mice developed hypertrophy of the liver and 47% developed hepatocellular adenoma. No differences in survival, however, were noted between treated animals and controls (Hoffman-Bohm and Simon 1992).

In a chronic toxicity test of hydroquinone orally administered to rats at doses up to 50 mg/kg and mice at doses up to 100 mg/kg for 2 years, at the highest dose, male rats had severe nephropathy. Renal tubular adenomas were seen in 7% of low-dose rats and 14% of high-dose rats, but not in female rats or control animals. Mononuclear cell leukemia increased with dosage in female rats (Kari et al. 1992).

In rats orally administered 25 or 50 mg/kg of hydroquinone 5 days a week for 2 years, there was some evidence of carcinogenic activity of hydroquinone for male and female F344/N rats, and B6C3F1 mice, as shown by marked increases in tubular cell adenomas of the kidney (male F344/N rats), increases in mononuclear cell leukemia (female F344/N rats), and increases in hepatocellular neoplasms (female B6C3F1 mice). No evidence was found for carcinogenic activity of hydroquinone in male B6C3F1 mice administered 50 or 100 mg/kg. Administration of hydroquinone was associated with thyroid follicular cell hyperplasia in both male and female mice and anisokaryosis, multinucleated hepatocytes, and basophilic foci of the liver in male mice (NTP 1989).

Genotoxicity

No mutagenic activity of uva-ursi was seen in the Ames test with *Salmonella typhimurium* or in the *Bacillus subtilis* rec-assay (ESCOP 2003; Hoffman-Bohm and Simon 1992). No mutagenicity of the compound arbutin was observed in rats subcutaneously administered 100 to 400 mg/kg daily (Itabashi et al. 1988).

In Ames and micronucleus tests of urine from human volunteers administered the compound arbutin at doses of 420 mg, no mutagenic or genotoxic activity was observed (Siegers et al. 1997). No mutagenicity of arbutin was observed in a gene mutation assay at a concentration of 0.01 *M*, whereas the compound hydroquinone caused an increase in mutation frequency at a concentration of 0.01 *M* (Mueller and Kasper 1996).

Reviews of the compound hydroquinone indicate that although genotoxic effects were observed in vitro and in animal tests using intraperitoneal or subcutaneous administration, such effects were generally not seen in animals orally administered the compound (DeCaprio 1999; McGregor 2007).

Arisaema spp.

Araceae

Arisaema amurense Maxim.
SCN: Chinese arisaema
PN: *tian nan xing* (rhizome)

Arisaema erubescens **(Wall.) Schott**
SCN: Chinese arisaema
Syn: *Arisaema consanguineum* Schott
PN: *tian nan xing* (rhizome)

Arisaema heterophyllum **Blume**
SCN: Chinese arisaema
PN: *tian nan xing* (rhizome)
Part: prepared rhizome

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 3 to 10 g of the processed rhizome as a decoction (Bensky et al. 2004; Chen and Chen 2004).

Editors' Notes

Before use, Chinese arisaema must be processed to reduce toxicity. Processing typically consists of soaking the herb in multiple changes of water with alum added in later soakings, followed by boiling with fresh ginger and alum. Processing with bile, according to traditional methods, is an alternate method that reduces toxicity of the herb (Bensky et al. 2004). Unprocessed Chinese arisaema is considered toxic and inappropriate for internal use (Bensky et al. 2004; Chen and Chen 2004). The prepared rhizome, that has been processed to reduce toxicity, is the subject of this entry.

Adverse Events and Side Effects

Adverse reactions to Chinese arisaema are generally associated with the incompletely processed herb or with overdose. Irritating calcium oxalate crystals are generally responsible for reactions, which may include numbness of the tongue and mouth, itching and burning sensations, swelling, salivation, and loss of taste (Bensky et al. 2004; Chen and Chen 2004; Wu and Zhong 2008).

Topical reactions may occur if fresh Chinese arisaema comes in contact with the skin. This reaction may include swelling, itching, and pain (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

While one text on traditional Chinese medicine indicates that Chinese arisaema should be used with extreme caution during pregnancy (Chen and Chen 2004), another text indicates that this herb is contraindicated in pregnancy (Bensky et al. 2004).

No information on the safety of Chinese arisaema during lactation was identified.

While this review identified equivocal concerns for pregnant women and none while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Adverse reactions to Chinese arisaema are generally associated with the incompletely processed herb or with overdose (standard dose listed as a decoction of 3 to 10 g). Reactions may include numbness of the tongue and mouth, itching,

burning sensations, swelling, edema, salivation, loss of taste, difficulty opening the mouth, slurred speech, erosion and necrosis of the oral and pharyngeal mucosa, headache, nausea, vomiting, dizziness, and palpitations. In severe cases, muscle spasms, convulsions, respiratory depression, or respiratory paralysis may occur (Bensky et al. 2004; Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

While one text on traditional Chinese medicine indicates that Chinese arisaema should be used with extreme caution during pregnancy (Chen and Chen 2004), another text indicates that this herb is contraindicated in pregnancy (Bensky et al. 2004).

No information on the safety of Chinese arisaema during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a decoction of processed Chinese arisaema orally administered in mice could not be determined at doses up to 150 g/kg. After intraperitoneal administration, the LD_{50} of the same extract in mice is 13.5 g/kg (Chen and Chen 2004).

Arisaema triphyllum (L.) Schott

Araceae

SCN: Jack-in-the-pulpit
OCN: Indian turnip

Part: dried tuber

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Do not exceed recommended dose (Felter 1922; Felter and Lloyd 1898).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 1 to 5 drops of tincture every 30 minutes to 1 hour (Felter 1922).

Editors' Note

Jack-in-the-pulpit contains water-insoluble calcium oxalate crystals that are destroyed by processing (heating or drying) (Felter and Lloyd 1898; Keating 2004; Nakata and McConn 2000; Nelson et al. 2006; Weber 1891).

Adverse Events and Side Effects

The calcium oxalate crystals, present in the unprocessed plant, are microscopic needlelike structures that mechanically irritate the skin and mucous membranes, causing a painful burning sensation of the lips and mouth after ingestion. Ingestion may cause an inflammatory reaction, often with edema and blistering, sometimes resulting in hoarseness and difficulty swallowing (Nelson et al. 2006).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Jack-in-the-pulpit in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

Armoracia rusticana P. Gaertn. et al.

Brassicaceae

SCN: horseradish
Syn: *Armoracia lapathifolia* Gilib.

Part: rhizome, root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with stomach or intestinal ulcers, or kidney disorders (Blumenthal et al. 1998).

Drug and Supplement Interactions

None known.

Editors' Note

Although the German Commission E indicates that horseradish should not be used in children under the age of 4 (Blumenthal et al. 1998), no basis for this caution is provided and no other information from the traditional or scientific literature was found to support this contraindication.

Adverse Events and Side Effects

Horseradish may cause gastrointestinal discomfort (Blumenthal et al. 2000).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of horseradish in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of horseradish in pregnancy or lactation was identified.

V. Toxicity Studies

Genotoxicity

A slight mutagenic effect of horseradish paste was observed in bacterial mutagenicity assays. The effect was significantly less than that of cabbage or Brussels sprouts (Kassie et al. 1996). Antimutagenic activity of horseradish was observed in rat bone marrow cells (Agabeili and Kasimova 2005).

Arnica spp. — Asteraceae

Arnica latifolia Bong.
SCN: arnica
Arnica montana L.
SCN: arnica
OCN: European arnica; leopard's bane; mountain tobacco
Part: flower, rhizome, whole plant

Quick Reference Summary

Safety Class: 3 (internal use), 2d (external use)
Interaction Class: A

Contraindications

Not for internal use except under the supervision of an expert qualified in the appropriate use of this substance (De Smet 1992; Felter and Lloyd 1898; Leung and Foster 1996; List and Hörhammer 1973; Wichtl 2004).

Do not use on open wounds or broken skin (Felter and Lloyd 1898; Mitchell 1983).

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as sunflower, marigold, or feverfew) should exercise caution with arnica, as allergic cross-reactivity to Asteraceae plants is common (Hausen 1996).

Drug and Supplement Interactions

None known.

Editors' Notes

Homeopathic preparations of arnica are commonly used and are distinct from herbal preparations of arnica that are the subject of this entry (Leivers 2005).

Arnica contains trace amounts of the nontoxic pyrrolizidine alkaloids tussilagine and isotussilagine (Passreiter et al. 1992).

Other species of arnica (*A. angustifolia, A. chamissonis, A. chamissonis* Less. ssp. *foliosa*, *A. cordifolia,* and *A. sororia*) are used interchangeably in trade (McGuffin et al. 1997).

Adverse Events and Side Effects

Allergic contact dermatitis to arnica has been reported and is associated in some cases with sensitivity to other species of plants in the Asteraceae and Lauraceae families (Brinkhaus et al. 2006; Hausen 1980, 1985, 1992, 1996; Hausen and Schulz 1978; Machet et al. 1993; Paulsen et al. 2008; Pirker et al. 1992; Schempp et al. 2002; Schwarzkopf et al. 2006).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Overdoses of arnica have led to miscarriage (Blaschek et al. 2002; Merdinger 1938). Uterine stimulation has been observed in rats and guinea pigs (Brunzell and Wester 1947; Kreitmair 1936).

No information on the safety of arnica during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for internal use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Arnica contains sesquiterpene lactones that produce contact dermatitis in sensitive persons (Hausen 1978, 1980, 1996; Herrmann et al. 1978). Studies on sensitivity to Asteraceae species have indicated that up to 1.4 % of the population may be prone to contact allergy to arnica (de Groot et al. 1988; Hausen 1996; Paulsen et al. 1993; Reider et al. 2001). Cross-reactivity to arnica and other species of Asteraceae, including sunflower (*Helianthus annuus*) and marigolds (*Tagetes* spp.), and to species of Lauraceae have been reported (Hausen 1996; Hausen and Schulz 1978; Machet et al. 1993; Paulsen et al. 2008; Pirker et al. 1992). Other cases of contact allergy to arnica or products containing arnica have been reported (Hausen 1980, 1985; Hörmann and Korting 1994, 1995; Pirker et al. 1992; Rudzki and Grzywa 1977; Schempp et al. 2002; Schwarzkopf et al. 2006; Spettoli et al. 1998).

Topical application of a cream containing 1.5% arnica was reported to trigger a case of leukemia-related Sweet's syndrome (Delmonte et al. 1998).

A young man mistakenly consumed tea made from an unknown amount of arnica flower and leaf. Two hours later he experienced myalgia, headache, chills, and developed hyperthermia, tachycardia, hypotension, and elevated serum levels of creatinine, aspartate aminotransferase, and alanine aminotransferase (Topliff and Grande 2000). Stomach cramping followed by death was reported in a man who had consumed 70 g of arnica tincture (Blaschek et al. 2002). Poisoning with arnica has been reported to cause death due to circulatory paralysis with secondary respiratory arrest (product and dose not specified) (Hänsel et al. 1993).

An older herbal text indicated that internal use of "large doses" of arnica may cause "heat in the throat, nausea, vomiting, purging, spasmodic contractions of the limbs, difficulty of respiration, and sometimes inflammation of the alimentary canal, and coma" (Felter and Lloyd 1898).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In an irritation study using New Zealand albino rabbits, the primary irritation index of arnica in a base of soybean oil and tocopherol was 0 (Henkel Corp. 1997). A mixture of arnica extract, butylene glycol, and water, applied topically, was not irritating to rabbits (Ichimaru Pharcos Co. 1995). Open application of arnica absolute and arnica resinoid was not irritating to mouse skin (RIFM 1996a, 1996b).

A raw extract, an ether extract, and a tincture of arnica produced sensitization reactions in Pirbright white guinea pigs (Hausen 1978). A mixture containing arnica extract, butylene glycol, and water was not phototoxic to guinea pigs, and arnica absolute and arnica resinoid were not phototoxic

to hairless mice (Ichimaru Pharcos Co. 1995; RIFM 1996a, 1996b).

In Vitro Pharmacological Studies

The compounds helenalin and 11a,13-dihydrohelenalin have been shown to inhibit collagen-induced platelet aggregation, thromboxane formation, and 5-hydroxytryptamine secretion in a concentration-dependent manner in human platelets (Schröder et al. 1990).

IV. Pregnancy and Lactation

Miscarriages have been reported after overdoses of arnica infusion (made from 20 g arnica flower) or arnica flower tincture (44 ml) (Blaschek et al. 2002; Merdinger 1938).

No change in uterine tone or contractility was observed in isolated pregnant rat uteruses treated with arnica tincture (Blaschek et al. 2002). Uterine stimulation was observed in rats intragastrically administered a hot aqueous extract of arnica flower (dose not specified) (Kreitmair 1936) and in guinea pigs administered arnica tincture (dose not specified) (Brunzell and Wester 1947).

A survey of medical records of women who had used herbs as abortifacients indicated that consumption of arnica (preparation and dose unspecified) led to two cases of multiple organ system failure (Ciganda and Laborde 2003).

No information on the safety of arnica during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered arnica extract in mice is 123 mg/kg (RTECS 1996), and could not be determined in rats at doses up to 5 g/kg (CTFA 1981). The LD_{50} of intraperitoneally administered arnica extract in mice is 31 mg/kg (RTECS 1996).

The dermal LD_{50} of arnica resinoid in rabbits is greater than 5 g/kg; slight irritant effects were observed at this dose level (RIFM 1996b).

Genotoxicity

In the Ames test for mutagenicity, ethanol extracts of arnica produced a two- to fourfold increase in the number of revertants, as compared to controls with *S. typhimurium* TA98 with and without metabolic activation and with *S. typhimurium* TA100 with metabolic activation; an increase was not seen with TA100 without metabolic activation (Goggelmann and Schimmer 1986). The authors indicated that the effect was likely due to the flavonol compounds in arnica, noting that "the origin of the plant is important for the presence of essential components" and that results can differ based on the district of growth and the preparation of the extract (Goggelmann and Schimmer 1986).

Artemisia abrotanum L.

Asteraceae

SCN: southernwood
OCN: lad's love

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (McGuffin et al. 1997).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Madaus 1938; Steinegger and Hänsel 1972); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Use of southernwood during pregnancy is not recommended (McGuffin et al. 1997). Southernwood has been reported to have emmenagogue activity (Madaus 1938; McGuffin et al. 1997; Steinegger and Hänsel 1972).

No information on the safety of southernwood during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a small study, a nasal spray preparation of southernwood essential oil was generally well tolerated in adults with allergic rhinitis. Immediately after local nasal administration, all patients reported a slight to moderate nasal stinging sensation that lasted from 5 to 20 s. The sensation was not experienced as unpleasant. During repeated and prolonged use, none of the patients reported untoward effects such as mucosal irritation or injury, bleeding, or dry nose (Remberg et al. 2004).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Use of southernwood during pregnancy is not recommended (McGuffin et al. 1997).

No information on the safety of southernwood during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Artemisia absinthium L. — Asteraceae

SCN: wormwood

Part: herb

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use during pregnancy or lactation (Blagojevic et al. 2006; McGuffin et al. 1997).

Not for long-term use; do not exceed recommended dose (Leung and Foster 1996; Pinto-Scognamiglio 1967; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

Not to exceed 1.5 g of dried herb in tea, two to three times daily (Wichtl 2004).

Notice

Thujone (α-thujone 0–20% of essential oil, β-thujone 1.3–46% of essential oil; essential oil content of plant is 0.2 to 1.5%) (Blagojevic et al. 2006; Lawrence 1995; Wichtl 2004); *see* Appendix 1

Editors' Notes

Several herbal reference texts do not substantiate toxicological concerns for wormwood, except with long-term use (Leung and Foster 1996), excessive doses, or use of the essential oil (Felter and Lloyd 1898; Weiss and Meuss 2001; Wichtl 2004).

Regulatory restrictions against the use of wormwood requiring finished food products to be thujone-free exist in the United States and other countries (CFR 2011; Leung and Foster 1996; Martindale and Reynolds 1996).

Wormwood contains α- and β-thujone, compounds that may cause convulsions and that bind to GABA receptors, resulting in excitation of the autonomic nervous system (Höld et al. 2000). High amounts of thujone and thujone metabolites in the body may provoke convulsions and unconsciousness (Lee and Balick 2005; Olsen 2000). Nicotinic acid receptor, muscarinic cholinergic receptor, and 5-HT_3 receptor activity has also been reported (Deiml et al. 2004; Lee and Balick 2005).

Adverse Events and Side Effects

No reports of adverse events or side effects of wormwood used at standard doses were identified. Overdose of wormwood essential oil has resulted in seizures, rhabdomyolysis (breakdown of muscle fibers), vomiting, gastrointestinal cramps, retention of urine, and, in severe cases, confusion and renal lesions (Berlin and Smilkstein 1996; Weisbord et al. 1997; Wichtl 2004).

Pharmacological Considerations

Thujone is a porphyrogenic terpenoid and thus may be hazardous to patients with an underlying defect in hepatic heme synthesis (Bonkovsky et al. 1992).

Pregnancy and Lactation

While safety classes 2b and 2c in this text indicate that use in pregnancy or lactation is acceptable under the supervision of an expert qualified in the use of the described substance, the editors of this text know of no reason for which wormwood would be used in pregnancy or lactation. Based on the bioactivity of thujone and other compounds, wormwood should not be used during pregnancy or lactation.

Limited information on the safety of wormwood use during pregnancy and lactation is available. One study in rats indicated anti-implantation activity of wormwood (Rao et al. 1988).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Acute renal failure caused by rhabdomyolysis resulting from tonic clonic seizures was reported in a man who ingested 10 ml of wormwood essential oil. The patient had no history of neuromuscular disease, kidney disease, or history of alcohol dependence. The manufacturer confirmed that the wormwood essential oil consumed was pure and not adulterated (Weisbord et al. 1997). Ingestion of 60 ml of wormwood essential oil led to altered mental status, seizures, and secondary complications including hyperthermia, rhabdomyolysis, and aspiration (Berlin and Smilkstein 1996).

Bradyarrhythmia was reported in a man with acute absinthe intoxication. The authors of the report noted that although tachyarrhythmias are frequently developed in acute alcohol intoxication, bradyarrhythmias are exceptional in this context (Benezet-Mazuecos and de la Fuente 2006).

A condition known as absinthism was observed in chronic consumers of the alcoholic beverage absinthe, which contains wormwood extract. The condition was described as a form of alcoholism that included delirium, hallucinations, tremors, and seizures (Lee and Balick 2005). While the compound thujone was once thought to be the primary cause of the psychotropic activity and toxicity of absinthe, recent analyses of absinthe indicate that the thujone content of historical and contemporary samples is insignificant and that other ingredients, such as the coloring agents copper sulfate or antimony chloride, may have been responsible for the adverse effects of absinthe (Blaschek et al. 2002; Lachenmeier et al. 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A decrease in attention performance was associated with thujone content of beverages administered to healthy volunteers at concentrations of 0, 10, or 100 mg/l thujone in alcohol, leading to an average thujone dose of 0, 0.026, or 0.26 mg/kg (doses were adjusted to provide equal amounts of alcohol in each dose). The thujone concentration was associated with a temporary counteracting of the anxiolytic effect of alcohol (Dettling et al. 2004).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Anti-implantation activity was reported in rats administered an ethanol extract of wormwood (Rao et al. 1988).

Wormwood is listed as an ingredient in two herbal abortifacient formulas traditionally used in Iran (Madari and Jacobs 2004). Toxic effects and death after consumption of large amounts of wormwood (extract not specified but believed to be the essential oil) have been reported in the context of using the plant as an abortifacient (Gessner 1974).

V. Toxicity Studies

Acute Toxicity

The LD_{50} value of wormwood liquid extract administered orally in mice is 2.5 g/kg (Lagarto Parra et al. 2001); that of an ethanol extract administered intraperitoneally in rats is 1 g/kg (Sharma et al. 1978); and that of the essential oil administered orally in rats is 96 mg/kg (Opdyke 1975).

No mortality was observed in rabbits orally administered hexane, chloroform, and water extracts of wormwood at doses up to 1.6 g/kg (Khattak et al. 1985).

The doses of intraperitoneally administered α- and β-thujone that produce convulsions have been reported as 590 mg/kg in mice (Wenzel and Ross 1957) and 100 mg/kg in rats (Sampson and Fernandez 1939).

Subchronic Toxicity

A 13-week repeated-dose toxicity study of wormwood extract performed in male and female rats indicated that the no-observed-adverse-effect level was equivalent to 1.27 g/kg daily in male rats and 2.06 g/kg daily in female rats (Muto et al. 2003).

Chronic Toxicity

Diminished life expectancy and growth but no increase in liver damage or tumor formation were observed in rats orally administered a total of 15.3 g of powdered wormwood over an 18-month period (Schmahl 1956).

Chronic administration of thujone is reported to lead to fatty degeneration of the liver (Pinto-Scognamiglio 1967).

Genotoxicity

No mutagenic activity was reported in an Ames test of wormwood extract (Schimmer et al. 1994).

Artemisia annua L.

Asteraceae

SCN: sweet wormwood
PN: *qing hao* (above-ground parts)
OCN: annual wormwood; sweet Annie
Part: above-ground parts

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Al Kadi 2007; Boareto et al. 2008).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Sweet wormwood contains the compound artemisinin. Artemisinin and compounds derived from sweet wormwood are widely used as antimalarial drugs (Meshnick 2002).

Adverse Events and Side Effects

No adverse effects from sweet wormwood are reported in texts on traditional Chinese medicine for normal doses prepared as a d ecoction (Bensky et al. 2004; Chen and Chen 2004), though use of an extract tablet (dosage not provided) is reported to have caused gastrointestinal side effects in 3.4% of patients (Bensky et al. 2004).

A case of hepatitis was reported in association with a supplement containing the compound artemisinin (Malhotra et al. 2009).

No serious adverse events have been reported from artemisinin or artemisinin derivatives used as antimalarial drugs. Mild adverse events associated with the use of these compounds include nausea, vomiting, and diarrhea, although these have also been noted as symptoms of malaria (Gordi and Lepist 2004; McGready et al. 1998; Meshnick 2002; Meshnick et al. 1996; Ribeiro and Olliaro 1998).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A review of antimalarial drugs indicated that artemisinin-based compounds are not recommended for use during the first trimester of pregnancy, due to lack of safety data, but the compounds may be used during the second and third trimesters (Al Kadi 2007). An animal study published after that review indicated that an increase in postimplantation losses was observed in animals given relatively high amounts (35 or 70 mg/kg) of the compound artemisinin but not in animals given amounts comparable to the standard human dose (7 mg/kg) (Boareto et al. 2008).

No information on the safety of sweet wormwood during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

In studies with the compound artemisinin in rodent malaria (a normally susceptible strain of *Plasmodium berghei*), marked potentiative synergism was found with the drugs mefloquine, tetracycline, and spiramycin. Some synergism was also observed with primaquine. Combinations of artemisinin with dapsone, sulfadiazine, sulfadoxine, pyrimethamine, pyrimethamine/sulfadoxine, and cycloguanil showed antagonism. A high degree of potentiation was shown between artemisinin and primaquine with a primaquine-resistant strain, while the combination with mefloquine showed enhanced potentiation with a mefloquine-resistant strain. Combinations of artemisinin with mefloquine, primaquine, tetracycline or clindamycin showed marked potentiation with an artemisinin-resistant strain (Chawira et al. 1987).

II. Adverse Events

Case Reports of Adverse Events

Reviews of animal toxicity studies of the compound artemisinin and artemisinin derivatives indicate that neurotoxic effects have been observed, notably in the brain stem. These reviews acknowledge, however, that such toxicity has not been observed after widespread use in humans. As of 1996, an estimated 2 million malaria patients had been treated with artemisinin and its derivatives, with no serious adverse events reported. Common nonserious adverse events include nausea, vomiting, and diarrhea, although these have also been noted as symptoms of malaria (Gordi and Lepist 2004; McGready et al. 1998; Meshnick 2002; Meshnick et al. 1996; Ribeiro and Olliaro 1998). Occasional neutropenia, reticulocytopenia, elevated liver enzymes, transient bradycardia, and prolonged QT intervals have also been reported (Ribeiro and Olliaro 1998).

Hepatitis was reported in a 52-year-old man who had been taking two capsules, three times daily for 1 week, of a supplement containing 100 mg per capsule of the compound artemisinin. Laboratory analyses confirmed the presence of artemisinin and the absence of adulterants (Malhotra et al. 2009).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Flavonol compounds isolated from sweet wormwood were found to potentiate the activity of berberine and norfloxacin against a multidrug-resistant strain of *Staphylococcus aureus* (Stermitz et al. 2002).

IV. Pregnancy and Lactation

In rats orally administered 7, 35, or 70 mg/kg of the compound artemisinin daily from gestational days 7 to 13 or 14 to 20, an increase in postimplantation losses was observed at the 35 and 75 mg/kg dose levels. The losses were correlated with a trend to lower maternal progestogens and a maternal testosterone decrease. Results indicate toxicity for both periods of treatment, with lower sensitivity at later stages of pregnancy (Boareto et al. 2008).

A review of antimalarial drugs indicated that, due to lack of safety data, artemisinin-based compounds are not recommended for use during the first trimester of pregnancy but the compounds may be used during the second and third trimesters (Al Kadi 2007).

No information on the safety of sweet wormwood during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound artemisinin in mice is 4.23 g/kg after oral administration, 3.84 g/kg after intramuscular administration, 1.59 g/kg after intraperitoneal administration, and 9 g/kg after subcutaneous administration (Zhu 1998). The LD_{50} of the compound artemisinin in rats is 5.58 g/kg after oral administration and 2.57 g/kg after intramuscular administration (Zhu 1998).

Artemisia dracunculus L. 'Sativa'

Asteraceae

SCN: French tarragon
OCN: estragon; tarragon

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Alkenylbenzenes (estragole 60–81% of the essential oil, essential oil content is 0.9–5.3%) (Arabhosseini et al. 2006; De Vincenzi et al. 2000; Ribnicky et al. 2004; Wichtl 2004); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

An animal study and traditional human use indicate that French tarragon may modify glucose regulation (Ribnicky et al. 2006; Swanston-Flatt et al. 1991). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

In vitro studies indicate that extracts of French tarragon may inhibit platelet aggregation (Shahriyary and Yazdanparast 2007; Tognolini et al. 2006).

Pregnancy and Lactation

No information on the safety of French tarragon in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic mice orally administered 500 mg/kg of an ethanol extract of French tarragon daily for 7 days, a reduction in blood glucose levels was observed (Ribnicky et al. 2006).

In Vitro Pharmacological Studies

In guinea pig and rat plasma, French tarragon essential oil exhibited antiplatelet activity against ADP-, arachidonic acid-, and U46619-induced platelet aggregation. The essential oil also demonstrated an ability to destabilize clot retraction (Tognolini et al. 2006).

Inhibition of platelet adhesion, aggregation, and secretion was observed in human platelets treated with a methanol extract of French tarragon (Shahriyary and Yazdanparast 2007).

IV. Pregnancy and Lactation

No information on the safety of French tarragon during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an ethanol extract of French tarragon orally administered to rats could not be determined at doses up to 5 g/kg (Ribnicky et al. 2004).

Subchronic Toxicity

In rats orally administered 10, 100, or 1000 mg/kg of an ethanol extract of French tarragon daily for 90 days, clinical chemistry, organ weights, and microscopic examination of organs indicated no adverse effects (Ribnicky et al. 2004).

Genotoxicity

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537, and TA102, no biologically relevant mutagenic activity of an ethanol extract of French tarragon was observed with or without metabolic activation by S9 (Ribnicky et al. 2004).

The essential oil of French tarragon exhibited mutagenic activity in the *Bacillus subtilis* rec-assay but not in the *Salmonella*/microsome reversion assay (Zani et al. 1991).

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Jamwal and Anand 1962; Riddle 1997; Saha et al. 1961; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Saha et al. 1961; Williamson 2003); *see* Appendix 2.

Thujone (~64% of the essential oil; *A. vulgaris* contains 0.03–0.3% essential oil) (Misra and Singh 1986); *see* Appendix 1.

Adverse Events and Side Effects

A review of contact dermatitis due to plant exposures indicated that mugwort was a relatively common cause of dermatitis (Kurz and Rapaport 1979; Saito et al. 1982).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Some reports indicate that mugwort has been used as an abortifacient or in abortifacient formulas (Jamwal and Anand 1962; Riddle 1997; Saha et al. 1961; Wichtl 2004). Based on this information, use in pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of mugwort during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A review of contact dermatitis due to plant exposures indicated that mugwort was a relatively common cause of dermatitis (Kurz and Rapaport 1979; Saito et al. 1982).

A severe allergic reaction was reported in a florist with a preexisting sunflower allergy after occupational contact with mugwort. Skin testing (prick and scratch) revealed strong sensitization to mugwort and French tarragon (Kurzen et al. 2003).

Skin prick testing in a patient that experienced anaphylaxis after pine nut ingestion indicated cross-reactivity to mugwort (Rodrigues-Alves et al. 2008). In a patient sensitized to lettuce, CAP inhibition testing indicated that the patient was also allergic to mugwort (Vila et al. 1998).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In nondiabetic mice orally administered 250 mg/kg of a methanol extract of mugwort, an increase in the blood glucose level was observed in the oral glucose tolerance test (Villasenor and Lamadrid 2006).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Some reports indicate that mugwort has been used as an abortifacient or in abortifacient formulas (Jamwal and Anand 1962; Riddle 1997; Saha et al. 1961; Wichtl 2004). No stimulant action of mugwort was observed in isolated guinea pig uteruses (Saha et al. 1961).

No information on the safety of mugwort during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Artemisia spp.

Asteraceae

Artemisia capillaris Thunb.
SCN: yin-chen wormwood
PN: *yin chen hao* (above-ground parts, herb)
OCN: capillaris; capillary artemisia

***Artemisia scoparia* Waldst. & Kit.**
SCN: yin-chen wormwood
PN: *yin chen hao* (herb)
Part: above-ground parts, herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Thujone (α-thujone 0.7% of *A. scoparia* essential oil, 0.1% of *A. capillaris* essential oil; β-thujone 0.3% of *A. scoparia* essential oil, trace amount in *A. capillaris* essential oil) (Cha et al. 2005); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of yin-chen wormwood herb or above-ground parts in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Rare cases of adverse events have been reported in persons taking relatively high (15 to 30 g) doses of yin-chen wormwood. Symptoms included headache, dizziness, numbness and tremor of the upper extremities, heart palpitations, fainting, and an oppressive feeling in the chest. Details on the exact doses, preparation, and relevant medical history were not reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Of 75 compounds isolated from yin-chen wormwood, 15 showed antiplatelet aggregation activity (Wu et al. 2001).

IV. Pregnancy and Lactation

Inhibition of implantation was observed in female rats orally administered 10 mg/kg of the compound scoparone. At doses of 25 or 50 mg/kg, the number of pups born, ratio of live/dead pups, and their weight gain were adversely affected, with skeletal abnormalities observed in some pups (Chandhoke 1979).

No information on the safety of yin-chen wormwood during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound capillarin intraperitoneally administered to mice is 262.5 mg/kg (Chen and Chen 2004).

Short-Term Toxicity

Oral administration of the compound scoparone to male rats at doses of 10, 25, or 50 mg/kg daily for 75 days produced a decrease in weight gain and dose-related mortality (Chandhoke 1979).

Genotoxicity

No mutagenic activity of an aqueous extract of yin-chen wormwood was observed in the Ames mutagenicity assay with *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation by S9 (Yin et al. 1991).

In the mouse micronucleus and chromosomal aberration assays, some mutagenic activity was observed in mice intraperitoneally administered an aqueous extract of yin-chen wormwood at doses of 4.5, 9, or 18 g/kg. In the micronucleus assay, an increase of polychromatic erythrocytes was observed at the 4.5, 9, and 18 g/kg dose levels. An increase in the incidence of chromosomal aberrations was observed at the 4.5, 9, and 18 g/kg dose levels, but not at the 0.9 g/kg dose level (Yin et al. 1991).

Asclepias asperula (Decne.) Woodson — Asclepiadaceae

SCN: inmortal

Part: root

Quick Reference Summary

Safety Class: 2b

Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Conway and Slocumb 1979; Moore 2003).

Other Precautions

Use with heart medications is cautioned (Moore 2003).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Overdose may cause nausea and vomiting (standard dose is listed as 2 teaspoons of root daily) (Moore 2003).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Inmortal has been used to facilitate childbirth and to induce abortions (Conway and Slocumb 1979). Based on this, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of inmortal during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No cases of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events associated with inmortal were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Some cardenolides isolated from inmortal have exhibited binding affinity for a p hysiological receptor, porcine kidney Na^+,K^+-ATPase. The order of binding affinities for the cardenolides from highest to lowest was uzarigenin, desglucouzarin, uzarin, and 6′-*O*-(*E*-4-hydroxycinnamoyl)desglucouzarin (Abbott et al. 1998).

IV. Pregnancy and Lactation

Hot and cold water extracts of inmortal have been used in childbirth and large doses of decoctions have been used to induce abortions. Large doses are reported to cause nausea (Conway and Slocumb 1979).

No information on the safety of inmortal during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Asclepias tuberosa L. — Asclepiadaceae

SCN: pleurisy root

Part: root

Quick Reference Summary

Safety Class: 2b

Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (List and Hörhammer 1973; Moore 2003).

Other Precautions

May cause nausea and vomiting (List and Hörhammer 1973).

Drug and Supplement Interactions

None known.

Notice

Emetic (List and Hörhammer 1973); *see* Appendix 2.

Editors' Note

While the standardized common name of the root of *A. tuberosa* is pleurisy root, that of the plant itself is butterfly weed (McGuffin et al. 2000).

Adverse Events and Side Effects

While one toxicology text indicates that ingestion of pleurisy root may cause irritation of the mouth, throat, and gastrointestinal tract (Lewis 1998), a pharmacy text written in the late 1800s, when pleurisy root was commonly used, did not list such adverse effects (Felter and Lloyd 1898).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Uterine stimulation and uterotonic activity has been reported in animal studies (Costello and Butler 1949). One reference indicates that pleurisy root is probably inappropriate for use in "delicate pregnancies" (Moore 2003). Based on these reports, use in pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of pleurisy root during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No cases of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events associated with pleurisy root were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In an older study, estrogenic activity of a pleurisy root extract was observed in castrated rats (Costello and Butler 1949).

In Vitro Pharmacological Studies

Inhibition of ouabain binding to membrane Na^+,K^+-ATPase and cross-reactivity with digoxin antibody in a radioimmunoassay from a pleurisy root aqueous extract were observed in vitro (Longerich et al. 1993).

IV. Pregnancy and Lactation

In vivo uterine stimulant action was observed in rabbits, dogs, and cats intravenously administered an ethanol- and isopropanol-based extract of pleurisy root (Costello and Butler 1949). Increased uterine tone was observed in cats and rabbits injected with an extract of pleurisy root (Hassan 1952).

One reference indicates that pleurisy root is probably inappropriate for use in "delicate pregnancies" (Moore 2003).

No information on the safety of pleurisy root during lactation was identified.

V. Toxicity Studies

Acute Toxicity

An alcohol extract of pleurisy root administered intravenously to rabbits and intraperitoneally to rats at doses of 0.04 ml/kg induced partial paralysis (Hassan 1952).

Short-Term Toxicity

Rats intraperitoneally administered 10 mg daily of an alcohol extract of pleurisy root developed diarrhea and continuous tremors after 5 days (Hassan 1952).

Asparagus adscendens Roxb.

Liliaceae

SCN: *Asparagus adscendens*
AN: *shveta mushali*

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of *Asparagus adscendens* in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Asparagus adscendens has traditionally been used to promote milk secretion in lactating women (Kapoor 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

Asparagus officinalis L.

Liliaceae

SCN: asparagus

Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Blumenthal et al. 1998; Fyfe and Scudder 1909; Jeaffreson 1855; Van Wyk and Wink 2004); *see* Appendix 2.

Adverse Events and Side Effects

Occupational allergic contact dermatitis from the above-ground parts of asparagus has been reported (Rademaker and Yung 2000; Tabar et al. 2004). Allergic reactions, including anaphylactic reactions, have been reported after ingestion of the above-ground parts of asparagus (Tabar et al. 2004). No relevance to asparagus root of these records of side effects for the above-ground parts has been established.

Pharmacological Considerations

See Notice.

Pregnancy and Lactation

No information on the safety of asparagus in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Occupational allergic contact dermatitis to asparagus was reported in a farm worker who worked with asparagus plants (Rademaker and Yung 2000).

Allergic reactions, including anaphylactic reactions, to asparagus have been reported and confirmed by patch testing and IgE immunoblotting (Tabar et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of asparagus in pregnancy or lactation was identified.

V. Toxicity Studies

Cytotoxicity

Several steroidal compounds isolated from the rhizome of asparagus had cytotoxic effects in human and mouse tumor cell lines (Huang et al. 2008).

Asparagus racemosus Willd. — Liliaceae

SCN: shatavari
AN: *shatavari*

Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Kapoor 2001; Williamson 2002); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

An animal study indicated that shatavari may have estrogenic activity (Pandey et al. 2005).

Pregnancy and Lactation

Shatavari is commonly used as a reproductive system tonic in India and has traditionally been used to prevent threatened miscarriage (Caldecott 2006). A review of the literature on shatavari indicated that, in Ayurveda, this herb is generally considered safe for use during pregnancy (Goyal et al. 2003). An animal study indicated adverse effects in developing fetuses of pregnant mice administered a methanol extract of shatavari during pregnancy (Goel et al. 2006). Shatavari is traditionally prepared in milk, ghee, or water and used throughout pregnancy. A methanol extract would provide larger amounts of steroidal compounds than traditional methods, which may account for the adverse effects reported in the animal study.

Shatavari has traditionally been used to promote milk secretion in lactating women (Joglekar et al. 1967; Kumar et al. 2008; Nadkarni 1954; Patel and Kanitkar 1969).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered 3 mg/kg of an alcohol extract of shatavari daily on days 1 to 15 of pregnancy, macroscopic findings revealed a prominence of the mammary glands, a dilated vaginal opening, and a transversely situated uterine horn. A thickening of the vaginal epithelium was observed. The authors of the study indicated that those results, along

with other reported changes in female reproductive tissues, suggest an estrogenic effect of shatavari on the female mammary gland and genital organs (Pandey et al. 2005).

A reduction in chemically induced tumor incidence was observed in rats administered a chloroform-methanol extract of shatavari (Rao 1981).

In Vitro Pharmacological Studies

The ethanol extract, and hexane, chloroform, and ethyl acetate fractions of shatavari extracts concentration-dependently stimulated insulin secretion in isolated perfused rat pancreas, isolated rat islet cells, and clonal beta-cells (Hannan et al. 2007).

IV. Pregnancy and Lactation

Increases in resorptions of fetuses, gross malformations, intrauterine growth retardation, and small placental size were observed in rats orally administered 100 mg/kg daily of a methanolic extract of shatavari daily for 60 days. A smaller litter size and decrease in pup body weight and length were associated with the treatment (Goel et al. 2006).

The saponin fraction of shatavari was reported to inhibit oxytocin in isolated rat uteri (Gaitonde and Jetmalani 1969).

Shatavari has traditionally been used to prevent threatened miscarriage (Caldecott 2006). A review of the literature on shatavari indicated that, in Ayurveda, this herb is generally considered safe for use during pregnancy (Goyal et al. 2003).

Shatavari has traditionally been used to promote milk secretion in lactating women (Joglekar et al. 1967; Kumar et al. 2008; Nadkarni 1954; Patel and Kanitkar 1969).

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in mice orally administered 1 g/kg of a shatavari extract (Debelmas and Hache 1976; Rege et al. 1999).

Short-Term Toxicity

No adverse effects were observed in mice and rats orally administered 1 g/kg of an aqueous extract of shatavari daily for 15 to 30 days (Rege et al. 1999).

Quick Reference Summary

Safety Class: 1
Interaction Class: B

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

Theoretically, astragalus could be incompatible with immune suppressant drugs such as cyclosporine and corticosteroids (Upton 1999). A limited number of human studies have indicated that astragalus increases the therapeutic effects of corticosteroids and cyclophosphamide in patients with autoimmune disease (Cai et al. 2006; Pan et al. 2008; Su et al. 2007), while animal studies have indicated a reversal of cyclophosphamide-induced immune suppression (Chu et al. 1988b, 1988c).

Astragalus has been shown to potentiate the therapeutic effects of alpha recombinant interferon 1 (rIFN-α-1) in humans (Qian et al. 1990), acyclovir in mice (Zuo et al. 1995), and interleukin 2 (rIL-2) and interferon in vitro (Chu et al. 1988a; Hou et al. 1981).

Editors' Note

The above-ground parts of certain chemically distinct species of astragalus are known to cause a disease called locoism which can cause reproductive abnormalities in livestock. The compound swainsonine, which causes locoism, is not present in *Astragalus mongholicus* (Rios and Waterman 1997).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of this herb in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Astragalus has been shown to potentiate the therapeutic effects of alpha recombinant interferon 1 (rIFN-α-1) in patients with human papillomavirus type 16 or herpes simplex virus type 2 (Qian et al. 1990).

A purified fraction of astragalus was shown to reverse cyclophosphamide-induced immune suppression in rats, enhancing the ability of the rats to reject xenogeneic grafts (Chu et al. 1988b).

In patients with systemic lupus erythematosus, concomitant administration (intraperitoneally) of astragalus and standard corticosteroid/immunosuppressant drug therapy (drug not specified in English language abstract) was shown to enhance the inhibitory function of the corticosteroid on apoptosis and regulate the ratio and function of T lymphocyte subsets as compared to standard corticosteroid treatment alone (Cai et al. 2006). In patients with systemic lupus erythematosus complicated by kidney damage, intravenous administration of 20 ml of astragalus 12 days per month for 3 months with cyclophosphamide administered once a month, a 4.3% infection rate was observed in the astragalus group, while the rate was 25% in the control group, indicating that astragalus used together with cyclophosphamide is more effective than cyclophosphamide alone in decreasing infection rate and urine protein and improving immune function for patients with lupus nephritis (Su et al. 2007).

Case Reports of Suspected Drug or Supplement Interactions

The T-cell-stimulating activity of astragalus could, theoretically, contradict the effects of immune suppressant drugs such as cyclosporine and corticosteroids.

Animal Trials of Drug or Supplement Interactions

A partially purified fraction of astragalus coadministered to mice with the immune suppressant cyclophosphamide after transplantation of mononuclear cells resulted in transplant rejection, indicating a reversal of cyclophosphamide action (Chu et al. 1988b).

Astragalus has been shown to potentiate the therapeutic effects of alpha recombinant interferon 1 (rIFN-α-1) in humans (Qian et al. 1990), acyclovir in mice (Zuo et al. 1995), and interleukin 2 (rIL-2) and interferon in vitro (Chu et al. 1988a; Hou et al. 1981).

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions including skin eruptions and pruritus have been reported in persons taking astragalus (Bensky et al. 2004). Overdoses may cause headache, tightness in the chest, insomnia, dizziness, and hypertension. Anaphylactic reactions have been reported in patients intravenously administered extracts of astragalus (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

CD25 expression on T cells was increased in healthy volunteers administered extracts equivalent to 1.23 g of astragalus daily for 7 days (Zwickey et al. 2007).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An aqueous extract of astragalus was shown to enhance immune function by increasing proliferation of spleen cells,

B cell IgG production, macrophage cytokine production of IL-6 and TNF, and enhancing induction of cytotoxic T cells (Yoshida et al. 1997).

IV. Pregnancy and Lactation

No information on the safety of astragalus during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of astragalus extract in mice has been reported as 40 g/kg (Chang and But 1987), although no toxicity was observed after administration of a concentrated aqueous extract to rats at doses equivalent to 100 g/kg (routes of administration unspecified in English translations of studies) (Chang and But 1987; Wagner et al. 1997). Intraperitoneal administration of 50 g/kg astragalus extract in mice led to prostration, paralysis, dyspnea, and cyanosis; in some animals, contracture of the extremities was observed before the death of the animals (Chang and But 1987).

Subchronic Toxicity

No signs of clinical toxicity were observed in rats intraperitoneally administered up to 39.9 g/kg astragalus extract for 12 weeks or in dogs intraperitoneally administered astragalus extract up to 19.5 g/kg for 17 weeks (Yu et al. 2007).

Mutagenicity

Astragalus has been reported to have no mutagenic effects (Wagner et al. 1997).

Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of cang-zhu atractylodes during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Extracts of cang-zhu atractylodes have been used in clinical studies to treat infants with rickets. In one study, oral doses of 0.066 ml of the essential oil were administered to 2- or 3-year-olds three times daily for 1 to 2 weeks (Chen and Chen 2004). In a s econd study, infants were treated with a syrup containing the equivalent of 4.5 g of cang-zhu atractylodes twice daily for 15 days (Chen and Chen 2004). No adverse event information was reported in English language translations.

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of cang-zhu atractylodes during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Atractylodes macrocephala Koidz. — Asteraceae

SCN: bai-zhu atractylodes
PN: *bai zhu* (rhizome)

Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

In one human study, a lengthening of prothrombin time (indicating a s lowing of blood clotting) was observed in patients treated with bai-zhu atractylodes. Information on the magnitude of effect on prothrombin time was not listed in the English language translation (Chen and Chen 2004).

Pregnancy and Lactation

Bai-zhu atractylodes is used in formulas during pregnancy in traditional Chinese medicine to "calm the fetus" (Bensky et al. 2004).

No information on the safety of bai-zhu atractylodes in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose (standard dose is a decoction of 6–15 g) or inappropriate use has been associated with vomiting of blood, nosebleeds, bloody stools, elevated temperature, and agitation (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A lengthening of prothrombin time was observed in healthy volunteers administered a 5% decoction of bai-zhu atractylodes three times daily for 4 days. Information on the magnitude of the effect on prothrombin time was not listed in the English language translation (Chen and Chen 2004).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Induction of the drug-metabolizing isoenzyme CYP3A4 was observed in human liver cells and rat liver microsomes treated with extracts of bai-zhu atractylodes (Dong et al. 2008a, 2008b).

IV. Pregnancy and Lactation

Bai-zhu atractylodes is used during pregnancy in traditional Chinese medicine to "calm the fetus" (Bensky et al. 2004).

Sesquiterpene lactones isolated from bai-zhu atractylodes inhibited contractions induced by acetylcholine and oxytocin in isolated rat uteri (Zhang et al. 2000).

No information on the safety of bai-zhu atractylodes during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a decoction of bai-zhu atractylodes intraperitoneally administered in mice is 13.3 g/kg (Chen and Chen 2004).

Cytotoxicity

Pro-oxidant and cytotoxic activities of the compound atractylenolide have been observed (Wang et al. 2006).

Atropa belladonna L. — Solanaceae

SCN: belladonna
OCN: deadly nightshade

Part: leaf

Quick Reference Summary

Safety Class: 3
Interaction Class: C

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Caksen et al. 2003; Felter and Lloyd 1898; Frohne and Pfänder 2000; Hsu et al. 1995; Kingsbury 1964; Lee 2007; Nelson et al. 2006; Witthaus 1911).

Other Precautions

None known.

Drug and Supplement Interactions

Interaction considerations are the same as those for the drug atropine (Caksen et al. 2003; Lee 2007).

Adverse Events and Side Effects

In overdose, belladonna elicits symptoms typical of anticholinergic poisoning, with symptoms colloquially described as "hot as a hare, dry as a bone, red as a beet, mad as a hatter, blind as a bat" (Lee 2007). The most common poisoning symptoms are redness of the face, dilation of the pupils, increased heart rate, meaningless speech, hallucinations, dry mouth, and agitation (Caksen et al. 2003; Lee 2007).

Pharmacological Considerations

The compound atropine, which has anticholinergic effects in the central and peripheral nervous system, is primarily responsible for the effects of belladonna (Leung and Foster 1996).

Pregnancy and Lactation

A retrospective study of women who had used belladonna in the first trimester of pregnancy indicated that belladonna use was associated with malformations; however, interpretation of data was difficult and no causality could be determined (Heinonen et al. 1977).

The compound atropine has been shown to rapidly cross the placenta (Kanto et al. 1981; Kivalo and Saarikoski 1977; Onnen et al. 1979) and has been used to test placental function in high-risk obstetric patients (Hellman and Fillisti 1965). Atropine has also been used to reduce gastric secretions before cesarean section with no fetal or neonatal effects observed (Diaz et al. 1980; Roper and Salem 1981).

Although the compound atropine is reported to cross into breast milk, and neonates are sensitive to anticholinergic agents, no adverse effects have been reported in nursing infants whose mothers were taking atropine (Briggs et al. 2008; Dart 2004). The American Academy of Pediatrics lists the compound atropine as being compatible with breastfeeding (AAP 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

The overdose symptoms of belladonna are those of anticholinergic poisoning, with symptoms colloquially described as "hot as a hare, dry as a bone, red as a beet, mad as a hatter, blind as a bat" (Lee 2007).

Intoxication with belladonna results in dry mouth with dysphonia, difficulty swallowing, increased heart rate, and urinary retention. Elevation of body temperature may be accompanied by flushed, dry skin. Mydriasis, blurred vision, excitement and delirium, headache, and confusion may be observed (Nelson et al. 2006).

In a review of 49 cases of belladonna poisoning in children, occurring over a 7-year period, cases were categorized into mild/moderate or severe intoxication. Cases with encephalopathy were considered severe, while those without were considered mild/moderate. In the mild/moderate group, the most common symptoms were tachycardia, flushing, mydriasis, meaningless speech, hyperglycemia, and agitation. In the severe group, the most common symptoms were meaningless speech, coma, mydriasis, lethargy, tachycardia, flushing, and convulsions (Caksen et al. 2003). The review did not indicate the part of the plant consumed, although the berries are most commonly responsible for poisoning in children (Lee 2007).

Belladonna poisoning has been reported after eating a rabbit that had been feeding on belladonna (Firth and Bentley 1921).

Intoxication with belladonna was reported in several families that had consumed tea labeled as mate (*Ilex paraguariensis*) and later discovered to be belladonna leaf. Symptoms of poisoning were consistent with belladonna intoxication, including agitation, flushing, mydriasis, hallucinations, disorientation, tachycardia, nausea, and vomiting (Hsu et al. 1995).

An early toxicology text describes a series of 379 cases of poisoning due to belladonna preparations (eye drops, plasters, and liniments) (Witthaus 1911). A review article on belladonna notes that medical use of belladonna has declined significantly, and such poisonings have become rare (Lee 2007).

Numerous other cases of belladonna intoxication have been reported in the literature and include adverse effects from accidental or intentional consumption of the leaf, berry, or root of belladonna (e.g., Ceha et al. 1997; Gabel 1968; Gibbons 1954; Lange and Toft 1990; Minors 1948; Montoya et al. 2009; Schneider et al. 1996; Southgate et al. 2000; Trabattoni et al. 1984).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered single doses of 1, 2, or 5 m1 of belladonna tincture (0.1 mg/ml alkaloid concentration, atropine/scopolamine = 2 0:1), RR interval and high-frequency spectral power of heart rate variability increased markedly after the 1 or 2 m1 doses. Decreases in RR interval, high-frequency spectral power of heart rate variability, and noninvasive baroreflex sensitivity were observed after the 5 m1 dose. The activity of the 2 m1 dose was characterized as vagotonic, while that of the 5 m1 dose was considered vagolytic. No significant effects on blood pressure were observed (Bettermann et al. 2001).

Animal Pharmacological Studies

In mice treated with belladonna tincture or atropine, the anticholinergic effects of belladonna were greater than those suggested by the alkaloid content of the tincture (Mazzanti et al. 1988).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A retrospective study of 554 women who had used belladonna in the first trimester of pregnancy indicated that belladonna was associated with eye and ear malformations, and also associated with increased risk of respiratory tract anomalies and hypospadias. The authors of the study indicated that interpretation of the data was difficult and that no causality could be determined. Among women who used belladonna any time in pregnancy, 1355 exposures were reported and no association with belladonna and malformations was observed in the group (Heinonen et al. 1977).

The compound atropine has been shown to rapidly cross the placenta (Kanto et al. 1981; Kivalo and Saarikoski 1977; Onnen et al. 1979) and has been used to test placental function in high-risk obstetric patients by producing fetal vagal blockade and subsequent tachycardia (Hellman and Fillisti 1965). Atropine has also been used to reduce gastric secretions before cesarean section with no fetal or neonatal effects observed (Diaz et al. 1980; Roper and Salem 1981).

Although the compound atropine is reported to cross into breast milk, and neonates are sensitive to anticholinergic agents, no adverse effects have been reported in nursing infants whose mothers were taking atropine (Briggs et al. 2008; Dart 2004). The American Academy of Pediatrics lists the compound atropine as being compatible with breastfeeding (AAP 2001).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound atropine orally administered in rats is 500 mg/kg, and in mice is 75 mg/kg; that after intravenous administration in rats is 73 mg/kg and in mice is 30 mg/kg. The LD_{50} of atropine in rats is 920 mg/kg after intramuscular administration and 280 mg/kg after intraperitoneal administration (Sax and Lewis 1992).

Part: spikelets

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic contact dermatitis to oat has been reported and confirmed by patch testing (De Paz Arranz et al. 2002; Pazzaglia et al. 2000).

Pharmacological Considerations

Animal studies have indicated that oat extracts may antagonize the effects of morphine and nicotine (Connor et al. 1975).

Pregnancy and Lactation

No information on the safety of oat or wild oat in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Alcohol extracts of oat antagonized the effects of morphine and nicotine injections in mice. The extracts did not affect the seizure threshold to bemegride or nicotine or the sleeping time induced by barbitone sodium (Connor et al. 1975).

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis to oats has been reported and confirmed by patch testing (De Paz Arranz et al. 2002; Pazzaglia et al. 2000).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In sensitization studies with oat proteins (1, 3, and 5%) in children with atopic dermatitis, skin prick tests to oat proteins were positive in 19% of children, whereas atopy patch tests were positive in 15% (Boussault et al. 2007).

In patients with biopsy-confirmed dermatitis herpetiformis, no adverse effects were observed after addition of oats to the strict gluten-free diet of the patients (maintained for an average of 15.8 years prior to the study). Serological tests for antigliadin, antireticulin, and antiendomysial antibodies were negative before oats were introduced into the diet and after they were discontinued, and villous architecture remained normal (Hardman et al. 1997).

In patients with celiac disease and dermatitis herpetiformis, no adverse effects were seen after ingestion of 2.5 g of the protein avenin daily (equivalent to 300 g of oats, or about 10 bowls of oatmeal) for 5 days. Biopsies of the small intestines indicated that that avenin did not change the ratio of the villous height to the crypt depth, the height of enterocytes, or intraepithelial lymphocyte counts (Hardman et al. 1999).

In a study introducing oats into the diets of patients with celiac disease, the addition of 50 g of oats daily for 12 weeks was generally well tolerated, although one patient developed partial villous atrophy and a rash after the introduction of oats. Several other patients showed positive levels of interferon gamma mRNA after introduction of oats (Lundin et al. 2003). Other studies have indicated that moderate quantities of oats are safe for persons with gluten intolerance (Janatuinen et al. 1995, 2002; Picarelli et al. 2001; Storsrud et al. 2003).

Animal Pharmacological Studies

In irritation tests using 2 to 200 % colloidal extracts of oats, no ocular or cutaneous toxicity were observed, nor any sensitization or photosensitization (Fabre 2004).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of oat or wild oat during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Azadirachta indica A. Juss. — Meliaceae

SCN: neem
Syn: *Melia azadirachta* L.
AN: *nimba*

OCN: bead tree; margosa
Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Changes in hormone levels and sperm production were observed in male rats intraperitoneally administered extracts of neem stem bark (Raji et al. 2003).

Pregnancy and Lactation

Other than one animal study that indicated anti-implantation activity of large doses (500 mg/kg) of neem bark extract (Bhargava and Prakash 2000), no information on the safety of neem in pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns thought to be clinically relevant for pregnant or nursing women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats intraperitoneally administered up to 150 mg/kg of an ethanol extract of neem bark daily for 10 weeks, dose-dependent decreases in weights of the testis, epididymis, and seminal vesicles, and an increased weight of the adrenal

gland were observed. The treatment caused a dose-dependent reduction in serum testosterone and LH but no change in FSH levels. Male rats were unable to impregnate female rats throughout the duration of the study, and female rats were later bred successfully with untreated male rats (Raji et al. 2003).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In female rats orally administered 500 mg/kg neem bark extract daily for 10 days, significant anti-implantation activity was observed. At that dose, fetal resorptions were observed although no changes in the number of corpora lutea were seen (Bhargava and Prakash 2000).

No information on the safety of neem during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Azadirachta indica A. Juss. — Meliaceae

SCN: neem
Syn: *Melia azadirachta* L.
AN: *nimba*

OCN: bead tree; margosa
Part: leaf

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for internal use by men attempting to conceive (Aladakatti and Ahamed 2005; Aladakatti et al. 2001; Awasthy 2001; Ghosesawar et al. 2003; Kataria et al. 2000; Kaushic and Upadhyay 1995; Mishra and Singh 2005; Parveen et al. 1993).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Ventricular fibrillation followed by heart attack was reported in a woman several hours after she consumed 1 liter of neem leaf extract. Causality could not be determined, and details on the concentration and type of extract were not reported (Sivashanmugham et al. 1984).

Pharmacological Considerations

Animal studies investigating the use of neem leaf as a male contraceptive have shown changes in the tissues responsible for sperm formation, changes in sperm shape and motility, and decreases in sperm counts (Aladakatti and Ahamed 2005; Aladakatti et al. 2001; Awasthy 2001; Ghosesawar et al. 2003; Kataria et al. 2000; Kaushic and Upadhyay 1995; Mishra and Singh 2005; Parveen et al. 1993). Doses studied ranged from 20 to 2000 mg/kg. Changes in tissues and sperm formation were shown to return to normal after cessation of treatment (Joshi et al. 1996; Mishra and Singh 2005). No human studies on the safety or efficacy of neem leaf as a male contraceptive have been completed.

Animal studies have demonstrated that neem leaf may modify glucose regulation (Chandra et al. 2008; Chattopadhyay 1999; Kar et al. 2003; Khosla et al. 2000). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

An animal study showed a decrease in thyroid hormone levels in animals treated with high doses (100 mg/kg) but not lower doses (40 mg/kg) of neem leaf (Panda and Kar 2000).

Pregnancy and Lactation

No adverse effects on fetal development were observed in rats fed the compound azadirachtin (0.5 mg/kg) for two generations, or in rats fed large doses (1.5 g/kg) of azadirachtin daily on days 6 to 15 of pregnancy.

No information on the safety of neem leaf during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse effects, including changes in liver or kidney function parameters, were reported in HIV/AIDS patients orally administered 1 g of fractionated acetone-water extracts of neem leaf daily for 12 weeks (Mbah et al. 2007).

Case Reports of Adverse Events

Ventricular fibrillation and cardiac arrest were reported in a 24-year-old woman 2 hours after she consumed 1 liter of neem leaf extract (type and concentration of extract unspecified) (Sivashanmugham et al. 1984).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Effects on Male Reproductive System

In male rats orally administered 50, 100, or 200 mg/kg aqueous extract of neem leaf daily for 28 days, animals administered the 200 mg/kg dose had marked alterations both in histological appearance and in the level of sialic acid in the epididymal duct, while those administered 50 or 100 mg/kg had no appreciable alterations in histological appearance of the epididymis. In treated animals, testes showed both normal and affected seminiferous tubules in the same sections. After 42 days of withdrawal of the treatment, the alterations in the reproductive organs returned to control levels (Mishra and Singh 2005).

No effects on spermatogenesis were observed in male rats orally administered 100 mg/kg daily of an ethanol extract of neem leaf for 21 days. In untreated females mated with treated males, anti-implantation effects were observed (Choudhary et al. 1990).

In rats orally administered 100 mg neem leaf powder daily (average rat weight 185 g) for 24 days, a decrease in the total sperm count, sperm motility, and forward velocity in vas deferens fluid was observed. The percentage of abnormal sperm increased and the fructose content decreased (Ghosesawar et al. 2003).

Decreases in the weight of the seminal vesicle and ventral prostate, sperm motility, sperm count, and relative percentage of normal sperm were observed in male rats orally administered 20, 40, or 60 mg of neem leaf powder (average rat weight 240 g) daily for 24 days (Parveen et al. 1993).

In male rats orally administered 100 mg/animal neem leaf powder daily for 48 days, decreases in the total sperm count, sperm motility, and forward velocity were observed. The percentage of abnormal sperm increased and the fructose content of caudal semen of the epididymis decreased (Aladakatti et al. 2001).

In male rats orally administered 500 mg/kg neem leaf daily for 48 days, atrophic seminiferous tubules with widening intercellular spaces, degeneration of Leydig cells, and pathological changes in the spermatozoa of the cauda epididymis were observed (Aladakatti and Ahamed 2005).

Reduction in the diameters of seminiferous tubule and nuclei of the germinal elements as well as atrophy of the spermatogenic elements and Leydig cells were observed in rats orally administered 100 mg/animal neem leaf powder daily (average rat weight 225 g) for 24 days. After cessation of neem administration, a gradual recovery was observed within 8 days (Joshi et al. 1996).

Histological and biochemical changes in the caput and cauda epididymis were observed in rats orally administered 20, 40, or 60 mg/animal of neem leaf powder daily for 24 days. In the treated rats, the height of the epithelium and the diameter of the nucleus in both the regions were reduced, and the lumen of the caput was packed with lymphocytes. Biochemically, a dose-dependent decrease in the protein content and acid phosphatase and increase in the alkaline phosphatase and lactate dehydrogenase activities were observed in both regions, along with a decrease in serum testosterone concentration (Kasturi et al. 1995).

In male rats orally administered 100 mg/animal neem leaf powder daily for 24 days, intracellular spaces and vacuolization were observed in Sertoli cells; in Leydig cells, cytoplasmic inclusions appeared diminished, and the configuration of granular endoplasmic reticulum appeared as a single unbranched tubule, leading the authors to conclude that neem leaf might affect spermatogenesis through antispermatogenic and antiandrogenic properties (Kasturi et al. 2002).

A reduction in sperm count and increased frequency of spermatozoa with abnormal head morphology was observed in mice orally administered 0.5, 1, or 2 g/kg neem leaf extract daily for 6 weeks (Awasthy 2001).

Effects on Female Reproductive System

In ovariectomized rats orally administered 0.5 ml aqueous extract of neem leaf daily for 3 days, an absence of open vagina, absence of epithelial cells in a vaginal smear, and incomplete development of the uterus were observed, indicating an absence of estrogenic activity (Mateenuddin et al. 1986).

Antidiabetic Activity

In diabetic and healthy rats, oral administration of 500 mg/kg of an aqueous neem leaf extract resulted in a decrease in blood glucose levels, with the effect being more pronounced in diabetic than in healthy animals. The effects were similar to that of the drug glibenclamide (Khosla et al. 2000).

A reduction in blood glucose levels was observed in diabetic rats orally administered 500 mg/kg neem extract (Chandra et al. 2008). A reduction in blood glucose levels was observed after 2 weeks of treatment in diabetic rats orally administered 500 mg/kg of an ethanolic neem leaf extract daily (Kar et al. 2003).

A reduction in blood glucose levels was observed in mice orally administered 50 to 400 mg/kg or rats orally administered 0.25 to 8 mg/kg of an alcohol extract of neem leaf (Chattopadhyay 1999).

Other Pharmacological Activity

In mice orally administered 40 or 100 mg/kg neem leaf extract daily for 20 days, animals in the higher dose group had a decrease in serum triiodothyronine (T_3) and increased serum thyroxine (T_4) concentrations. No significant alterations of T_3 or T_4 levels were observed in the lower dose group (Panda and Kar 2000).

Intravenous administration of 100, 300, or 1000 mg/kg of an alcohol extract of neem leaf to rats produced an initial bradycardia followed by cardiac arrhythmia. A significant and dose-related fall in blood pressure was observed and was immediate, sharp, and persistent. Pretreatment with either atropine or mepyramine did not alter the hypotensive activity of the neem leaf extract (Koley and Lal 1994).

In Vitro Pharmacological Studies

In a study of the concentration of neem leaf extract needed to immobilize and kill 100% of human spermatozoa within 20 seconds, the minimum effective spermicidal concentration was approximately 2.85 mg/million sperm. The effect of extracts on morphology and viability of sperm was also studied and no change was observed in morphology of head, midpiece, or tail. The extract made from "tender" leaf was more effective than the extract made from "old" leaf (Khillare and Shrivastav 2003).

IV. Pregnancy and Lactation

In pregnant rats orally administered 0.5, 1, or 1.5 g/kg of the compound azadirachtin daily on gestational days 6 to 15, no significant adverse effects were observed on fetal development, number of implantations, post-implantation loss, or other reproductive parameters. Some minor malformations were observed in high doses but were not compound- or dose-related (Srivastava and Raizada 2001).

No adverse effects on reproductive function or fetal or pup development were observed over two generations of rats fed diets containing the equivalent of 5, 25, or 50 mg/kg of the compound azadirachtin daily (Srivastava and Raizada 2007).

No information on the safety of neem leaf during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered aqueous neem leaf extract in mice could not be determined at doses up to 2.5 g/kg (Dorababu et al. 2006).

Acute toxicity, including nervous symptoms (head movements, walking in circles) with dyspnea, an increase in body temperature, hepatic failure, and tympanites, was observed in a sheep that ate 100 g of neem leaf. The symptoms lasted for 12 hours and were followed by death of the animal (Ali and Salih 1982).

Short-Term Toxicity

No adverse effects were observed in rats orally administered 1 g/kg neem leaf extract daily for 28 days. Observed parameters included body and tissue weights, food and water intake, hematological profile, and various liver and kidney function tests (Dorababu et al. 2006).

No adverse effects, including changes in body weight, organ-body weight ratios, or liver enzyme levels were observed in mice subcutaneously administered 0.5 or 1 mg neem leaf aqueous extract daily for 28 days (Haque et al. 2006).

In rats administered 100 mg/kg neem leaf extract daily for 49 days, decreases in appetite, body weight, and pupillary reflex were observed. Histopathological studies revealed congestion in the liver, kidneys, lungs, and brain (Hore et al. 1999).

Subchronic Toxicity

In goats and guinea pigs orally administered 50 or 200 mg/kg fresh or dried neem leaf daily for up to 8 weeks, a progressive decrease in body weight, weakness, inappetence, and loss of condition were observed along with a decrease in heart rate, pulse rate, and respiratory rates. Diarrhea was observed in animals given the fresh leaf. In goats, the higher doses of the plant leaf produced tremors and ataxia during the last few days of treatment. No statistically significant hematological changes were observed. On necropsy

of treated goats, there were areas of hemorrhagic erosions. Histopathologically, various degrees of hemorrhage, congestion, and degeneration were seen in the liver, kidney, lung, duodenum, and brain, along with degeneration of the seminiferous tubules (Ali 1987).

Chronic Toxicity

In rats fed diets containing the equivalent of 5, 25, or 50 mg/kg of the compound azadirachtin daily for two generations, no toxicological effects, including enzymatic parameters (AST, ALT, ALP), bilirubin, cholesterol, total protein, or histopathology of liver, brain, kidney, testes, or ovary were observed (Srivastava and Raizada 2007).

Genotoxicity

Chromosome strand breakages or spindle disturbances as well as the regulation of genes responsible for sperm shaping were affected in mice orally administered 0.5, 1, or 2 g/kg neem leaf extract daily for 6 weeks (Awasthy 2001).

An increase in the incidence of structural and mitotic disruptive changes in metaphase chromosomes of bone marrow cells was observed on days 8, 15, and 35 in rats orally administered 0.5, 1, or 2 g/kg neem leaf ethanolic extract daily (Awasthy et al. 1999).

In the Ames test for mutagenicity, a weak antimutagenic effect of the ethanol extract of neem leaf was observed in *Salmonella typhimurium* TA100 (Kusamran et al. 1998).

Bacopa monnieri (L.) Pennell

Scrophulariaceae

SCN: bacopa
Syn: *Herpestis monniera* (L.) Kunth
AN: *brahmi; mandukaparni*

OCN: herb-of-grace; Indian pennywort; water hyssop
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

See Pharmacological Considerations.

Drug and Supplement Interactions

None known.

Editors' Note

As a general rule, *Bacopa monnieri* is *brahmi* in Kerala and *mandukaparni* in north and west India, whereas *Centella asiatica* is called *brahmi* in north and west India and *mandukaparni* in Kerala (south India) (McGuffin et al. 2000).

Adverse Events and Side Effects

Human dose escalation and safety studies have indicated that bacopa is generally well tolerated, with only minor and transient adverse events, primarily gastrointestinal discomfort, reported (Pravina et al. 2007; Singh and Dhawan 1997).

Pharmacological Considerations

An animal study with large doses (250 mg/kg) of bacopa demonstrated a decrease in sperm count and viability. All parameters were shown to return to normal several weeks after cessation of treatment (Singh and Singh 2009). No human studies on the safety or efficacy of bacopa as a male contraceptive have been completed.

Pregnancy and Lactation

No information on the safety of bacopa in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a phase I safety evaluation study, healthy volunteers were orally administered 300 mg of a standardized bacopa extract daily for 15 days, followed by 450 mg daily for the next 15 days.

No adverse effects on hematological, biochemical, or electrocardiographic parameters were observed. Mild gastrointestinal disturbances, which subsided spontaneously without the need for stopping treatment, were reported in two volunteers at the 300 mg dose and in one volunteer at the 450 mg dose (Pravina et al. 2007).

In a dose tolerance study, healthy volunteers were orally administered a combination of isolated bacosides A and B at doses of 20 to 200 mg daily for 4 weeks, or a single dose of 300 mg. No adverse effects were reported, and monitoring of clinical, hematological, and biochemical parameters did not reveal any drug-related abnormalities (Singh and Dhawan 1997).

Animal Pharmacological Studies

In male rats orally administered 250 mg/kg of bacopa daily for 28 or 56 days, a reversible reduction in sperm motility, viability, and number and changes in sperm morphology were observed along with changes of cells and tissues in the testes. No changes were observed in libido, levels of testosterone, alanine aminotransferase, aspartate aminotransferase, and creatinine in blood serum, hematological parameters, or in liver and kidney histology. All treatment-related effects returned to control levels within 56 days after treatment (Singh and Singh 2009).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of bacopa during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered bacopa in rats is 5 g/kg for an aqueous extract, 17 g/kg for an alcohol extract (Martis et al. 1992), and 2.2 g/kg for a standardized extract (Joshua Allan et al. 2007). The LD_{50} of intraperitoneally administered bacopa rats is 1 g/kg for the aqueous extract and 15 g/kg for the alcohol extract (Martis et al. 1992).

In the brine shrimp lethality assay, the LC_{50} of various extracts of bacopa is 295 µg/ml for the ethanol extract, 5332 µg/ml for the water extract, 95 µg/ml for the saponin-rich fraction, and 38 µg/ml for the compound bacoside A (D'Souza et al. 2002).

Short-Term Toxicity

In rats orally administered 250, 500, or 1000 mg/kg of a standardized extract of bacopa daily for 14 days, a mild reduction in body weight gain was observed in treated males (Joshua Allan et al. 2007).

Subchronic Toxicity

In rats orally administered 85, 210, or 500 mg/kg of a standardized extract of bacopa daily for 90 days, no evidence of toxicity was observed. Observed parameters included clinical signs, food consumption, body weight gain, relative organ weights, histopathology, and blood biochemistry (Joshua Allan et al. 2007).

Genotoxicity

In the Ames test for mutagenicity in *Salmonella typhimurium*, no mutagenic activity of a standardized extract of bacopa was observed at concentrations of up to 5000 µg/plate (Deb et al. 2008).

In a clastogenicity assay, no significant activity of a standardized extract of bacopa was observed at concentrations up to 62.5 µg/ml. At a concentration of 125 µg/ml, mild clastogenic activity was observed without, but not with, metabolic activation. The extract demonstrated dose-dependent protection against tested clastogens, with maximum protection observed with metabolic activation (Deb et al. 2008).

Ballota nigra L. — Lamiaceae

SCN: black horehound

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of black horehound in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
A decrease in blood glucose levels was observed in healthy rats orally administered 400 mg/kg of an alcohol extract of black horehound daily for 7 days (Nusier et al. 2007a). In a glucose tolerance test, healthy rats administered a single 400 mg/kg dose of the same extract showed a significant decrease in blood glucose levels with a significant increase in serum insulin levels (Nusier et al. 2007a). In diabetic rats, this extract significantly reduced elevated glucose levels associated with the diabetic condition (Nusier et al. 2007b).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the use of black horehound during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
No changes in aspartate aminotransferase (AST) or alanine aminotransferase (ALT) levels were observed in rats orally administered 400 mg/kg of an alcohol extract of black horehound daily for 7 days (Nusier et al. 2007a).

Baptisia tinctoria (L.) R. Br.

Fabaceae

SCN: wild indigo
OCN: false indigo

Part: root

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications
Not for use in pregnancy except under the supervision of a qualified healthcare practitioner.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

"Large" doses can cause vomiting and diarrhea (Felter and Lloyd 1898).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of wild indigo during pregnancy or lactation was identified. Based on the activity and uses of this herb, however, the editors of this text believe that use in pregnancy should be under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Chromatographically purified fractions of aqueous-ethanolic extracts from wild indigo produced a strong lymphocyte DNA synthesis-stimulating activity (Beuscher et al. 1989).

Arabinogalactan-containing proteins isolated from wild indigo increased proliferation of mouse spleen cells, IgM production of mouse lymphocytes, IL6 production in alveolar mouse macrophage cultures, and NO_2 production in alveolar mouse macrophage cultures (Classen et al. 2006).

IV. Pregnancy and Lactation

No information on the safety of wild indigo during pregnancy or lactation was identified. Based on the activity and uses of this herb, however, the editors of this text believe that use in pregnancy should be under the supervision of a qualified healthcare practitioner.

V. Toxicity Studies

Acute Toxicity

In rats intraperitoneally administered a decoction or infusion of wild indigo, the fatal dose was reported to be 1 ml per 100 g (Macht and Black 1927).

In rabbits (1.5 kg) administered 10 ml of wild indigo infusion via stomach tube, some narcotic effects and a slight paralysis of the hind limbs were observed. Rabbits intravenously administered 3 ml of the same preparation experienced diarrhea and weakness of the limbs (Macht and Black 1927).

In cats (2.5 kg) subcutaneously administered 5 ml of a decoction or infusion of wild indigo, salivation and vomiting resulted, followed by dilation of the pupils, muscle spasms, and decreased respiration and heart rate (Macht and Black 1927).

Bauhinia forficate Link — Fabaceae

SCN: cow's foot
OCN: *pata de vaca*

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Although one human study showed no effect of cow's foot on serum glucose levels (Russo et al. 1990), several animal studies have demonstrated that cow's foot modifies glucose regulation (Lino et al. 2004; Pepato et al. 2002; Silva et al. 2002). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Several animal studies indicated no adverse effects on maternal weight gain, reproductive performance, or fetal or placental development in rats treated with aqueous extracts of cow's foot at varying doses from 500 to 1000 mg/kg daily on days 0 to 20 of pregnancy (Calderon et al. 2001; Damasceno et al. 2004; Rudge et al. 2001; Volpato et al. 2008). In one study, a reduction in postimplantation losses was observed in pregnant diabetic rats administered 200 mg/kg daily cow's foot during pregnancy (Volpato et al. 1999).

No information on the safety of cow's foot during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No acute or chronic effects on plasma glucose levels or glycated hemoglobin were observed in healthy volunteers or volunteers with type II diabetes who consumed infusions of 3 g of cow's foot daily for 56 days (Russo et al. 1990).

Animal Pharmacological Studies

Significant reductions in plasma glucose levels were observed in diabetic rats orally administered aqueous, ethanolic, and hexanic extracts of cow's foot daily for 7 days (Lino et al. 2004). Similarly, a reduction in serum and urinary glucose levels was observed in diabetic rats provided a decoction of cow's foot as the sole source of drinking water (150 g leaf/l water; mean daily dose of 3.52 ml/kg) (Pepato et al. 2002). A significant reduction of blood glucose levels was observed in healthy and in diabetic rats orally administered 500 to 600 mg/kg of the *n*-butanol fraction of cow's foot (Silva et al. 2002).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Several studies have examined the safety of cow's foot in pregnant diabetic and healthy rats using an orally administered aqueous extract at doses of 500 mg/kg on gestational days (GD) 0 to 4, 600 mg/kg on GD 5 to 14, and 1000 mg/kg on GD 15 to 20. No teratogenic activity and no effects on maternal weight gain, reproductive performance, or fetal or placental development were observed. Treatment with cow's foot reduced the number of skeletal abnormalities and visceral malformations observed in offspring of

diabetic animals, as compared to controls. No effects on maternal blood glucose levels were observed in either the healthy or diabetic rats (Calderon et al. 2001; Damasceno et al. 2004; Rudge et al. 2001; Volpato et al. 2008).

A reduction in postimplantation losses was observed in pregnant diabetic rats orally administered 200 mg/kg daily during pregnancy (Volpato et al. 1999).

No information on the safety of cow's foot during lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

No changes in serum levels of lactate dehydrogenase, creatine kinase, amylase, angiotensin-converting enzyme, or bilirubin were observed in normal or diabetic rats provided a decoction of cow's foot (150 g/l) in place of drinking water daily for 33 days (Pepato et al. 2004).

Genotoxicity

Aqueous extracts of cow's foot demonstrated mutagenic activity in the Ames test for mutagenicity in *Salmonella typhimurium* strains TA98 with or without metabolic activation, and in strain TA100 without metabolic activation. No mutagenic activity was observed when the same extract was tested in TA100 with metabolic activation, or in TA97a and TA104 with or without metabolic activation (Rivera et al. 1994).

Berberis vulgaris L.

Berberidaceae

SCN: barberry
OCN: European barberry

Part: root, root bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Jahnke et al. 2006).

Other Precautions

Use of barberry during lactation is not recommended (Chan 1993).

Use is cautioned in persons with severe or acute hepatocellular disease, septic cholecystitis, unconjugated hyperbilirubinemia, intestinal spasms or ileus, or liver cancer (Chan 1993; Mills and Bone 2005).

Drug and Supplement Interactions

None known.

Notice

Berberine (root bark: 6.1%; woody portion of root: 0.4%) (De Smet 1992; Leung and Foster 1996); *see* Appendix 1.

Editors' Notes

Most safety concerns reported for barberry are based on studies of the compound berberine and other alkaloids. Data regarding isolated compounds may not apply directly to products or extracts made from the root or root bark.

The compound berberine has been shown to exhibit a number of bioactivities including cytotoxicity in cancer cell lines (Kettmann et al. 2004; Kim et al. 2005; Orfila et al. 2000) and topoisomerase I and II inhibition (Kim et al. 1998; Mantena et al. 2006; Pasqual et al. 1993). Studies have indicated that the antimicrobial action of berberine may be potentiated by non-antimicrobial compounds found in berberine-containing plants, indicating a synergistic action of compounds (Stermitz et al. 2000).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Human studies have provided mixed results on the effects of the compound berberine on cyclosporine A, with one

study indicating an increase in cyclosporine A bioavailability after repeated coadministration (Wu et al. 2005) and a second study indicating increased bioavailability after a single dose of the compound berberine but no change after repeated dosing of berberine (Xin et al. 2006).

Pregnancy and Lactation

Barberry is contraindicated or cautioned against in pregnancy in several contemporary texts on herbal safety (Brinker 2001; Mills and Bone 2005). These contraindications are based primarily on the uterine stimulant activity of the isolated compound berberine in excised mouse uteri (Furuya 1957; Imaseki et al. 1961) and the potential ability of berberine to displace bilirubin and cause neonatal jaundice (Chan 1993). Although definitive data confirming the safety of barberry during pregnancy is lacking, several reproductive toxicity studies of the isolated compound berberine in mice and rats have shown no adverse effects on the fetus at doses equivalent to more than 75 times the standard human dose (Jahnke et al. 2006).

Berberine-containing plants have been reported to induce uterine stimulation (Furuya 1957; Imaseki et al. 1961); however, no uterine stimulation was noted in rats administered high doses of berberine during pregnancy (Jahnke et al. 2006), and a study of berberine-containing herbal extracts on isolated uteri showed no correlation between uterine stimulation and berberine concentration (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In a randomized controlled trial of renal transplant patients taking cyclosporine A and 200 mg of the compound berberine three times daily for 3 months, the minimum blood concentrations of cyclosporine A increased by 88.9% and the ratios of concentration/dose of cyclosporine A in the berberine-treated group increased by 98.4%. In the control group, the increase in trough blood concentrations of cyclosporine A was 64.5% and the increase in the ratio of concentration/dose of cyclosporine A was 69.4%. The authors indicated that the mechanism for this interaction is most likely an inhibition of CYP3A4 by berberine (Wu et al. 2005).

An increase in bioavailability of orally administered cyclosporine A was observed after healthy male volunteers were administered a single dose of 3 mg cyclosporine A followed by a single oral dose of 300 mg of the compound berberine. The increase in area under the time-concentration curve of cyclosporine A was 19.2%; no changes in elimination half-life, maximum blood drug concentration, time to maximum concentration, or apparent oral clearance were observed (Xin et al. 2006). Conversely, no changes in bioavailability of orally administered cyclosporine A were observed after healthy male volunteers were administered 300 mg of the compound berberine twice daily for 10 days followed by a single dose of 6 mg cyclosporine A (Xin et al. 2006).

No effects of oryzanol (a derivative of rice bran oil that includes sterols and ferulic acid) on berberine absorption were observed in healthy volunteers (Li et al. 2000).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

The compound berberine has been shown to significantly prolong pentobarbital-induced sleeping time in rats (Janbaz and Gilani 2000).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Intravenous administration of the compound berberine (0.2 mg/kg/min) caused a significant decrease in blood pressure in patients with severe congestive heart failure (Marin-Neto et al. 1988).

Animal Pharmacological Studies

Chronic administration of berberine to rats was shown to significantly decrease bilirubin protein binding at doses of 10 to 29 mg/kg (administered intraperitoneally), although at doses of 2 mg/kg the displacement was not significant (Chan 1993). Berberine is speculated to have possible interactions with drugs that displace bilirubin protein binding (Mills and Bone 2005).

Berberine was shown to promote blood coagulation in mice and rats (Ziablitskii et al. 1996).

In Vitro Pharmacological Studies

Berberine has been shown to increase the efflux of paclitaxel and rhodamine in human digestive tract and liver cancer cells by inducing P-glycoprotein (Blaschek et al. 2002). Berberine may interfere with the action of tetracycline in the treatment of cholera (Khin Maung et al. 1985).

IV. Pregnancy and Lactation

In pregnant rats fed the compound berberine chloride dihydrate on gestational days (GD) 6 to 20, some reduction in maternal weight gain was observed, with a lowest-observed-adverse-effect level (LOAEL) of 530 mg/kg daily. Only a mild reduction in fetal weights was observed, and the LOAEL based on fetal weight reduction was 1000 mg/kg (Jahnke et al. 2006). Similarly, in mice administered berberine on GD 6 to 17 at doses up to 1155 mg/kg daily, the maternal LOAEL was determined to be 531 mg/kg daily, and the developmental toxicity level was 1000 mg/kg daily. In mice, 33% of the treated females died. Surviving animals had increased relative water intake, and average fetal body weight per litter decreased 5–6% with no change in live litter size (Jahnke et al. 2006).

Berberine has been shown to stimulate uterine contractions in both pregnant and nonpregnant mice (Furuya 1957; Imaseki et al. 1961). A study of various berberine-containing herbal extracts on isolated uteri, however, indicated that relaxation or stimulation of the uterus did not correlate with the concentration of berberine in the extract, suggesting that not all berberine-containing herbs will have the same effect on the uterus (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered barberry root extract fraction (containing 80% berbamine and three other isoquinoline alkaloids) in mice is 520 mg/kg, and in rats is 1280 mg/kg (Manolov et al. 1985). The LD_{50} of orally administered barberry root in mice was determined to be equivalent to 2600 mg/kg of the powdered root (Peychev 2005).

The LD_{50} of orally administered berberine in mice is 329 mg/kg (Haginiwa and Harada 1962). The LD_{50} of orally administered berberine sulfate in rats is greater than 1000 mg/kg (Kowalewski et al. 1975).

Genotoxicity

No mutagenic activity of berberine was observed in *Salmonella typhimurium* TA100 and TA98 with or without metabolic activation by S9 mix. Berberine hydrochloride was weakly mutagenic to strain TA98 without S9 mix but showed no mutagenic activity in TA100 without S9 mix (Nozaka et al. 1990).

No genotoxic, mutagenic, or recombinogenic activity of berberine with or without metabolic activation was observed in the SOS chromotest. Berberine did not induce significant cytotoxic, mutagenic or recombinogenic effects during treatments performed under nongrowth conditions; however, in dividing cells, this alkaloid induced cytotoxic and cytostatic effects in proficient and repair-deficient strains of *Saccharomyces cerevisiae*. In dividing cells, the induction of frameshift and mitochondrial mutations, as well as crossing over, indicated that berberine is not a potent mutagenic agent (Pasqual et al. 1993).

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of sweet birch during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of the compound methyl salicylate (which comprises 97–99% of sweet birch essential oil) is 1110 mg/kg in mice, 887 or 1250 mg/kg in rats, 1060 mg/kg in guinea pigs, 1300 or 2800 mg/kg in rabbits, and 2100 mg/kg in dogs (FAO/WHO 1967). The adult human oral LD_{50} is estimated at 500 mg/kg (FAO/WHO 1967).

Subchronic Toxicity

In dogs orally administered 50, 100, 250, 500, 800, or 1200 mg/kg methyl salicylate for up to 10 weeks, no adverse effects were noted in animals receiving 250 mg/kg or less, but an increasing dose-dependent fatty metamorphosis of the liver was observed at higher test levels (Webb and Hansen 1963).

In rats fed diets containing 0.1, 0.5, or 1.0% methyl salicylate for 17 weeks, both sexes showed a significant reduction in growth rate at the 1.0% level, but histological examination of the major organs revealed no abnormality. In a related experiment, in rats fed a diet containing 2% methyl salicylate for up to 10 weeks, bone growth was reduced and excessive density of bone with reduced chondroclastic and osteoclastic activity was observed (Webb and Hansen 1963).

Chronic Toxicity

In rats fed diets containing 0.1, 0.5, 1.0, or 2.0% methyl salicylate for 2 years, animals fed the highest dose did not survive past 49 weeks. At the 1% level, growth rates were considerably reduced and enlargement of male testes and female hearts and kidneys were noted. Excess cancellous bone formation was seen at the 2.0, 1.0, and 0.5% levels (Webb and Hansen 1963). Another 2-year feeding study revealed no adverse effects, including bone changes, at dietary levels up 0.21% of methyl salicylate (Packman et al. 1961).

In dogs orally administered 0, 50, 150, and 250 mg/kg methyl salicylate daily for 2 years, some growth retardation and liver enlargement was noted at the 150 and 250 mg/kg level, and histology revealed enlarged hepatic parenchymal cells (Webb and Hansen 1963).

OCN: *achiote*; lipstick tree

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to annatto, including anaphylactic reactions and urticaria, have been reported and confirmed by patch testing (Nish et al. 1991).

Pharmacological Considerations

Several animal studies have indicated that annatto may modify glucose regulation (Fernandes et al. 2002; Morrison et al. 1991; Morrison and West 1985; Russell et al. 2005, 2008). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No adverse effects on pregnancy outcomes were observed in two rat studies on the use of annatto in pregnancy (Paumgartten et al. 2002; van Esch et al. 1959). One of the studies concluded that the maternal and fetal no-observed-adverse-effect level for orally consumed annatto was over 500 mg/kg daily (Paumgartten et al. 2002).

No information on the safety of annatto during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to annatto, including anaphylactic reactions and urticaria, have been reported and confirmed by patch testing (Nish et al. 1991).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In studies of patients with recurrent or chronic urticaria, one study yielded reactions in 26% of the patients treated topically with 25 µl of annatto extract (0.065% bixin) (Mikkelsen et al. 1978), while 10% of patients orally administered 10 mg annatto extract reacted to the annatto (Juhlin 1981).

Animal Pharmacological Studies

In anesthetized dogs intragastrically administered the compound bixin at doses of 50 ml of a chloroform extract dissolved in oil or 15 ml of a chloroform extract dissolved in ethanol, a reduction in the blood sugar increase rate was observed after the oral glucose tolerance test (Morrison and West 1985). A reduction in blood glucose levels was observed in dogs administered a partially purified annatto extract at a dose of 80 mg/kg (Russell et al. 2005). A reduction in fasting glucose levels was observed in healthy and diabetic dogs orally administered an extract of annatto (Russell et al. 2008). Hyperglycemia was observed in anesthetized dogs treated with the compound *trans*-bixin (Morrison et al. 1991).

In rats administered drinking water containing 0.8, 8.5, or 74 mg/kg norbixin daily for 21 days, norbixin induced dose-dependent hyperglycemia. Conversely, in mice administered drinking water containing 0.8, 7.6, 66, or 274 mg/kg norbixin daily for 21 days, norbixin induced dose-dependent hypoglycemia. These effects were not observed in animals treated with annatto extracts containing 50% norbixin. Rats and mice treated with annatto pigments

showed hyperinsulinemia and hypoinsulinemia, respectively, indicating that pancreatic beta-cells were affected (Fernandes et al. 2002).

In the local lymph node assay, a threefold increase in the proliferation of auricular lymph node cells was observed in mice treated topically with the compound bixin (1-25% w/v) at concentrations of 5 to 25%. In the mouse ear swelling test, a significant increase in percent ear swelling was observed in animals treated with 5 to 10% bixin. Bixin was classified as a nonirritant at concentrations of 1 to 25% (w/v) but was considered a contact sensitizer. In these same tests, the compound norbixin (1–20% w/v) showed no irritation or contact sensitization (Auttachoat et al. 2005).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In pregnant rats orally administered annatto (28% bixin) on days 6 to 15 of pregnancy at doses of 0 to 500 mg/kg, no increase in embryo lethality and no reduction of fetal body weight were observed among annatto-exposed rats, and annatto did not induce any increase in the incidence of externally visible, visceral, or skeletal anomalies in the exposed offspring. The maternal and fetal no-observed-adverse-effect level (NOAEL) for orally consumed annatto was over 500 mg/kg daily (Paumgartten et al. 2002).

No teratogenic effects or other adverse effects on growth or reproduction were observed in rats fed diets containing 0.05% fat-soluble annatto and 0.05% water-soluble extracts of annatto for three generations (van Esch et al. 1959).

No information on the safety of annatto during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered annatto in rats is over 50 g/kg for the fat-soluble extract, and over 35 g/kg for the water-soluble extract (Hallagan et al. 1995; van Esch et al. 1959).

Short-Term Toxicity

In rats orally administered 2 g/kg of annatto powder (27% bixin) 20 times over a 4-week period, no changes in hematological or plasma biochemical parameters were observed. A decrease in body weight gain was observed in male rats, and kidney apoptosis in restricted areas without proliferation or tubular segments modification was observed in 20% of female rats. The precise nature of apoptosis was not investigated. The authors concluded that annatto was not toxic to the rat (Bautista et al. 2004).

Disarrangement of mitochondria structure, fusion of mitochondria, and formation of residual bodies were observed in the liver and pancreas of dogs (9 to 16 kg each) orally administered 2 g of a dried chloroform extract of annatto dissolved in ethanol daily for 14 days. Stacking of hepatic mitochondria was also observed in these animals. Mitochondrial changes were not observed in animals fed 3 mg riboflavin in addition to the annatto extract (Morrison et al. 1987).

No carcinogenic activity was observed in rats fed a diet containing up to 1000 ppm annatto (4.23 g/kg bixin daily) for 2 weeks before or 8 weeks after treatment with diethylnitrosamine (Agner et al. 2005).

In a 21-day study, mice were given drinking water containing annatto extract (56 or 351 mg/kg) or the compound norbixin (0.8, 7.6, 66, or 274 mg/kg), and rats were given drinking water containing annatto extract (0.8, 7.5 or 68 mg/kg) or norbixin (0.8, 8.5, or 74 mg/kg). In rats, no toxicity was detected by plasma chemistry. In mice, norbixin induced an increase in plasma alanine aminotransferase activity (Fernandes et al. 2002).

Subchronic Toxicity

In beagle dogs fed a diet containing 2.7% fat-soluble extract of annatto seed for 9 weeks, then fed normal diet for 5 weeks, and then fed only 1.35% extract for 38 weeks, no abnormalities were found in growth, food intake, mortality, liver and kidney function, hematology, or histopathology. One dog in the test group died and had hepatocellular degeneration, although it is not clear whether the death was treatment related (Kay and Calandra 1961).

In beagle dogs fed a diet of up to 10% aqueous extract of annatto for 1 year, or fed 20% aqueous extract of annatto for 16 weeks, then the same amount half in diet and half in gelatin capsules daily for 36 weeks, liver or kidney function tests, hematology, and histopathology of all major tissues showed no abnormalities attributable to the test substance (Kay and Calandra 1961).

In rats fed annatto extract at dietary levels of 0, 0.1, 0.3, or 0.9% for 13 weeks, no treatment-related adverse effects were observed on body weight, food and water consumption, or ophthalmological or hematological data. Blood biochemical analysis revealed changes in rats of both sexes in the 0.9% and 0.3% diet groups, including increased alkaline phosphatase, phospholipid, total protein, albumin, and albumin/globulin ratio. Marked elevation in absolute and relative liver weights was also found in both sexes of the 0.9% and 0.3%, but not the 0.1%, groups. In the 0.9% group, hepatocyte hypertrophy was evident and an additional electron microscopic examination demonstrated this to be linked to abundant mitochondria after exposure. The authors of this study concluded that the no-observed-adverse-effect-level (NOAEL) of annatto was 0.1% of the diet, equivalent to 69 mg/kg daily for males and 76 mg/kg daily for females (Hagiwara et al. 2003).

No changes in food intake, growth, hematological examination, organ weights, or histopathology of major organs were observed in pigs administered a diet of 1%

fat-soluble and 1% water-soluble extract of annatto daily for 21 weeks (van Esch et al. 1959).

Cyst formation was observed at the site of injection in mice subcutaneously administered 0.1 ml of fat-soluble extract of annatto three times a week for 17 months (van Esch et al. 1959).

No changes in food intake, growth, hematological examination, organ weights, or histopathology of major organs were observed in rats fed a diet of 2% fat-soluble annatto, and 2% water-soluble annatto daily for 13 weeks (van Esch et al. 1959). No adverse effects were seen in rats orally administered 1 g/kg annatto extract daily for 100 days (Zbinden and Studer 1958).

No adverse effects were observed in rats subcutaneously administered 0.05 ml of fat-soluble annatto extract three times a week, at the same injection site, for 36 weeks. The rats were observed for a total of 24 months (van Esch et al. 1959).

No adverse effects and no accumulation of carotenoid compounds (bixin and norbixin) were observed in rats orally administered diets of 0.1% of annatto extracts containing primarily bixin or norbixin daily for 52 weeks (Philip 1981).

No skin papillomas or other tumors were observed on mice treated topically, twice a week, with 0.025 ml of annatto extract for 3 months (Engelbreth-Holm and Inversen 1955).

Chronic Toxicity

No pathological effects were observed in rats orally administered 26 mg annatto daily in soy oil for 26 months (Engelbreth-Holm and Inversen 1955).

Genotoxicity

In comet assays, no mutagenic activity was observed in rats fed a diet containing up to 1000 ppm annatto (4.23 g/kg bixin daily) for 2 weeks before or 8 weeks after treatment with diethylnitrosamine (Agner et al. 2004, 2005), and no enhancement in DNA breakage was detected in liver or kidney from mice treated with annatto pigments at doses up to 351 mg/kg daily for 21 days (Fernandes et al. 2002).

In the micronucleus test, no mutagenic activity was observed in the bone marrow cells of mice fed diets containing 1330, 5330, or 10,670 ppm annatto daily for 7 days. An increased frequency of micronucleated cells was observed with coadministration of cyclophosphamide in animals fed the highest concentration of annatto, as compared to cyclophosphamide alone (Alves de Lima et al. 2003).

No mutagenic activity was observed in *E. coli* treated with annatto at a concentration of 0.5 g/100 ml (Lück and Rickerl 1960). Other earlier studies have shown a lack of genotoxic effects of annatto in various test systems (Hallagan et al. 1995).

No clastogenic activity was observed in human lymphocytes treated with the compound bixin at concentrations up to 10 µg/ml (Antunes et al. 2005).

No detectable genotoxicity was observed in reverse mutation assays with *E. coli* or *Salmonella typhimurium* TA1538 with or without metabolic activation (Haveland-Smith 1981).

No genotoxic effects of the compound norbixin were observed in murine fibroblasts (Kovary et al. 2001).

Boerhavia diffusa L.

Nyctaginaceae

SCN: boerhavia
AN: *punarnava*

OCN: spreading hogweed
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use in persons with diarrhea is not recommended (Pole 2006).

Drug and Supplement Interactions

None known.

Notice

Diuretic (Chowdhury 1955; Kapoor 2001; Singh et al. 1992; Taylor 2005); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that boerhavia may modify glucose regulation. People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Although one reference notes, without details, that boerhavia has been used for abortion (Taylor 2005), an animal study indicated no adverse effects at relatively high doses (250 mg/kg) of boerhavia in pregnancy (Singh et al. 1991).

No information on the safety of boerhavia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic rats orally administered 200 mg/kg of a boerhavia extract daily for 4 weeks, a reduction in fasting blood glucose levels was observed (Pari and Satheesh 2004). In diabetic rats orally administered single doses of 100, 200, or 400 mg/kg of an aqueous extract of boerhavia, a reduction in blood glucose levels was observed (Chude et al. 2001).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No adverse effects on fetal development in rats were observed after oral administration of 250 mg/kg of an ethanol extract of boerhavia daily throughout pregnancy (Singh et al. 1991).

One reference notes that boerhavia has been used for abortion. Details were not reported on part used, dose, route of administration, and whether the plant was used singly or in a formula (Taylor 2005).

No information on the safety of boerhavia during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an aqueous extract of boerhavia orally administered to rats and mice could not be determined at doses up to 2 g/kg (Orisakwe et al. 2003). The oral LD_{50} of an ethanol extract of boerhavia in rats was 1 g/kg (Dhar et al. 1968).

Subchronic Toxicity

No signs of toxicity were observed in rats and mice orally administered 500, 1000, or 2000 mg/kg of an aqueous extract of boerhavia daily for 90 days. The parameters measured included absolute and relative weight of various organs, hematological parameters, and tests for liver function. Rats in the treatment group had an increase in food and fluid intake as compared to control that resulted in a greater weight gain in the group administered boerhavia extract (Orisakwe et al. 2003).

Borago officinalis L.

Boraginaceae

SCN: borage

Part: herb

Quick Reference Summary

Safety Class: 2a
Interaction Class: A

Contraindications

For external use only (Dodson and Stermitz 1986; Herrmann et al. 2002; Huizing and Malingré 1981; Wretensjö and Karlberg 2003).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Pyrrolizidine alkaloids (0.0002–0.001%) (Dodson and Stermitz 1986; Herrmann et al. 2002; Huizing and Malingré 1981; Wretensjö and Karlberg 2003); *see* Appendix 1.

Editors' Notes

The American Herbal Products Association has established a trade requirement (AHPA 2011) that all products with botanical ingredients that contain toxic pyrrolizidine alkaloids, including borage herb, are not offered for sale for internal use and display the following cautionary label: "For external use only. Do not apply to broken or abraded skin. Do not use when nursing."

Borage herb contains relatively minor amounts of pyrrolizidine alkaloids (PA), including lycopsamine, amabiline, supinine, 7-acetyllycopsamine, intermedine, acetylintermedine, and thesinine (Herrmann et al. 2002; Larson et al. 1984; Roitman 1983). Of these compounds, all but thesinine are unsaturated PAs, a group of compounds that are generally classified as toxic (De Smet 1993). Within the unsaturated PAs, toxicity ranges from mild to severe. Lycopsamine is a monoesterified, unsaturated PA that is less toxic than diesterified, unsaturated PAs that occur in other PA-containing plants.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of borage herb during pregnancy or lactation was identified. Based on the presence of pyrrolizidine alkaloids, use during pregnancy or lactation is not recommended.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Borage and foxglove (*Digitalis purpurea*) have botanically similar leaves. Adverse cardiovascular effects due to foxglove consumption have been reported in persons that mistook foxglove leaf for borage leaf (Brustbauer and Wenisch 1997; Cardano et al. 2002; Maffe et al. 2009).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of borage herb during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Borago officinalis L.

Boraginaceae

SCN: borage

Part: seed oil

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Borage seed oil is commonly traded as a source of gamma-linolenic acid (GLA). Processing methods eliminate pyrrolizidine alkaloids (PA) from the finished material (Wretensjö and Karlberg 2003). A study of the effects of the borage seed oil refinement process on the content of pyrrolizidine alkaloids in the oil indicated that processing reduces the PA content by a factor of about 30,000. In finished samples, no PAs were present above the detection limit of 20 ppb (Langer and Franz 1997; Wretensjö and Karlberg 2003). The seeds themselves contain only small amounts of the saturated (nontoxic) pyrrolizidine alkaloid thesinine (De Smet 1993; Dodson and Stermitz 1986).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of borage seed oil in pregnancy was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant women, safety has not been conclusively established.

Gamma-linolenic acid (GLA), one of the primary constituents of borage seed oil, is a compound naturally formed in the human body and is a component of human breast milk (Carter 1988).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No effects on platelet aggregation were observed in healthy volunteers orally administered 3 g of borage seed oil daily for 6 weeks (Bard et al. 1997).

No changes in hematological or biochemical parameters were observed in adults and children with atopic eczema orally administered 2 g (adult dose) or 1 g (child dose) of borage seed oil daily for 12 weeks. Adverse events in the treatment group were similar to or less than those reported in the control group (Takwale et al. 2003).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of borage seed oil during pregnancy was identified. Gamma-linolenic acid (GLA), one of the primary constituents of borage seed oil, is a compound naturally formed in the human body and is a component of human breast milk (Carter 1988).

V. Toxicity Studies

No toxicity studies were identified.

OCN: (oleo gum resin): frankincense; Indian olibanum
Part: gum resin

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Frankincense may be irritating to the stomach and the bitter taste may cause nausea and vomiting (Bensky et al. 2004; Chen and Chen 2004).

Allergic reactions to frankincense and Indian frankincense have been reported (Acebo et al. 2004; Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

While texts on traditional Chinese medicine indicate that frankincense should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004), in Yemen, women chew frankincense during pregnancy (Ghazanfar 1994).

No information on the safety of frankincense during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of clinical trials of Indian frankincense products indicated that adverse effects related to Indian frankincense were minor and not significantly different from those observed in control treatment or placebo groups. Diarrhea, abdominal pain, and nausea were reported in several of the seven studies reviewed (Frank and Unger 2006). In a study not included in the review, epigastric pain, abdominal fullness, gastroesophageal reflux, diarrhea, and nausea were reported in 18% of patients with ulcerative colitis receiving 1.5 g of Indian frankincense daily for 6 weeks (Gupta et al. 1997).

Case Reports of Adverse Events

Allergic contact dermatitis to Indian frankincense has been reported (Acebo et al. 2004).

A 17-year-old woman developed an epigastric bezoar of frankincense after repeated ingestion of "large quantities" of frankincense over an unspecified period of time (El Fortia et al. 2006).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Primary skin and eye irritation tests in rabbits indicated that an Indian frankincense extract containing 30% 3-*O*-acetyl-11-keto-β-boswellic acid was nonirritating to the skin and mildly irritating to the eyes (Lalithakumari et al. 2006).

Indian frankincense and fractions of Indian frankincense have exhibited immunomodulatory activity in several animal studies (Khajuria et al. 2008; Pungle et al. 2003; Sharma et al. 1996).

In Vitro Pharmacological Studies

Methanolic extracts of frankincense and Indian frankincense nonselectively inhibited the human drug-metabolizing isoenzymes CYP 1A2, 2C8, 2C9, 2C19, 2D6, and 3A4 (Frank and Unger 2006).

Inhibition of P-glycoprotein (P-gp) was observed in human lymphocytic leukemia cells and porcine brain capillary endothelial cells treated with Indian frankincense extract with inhibitory concentrations in the micromolar range. The authors of the study indicated that inhibition of P-gp at the blood-brain barrier is probably not relevant for the brain availability of other P-gp substrates, due to low plasma levels determined for selected boswellic acids, but the data cannot exclude the possibility of drug interactions caused by modulation of gastrointestinal P-gp (Weber et al. 2006).

IV. Pregnancy and Lactation

While texts on traditional Chinese medicine indicate that frankincense should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004), in Yemen, women chew frankincense during pregnancy (Ghazanfar 1994).

No information on the safety of frankincense or Indian frankincense during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally or intraperitoneally administered extracts of Indian frankincense in mice and rats could not be determined at doses up to 2 g/kg (Singh and Atal 1986).

The LD_{50} of an Indian frankincense extract containing 30% 3-*O*-acetyl-11-keto-β-boswellic acid orally administered to rats could not be determined at doses up to 5 g/kg. The acute dermal LD_{50} of the same extract could not be determined at doses up to 2 g/kg (Lalithakumari et al. 2006).

Subchronic Toxicity

No changes in hematology, clinical chemistry, or histopathology were observed in rats fed diets containing 0 to 2.5% of an Indian frankincense extract containing 30%

3-*O*-acetyl-11-keto-β-boswellic acid daily for 90 days (Lalithakumari et al. 2006).

Chronic Toxicity

In rats with chemically induced colitis fed diets containing 0.1 or 1% Indian frankincense hexane and water fractions daily for their lifetime, hepatotoxicity with pronounced hepatomegaly and steatosis was observed. Microarray analyses of hepatic gene expression demonstrated dysregulation of a number of genes, including a large group of lipid metabolism-related genes and detoxifying enzymes, a response consistent with that of hepatotoxic xenobiotics (Kiela et al. 2005).

Genotoxicity

No changes in hepatic DNA fragmentation were observed in rats fed diets containing 0 to 2.5% of an Indian frankincense extract containing 30% 3-*O*-acetyl-11-keto-β-boswellic acid daily for 90 days (Lalithakumari et al. 2006).

Cytotoxicity

Mild to low toxicities of Indian frankincense gum resin and 3-*O*-acetyl-11-keto-β-boswellic acid were observed in undifferentiated keratinocytes (HaCaT and NCTC 2544) and fetal dermal fibroblasts (HFFF2) (Burlando et al. 2008).

Quick Reference Summary

Safety Class: 1 (internal), 2d (external)

Interaction Class: A

Contraindications

Internal Use

None known.

External Use

Not for external use with children under 6 years of age (Felter and Lloyd 1898; List and Hörhammer 1973; Watt and Breyer-Brandwijk 1962).

Not for use in persons with varicose veins, severe circulatory damage, or other venous disorders (Wichtl 2004).

Other Precautions

Internal Use

Mustards may irritate the gastrointestinal tract and should be used with caution in patients with peptic ulcer or gastric hemorrhage (Bensky et al. 2004).

External Use

If left on the skin for more than 15 to 30 minutes, plasters made from mustards can cause blistering that may be accompanied by suppurating, poorly healing ulcerations and necrosis (Wichtl 2004).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

The local skin irritant effect of topically applied mustards lasts for 24 to 48 hours (Wichtl 2004). Blistering, often accompanied by suppurating, poorly healing ulcerations and necrosis, may occur if topical black mustard plasters are applied for more than 15 to 30 minutes (Wichtl 2004).

Large doses (standard dose listed as an aqueous extract of 3–9 g) of mustards can cause enteritis, abdominal pain, and diarrhea (Bensky et al. 2004).

Allergic reactions to mustards have been reported after both internal and topical use. Reactions included anaphylactic shock and urticaria, and were confirmed by patch testing (Bensky et al. 2004; Morisset et al. 2003).

Pharmacological Considerations

Several animal studies have demonstrated that black mustard seed may modify glucose regulation. Diabetic persons are advised to discuss the use of this herb with a qualified healthcare practitioner prior to use (Anand et al. 2007, 2009; Yadav et al. 2004).

Pregnancy and Lactation

No information on the safety of mustards in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Toxicosis was reported in cattle that ingested significant amounts of mustard seed (Katamoto et al. 2001; Semalulu and Rousseaux 1989). The compound allyl isothiocyanate, which has an LD_{50} of 10 mg/kg in cattle (Kingsbury 1964) and 339 mg/kg in rats (Jenner et al. 1964), is believed to be responsible for the toxicosis.

Topical application of mustard seed as a plaster has been associated with tachypnea, sweating, dizziness, agitation, and low blood pressure, with symptoms appearing 40 minutes after topical application (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Mustard seed allergy accounts for 1.1% of food allergies in children (Morisset et al. 2003).

In a study of 30 subjects, age 3 to 20, presenting positive prick tests to ground black mustard seed (*B. nigra*), mustard flour (*B. juncea*), metabisulfite-free strong mustard seasoning (*B. juncea*), or a commercialized allergenic extract (*B. nigra*), 27 subjects were screened for mustard-specific immunoglobulin E (IgE) and single- or double-blind placebo-controlled food challenges were completed with up to 1340 mg of the metabisulfite-free seasoning. The mean diameter of the wheal induced by prick tests with the allergenic extract was lower than that induced by the native mustard products, ground black mustard seed, mustard flour, or the strong mustard seasoning. The mean of mustard specific-IgE values was 8.7 KU/l (Morisset et al. 2003).

Animal Pharmacological Studies

A decease in serum glucose and increase in serum insulin were observed in diabetic rats orally administered 200 mg/kg black mustard seed daily for 2 months (Anand et al.

2009). In the oral glucose tolerance test, the effective dose of the aqueous extract of black mustard seed was 200 mg/kg, with the aqueous extract being more effective than chloroform, acetone, or ethanol extracts (Anand et al. 2007). In rats fed a diet containing 10% black mustard seed for 30 days, significant decreases in fasting serum glucose and insulin were observed, although the levels were not normalized (Yadav et al. 2004).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of mustards in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered black mustard seed extract in rats could not be determined at doses up to 3 g/kg (Anand et al. 2009).

Genotoxicity

Antimutagenic activity of mustard seed was observed in rats exposed to a chemical mutagen after being fed a diet containing 1 to 10% mustard seed daily for 30 days (Polasa et al. 1994).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

An allergic reaction to bupleurum has been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of bupleurum in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An allergic reaction to bupleurum has been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound saikosaponin inhibited human platelet aggregation induced by ADP, with a potency of inhibition comparable to that of aspirin, and dose-dependently inhibited platelet thromboxane formation from exogenous and endogenous arachidonic acid. Effects were similar to that of epigallocatechin isolated from green tea (Chang and Hsu 1991).

The compounds eugenin and saikochromone inhibited CD28-costimulated activation of human peripheral blood T cells (Chang et al. 2003).

In human G6PD-deficient red blood cells, an aqueous extract of bupleurum demonstrated dose-dependent reduction of reduced glutathione (GSH) and methemoglobin (MetHb) at concentrations of 5–10 mg/ml (Ko et al. 2008).

No estrogenic activity of an ethanol extract of bupleurum was observed in a recombinant yeast system (Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the use of bupleurum during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered bupleurum essential oil in mice is 1.19 g/kg, while that of intraperitoneally administered saikosaponin is 1.9 g/kg (Chen and Chen 2004).

The LD_{50} of the crude saponin fraction of bupleurum in mice is 4700 mg/kg after oral administration, 1800 mg/kg after subcutaneous administration, 112 mg/kg after intraperitoneal administration, and 70 mg/kg after intravenous administration. In guinea pigs, the LD_{50} of the same fraction is 58.3 mg/kg after intraperitoneal administration (Takagi and Shibata 1969).

No adverse effects were observed in rats 14 days after intranasal administration of bupleurum essential oil made from 10 g of bupleurum root (50 times the human clinical dose) (Xie et al. 2006).

Cytotoxicity

The compound saikosaponin d induced apoptosis in human hepatocellular carcinoma cells (HepG2) through the activation of caspases 3 and 7, resulting in poly(ADP-ribose)-polymerase (PARP) cleavage. DNA fragmentation was clearly noted at more than 6 hours after exposure to saikosaponin d (Chiang et al. 2003).

Buxus sempervirens L. — Buxaceae

SCN: boxwood

Part: leaf

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Kingsbury 1964; List and Hörhammer 1973).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of boxwood during pregnancy or lactation was identified. While this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

After ingestion of an unknown amount of boxwood leaf, a 1-year-old was reported to be apathetic then overexcited (Frohne and Pfänder 2000).

Poisoning has been reported in livestock that have eaten boxwood. A horse died after consuming 1.5 pounds of boxwood (0.15% of the animal's body weight) (Frohne and Pfänder 2000; Kingsbury 1964).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In anesthetized cats administered 1.25 µmol/kg of the compound buxaminol-E, a small short-lasting increase in blood pressure followed by marked hypotension was observed. Atropine inhibited the hypotensive effect almost completely and methylatropine partially inhibited the effect (Kvaltínová et al. 1991).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of boxwood during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Calendula officinalis L.

Asteraceae

SCN: calendula
OCN: marigold; pot marigold

Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as feverfew, chamomile, or *Echinacea* species) should exercise caution with calendula, as allergic cross-reactivity to Asteraceae plants is common (Paulsen 2002).

Drug and Supplement Interactions

None known.

Editors' Note

The Cosmetic Ingredient Review deemed calendula "safe as used" as a topical cosmetic product (CIR 2009).

Adverse Events and Side Effects

Allergic reaction to calendula, including anaphylactic reaction, is rare but has been reported (Fiume 2001; Goldman 1974). Irritation and sensitization studies in animals have indicated that calendula is nonirritating and nonsensitizing (Fiume 2001).

Pharmacological Considerations

None known.

Pregnancy and Lactation

An animal study on a water-ethanol extract of calendula at doses up to 1.0 g/kg indicated no adverse effects on fetal development (Silva et al 2009).

No information on the safety of calendula during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Calendula has been shown to increase the hexobarbital-induced sleeping time in rats (Samochowiec 1983).

II. Adverse Events

Case Reports of Adverse Events

Patch testing with calendula preparations has indicated a 0–2% incidence of reaction to such testing with ointments containing 10% calendula (Bruynzeel et al. 1992), an ether extract of calendula (Reider et al. 2001), an ethanol extract of calendula (de Groot et al. 1988), and calendula absolute (Rodriquez and Mitchell 1977). In one set of patch tests, patients sensitive to calendula were also sensitive to nickel, propolis, fragrance mix, and balsam of Peru (*Myroxylon balsamum* var. *pereirae*). Sensitization to calendula can be assessed only by use of an Asteraceae mix or a sesquiterpene mix (Reider et al. 2001).

Anaphylactic reaction to a calendula infusion has been reported (Goldman 1974). Contact dermatitis from contact with a calendula plant has been reported (Wrangsjö et al. 1990).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Little to no irritation was observed in animal dermal and ocular irritation studies of a variety of calendula extracts (Fiume 2001). Similarly, in animal sensitization studies, calendula did not produce sensitization reactions (Fiume 2001).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In a reproductive toxicity assessment of a hydroalcoholic extract of calendula, female rats were orally administered (by gavage) 0, 0.25, 0.5, or 1.0 g/kg of the extract on days 1 to 6, 7 to 14, or 15 to 19 of gestation. On day 20 of gestation, rats were killed for evaluation of maternal and fetal parameters. The treatment did not cause any changes in the number of corpora lutea, implantation sites, or resorption sites and no significant differences were found in the preimplantation and postimplantation loss rates in the treated groups as compared to the control. The number of live fetuses and the fetal weight was similar in the treatment and control groups. A dose-dependent reduction in maternal weight gain was observed in the group administered calendula on gestational days 15 to 19, although fetal weight was not affected (Silva et al. 2009).

In isolated rabbit and guinea pig uteruses, an aqueous extract of calendula exhibited uterotonic activity (Shipochliev 1981). The relevance of that finding to human use is unknown.

Older studies and references report emmenagogic activity of calendula (Palma 1964; Puri 1971; Saha et al. 1961).

No information on the safety of calendula during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered hydroalcoholic extract in rats and mice could not be determined at doses up to 5 g/kg (CTFA 1980; Silva et al. 2007). The LD_{50} of intraperitoneally administered calendula extract in mice is 300 mg/kg (Dhar et al. 1968).

Short-Term Toxicity

In rats and mice administered a hydroalcoholic extract of calendula at doses up to 1 g/kg daily for 30 days, no hematological alterations were observed at doses up to 1 g/kg, and no morphological changes in the brain, kidney, and heart were seen. An increase in blood urea nitrogen and in alanine transaminase levels was observed, and inflammatory sites were found in the lung (associated with oral gavage) and liver (Silva et al. 2007).

Genotoxicity

No mutagenic activity of saponins isolated from calendula was seen in the Ames test using *Salmonella typhimurium* TA98 without and with metabolic activation (Elias et al. 1990). No mutagenic activity of an aqueous extract of calendula was seen in a somatic mutation and recombination test using *Drosophila melanogaster*. Two flavonols, quercetin and rutin, had weak genotoxic activity (Graf et al. 1994).

No chromosomal damage was observed in the bone marrow micronucleus test after mice were orally administered up to 1 g/kg calendula aqueous-ethanolic extract daily for 2 days (Ramos et al. 1998). An aqueous-ethanolic extract of calendula exhibited dose-dependent toxicity and genotoxicity (both mitotic crossing-over and chromosome malsegregation) to *Aspergillus* at concentrations of 0.1 to 1.0 mg solids/ml (Ramos et al. 1998). No mutagenic activity of an aqueous-ethanolic calendula extract at concentrations ranging from 50 to 5000 µg/plate was seen in several *Salmonella* strains with or without S9 activation (Ramos et al. 1998).

At low doses, aqueous and aqueous-ethanolic extracts of calendula provided effects against unscheduled DNA synthesis induced by diethylnitrosamine, whereas at high concentrations without diethylnitrosamine, the same extracts produced some genotoxic effects (Perez-Carreon et al. 2002).

Cytotoxicity

In vitro cytotoxic activity of calendula extracts was observed in MRC5, Hep2, and Ehrlich cell lines. When the same extracts were tested in mice, one was inactive and three were poorly active, whereas the most saponin-rich extract did not produce development of ascites (Boucaud-Maitre et al. 1988).

Camellia sinensis (L.) Kuntze — Theaceae

SCN: tea
Syn: *Thea sinensis* L.

OCN: black tea
Part: fully fermented leaf, stem

Quick Reference Summary

Safety Class: 1
Interaction Class: C*

Contraindications

None known.

Other Precautions

Many black tea extracts contain caffeine, a nervous system stimulant. If taken in large amounts, black tea products containing caffeine can cause insomnia, nervousness, and the other well-known symptoms of excess caffeine intake (Donovan and DeVane 2001).

Due to the CNS stimulant effects of caffeine, use of caffeine-containing products is cautioned in persons with heart disorders, as excessive caffeine consumption may increase heart rate or exacerbate arrhythmias; or psychological disorders, as caffeine may aggravate depression or induce anxiety (Brinker 2001).

Drug and Supplement Interactions

Use of caffeine with other central nervous system (CNS) stimulants, including bronchodilators or adrenergic drugs, may cause excessive central nervous system stimulation resulting in nervousness, irritability, insomnia, and possibly convulsions or cardiac arrhythmias (PDR 2006).

Caffeine is metabolized by the isoenzyme CYP1A2. Drugs that inhibit this isoenzyme (including fluvoxamine, ciprofloxacin, cimetidine, amiodarone, fluoroquinolones, furafylline, interferon, methoxsalen, and mibefradil) may slow the metabolism of caffeine resulting in high blood levels of caffeine in persons drinking multiple cups of black tea daily (Carrillo and Benitez 2000).

Notice

Caffeine (0.9–5.0% caffeine) (Wichtl 2004; Williamson 2003); *see* Appendix 1.

Diuretic (Brunton et al. 2006); *see* Appendix 2.

Tannins (12.9%) (List and Hörhammer 1973; Martindale and Reynolds 1996; Wichtl 2004); *see* Appendix 1.

Editors' Note

The American Herbal Products Association has established a trade requirement (AHPA 2011) that dietary supplement products that contain caffeine, whether as a direct ingredient or as a constituent of herbal ingredients, be labeled to disclose the presence of caffeine in the product and the quantity of added caffeine if greater than 25 mg; be formulated and labeled in a manner to recommend a maximum of 200 mg of caffeine per serving, not more often than every 3 to 4 hours; and bear the following or similar statement on the label of any dietary supplement that contains caffeine in sufficient quantity to warrant such labeling:

Too much caffeine may cause nervousness, irritability, sleeplessness, and, occasionally, rapid heartbeat. Not recommended for use by children under 18 years of age.

* For caffeine-free preparations, no interactions are expected.

See Appendix 1 for more specific details on this AHPA trade requirement.

Adverse Events and Side Effects

A review of clinical trials on black tea did not indicate any adverse effects associated with black tea in the trials (Gardner et al. 2007).

Pharmacological Considerations

Black tea consumption may reduce absorption of iron, calcium, and magnesium (Disler et al. 1975; Gardner et al. 2007; Merhav et al. 1985).

Pregnancy and Lactation

No studies on the safety of black tea during pregnancy or lactation were identified. Pregnant women are advised to limit use of caffeinated black tea products to 300 mg caffeine (approximately six cups black tea) daily (PDR 2006). Nursing women are advised to limit use of caffeinated black tea products to two to three cups (~150 mg caffeine) daily (AAP 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of interactions with black tea were identified. A number of interaction studies on the compound caffeine have been completed; *see* Caffeine in Appendix 1.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of interactions with black tea or black tea extract were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical trials on black tea did not indicate any adverse effects associated with black tea in the trials (Gardner et al. 2007).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Human studies have shown increased urinary excretion and decreased calcium and magnesium absorption in women administered the minerals and caffeine at the same time (Bergman et al. 1990; Heaney and Recker 1982), although an epidemiological study of approximately 1000 people over age 30 indicated a higher bone mineral density in persons who had habitually consumed tea for 19 years or more, as compared with nonhabitual tea drinkers (Nesher et al. 2003).

Black tea has been shown to reduce iron absorption, especially in individuals who have an increased risk of anemia (Disler et al. 1975; Merhav et al. 1985). The postulated mechanism of action is the formation of iron complexes with black tea tannins in the gut (South et al. 1997). However, in a review of clinical trials and epidemiological studies of black tea, no change in iron status was noted except in populations that were at risk for anemia (Gardner et al. 2007).

Caffeine is a substrate of the drug-metabolizing isoenzyme CYP1A2 (Nordmark et al. 1999).

Animal Pharmacological Studies

Animal studies were available but omitted due to the presence of human data.

In Vitro Pharmacological Studies

In vitro studies were available but omitted due to the presence of human data.

IV. Pregnancy and Lactation

Caffeine is in the FDA pregnancy category C and has been shown to cross the placenta and achieve blood and tissue concentrations in the fetus. Excessive intake of caffeine by pregnant women has been associated with fetal arrhythmias. Pregnant women are advised to limit caffeine intake to less than 300 mg (approximately six cups black tea) daily (PDR 2006).

Caffeine is listed as a "Maternal Medication Usually Compatible with Breastfeeding" by the American Academy of Pediatrics Committee on Drugs. The Committee noted that maternal consumption of caffeine may cause irritability and poor sleeping patterns in nursing infants, and that maternal consumption of caffeinated beverages should be limited to two to three cups daily (AAP 2001).

Epidemiological studies have indicated an association between high caffeine intake during pregnancy and an increased risk of spontaneous abortions. An analysis concluded that methodological flaws in many of the studies led to biased results and that a causal link between caffeine consumption and abortion cannot yet be confirmed (Signorello and McLaughlin 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered caffeine in rats is 335 mg/kg (Mills and Bone 2005).

Camellia sinensis (L.) Kuntze — Theaceae

SCN: tea
Syn: *Thea sinensis* L.

OCN: green tea
Part: unfermented leaf, stem

Quick Reference Summary

Safety Class: 1
Interaction Class: C*

Contraindications

None known.

Other Precautions

Green tea and many green tea extracts contain caffeine, a nervous system stimulant. If taken in large amounts, green tea products containing caffeine can cause insomnia, nervousness, and the other well-known symptoms of excess caffeine intake (Donovan and DeVane 2001).

Due to the CNS stimulant effects of caffeine, use of caffeine-containing products is cautioned in persons with heart disorders, as excessive caffeine consumption may increase heart rate or exacerbate arrhythmias; or psychological disorders, as caffeine may aggravate depression or induce anxiety (Brinker 2001).

Ethanol extracts of green tea should be taken with a meal (Sarma et al. 2008).

Drug and Supplement Interactions

Use of caffeine with other central nervous system (CNS) stimulants, including bronchodilators or adrenergic drugs, may cause excessive central nervous system stimulation resulting in nervousness, irritability, insomnia, and possibly convulsions or cardiac arrhythmias (PDR 2006).

Notice

Caffeine (0.9–5.0% caffeine) (Leung and Foster 1996; Martindale and Reynolds 1996; Wichtl 2004); *see* Appendix 1.

Diuretic (Brunton et al. 2006); *see* Appendix 2.

* For caffeine-free preparations, no interactions are expected.

Tannins (22.2%) (Martindale and Reynolds 1996; Wichtl 2004); *see* Appendix 1.

Editors' Notes

Green, unfermented tea is the world's second most consumed beverage, after water (Graham 1992). A typical cup of green tea contains 15 to 40 mg of caffeine (Chin et al. 2008).

The American Herbal Products Association has established a trade requirement (AHPA 2011) that dietary supplement products that contain caffeine, whether as a direct ingredient or as a constituent of herbal ingredients, be labeled to disclose the presence of caffeine in the product and the quantity of added caffeine if greater than 25 mg; be formulated and labeled in a manner to recommend a maximum of 200 mg of caffeine per serving, not more often than every 3 to 4 hours; and bear the following or similar statement on the label of any dietary supplement that contains caffeine in sufficient quantity to warrant such labeling:

Too much caffeine may cause nervousness, irritability, sleeplessness, and, occasionally, rapid heartbeat. Not recommended for use by children under 18 years of age.

See Appendix 1 for more specific details on this AHPA trade requirement.

Adverse Events and Side Effects

Cases of liver toxicity have been reported in persons taking products that contain green tea extracts (Abu el Wafa et al. 2005; Bonkovsky 2006; Duenas Sadornil et al. 2004; Federico et al. 2007; Garcia-Moran et al. 2004; Gloro et al. 2005; Javaid and Bonkovsky 2006; Jimenez-Saenz and Martinez-Sanchez 2006; Mazzanti et al. 2009; Molinari et al. 2006; Pedros et al. 2003; Seddik et al. 2001; Thiolet et al. 2002; Vial et al. 2003). These cases were primarily associated with ethanolic extracts of green tea, although several cases were associated with aqueous extracts (Federico et al. 2007; Jimenez-Saenz and Martinez-Sanchez 2006; Mazzanti et al. 2009). A review of the reported cases indicated that most patients developed severe hepatocellular injury with elevated levels of bilirubin and the liver enzyme alanine aminotransferase, suggesting idiosyncratic drug-induced liver injury rather than immunoallergic injury (Javaid and Bonkovsky 2006). Two case reports involved inadvertent re-exposure to the green tea extract, with a return of liver symptoms (Bonkovsky 2006; Jimenez-Saenz and Martinez-Sanchez 2006).

A systematic review of studies on the effects of green tea on liver disease indicated that 8 of 10 studies examined indicated a significant protective role of green tea against various liver diseases including liver cancer, cirrhosis, and fatty liver disease (Jin et al. 2008).

Pharmacological Considerations

A review of the safety of green tea extracts indicated that human and animal data showed that the maximum plasma concentration of the compound epigallocatechin gallate (EGCG) was significantly higher when administered under fasting conditions than with or after a meal, leading to the recommendation that green tea extracts be taken with a meal (Kapetanovic et al. 2009; Sarma et al. 2008).

Caffeine is a substrate of the drug-metabolizing isoenzyme CYP1A2 (Nordmark et al. 1999). No significant effects of decaffeinated green tea extract were observed on the drug-metabolizing isoenzymes CYP3A4 or CYP2D6 (Donovan et al. 2004). No clinically significant changes in CYP1A2, CYP2D6, or CYP2C19 were observed in humans administered green tea catechins (Chow et al. 2006).

Green tea may reduce the absorption of iron (Samman et al. 2001). Caffeine may decrease calcium and magnesium absorption (Bergman et al. 1990; Heaney and Recker 1982).

Pregnancy and Lactation

Pregnant women are advised to limit caffeine intake to less than 300 mg (approximately eight cups green tea) daily (PDR 2006). Lactating women are advised to limit consumption of caffeinated beverages to two to three cups daily (AAP 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of green tea or green tea extract interactions were identified. A number of interaction trials on the compound caffeine have been completed. *See* Caffeine in Appendix 1.

Case Reports of Suspected Drug or Supplement Interactions

Decreased INR (international normalized ratio, a system used to report the results of blood coagulation tests) was reported in a patient taking warfarin and drinking one-half to one gallon of green tea daily (Taylor and Wilt 1999). Warfarin works by interfering with vitamin K metabolism, a vitamin essential for blood clotting, and patients taking warfarin must limit dietary intake of vitamin K. The vitamin K content of green tea is relatively high, although brewed green tea contains less than 0.01% of the leaf content of vitamin K (Booth et al. 1995).

Animal Trials of Drug or Supplement Interactions

In rats orally administered 175 mg/kg of a green tea extract 4 days prior to oral administration of clozapine, a reduction in serum levels of clozapine was observed (Jang et al. 2005).

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a study of green tea standardized ethanolic extract (375 mg catechins daily) in obese volunteers, 1 of the 70 trial participants had an increase in liver transaminases after 3 months of green tea extract ingestion (Chantre and Lairon 2002).

Case Reports of Adverse Events

Cases of hepatotoxicity have been reported in persons taking products that contain green tea extracts (Abu el Wafa et al. 2005; Bonkovsky 2006; Duenas Sadornil et al. 2004; Federico et al. 2007; Garcia-Moran et al. 2004; Gloro et al. 2005; Javaid and Bonkovsky 2006; Jimenez-Saenz and Martinez-Sanchez 2006; Mazzanti et al. 2009; Molinari et al. 2006; Pedros et al. 2003; Seddik et al. 2001; Thiolet et al. 2002; Vanstraelen et al. 2008; Verhelst et al. 2009; Vial et al. 2003). Supplement use duration in these cases ranged from 5 to 120 days and cumulative doses ranged from 6 to 240 g (Bonkovsky 2006). Hepatotoxicity cases were primarily associated with ethanolic extracts of green tea, although several cases were associated with aqueous extracts (Federico et al. 2007; Jimenez-Saenz and Martinez-Sanchez 2006; Mazzanti et al. 2009). Two case reports involved inadvertent re-exposure to the green tea extract, with a return of liver symptoms (Bonkovsky 2006; Jimenez-Saenz and Martinez-Sanchez 2006). One review of the reported cases indicated that most patients developed severe hepatocellular injury with elevated levels of bilirubin and the liver enzyme alanine aminotransferase, suggesting idiosyncratic drug-induced liver injury rather than immunoallergic injury (Javaid and Bonkovsky 2006). A second review of published adverse events and those reported to pharmacovigilance centers indicated that of 34 identified case reports, "probable" causality was found in 7 cases and "possible" causality was found in the remainder of the cases (Sarma et al. 2008), based on the Naranjo causality algorithm scale (Naranjo et al. 1981). Notable diversity was seen in the products involved in these case reports, and product composition was verified in only one report (Sarma et al. 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A systematic review of studies on the effects of green tea on liver disease indicated that 8 of 10 studies showed a significant protective role of green tea against various liver diseases including liver cancer, cirrhosis, and fatty liver disease (Jin et al. 2008).

In men with positive prostate biopsies, oral administration of a standardized green tea extract containing 1.3 g green tea polyphenols (800 mg EGCG) daily for 12 to 214 days (mean of 34 days) was studied; a decrease in liver enzyme levels, including aspartate aminotransferase, alkaline phosphatase, and amylase, was observed (McLarty et al. 2009).

Human studies have shown increased urinary excretion and decreased calcium and magnesium absorption in women administered the minerals and caffeine at the same time (Bergman et al. 1990; Heaney and Recker 1982), although an epidemiological study of approximately 1000 people over age 30 indicated a higher bone mineral density in persons who had habitually consumed tea for 19 years or more, as compared with nonhabitual tea drinkers (Nesher et al. 2003).

Green tea has been shown to reduce iron absorption, especially in individuals who have an increased risk of anemia (Samman et al. 2001). The postulated mechanism of action is the formation of iron complexes with green tea tannins in the gut (South et al. 1997).

No significant effects of decaffeinated green tea extract (800 mg daily for 14 days) were observed on the drug-metabolizing isoenzymes CYP3A4 or CYP2D6 (Donovan et al. 2004). Green tea catechins were observed to have no effect on CYP1A2, CYP2D6, or CYP2C19, and clinically insignificant inhibition of CYP3A4 (Chow et al. 2006). Caffeine is a substrate of the drug-metabolizing isoenzyme CYP1A2 (Nordmark et al. 1999).

No changes in liver enzyme levels were observed in healthy men orally administered 6 capsules containing 384 mg (119 mg polyphenols) of an aqueous green tea extract daily (2 capsules before each meal) for 3 weeks (Frank et al. 2009).

Animal Pharmacological Studies

Animal studies were identified but omitted due to the presence of human data.

In Vitro Pharmacological Studies

In vitro studies were identified but omitted due to the presence of human data.

IV. Pregnancy and Lactation

Caffeine is in the FDA pregnancy category C and has been shown to cross the placenta and achieve blood and tissue concentrations in the fetus. Excessive intake of caffeine by pregnant women has been associated with fetal arrhythmias. Pregnant women are advised to limit caffeine intake to less than 300 mg (approximately eight cups green tea) daily (PDR 2006).

Caffeine is listed as a "Maternal Medication Usually Compatible with Breastfeeding" by the American Academy of Pediatrics Committee on Drugs. The Committee noted that maternal consumption of caffeine may cause irritability and poor sleeping patterns in nursing infants, and that maternal consumption of caffeinated beverages should be limited to two to three cups daily (AAP 2001).

In rats fed green tea extract and catechins during pregnancy, fetuses were found to have one-hundredth of the catechins found in maternal plasma (Chu et al. 2006). Catechins were identified in several different fetal organs,

with eyes having the highest concentration of these compounds (Chu et al. 2007).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered caffeine in rats is 335 mg/kg (Mills and Bone 2005). The LD_{50} of orally administered EGCG in rats is 2000 mg/kg (Isbrucker et al. 2006b).

In mice orally administered a single dose of 1500 mg/kg of the compound EGCG, plasma levels of alanine aminotransferase (ALT) increased by 138-fold and reduced survival by 85%. A greater increase in ALT levels was observed after doses of 750 mg/kg of EGCG daily for 2 days (Lambert et al. 2010).

Short-Term Toxicity

In rats orally administered 2.5 or 5 g/kg of Pu-erh green or Pu-erh black tea extract daily for 28 days, alanine aminotransferase increased in males at the 5 g/kg dose, and creatinine increased in all animals at the 5 g/kg dose and in males at the 2.5 g/kg dose. Slight bile duct hyperplasia in the liver was also observed. No adverse effects were observed in animals treated with Pu-erh black tea extract (Wang et al. 2010).

Subchronic Toxicity

No signs of toxicity were observed in rats after administration of 500 mg/kg daily EGCG for 13 weeks (Isbrucker et al. 2006b). No adverse effects were observed in prefed dogs administered 500 mg/kg EGCG daily in divided doses for 13 weeks, although morbidity was observed in fasted dogs fed 500 mg/kg in a single dose. This dose was noted by the study authors to be unrealistic as compared to standard human use (Isbrucker et al. 2006b). A no-observed-adverse-effect level (NOAEL) for human consumption of EGCG was estimated to be 500 mg/kg daily (Isbrucker et al. 2006b).

In rats fed diets containing 0.3, 1.25, or 5.0% green tea catechins for 90 days (daily intake of catechins was 184, 792, 3533 mg/kg), no mortality or obvious clinical signs were observed. Increased relative liver weight, alanine transaminase, and alkaline phosphatase were observed at the 5% level in both sexes. Aspartate transaminase was increased in females at the 5% level. Hematology and histopathological observation revealed no toxicological changes. The no-observed-adverse-effect level was estimated to be 764 mg/kg for males and 820 mg/kg for females (Takami et al. 2008).

In beagle dogs orally administered 200, 500, or 1000 mg/kg daily of green tea extract (56–72% EGCG), on an empty stomach, for a planned duration of 9 months, extensive morbidity, mortality, and pathology of many major organs led to termination of the study at 6.5 months and prevented identification of the toxicity mechanisms. In a 13-week follow-up study, animals were fed 175 to 200 mg/kg of the same extract daily on an empty stomach or after daily feeding. Dosing in a fed state resulted in considerably lower and less variable exposure than found under fasted conditions. Toxicity was less frequent and of lesser severity with lower exposure (Kapetanovic et al. 2009).

High concentrations of hydroalcoholic green tea extracts have been shown to exert acute toxicity in rat liver cells *in vitro*. The compound (–)-epigallocatechin-3-gallate (EGCG) was noted as the constituent that was likely responsible for this effect. The bioavailability of catechins is relatively low with oral ingestion, however, suggesting that EGCG is not responsible for the hepatotoxicity reported in human studies (Schmidt et al. 2005).

Administration of a single dose of the green tea phenolic acid gallic acid (100–800 mg/kg), propyl gallate (100 - 200 mg/kg), and the green tea catechin EGCG (100 mg/kg) resulted in a dose-dependent increase in plasma ALT levels in mice, indicative of liver injury (Galati et al. 2006).

Genotoxicity

Studies on the compound EGCG indicated a lack of genotoxicity in tests on *Salmonella typhimurium* and in rats (oral administration up to 2000 mg/kg) (Isbrucker et al. 2006a).

Cananga odorata (Lam.) Hook. f. & Thomson

Annonaceae

SCN: ylang ylang

Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to ylang ylang have been reported and confirmed by patch testing (Burdock and Carabin 2008).

Pharmacological Considerations

Allergic patch tests and sensitization tests in normal or fragrance-sensitive volunteers treated with ylang ylang essential oil have elicited reactions in 0–6.2% of tested populations (Burdock and Carabin 2008).

Pregnancy and Lactation

No information on the safety of ylang ylang in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No effect on pentobarbital-induced sleeping time was observed in rats exposed to air odorized with ylang ylang essential oil (concentration in air not reported) (Komori et al. 1997, 2006).

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to ylang ylang essential oil, including occupational contact dermatitis, have been reported and confirmed by patch testing (Burdock and Carabin 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No sensitization or irritation was observed in a closed patch test in test subjects treated with 10% ylang ylang essential oil in a petroleum base (Opdyke 1979).

In human patch tests, ylang ylang essential oil tested at concentrations between 0.2 and 10% elicited positive skin reactions in 1.3 to 6.2% of volunteers in different testing centers (Frosch et al. 2002).

Tested at concentrations of 5%, ylang ylang absolute caused dermatitis and eczema in approximately 5% of test subjects, while the essential oil elicited reactions in 3.4% of subjects (Itoh et al. 1988).

In patch testing with 65 allergens in over 4900 volunteers, ylang ylang essential oil elicited contact dermatitis in 1.1% of volunteers, and ranked 47th out of the allergens tested (Pratt et al. 2004).

In repeated-insult patch tests, 0 or 5% of subjects became sensitized after being treated with 10% ylang ylang essential oil in a petroleum base. In a rechallenge patch test

with the same test substance, no sensitization reactions were observed (Opdyke 1979).

Animal Pharmacological Studies

In irritation tests, ylang ylang essential oil was not irritating when applied undiluted to the back of hairless mice or on intact or abraded rabbit skin (Opdyke 1979).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of ylang ylang during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered ylang ylang essential oil in rats and the acute dermal LD_{50} in rabbits could not be determined at doses up to 5 g/kg (Opdyke 1979).

Canarium album (Lour.) Räusch. — Burseraceae

SCN: Chinese white olive
PN: *qing guo* (fruit)

OCN: white canary tree
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

In addition to being used medicinally, the fruit of Chinese white olive is consumed as an edible fruit in China (Jin et al. 1999).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Chinese white olive in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Capsella bursa-pastoris (L.) Medik.

Brassicaceae

SCN: shepherd's purse

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chadha 1988; Kuroda and Takagi 1968, 1969; Shipochliev 1981; Watt and Breyer-Brandwijk 1962).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Uterine stimulant (Williamson 2003); *see* Appendix 2.

Editors' Notes

Early references note, and contemporary herbalists maintain, that extracts made from the fresh herb are more active than those from the dried herb (Felter and Lloyd 1898, 1901). While this does not relate to the safety of the extract itself, one of the primary indications of shepherd's purse is to stop postpartum bleeding, a setting in which the use of a nonefficacious product may present a safety concern.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Limited information on the safety of shepherd's purse in pregnancy or lactation was identified. Older animal and in vitro studies indicate that shepherd's purse may stimulate uterine contractions (Kuroda and Takagi 1968, 1969; Shipochliev 1981). Older, primarily ethnobotanical surveys report that shepherd's purse was traditionally used as an emmenagogue and abortifacient (Casey 1960; de Laszlo and Henshaw 1954; Palma 1964; Watt and Breyer-Brandwijk 1962). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Shepherd's purse contains glucosinolates, compounds present in many plants in the Brassicaceae family (e.g., cauliflower and Brussels sprouts). These compounds have been shown to cross the placenta and to be present in breast milk (Panter and James 1990). At high concentrations, glucosinolates inhibit iodine uptake by the thyroid, although at lower concentrations cancer-preventive effects have been shown (Stoewsand 1995).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of suspected drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Hypotensive activity of shepherd's purse observed in rats is inhibited by a β-adrenoceptor blocker but not by atropine, dismissing earlier reports of cholinergic activity (Jurisson 1971; Kuroda and Takagi 1968).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In isolated animal uterine tissue, an infusion of shepherd's purse exhibited uterine tonic activity at a concentration of 1 to 2 mg/ml. The effect was less than that exhibited by chamomile (Shipochliev 1981). A fraction of an ethanol extract of shepherd's purse intravenously administered to rats increased experimentally induced contractions (Kuroda and Takagi 1969). The same extract exerted contractile activity on isolated rat uteruses (Kuroda and Takagi 1968). Shepherd's purse has been used traditionally to stimulate uterine contractions during childbirth (Bastien 1983). Older, primarily ethnobotanical surveys report that shepherd's purse was traditionally used as an emmenagogue and abortifacient (Casey 1960; de Laszlo and Henshaw 1954; Palma 1964; Watt and Breyer-Brandwijk 1962). The ancient Greek physician Pedanius Dioscorides wrote that shepherd's purse "moves the menstrual and destroys the embrya," an early observation of some of the physiological activity reported above (Dioscorides 512).

Shepherd's purse contains glucosinolates, compounds present in many plants in the Brassicaceae family (e.g., cauliflower and Brussels sprouts). Placental transfer of glucosinolate compounds has been observed (Panter and James 1990), and some adverse developmental effects have been reported in offspring of animals administered high levels of dietary glucosinolates (Panter and James 1990). No teratogenic effects were seen in fetuses of rats subcutaneously administered selected glucosinolates on gestational day 8 and or 9 (Nishie and Daxenbichler 1980).

At high doses, glucosinolate compounds inhibit iodine uptake although cancer-preventive properties have been shown at lower doses (Stoewsand 1995).

Glucosinolate compounds have been detected in breast milk of animals (Cheeke and Shull 1985).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered ethanol extract of shepherd's purse in rats is 1000 mg/kg (Sharma et al. 1978). Other LD_{50} values of shepherd's purse (type of extract not available in English language information) are 1500 mg/kg for intraperitoneal administration and 3100 mg/kg for subcutaneous administration. Symptoms of toxicity included sedation, dilation of pupils, paralysis of hind limbs, respiratory difficulty, and death (Jurisson 1971). Fractions of an ethanol extract of shepherd's purse in mice showed "low" toxicity (Kuroda and Takagi 1969).

Short-Term Toxicity

In guinea pigs administered shepherd's purse as 20 or 40% of the diet, no effects on fertility were observed at the 20% level; at 40%, temporary infertility was observed in males and females, and a reduction in ovulation was observed. No estrogenic activity was demonstrated (East 1955).

Cytotoxicity

The therapeutic ratio of anti-HIV activity of an aqueous extract of shepherd's purse versus toxicity to MT2 lymphoblastoid cells was less than 1 (Abdel-Malek et al. 1996).

Capsicum spp.

Solanaceae

Capsicum annuum L. var. ***annuum***
SCN: cayenne
Syn: *Capsicum frutescens* L.
OCN: cayenne pepper; chili pepper; paprika; red pepper; tabasco pepper

***Capsicum annuum* L. var. *glabriusculum* (Dunal) Heiser & Pickersgill**
SCN: bird pepper
OCN: African bird pepper; piquin
Part: fruit

Quick Reference Summary

Safety Class: 1 (internal use), 2d (external use)
Interaction Class: A

Contraindications

External Use

Not for use in or near eyes (Agrawal et al. 1985; Fett 2003; Johnson 2007).

Other Precautions

Internal Use

In sensitive individuals, excessive doses may cause gastrointestinal irritation or heartburn, or exacerbate gastroesophageal reflux (Chadha 1988; Felter and Lloyd 1898; Martindale and Reynolds 1996; Milke et al. 2006; Myers et al. 1987; Viranuvatti et al. 1972; Watt and Breyer-Brandwijk 1962).

External Use

Cayenne preparations irritate the mucous membranes and injured or broken skin even at very low concentrations, and may cause a painful burning sensation (Fett 2003; Johnson 2007).

Drug and Supplement Interactions

Use of topical cayenne products may exacerbate cough caused by angiotensin-converting enzyme (ACE) inhibitors, although cayenne is not believed to affect the efficacy of these drugs (Stargrove et al. 2008; Yeo et al. 1994, 1995).

Editors' Note

The German Commission E suggests that *Capsicum* should not be applied externally for more than 2 days, with a 14-day time lapse between applications (Blumenthal et al. 2000). However, two systematic reviews of human studies of topically applied products containing the compound capsaicin (0.025–0.075%) as the active ingredient indicated that study periods were generally 4 to 8 weeks in duration (Mason et al. 2004; Zhang and Po 1994).

Adverse Events and Side Effects

Topical application of cayenne may produce a burning sensation, often accompanied by erythema (redness of the skin due to capillary congestion). Repeated topical use generally causes desensitization that is reversible on discontinuation of the drug (Hautkappe et al. 1998; Johnson 2007). Cayenne preparations irritate mucous membranes even at very low concentrations, and may cause a painful burning sensation (Fett 2003).

Ingestion of cayenne may cause or exacerbate gastric irritation, heartburn, or gastroesophageal reflux (GER) in sensitive individuals (Milke et al. 2006).

Pharmacological Considerations

One study in rats indicated that cayenne reduced the bioavailability of aspirin and salicylic acid (Cruz et al. 1999). A study in rabbits indicated that cayenne increased the plasma levels of orally but not intravenously administered theophylline (Bouraoui et al. 1995). The relevance of those data to human use is not known.

Pregnancy and Lactation

Information on the safety of cayenne use in pregnancy is limited. One animal study showed no adverse effects of cayenne after administration to pregnant rats for 5 days (Pellicer et al. 1996).

No information on use of cayenne during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Exacerbation of ACE inhibitor-induced cough by capsaicin has been reported in two small studies in humans (Yeo et al. 1994, 1995).

Case Reports of Suspected Drug or Supplement Interactions

Topical application of a capsaicin-containing cream (0.075% capsaicin) induced cough in a woman taking an unspecified ACE inhibitor. The cough occurred just after the cream was applied (Hakas 1990).

Animal Trials of Drug or Supplement Interactions

Coadministration of aspirin or salicylic acid and cayenne extract (300 mg/kg, 10% capsaicin) orally to rats significantly reduced the bioavailability of salicylic acid and aspirin. Chronic oral administration of aspirin or salicylic acid and cayenne extract (100 or 300 mg/kg) resulted in undetectable plasma levels of aspirin and significantly reduced blood levels of salicylic acid (Cruz et al. 1999). The compound capsaicin increased the absorption of acetaminophen in rats (Metwally and Kandil 1985).

Oral coadministration of 5 ml/kg of a cayenne suspension (10% cayenne) and 20 mg/kg theophylline to rabbits significantly increased the plasma levels of theophylline (Bouraoui et al. 1988), whereas oral administration of cayenne (5 ml/kg of a 10% cayenne suspension) and intravenous administration of theophylline (12 mg/kg) did not affect the plasma levels of theophylline (Bouraoui et al. 1995). Dosing with cayenne and theophylline for 7 days in rabbits significantly reduced urinary excretion of the theophylline metabolite 1-methyluric acid (Bouraoui et al. 1995).

Administration of 0.1 µg/kg of the compound capsaicin to rats protected the stomach from mucosal damage by ethanol. Doses of 10 to 30 mg/kg capsaicin, however, aggravated the damage caused by ethanol (Salam et al. 1995).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of herbal medicines for lower back pain identified two trials of topical cayenne monopreparations and reported that adverse events in cayenne treatment groups were inflammatory contact eczema, urticaria, minute hemorrhagic spots, and vesiculation or dermatitis. In one trial, 15 adverse events were reported in the cayenne group and 9 in the placebo group (Gagnier et al. 2007). In a clinical trial of a topical capsicum plaster or placebo, localized adverse drug reactions were found in 7.5% of the patients on capsicum and 3.1% on placebo (Frerick et al. 2003).

A review of clinical trials of the compound capsaicin indicated that repeated topical applications of capsaicin to the skin produce an initial burning sensation followed by gradual desensitization that is reversible on discontinuation of the drug (Hautkappe et al. 1998).

A meta-analysis of topical capsaicin for the treatment of chronic pain, including 6 studies with a total of 656 patients, reported that 54% of patients using capsaicin had one or more local adverse events compared with 15% in the placebo group. Coughing was reported in 8% of patients using products with 0.075% capsaicin and none using products with 0.025% capsaicin. One active-controlled trial reported coughing in 1 of 32 patients using 0.025% capsaicin and in 7 using 0.25% capsaicin (Mason et al. 2004).

Case Reports of Adverse Events

Topical reactions to cayenne, including contact dermatitis and urticaria, have been reported (Burnett 1989; Feldman and Levy 2003).

C

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A review of the effects of cayenne on gastric ulcers indicated that large doses of chili pepper administered directly into the stomach of normal fasting subjects generally produced a mild response consisting of a small increase in gastric acid secretion and an increased blood flow (Ayad 1995). Intragastric administration of 3 g cayenne in healthy subjects with varying histories of cayenne consumption caused no detectable changes in 13 of the 20 subjects, mild to moderate edema or increased blood flow in 6 subjects, and a hemorrhage in 1 subject (Viranuvatti et al. 1972). An assessment of cayenne on human gastric mucosa in healthy volunteers indicated that administration of 0.1 to 1.5 g cayenne exhibited dose-dependent parietal secretion, pepsin secretion, potassium loss, and gastric cell exfoliation, and that the gastric effects were similar to those of aspirin (Myers et al. 1987).

Consumption of 20 g of cayenne provided a protective effect against gastrointestinal mucosal damage induced by aspirin (600 mg) in a study of healthy volunteers (Yeoh et al. 1995).

A study on the effects of chronic chili ingestion on gastroesophageal reflux (GER) symptoms indicated that daily ingestion of 3 g of chili (two different varieties of chilies, one with 0.048% capsaicin, the other with 0.088% capsaicin) induced GER and that the magnitude of the induced reflux was related to the kind of chili (Milke et al. 2006).

A trial of guajillo chili (a cultivar of *Capsicum annuum* L. var. *annuum*) in patients with irritable bowel syndrome (IBS) indicated that ingestion of 1 g of guajillo chili (0.112% capsaicin) did not change IBS symptoms but did induce upper abdominal discomfort and lowered the rectal pain threshold. The authors indicated that guajillo chili may induce rectal hyperalgesia (high sensitivity to pain) in persons with IBS (Schmulson et al. 2003).

No exacerbation of hemorrhoidal symptoms was observed after administration of 10 mg of ground cayenne pepper in patients with hemorrhoids (Altomare et al. 2006).

Ingestion of iron with a meal supplemented with 4.2 g of freeze-dried chili significantly inhibited iron absorption (Tuntipopipat et al. 2006).

A "sensory hyperreactivity" cough induced by inhalation of the compound capsaicin has been described (Millqvist 2000; Millqvist and Bende 2001; Millqvist et al. 2000). Cough was reported as an adverse event in a study of topical application of a capsaicin cream (0.075% capsaicin) (Ellison et al. 1997). The effects are believed to be due to aerosolization and subsequent inhalation of particles of dried cream (McKenna et al. 2002). Capsaicin activates the type 1 vanilloid receptor, a sensory receptor that stimulates coughing (Kissin 2008; Knotkova et al. 2008; Morice and Geppetti 2004; Nagy et al. 2004; Pingle et al. 2007; Szolcsanyi 2004).

Animal Pharmacological Studies

Topical application of cayenne tinctures at concentrations of 0.1 to 1% to rabbits indicated that such concentrations were nonirritant (Maruzen Pharmaceuticals 2002).

In Vitro Pharmacological Studies

The compound capsaicin inhibits the drug-metabolizing isoenzyme CYP2E1 (Surh and Sup Lee 1995).

In human ileocarcinoma cells, cayenne increased cell permeability (tight junction gap increase) (Jensen-Jarolim et al. 1998).

IV. Pregnancy and Lactation

A study on the administration of cayenne (2.75 mg capsaicin) daily for 5 days to rats during pregnancy indicated no adverse developmental effects on the fetus. Offspring of the rats showed a delayed response to acute heat stimuli. The authors of this study indicate that the compound capsaicin is capable of crossing the placental barrier (Pellicer et al. 1996).

No effects on parturition time, skeletal development, or weight of offspring was observed in rats subcutaneously administered 50 to 200 mg/kg of the compound capsaicin every other day on gestational days (GD) 7 through 15 (Perfumi and Sparapassi 1999). In rats subcutaneously administered 50 mg/kg capsaicin on GD 14, 16, 18, or 20, or on days 15 and 16, or 16 and 17, a reduced crown-rump length of fetuses was observed only in dams injected on day 18, and a decrease in fetal spontaneous activity and loss of fetal responsiveness to morphine were observed in offspring of mothers treated on days 16 and 17, but not on days 15 and 16. No skeletal or soft tissue malformations, differences in fetal weight or average number of fetuses, or incidences of resorption were observed (Kirby et al. 1982). Capsaicin was shown to cross the placenta in rats subcutaneously administered the compound at doses of 20 to 50 mg/kg (Atkinson and Chaggar 1983).

No information on the safety of cayenne during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of cayenne extract orally administered to rats is 23.58 ml/kg (Winek et al. 1982). The LD_{50} values of the compound capsaicin in mice via various routes of administration are 190 mg/kg (oral), 7.65 mg/kg (intraperitoneal), and 0.56 mg/kg (intravenous) (Glinsukon et al. 1980).

Short-Term Toxicity

In mice fed a diet of up to 10% cayenne for 4 weeks, only minor effects of cayenne were observed, including a slight glycogen depletion and anisocytosis of hepatocytes. General health, body weight, and food intake were apparently not affected, and no treatment-related changes were observed in any of the tissues examined (Jang et al. 1992).

Subchronic Toxicity

In rats intragastrically administered 0.5 g/kg cayenne powder daily for 60 days, some reduction in growth rate was observed as compared to control but no significant differences from control were observed in rectal temperature, water intake, plasma chemistry, urine dilution and concentration, or relative organ weights (Monsereenusorn 1983).

No significant adverse effects were observed in rats fed a diet of 2% cayenne for 8 weeks. In rats fed a diet of 10%, however, feed intake and growth rate were depressed and exfoliation of the intestinal epithelium into the lumen, cytoplasmic fatty vacuolation, and necrosis of the centrilobular hepatocytes were observed (al-Qarawi and Adam 1999).

Chronic Toxicity

Chronic administration of 20 µl cayenne extract (2.5 mg/ml capsaicin) to the cheek pouch of hamsters induced shrunken eyeballs and closing of the eyelids in 23% of the animals. This effect was not observed in hamsters that received a single application of the potent carcinogen methyl(acetoxymethyl) nitrosamine prior to repeated treatment with the cayenne extract (Agrawal et al. 1985).

In rabbits administered 5 mg/kg of cayenne daily for 12 months, spleen and liver weights were increased as compared to control animals. Microscopic observation of these organs revealed effects at the cellular level (Lee 1963).

Genotoxicity

Mutagenic activity of chilies (species unspecified) and the compound capsaicin was observed in the Ames mutagenicity test with *Salmonella typhimurium* with metabolic activation from S9 mix (Nagabhushan and Bhide 1986).

Cayenne extract and the compound capsaicin exhibited mutagenic activity in *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537, and TA1538 with metabolic activation. Capsaicin had more potent mutagenic effects than cayenne. Mutagenic activity of the same products was not observed in the micronucleus test or in the 8-azaguanine-resistant mutagenesis assay with Chinese hamster cells. Capsaicin inhibited DNA synthesis in the testes of Swiss mice injected at two dose levels (Nagabhushan and Bhide 1985).

Carcinogenicity

A case-control study of men in India with cancers of the oral cavity indicated that use of red chili powder was associated, in a dose-related manner, with an increased risk of cancers. Tea drinking was also observed to be a risk factor for esophageal cancers and, to a lesser extent, for pharyngeal cancers (Notani and Jayant 1987). Similarly, a case-control study of men and women in Mexico indicated that a dose-related trend of increasing risk of gastric cancer was reported with consumption of chili peppers (López-Carnllo et al. 1994). Conversely, a case-control study of men and women in Italy indicated that consumption of chili peppers was associated with a decreased risk of gastric cancer (Buiatti et al. 1989).

In rats administered cayenne as 10% of the diet for 2 years, neoplastic changes in the liver were observed after 6 months of treatment, with males more prone to tumor development. In female rats, cystic cholangiomas, solid cholangiomas, adenocarcinomas, and hepatomas were observed (Hoch-Ligeti 1951).

Rats fed 4 g/kg cayenne as part of the diet for 12 months were found to have a 35% incidence of adenocarcinoma of the abdomen, with no adenocarcinoma observed in the control group (Balachandran and Sivaramkrishnan 1995). A dose of 80 mg/kg daily cayenne for 30 days was associated with an 83% incidence of intestinal tumors or polyps, a 90% incidence of tumors or polyps in the positive control group treated with the carcinogen 1,2-dimethylhydrazine (DMH), and no such abnormalities in the untreated control group (Nalini et al. 1997). In rats administered cayenne alone, DMH alone, or a combination of the two, incidences of intestinal and colon tumors were 90% in the cayenne group, 93% in the DMH group, and 96% in the combination group. The authors of the study concluded that cayenne promoted the carcinogenesis of DMH (Chitra et al. 1997).

A review of studies on the anticarcinogenic and carcinogenic effects of the compound capsaicin indicated that small amounts of capsaicin had few or no deleterious effects, while heavy ingestion of the compound has been associated with necrosis, ulceration, and carcinogenesis. Capsaicin has also been shown to alter the metabolism of certain carcinogens, acting as a chemopreventive compound (Surh and Lee 1996).

Cytotoxicity

The compounds capsaicin and resiniferatoxin (both vanilloids) inhibit the NADH-electron transport system, activate c-Jun kinase (JNK) but not AP1, and induce apoptosis in transformed cells (Macho et al. 1998). Capsaicin, dihydrocapsaicin, and resiniferatoxin inhibit NADH oxidase and induce apoptosis (Vaillant et al. 1996; Wolvetang et al. 1996).

Carica papaya L.

Caricaceae

SCN: papaya

Part: leaf

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Adebiyi et al. 2002).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Animal studies on the compound papain provide conflicting information on the safety of this compound in pregnancy, with some studies demonstrating no adverse effects and other studies indicating an increase in fetal losses and other adverse effects on fetuses (Adebiyi et al. 2002; Devi and Singh 1978, 1979; Schmidt 1995; Singh and Devi 1976). Unripe papaya fruit is traditionally avoided by pregnant women in many Asian countries (Adebiyi et al. 2002). Different parts of the papaya plant have been used to produce abortion and to induce labor (Adebiyi et al. 2002; Kamatenesi-Mugisha and Oryem-Origa 2007).

No information on the safety of papaya leaf during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Testing of serum samples from 136 patients with well-documented, clinically relevant, immediate-type hypersensitivity against latex proteins ("latex fruit allergy") for IgE antibodies against a panel of different fruits indicated that 50% of test subjects had positive tests to papaya (Brehler et al. 1997). Sensitization to latex-containing fruits such as papaya, avocado, banana, fig, and kiwi has been reported in persons allergic to latex (Diaz-Perales et al. 1999; Marin et al. 2002).

Cases of occupational sensitization to the compound papain have been reported in a number of persons working with this compound. Sensitization has been confirmed by skin prick testing, detection of specific IgE antibodies, and specific bronchoprovocation tests (Van Kampen et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In rats orally administered 800 mg/kg of the compound papain daily on gestational days 0 to 6 or 6 to 15, a reduction in preimplantation losses was observed along with a lack of fetal abnormalities (Schmidt 1995).

Gross and histological examination indicated changes in the placenta of rats orally or intraperitoneally administered the compound papain on gestational days 8 to 17 (Devi and Singh 1978).

Intraperitoneal administration of the compound papain to pregnant rabbits on gestational days 10 to 20 was associated with fetal stunting, visceral and subcutaneous hemorrhages, and edema of various organs (Devi and Singh 1979; Singh and Devi 1976).

A slight increase in postimplantation losses was observed in rats fed diets containing papain on gestational days 4 to 8 (Gopalakrishnan and Rajasekharasetty 1978).

An ethnobotanical survey indicated that papaya leaf, fruit, and root are used in Uganda to induce labor (Kamatenesi-Mugisha and Oryem-Origa 2007). In isolated rat uteruses, papaya latex and the compounds papain and chymopapain induced spasmodic contraction of the uterine muscles (Adaikan and Adebiyi 2004; Adebiyi et al. 2002).

No information on the safety of papaya leaf during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Carthamus tinctorius L. — Asteraceae

SCN: safflower
AN: *kusumbha*
PN: *hong hua* (flower)
Part: flower

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: B

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bahmanfour and Javidnia 2003; Bahmanpour et al. 2003; Bensky et al. 2004; Chadha 1988; Chen and Chen 2004; Leung and Foster 1996; List and Hörhammer 1973; Tang and Eisenbrand 1992).

Not for use in patients with bleeding disorders, hemorrhagic diseases, or peptic ulcers (Bensky et al. 2004; Chang and But 1986; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

Concomitant use with anticoagulant medications should be under the supervision of a qualified healthcare practitioner (Chen and Chen 2004).

Notice

Abortifacient (List and Hörhammer 1973); *see* Appendix 2.

Uterine stimulant (Bensky et al. 2004; Chen and Chen 2004); *see* Appendix 2.

Editors' Note

The oil extracted from safflower and commonly used in cooking is distinct from the flower that is the subject of this entry. Concerns and considerations for the flower do not apply to the seed oil.

Adverse Events and Side Effects

Allergic reactions, including anaphylactic reactions, to safflower have been reported (Bensky et al. 2004).

Pharmacological Considerations

Safflower, and the food colorant safflower yellow, have been shown to have antiplatelet activity in animal and in vitro studies and may prolong blood coagulation time (Chen and Chen 2004; Zang et al. 2002; Zhu 1998).

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that safflower should not be used in pregnancy (Bensky et al. 2004; Chen and Chen 2004). Animal studies have shown that safflower has stimulating effects on the uterus and increases muscular contractions (Chen and Chen 2004; Shi et al. 1995; Wang 1983). Adverse effects on fetuses and embryos have been observed in pregnant rats administered safflower extracts (Bahmanfour and Javidnia 2003; Bahmanpour et al. 2003; Nobakht et al. 2000).

No information on the safety of safflower during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose (standard dose listed as 3–10 g in decoction) of safflower has been associated with bleeding, nausea, headache, dilated pupils, and an increase in intraocular pressure (Bensky et al. 2004; Chen and Chen 2004).

Allergic reactions, including anaphylactic reactions, to safflower have been reported (Bensky et al. 2004). Occupational asthma was reported in a worker that routinely handled dried safflower flowers (Compes et al. 2006).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In dogs intravenously administered 10 mg/kg aqueous extract of safflower, a 58% increase in coronary blood flow was observed. The alcohol extract, however, had no effect when administered at doses of 10 to 30 mg/kg (Wang 1983).

In dogs, an alcohol extract of safflower prolonged clotting time and serum thrombin time, and reduced serum prothrombin time. The compound carthamin inhibited ADP-induced platelet aggregation in rabbits. Doses used in these studies were not reported in the available English language translations (Zhu 1998).

In rats administered an extract of safflower, the extract was 73% effective in preventing the formation of thrombi. Dose, duration, and route of administration were not listed in the available English language translation (Chen and Chen 2004).

In Vitro Pharmacological Studies

Alcoholic and aqueous extracts of safflower inhibited ADP- and collagen-induced aggregation of rabbit and rat platelets (Zhu 1998). The food colorant safflower yellow inhibited ADP-induced platelet aggregation in rabbit blood platelets and prolonged the rabbit plasma prothrombin time (Zang et al. 2002).

An increase in the proliferation of estrogen receptor-positive human breast cancer cells (MCF-7) was observed in cells treated with serum from mice that had been administered a safflower extract. In cells treated with serum from animals administered diethylstilbestrol or diethylstilbestrol and safflower, the cells treated with the combination showed less proliferation than those administered diethylstilbestrol alone (Zhao et al. 2007).

In mice intraperitoneally administered 50 to 450 mg/kg of the food colorant safflower yellow daily for 8 days, a decrease in serum lysozyme concentration and phagocytosing functions of both peritoneal macrophages and peripheral leukocytes was observed. The treatment also diminished the production of plaque-forming cells and specific rosette-forming cells, and inhibited the delayed-type hypersensitivity reaction and the activation of T suppressor cells elicited by supraoptimal immunization (Lu et al. 1991).

IV. Pregnancy and Lactation

In mice intraperitoneally administered 1, 10, 25, or 50 mg/kg aqueous extract of safflower on days 7 or 8 of pregnancy as single dose and days 9 and 10 as multidose, congenital malformations were observed. Malformations included exencephaly, spina bifida, tail and limb necrosis, and malformation of the eye and eyelid (Bahmanfour and Javidnia 2003; Bahmanpour et al. 2003).

In mice orally administered 0.2, 0.8, 1.2, 1.6, or 2.0 mg/kg safflower aqueous extract daily on days 0 through 8 of gestation, resorption of embryos was observed in the animals receiving 1.6 and 2 mg/kg daily. In animals receiving 1.2 mg/kg daily, changes in external, internal, and longitudinal diameters as well as cellular orientation and degeneration were observed (Nobakht et al. 2000).

An extract of safflower was found to have a stimulating effect on the H1-receptor and α-adrenergic receptor in isolated rat uteri (Shi et al. 1995). A translation of the Chinese scientific literature indicates that several animal studies have shown that safflower has a stimulating effect on the smooth muscle of the uterus and increases muscle contraction, with the effect being more pronounced in pregnant uteri (Chen and Chen 2004; Wang 1983).

No information on the safety of safflower during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound carthamin orally administered to mice could not be determined at doses up to 8 g/kg (Zhu 1998). The LD_{50} of the food colorant safflower yellow intraperitoneally administered to mice was 7.54 g/kg (Zang et al. 2002).

Subchronic Toxicity

No abnormalities were observed in the liver, kidney, heart, stomach, or intestines of rats administered up to 1.5 g/kg safflower extract daily for 90 days. Route of administration was not specified in the available English language translation (Chen and Chen 2004).

In rats intraperitoneally administered 20, 60, or 180 mg/kg of the food colorant safflower yellow daily for 90 days, a prolonged blood coagulation time without changes in the normal blood coagulation process was observed in animals administered 60 or 180 mg/kg. The prolonged blood coagulation time was recovered to a normal level on the 28th day after withdrawing the test product. At the 180 mg/kg dose, some kidney injury was observed along with increases in the liver index without obvious pathological changes in liver histology. No adverse effects were observed in other organs (Liu et al. 2004). Conversely, intraperitoneal administration of safflower extract has been shown to reduce renal dysfunction and injury in rats with induced renal ischemia and reperfusion (Gao et al. 2006).

Genotoxicity

No significant mutagenic activity of an aqueous safflower extract was observed in the Ames test in *Salmonella typhimurium* strains TA98 or TA100, nor in micronucleus or chromosomal aberration assays in mice (Yin et al. 1991).

Carum carvi L.

Apiaceae

SCN: caraway
AN: *krishna jiraka*

Part: fruit (commonly known as "seed")

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that caraway may modify glucose regulation (Eddouks et al. 2004; Ene et al. 2008). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of caraway in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a patient with occupational allergy to anise seed, a skin prick test showed immediate positive responses to caraway and other spices and foods including coriander, cumin, dill, fennel, and asparagus. Skin prick tests with celery, carrot, birch pollen, and mugwort pollen extracts were negative (Garcia-Gonzalez et al. 2002).

Caraway seed oil was nonirritating when applied for 48 hours at a c oncentration of 4% in human patch tests (Opdyke 1979).

Animal Pharmacological Studies

A significant decrease in blood glucose was observed in diabetic rats orally administered a single dose of 20 mg/kg aqueous extract of caraway seed. In diabetic animals administered 20 mg/kg of the extract daily for 15 days, blood glucose levels were nearly normalized. No highly significant changes in blood glucose were observed in healthy rats under either the single or repeated treatments (Eddouks et al. 2004). In diabetic rats orally administered 5, 10, 20, 40, or 80 mg/kg caraway seed oil daily for 10 weeks, a significant reduction in blood glucose was observed in animals receiving the 10 mg/kg dose (Ene et al. 2008).

No irritation was observed after caraway seed oil was applied to the back of hairless mice, although irritating effects were observed after application to intact or abraded rabbit skin (Opdyke 1979).

In Vitro Pharmacological Studies

No relevant in vitro studies were identified.

IV. Pregnancy and Lactation

No information on the safety of caraway in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered caraway seed oil in rats is 3.5 ml/kg. The dermal LD_{50} of the same product applied to rabbits is 1.78 ml/kg (Opdyke 1979).

Subchronic Toxicity

In rats orally administered 5, 10, 20, 40, or 80 mg/kg caraway seed oil daily for 10 weeks, elevated levels of liver marker enzymes (AST, ALT, ALP) were observed in animals receiving doses of 20 mg/kg or more (Ene et al. 2006).

Genotoxicity

In Ames tests for mutagenicity, no mutagenic activity of water, methanol, or hexane extracts of caraway was observed in *Salmonella typhimurium* strains TA98 and TA100 (Higashimoto et al. 1993), while an ethanol extract showed moderate mutagenic activity in strains TA98 and TA102 (Mahmoud et al. 1992).

Catharanthus roseus (L.) G. Don — Apocynaceae

SCN: Madagascar periwinkle
Syn: *Vinca rosea* L.

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Gupta 2009; Gupta and Mathur 2009; List and Hörhammer 1973; Mathur et al. 1996).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Gupta 2009; List and Hörhammer 1973; Mathur et al. 1996); *see* Appendix 2.

Editors' Note

The compounds vinblastine and vincristine, isolated from Madagascar periwinkle, are used as chemotherapy agents in the treatment of various cancers (Leveque and Jehl 2007; van Der Heijden et al. 2004). The concentration of these compounds in Madagascar periwinkle is very low (~2 ppm for vinblastine) (van Der Heijden et al. 2004).

Adverse Events and Side Effects

Animal studies have demonstrated adverse effects of high doses of Madagascar periwinkle on testicular cells (Mathur et al. 1996; Mathur and Chaudan 1985).

A case of severe bone marrow depression has been reported in association with use of Madagascar periwinkle (Wu et al. 2004). Animal studies have indicated depletion of white blood cells and bone marrow depression after injections, but not after oral use, of Madagascar periwinkle (Noble et al. 1958; Svoboda et al. 1962).

Pharmacological Considerations

Animal studies have demonstrated that Madagascar periwinkle may modify glucose regulation (Ahmed et al. 2007; Chattopadhyay et al. 1991; Nammi et al. 2003; Singh et al. 2001). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Studies have indicated that Madagascar periwinkle reduced the number of viable fetuses in pregnant animals (Gupta 2009; Gupta and Mathur 2009; Mathur et al. 1996). Based on this information, use in pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of Madagascar periwinkle during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Severe bone marrow depression was reported in a 67-year-old woman with a history of diabetes, hepatitis C, and liver cancer. The woman had consumed unspecified amounts of the juice of Madagascar periwinkle for 5 days prior to the onset of symptoms (Wu et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Injections of different extracts and extract fractions of Madagascar periwinkle led to depletion of white cells and bone marrow depression in rats. Such effects were reportedly not seen after oral administration (Noble et al. 1958; Svoboda et al. 1962).

In male rats orally administered 150 or 300 mg/kg of an ethanol extract of Madagascar periwinkle, testicular necrosis, hyalinization of tubules and Sertoli cell-only-syndrome was observed. Biochemical studies revealed reductions in glycogen and fructose levels in reproductive tissues (Mathur and Chaudan 1985).

Decreases in the weights of the prostate and seminal vesicles were observed in male mice intramuscularly administered 10 mg of a petroleum ether extract or ethanol extract of Madagascar periwinkle every other day for 20 days (Mathur et al. 1996).

In mice intramuscularly administered 10 mg daily of a petroleum ether extract of Madagascar periwinkle along with 17β-estradiol, inhibition of uterine weight gain was observed as compared to estradiol alone (Gupta 2009).

In diabetic rats orally administered 0.5 or 1 ml/kg of Madagascar periwinkle juice, or 300 or 450 mg/kg of an aqueous extract of Madagascar periwinkle, a reduction in serum glucose levels was observed (Ahmed et al. 2007). In diabetic rats orally administered 500 mg/kg of a dichloromethane-methanol extract of Madagascar periwinkle daily for 7 or 15 days, significant hypoglycemic activity was observed (Singh et al. 2001).

Oral administration of 0.5, 0.75, and 1.0 ml/kg of Madagascar periwinkle juice to healthy or diabetic rabbits resulted in dose-dependent reduction in blood glucose of both healthy and diabetic rabbits. Activity was comparable to the positive control, 40 µg/kg glibenclamide (Nammi et al. 2003).

In Vitro Pharmacological Studies

An aqueous extract of Madagascar periwinkle inhibited the drug-metabolizing isoenzyme CYP2D6 (Usia et al. 2006). The compounds serpentine and ajmalicine were identified as the most potent inhibitors among tested compounds from Madagascar periwinkle (Usia et al. 2005).

A dichloromethane–methanol–water extract of Madagascar periwinkle demonstrated toxicity in Chang liver cells and adipose cells at concentrations of 12.5 µg/ml (van de Venter et al. 2008).

IV. Pregnancy and Lactation

Total inhibition of pregnancy was observed in mice administered 10 mg (per mouse) of a petroleum ether extract or ethanol extract of Madagascar periwinkle on gestational days 7 to 9 (Mathur et al. 1996).

A study in rats indicated abortifacient activity of Madagascar periwinkle administered on days 1 to 10 of pregnancy. Details on dose and product used were lacking (Adhikary et al. 1990).

In mice intramuscularly administered 2, 5, or 10 mg daily of petroleum ether extract of the leaf of Madagascar periwinkle on gestational days 7 to 9, no implantation sites were found in animals given the 10 mg dose, while 20% implantation was observed at the 2 mg dose and 48% implantation was observed at the 5 mg dose, as compared to 85% implantation in the control group (Gupta 2009; Gupta and Mathur 2009).

No information on the safety of Madagascar periwinkle during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an aqueous extract of Madagascar periwinkle intraperitoneally administered in mice is 3.16 g/kg (Sarma et al. 1997).

No mortalities were observed in mice orally administered 10 g/kg of an aqueous extract of Madagascar periwinkle (Sarma et al. 1997).

No adverse effects were observed in rats intraperitoneally administered up to 4 g /kg of a water-soluble fraction of ethanolic extract of Madagascar periwinkle (Chattopadhyay et al. 1991).

Genotoxicity

In the Ames test for mutagenicity, with *Salmonella typhimurium* strains TA98 and TA100, a methanol extract of Madagascar periwinkle exhibited some mutagenic activity in strain TA98 with but not without metabolic activation. No mutagenic activity was observed in strain TA100 or in the VitoTOX assay (Elgorashi et al. 2003).

Caulophyllum thalictroides (L.) Michx.

Berberidaceae

SCN: blue cohosh
OCN: papoose root

Part: root

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use during pregnancy except under the supervision of a q ualified healthcare practitioner (Dugoua et al. 2008; Flynn et al. 1998; Kennelly et al. 1999).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (De Smet 1993); Emmenagogue (De Smet 1993); *see* Appendix 2.

Editors' Note

Blue cohosh contains *N*-methylcytisine, an alkaloid that is similar in action to nicotine in its ability to stimulate intestinal activity, increase respiration, and elevate blood pressure. Blue cohosh also contains caulosaponin, a g lycoside that can act as a coronary vasoconstrictor and is believed to be responsible for stimulation of uterine contractions and induction of labor (Ferguson and Edwards 1954; McFarlin et al. 1999; Satchithanandam et al. 2008; Scott and Chin 1943).

Adverse Events and Side Effects

Myocardial infarction, profound congestive heart failure, multiorgan failure, and perinatal stroke have been reported in infants born of mothers using blue cohosh, sometimes in combination with black cohosh or other herbs, before birth (Finkel and Zarlengo 2004; Gunn and Wright 1996; Jones and Lawson 1998).

Pharmacological Considerations

Increased uterine tone and uterine spasms have been reported in human and animal studies of isolated compounds of blue cohosh (Ferguson and Edwards 1954; Pilcher et al. 1916; Pilcher and Mauer 1918; Vinks et al. 1982).

Pregnancy and Lactation

Blue cohosh has been used to augment labor and also for up to several weeks prior to the due date as a parturifacient (Felter and Lloyd 1898) and was officially listed as a labor inducer in the U.S. Pharmacopoeia from 1882–1905. There have been a small number of serious adverse events reported in infants born to mothers taking blue cohosh several weeks prior to birth. A 1999 survey of nurse midwives found that 64% used blue cohosh, often in combination with black cohosh, to augment labor during delivery. This survey noted that blue cohosh is the herb midwives have the least comfort with during pregnancy and a significant number had observed an increased rate of meconium, tachycardia, and need for resuscitation in association with its use (McFarlin et al. 1999). It is unclear, however, whether these adverse events were associated with the use of blue cohosh itself or with the conditions that led to its use, such as post-term pregnancy (Romm 2005).

Eclectic physicians of the early 20th century and some midwives today utilize small amounts of blue cohosh during pregnancy for threatened miscarriage. The safety of blue cohosh in early pregnancy is questionable, however, given that compounds isolated from blue cohosh caused fetal malformations in rat embryo cultures (Flynn et al. 1998; Kennelly et al. 1999).

Given the current information, it is advisable to limit use of blue cohosh in pregnancy only under the supervision of a practitioner who is familiar with its use and who can appropriately monitor both the mother and infant for possible adverse effects. *Also see* Adverse Events and Side Effects *and* Pharmacological Considerations for this entry.

No information on the safety of blue cohosh during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of suspected drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A survey of 172 nurse midwives indicated that 90 regularly used herbal preparations to stimulate labor. Of these 90, 64% reported using blue cohosh. Adverse events data included in the results of this survey did not separate black cohosh (*Actaea racemosa*) and blue cohosh; the adverse events reported for the two botanicals were nausea, increased meconium-stained fluid, and transient fetal tachycardia. The frequency of these events was not indicated (McFarlin et al. 1999).

Acute myocardial infarction, congestive heart failure, and cardiogenic shock were reported in a newborn infant whose mother had taken blue cohosh. The mother had taken 3 tablets of blue cohosh daily for 3 weeks at the end of her pregnancy, although the recommended dose was 1 tablet daily (Jones and Lawson 1998). A review of the traditional herbal literature indicated that the dose taken in the case constituted an overdose (Bergner 2001).

After an apparently healthy pregnancy and normal labor, a newborn infant was not able to breathe spontaneously and had CNS hypoxic-ischemic damage. The midwife attending the birth had given blue cohosh and black cohosh (dose and duration unspecified) to induce labor. At 3 months of life, the child had lower limb spasticity and required nasogastric tube feeding (Gunn and Wright 1996).

Perinatal stroke was reported in a 26-hour-old infant whose mother had taken a blue cohosh-containing tea (dose and duration unspecified). Urine and stool samples of the infant tested positive for the cocaine metabolite benzoylecgonine. Analyses of the blue cohosh product that the mother had taken and a different preparation of blue cohosh were also reported to test positive for benzoylecgonine. The authors of this report suggested that either benzoylecgonine is a metabolite of both cocaine and blue cohosh or that the blue cohosh was contaminated with cocaine (Finkel and Zarlengo 2004). Comments on this report have indicated

that no published evidence exists that blue cohosh contains benzoylecgonine or any compound that could be metabolized to benzoylecgonine (Chan and Nelson 2004; Potterton 2004). In response to these comments, the reporting physicians indicated that maternal cocaine use, an insensitive immunoassay, or incorrect interpretation of chemical analysis of the product were possible explanations for the detection of benzoylecgonine (Finkel and Zarlengo 2004). Another analysis of the case report indicated that a false-positive reading from the analytical test used was likely and that blue cohosh contains a phytochemical that looks like the cocaine metabolite in terms of the tests used but is not related in any way to cocaine (Mills and Bone 2005).

A 21-year-old woman who had taken 10 to 20 doses (dose amount unspecified) of blue cohosh tincture daily for 4 days during weeks 5 or 6 of pregnancy in an attempt to induce abortion was diagnosed with nicotinic toxicity. Symptoms included hypertension, tachycardia, vomiting, diaphoresis, and muscle fasciculations of the abdominal wall. The woman was also taking slippery elm orally and using slippery elm and parsley douches (Rao and Hoffman 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

The compound sparteine was found to cause uterine spasms in a small percentage (~5%) of women who were unable to metabolize the compound (Eichelbaum et al. 1979; Vinks et al. 1982).

Animal Pharmacological Studies

In dogs administered an extract of blue cohosh, no effect on the uterus was observed (Pilcher and Mauer 1918). Intravenous administration of caulosaponin to rats and to in situ rat uteruses at a dose of 5 or 10 mg/kg increased uterine tone and rate of contraction (Ferguson and Edwards 1954).

In Vitro Pharmacological Studies

A methanol extract of blue cohosh showed no effects on CYP450 isoenzymes. A combination of alkaloids isolated from the extract showed inhibition of CYP2C19, CYP3A4, CPY2D6, and CYP1A2 (Madgula et al. 2009).

IV. Pregnancy and Lactation

Also see Case reports of adverse events *and* Pharmacology and Pharmacokinetics for this entry.

In a rat embryo culture system, the compound caulophyllumine was embryotoxic, producing 100% lethality at a concentration of 5 µg/ml, and the compound *N*-methylcytisine was described as potentially teratogenic with neural tube defects observed at a concentration of 80 µg/ml. No teratogenic effects were observed for the compound anagyrine at a concentration of 500 µg/ml, although inhibition of embryo growth and development was observed (Flynn et al. 1998). A second rat embryo culture study on alkaloids of blue cohosh found that *N*-methylcytisine exhibited teratogenic activity, whereas taspine showed high embryotoxicity but no teratogenic activity, and other alkaloids did not produce teratogenic effects (Kennelly et al. 1999).

No information on the safety of blue cohosh during lactation was identified.

V. Toxicity Studies

Acute Toxicity

In mice, the LD_{50} of methylcytisine could not be determined at doses up to 500 mg/kg after oral administration, and is 51 mg/kg after intraperitoneal administration and 21 mg/kg after intravenous administration (Barlow and McLeod 1969).

The LD_{50} of intravenously administered caulosaponin in mice is 12 mg/kg and in rats is 20 mg/kg. In these studies, increases in activity, ataxia, and clonic seizures were observed, and death was attributed to asphyxia (Ferguson and Edwards 1954).

Subchronic Toxicity

Subcutaneous administration of caulosaponin to rats at a dose of 5 mg/kg daily for 60 days did not produce any signs of toxicity (Ferguson and Edwards 1954).

Ceanothus americanus L. — Rhamnaceae

SCN: red root
OCN: Jersey tea; New Jersey tea

Part: root, root bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See *Pharmacological Considerations* below.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Early human, animal, and in vitro studies indicated that red root causes an increase in the speed of blood coagulation (Groot 1927; Lynch 1966; Lynch et al. 1958; Taylor 1927; Tharaldsen 1929; Tharaldsen and Krawetz 1927).

Pregnancy and Lactation

No information on the safety of red root in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A reduction in blood coagulation time was observed in healthy volunteers orally administered 15 or 30 ml of a hydroalcoholic extract of red root (Groot 1927).

Animal Pharmacological Studies

A reduction in blood coagulation time was observed in dogs intravenously administered a hydroalcoholic extract of red root, while no effects on coagulation time were observed after oral administration (Groot 1927).

Intravenous administration of 4 ml of red root hydroalcoholic extract to dogs was reported to lower blood pressure, while no effects on blood pressure were observed after oral administration (Groot 1927).

In Vitro Pharmacological Studies

A reduction in blood coagulation time was observed in blood treated with various fractions of red root extract (Lynch et al. 1958).

IV. Pregnancy and Lactation

No information on the use of red root during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Centaurium erythraea Rafn — Gentianaceae

SCN: centaury
OCN: common centaury; lesser centaury

Part: flowering top

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

An animal study indicated diuretic effects of centaury after several days of administration (Haloui et al. 2000).

Pregnancy and Lactation

No information on the safety of centaury in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered 10 ml/kg of an 8 or 16% aqueous extract of centaury daily for 7 days, enhanced diuresis was observed after 5 days. No increase was recorded for 24 hour urinary excretion of sodium, potassium, and calcium during the first 4 days of treatment with either extract, whereas the effects on those parameters were highly significant thereafter. No changes in plasma electrolytes or urea were observed (Haloui et al. 2000).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of centaury during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

In the brine shrimp lethality assay, the LC_{50} values of compounds isolated from centaury are 8 µg/ml for swertiamarin, 34 µg/ml for sweroside, and 24 µg/ml for gentiopicroside (Kumarasamy et al. 2003a, 2003b).

Genotoxicity

No mutagenic activity of a tincture or fluid extract of centaury was observed in *Salmonella typhimurium* strains TA98 or TA100, while an evaporated extract exhibited weak mutagenic activity in TA98 (Schimmer et al. 1994). Strong antimutagenic activity of the compounds eustomin and demethyleustomin were observed in *Salmonella typhimurium* strains TA98, TA100, and TA102 (Schimmer and Mauthener 1996).

Centella asiatica (L.) Urb.

Apiaceae

SCN: gotu kola
Syn: *Hydrocotyle asiatica* L.
AN: *brahmi; mandukaparni*

PN: *ji xue cao* (whole plant)
OCN: Asiatic pennywort; Indian pennywort
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

As a general rule, *Centella asiatica* is called "brahmi" in north and west India and "mandukaparni" in Kerala (south India), whereas *Bacopa monnieri* is "brahmi" in Kerala and "mandukaparni" in north and west India.

Adverse Events and Side Effects

Allergic contact dermatitis, confirmed by patch testing, has been reported after topical application of products containing gotu kola (Bilbao et al. 1995; Eun and Lee 1985; Izu et al. 1992; Morante et al. 1998; Santucci et al. 1985; Vena and Angelini 1986).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No adverse effects on fetal development were observed in the offspring of mice administered fresh juice of gotu kola (equivalent to 20 to 80 g/kg of fresh plant) for either 14 or 21 days beginning 7 days prior to mating (Dutta and Basu 1968).

No information on the safety of gotu kola during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Cases of jaundice and hepatotoxicity were reported in three women taking gotu kola tablets for weight loss for 21 to 60 days (products and doses not specified). The pathological diagnoses were granulomatous hepatitis with marked necrosis and apoptosis, chronic hepatitis with cirrhotic transformation and intense necroinflammatory activity, and granulomatous hepatitis. All patients improved after cessation of gotu kola, and one patient experienced a recurrence of jaundice after 2 weeks of re-exposure (Jorge and Jorge 2005).

Night eating syndrome was observed in a 41-year-old woman who had been taking a tincture of gotu kola (dose unspecified) for approximately 2 years. Onset of the syndrome was temporally associated with the use of gotu kola, and symptoms resolved after cessation of the tincture (O'Brien 2005).

Allergic contact dermatitis, confirmed by patch testing, has been reported after topical application of products containing gotu kola (Bilbao et al. 1995; Eun and Lee 1985; Izu et al. 1992; Morante et al. 1998; Santucci et al. 1985; Vena and Angelini 1986).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Weak sensitization capacity of gotu kola was observed in guinea pigs after repeated topical application (Hausen 1993).

A reduction in conception rates was observed in mice orally administered fresh juice of gotu kola (equivalent to 20–80 g/kg of fresh plant) for either 14 or 21 days beginning 7 days prior to mating. Conception rates were approximately 45% for treated animals and 85% for untreated controls (Dutta and Basu 1968).

Administration of ethanol, methanol, and *n*-butanol extracts but not a water extract of gotu kola to rats at doses of 28 ml/kg daily for 14 days inhibited in vitro platelet reactivity. The ethanol extract also inhibited dynamic coagulation (Satake et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No adverse effects on fetal development were observed in the offspring of mice orally administered fresh juice of gotu kola (equivalent to 20–80 g/kg of fresh plant) for either 14 or 21 days beginning 7 days prior to cohabitation with males (Dutta and Basu 1968).

No information on the safety of gotu kola during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered hydroalcoholic extract of gotu kola in rats could not be determined at doses up to 675 mg/kg (De Lucia et al. 1997).

Short-Term Toxicity

No adverse effects were observed in rats orally administered 150 mg/kg of a hydroalcoholic extract of gotu kola daily for 30 days. Plasma glucose and protein levels showed no changes, and no alterations in the stomach, liver, spleen, or kidneys were observed (De Lucia et al. 1997).

No adverse effects were observed in mice orally administered up to 1 mg/kg gotu kola aqueous extract daily for 15 days (Rao et al. 2005).

Genotoxicity

Mutagenic activity of aqueous and ethanolic extracts of gotu kola was observed in *Salmonella typhimurium* strain TA98 with but not without metabolic activation (Mills and Bone 2005; Rivera et al. 1994). Conversely, weak to moderate inhibition of mutagenicity was observed in *Salmonella*

typhimurium strains TA98 and TA100 treated with a gotu kola extract (Yen et al. 2001), and a dose-dependent decrease in chemically induced genotoxic damage (chromosomal aberrations and sister chromatid exchanges) was observed in human lymphocytes treated with gotu kola extracts (Siddique et al. 2008).

Cephaelis ipecacuanha (Brot.) Tussac — Rubiaceae

SCN: ipecac
Syn: *Psychotria ipecacuanha* (Brot.) Stokes

OCN: Brazilian ipecac; ipecacuanha; Rio ipecac
Part: rhizome

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (CFR 2011; Manno and Manno 1977; Manoguerra and Cobaugh 2005; Quang and Woolf 2000).

Other Precautions

Sufficient doses will cause nausea and vomiting in most people (Lloyd 1897; Manno and Manno 1977; Manoguerra and Cobaugh 2005; Silber 2005; Wichtl 2004; Wood and LaWall 1926).

Drug and Supplement Interactions

None known.

Standard Dose

The emetic dose of ipecac syrup (U.S.P.) is 15 ml (CFR 2011). The standard therapeutic dose for ipecac as an expectorant is achieved at an adult dose of 0.4 to 1.4 ml of ipecac syrup (U.S.P.) (Martindale and Reynolds 1996).

For emetic purposes, a single dose is required for 80–85% of patients, while 10–15% require two doses, and 4–5% of patients do not vomit after administration of ipecac (Manoguerra and Cobaugh 2005).

Notice

Emetic (Leung and Foster 1996; Martindale and Reynolds 1996; Wichtl 2004; Wood and LaWall 1926); *see* Appendix 2.

Editors' Notes

Ipecac syrup sold in the United States must be in packages of less than 1.0 ounce and labeled with contraindications for use in unconscious persons, or following the consumption

of "strychnine, corrosives such as alkalies (lye) and strong acids, or petroleum distillates such as kerosene, gasoline, coal oil, fuel oil, paint thinner, or cleaning fluid." Packaging must also direct the user to call a physician, poison control center, or hospital prior to use, and to keep the product out of reach of children. Labeling should also indicate that the standard dose of ipecac syrup is 1 tablespoon (15 ml) in persons over 1 year of age (CFR 2011).

Concentrated preparations such as fluid extracts of ipecac can be extremely toxic (Gilman et al. 1985; Martindale and Reynolds 1996) and should be used only under proper supervision. Ipecac has an irritant effect on the skin and mucous membranes and should be handled with care. Inhalation of airborne dust from ipecac has been associated with induction of asthma and sensitization to ipecac (Persson 1991; Wichtl 2004).

Adverse Events and Side Effects

Sufficient doses of ipecac syrup generally induce vomiting within 15 to 30 minutes after ingestion (Manoguerra and Cobaugh 2005).

Adverse events associated with use of ipecac for induction of vomiting include violent and prolonged vomiting, diarrhea, atypical lethargy, rupture of the stomach, tears of the upper gastrointestinal tract, hemorrhagic gastroenteritis, slowing of the heart rate, brain hemorrhages, and air in the space between the lungs (pneumomediastinum) (Czajka and Russell 1985; Quang and Woolf 2000).

Chronic ipecac abuse by anorexic or bulimic individuals has been associated with cardiac toxicity, generalized muscle weakness, metabolic disturbances, shock, and death (Quang and Woolf 2000).

Pharmacological Considerations

Use of ipecac in the management of poisonings is now discouraged by a number of organizations, with activated charcoal or other treatment protocols being recognized as safer and more effective (Manoguerra and Cobaugh 2005; Meadows-Oliver 2004; Silber 2005).

In 2003, the American Academy of Pediatrics issued a policy statement recommending that ipecac syrup no longer be routinely used in the home as a poison treatment strategy (AAP 2003). A 1997 joint statement issued by American and European toxicology organizations recommended that ipecac syrup not be routinely administered in the management of poisoned patients (Krenzelok et al. 1997). A 2005 statement from the American Association of Poison Control Centers provided further clinical guidelines indicating that ipecac may be appropriate for use in a limited number of situations. These guidelines indicate that, for emetic purposes, ipecac syrup should not be used unless directed by a healthcare professional, and should not be used if:

- A patient is comatose or has altered mental status and the risk of breathing in the stomach contents is high.
- The patient is having convulsions.
- The substance ingested is capable of causing altered mental status or convulsions.
- The substance ingested is a caustic or corrosive agent.
- The substance ingested is a low viscosity petroleum distillate with the potential for pulmonary aspiration.
- The patient has a medical condition that may be exacerbated by vomiting (e.g., severe hypertension, bradycardia, hemorrhagic diathesis) (Manoguerra and Cobaugh 2005).

Other guidelines list additional "relative contraindications" beyond the "absolute contraindications" listed above. These guidelines indicate that ipecac should not be used if:

- The patient is already vomiting.
- More than 1 hour has passed since ingestion of the product of concern.
- The patient is susceptible to bleeding or hemorrhaging (bleeding diathesis).
- An oral antidote to the consumed poison is available.
- The patient is less than 6 months of age.
- The patient is elderly or has a history of heart disease.
- The patient ingested cardiotoxic drugs (calcium-channel blockers, beta blockers) (Quang and Woolf 2000).

Ipecac should not be used in persons with heart disease (Gilman et al. 1985; Mitchell 1983).

Pregnancy and Lactation

No studies on the safety of ipecac during pregnancy or lactation were identified. Based on the emetic effects, use of ipecac during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Adverse events associated with use of ipecac for induction of vomiting include violent and persistent vomiting, gastric rupture, Mallory-Weiss tears, hemorrhagic gastroenteritis, bradycardia, cerebral hemorrhages, and air in the space between the lungs (pneumomediastinum) (Quang and Woolf 2000). Cases of protracted vomiting (in some cases, lasting for several days) have been reported in 2- to 4-year-olds administered 15 to 30 ml of ipecac syrup. Some of these cases were fatal (Manno and Manno 1977).

Chronic ipecac abuse by anorexic or bulimic individuals has been associated with cardiac toxicity characterized by PR prolongation, T-wave abnormalities, QRS abnormalities, congestive cardiomyopathy, and atrial and ventricular dysrhythmia. Generalized muscle weakness, myopathy, diarrhea, mild tremors, edema, dehydration, metabolic disturbances (hypokalemia, hypochloremic acidosis, elevation of creatinine phosphokinase), shock, and death have also been reported after chronic use (Manno and Manno 1977; Quang and Woolf 2000).

Ipecac has an irritant effect on the skin and mucous membranes and should be handled with care. Inhalation of airborne dust from ipecac has been associated with induction of asthma and sensitization to ipecac (Persson 1991; Wichtl 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A follow-up study with 146 patients that had been administered ipecac syrup indicated that within 4 hours after ipecac-induced emesis, 33.6% had no symptoms and 17.1% experienced protracted emesis. Incidences of diarrhea and atypical lethargy were higher after ipecac-induced emesis than in patients not receiving ipecac syrup (Czajka and Russell 1985).

Animal Pharmacological Studies

In an animal model of anorexia nervosa, rats were intraperitoneally administered ipecac daily for 4 to 10 weeks. The treatment induced myopathy that resolved completely after 6 to 12 weeks after cessation of ipecac (Hopf and Goebel 1993).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No studies on the safety of ipecac during pregnancy or lactation were identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound emetine intraperitoneally administered in rats is 12.1 mg/kg, while that of the compound cephaeline is 9.9 mg/kg (Radomski et al. 1952).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No adverse effects of carob bean gum on fetal development were observed in animal studies (FAO/WHO 1981).

No information on the safety of carob bean gum during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Occupational asthma from repeated exposure to carob flour has been reported (Scoditti et al. 1996; van der Brempt et al. 1992). An allergic reaction to carob bean gum has been reported (Savino et al. 1999).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy human volunteers, the addition of carob bean gum (9.5 g/1000 kcal) to the diet for 2 weeks resulted in a significant reduction in the absorption of calcium, iron, and zinc as compared to the control diet, while the absorption of copper remained unchanged (Harmuth-Hoene et al. 1982).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No teratogenic effects of carob bean gum were observed in rats or mice orally administered up to 1300 mg/kg, hamsters administered up to 1000 mg/kg, or rabbits administered up to 196 mg/kg. A dose of 910 mg/kg was lethal to most pregnant rabbits, and a dose of 1300 mg/kg was lethal to 25% of pregnant mice (FAO/WHO 1981).

No information on the safety of carob bean gum during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered carob bean gum in rats could not be determined at doses up to 5 g/kg (FAO/WHO 1981).

Chronic Toxicity

No histopathological effects were observed in rats and mice fed diets containing 2.5 or 5.0% locust bean gum daily for 103 weeks. In male mice on the 5.0% diet, a depression in body weight gain was observed (Melnick et al. 1983; NTP 1981).

Genotoxicity

Weak mutagenic activity of a carob extract was observed in *Salmonella typhimurium* strains TA98 and TA100 (Alkofahi et al. 1990).

Part: thallus

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Iceland moss in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In clinical studies, pastilles containing amounts equivalent to 0.5 to 5 g of Iceland moss were generally well tolerated when taken daily for 4 or 5 days (Bradley 2006; ESCOP 2003).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

As compared to control animals, significantly less arthritis was observed in mice with antigen-induced arthritis subcutaneously administered 2.5 mg/kg of an aqueous Iceland moss extract twice a week for 14 days before arthritis was induced and continuing for 36 days after (Freysdottir et al. 2008).

In Vitro Pharmacological Studies

Upregulation of IL10 and IL12p40 secretion was observed in human monocyte-derived immature dendritic cells cultured with an aqueous extract from Iceland moss (Freysdottir et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of Iceland moss in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

Gastrointestinal upset was observed in mice fed diets containing 50% Iceland moss daily, and the mice died within 6 days (Airaksinen et al. 1986a).

Subchronic Toxicity

In rats fed diets containing 25% Iceland moss (pretreated either by boiling for 10 min, or soaking in a 2% wood ash solution for 2 days) for 3 months, kidneys of some animals had focal tubular damage and an increase in glomerular cell counts. Urinary protein levels were higher as compared to control. A reduction in weight gain was observed (Airaksinen et al. 1986b).

Chaenomeles speciosa (Sweet) Nakai — Rosaceae

SCN: flowering quince
Syn: *Chaenomeles lagenaria* (Loisel.) Koidz.
PN: *mu gua* (fruit)

OCN: Chinese quince; Japanese quince
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Although one reference text on traditional Chinese medicine contraindicates flowering quince in persons with excessive stomach acid (Bensky et al. 2004), another reference does not indicate any such concern (Chen and Chen 2004).

Adverse Events and Side Effects

Allergic reactions have been reported after topical exposure to flowering quince (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of flowering quince in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions have been reported after topical exposure to flowering quince (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

Chamaelirium luteum (L.) A. Gray — Liliaceae

SCN: false unicorn
OCN: blazing star; fairy wand; helonias

Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Large doses (standard dose listed as 0.5–1 g of powdered root) of false unicorn may be emetic (Felter and Lloyd 1898).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Historically, false unicorn has been used to treat morning sickness and to reduce the risk of miscarriage in women with a history of miscarriage (Felter and Lloyd 1898).

No information on the safety of false unicorn in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An aqueous-ethanolic extract of false unicorn showed no significant binding activity in assays with estradiol and progesterone receptors (Zava et al. 1998).

IV. Pregnancy and Lactation

Historically, false unicorn has been used to treat morning sickness and to reduce the risk of miscarriage in women with a history of miscarriage (Felter and Lloyd 1898).

No information on the safety of false unicorn during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Chamaemelum nobile (L.) All. — Asteraceae

SCN: Roman chamomile
Syn: *Anthemis nobilis* L.

OCN: dog fennel; English chamomile
Part: flower

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Kochmann 1931; van Itallie et al. 1932).

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as feverfew or chamomile) should exercise caution with Roman chamomile, as allergic cross-reactivity is common to Asteraceae plants (Hausen 1979).

Drug and Supplement Interactions

None known.

Notice

Abortifacient (List and Hörhammer 1973); *see* Appendix 2.

Emmenagogue (List and Hörhammer 1973; Palma 1964; Saha et al. 1961); *see* Appendix 2.

Adverse Events and Side Effects

Allergic reactions to Roman chamomile have been reported and confirmed by patch testing (Bossuyt and Dooms-Goossens 1994; Giordano-Labadie et al. 2000; Hausen 1979; McGeorge and Steele 1991; Paulsen 2002; Pereira et al. 1997).

Pharmacological Considerations

None known.

Pregnancy and Lactation

References from the 1930s indicate that Roman chamomile was an ingredient in abortifacient formulas sold in

Germany at that time (Kochmann 1931; van Itallie et al. 1932). Emmenagogue activity of Roman chamomile has been reported (Palma 1964; Saha et al. 1961). Based on these reports, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of Roman chamomile during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A student in an aromatherapy class became light-headed, with tachycardia, high blood pressure, and nausea, after inhaling Roman chamomile essential oil (Maddocks-Jennings 2004).

Contact dermatitis from Roman chamomile tea and a topical cream containing Roman chamomile have been reported and confirmed by patch testing (Bossuyt and Dooms-Goossens 1994; Giordano-Labadie et al. 2000; McGeorge and Steele 1991; Pereira et al. 1997). Sesquiterpene lactone compounds in Roman chamomile are generally recognized as being responsible for this effect (Paulsen 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Among 290 patients with eczema, patch testing with 5% Roman chamomile elicited a positive reaction in only one person (Meneghini et al. 1971). Patch testing with Roman chamomile in individuals with prior allergy to different Compositae plants indicated that 2 of 25 patients were allergic to Roman chamomile (Hausen 1979). A maximization test in 25 healthy volunteers indicated no sensitization reactions to 4% Roman chamomile essential oil (Opdyke 1979).

Animal Pharmacological Studies

In rats intravenously administered 50, 100, or 200 mg/kg of an aqueous extract of Roman chamomile, an increase in urine output was observed at the highest dose. Dose-dependent hypotensive activity was observed at all dose levels (Zeggwagh et al. 2007).

Undiluted Roman chamomile oil applied to the backs of hairless mice produced no irritating effects. Mild irritation was observed after the oil was applied full strength to intact or abraded rabbit skin for 24 hours (Opdyke 1979).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

References from the 1930s indicate that Roman chamomile was an ingredient in abortifacient formulas sold in Germany at that time (Kochmann 1931; van Itallie et al. 1932). Emmenagogue activity of Roman chamomile has been reported (Palma 1964; Saha et al. 1961).

No information on the safety of Roman chamomile during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of Roman chamomile could not be determined at doses up to 5 g/kg after oral or topical administration (Opdyke 1979).

Genotoxicity

No mutagenic activity of Roman chamomile essential oil was seen in the *Bacillus subtilis rec* assay and the *Salmonella*/microsome reversion assay (Zani et al. 1991).

Chamaesyce hirta (L.) Millsp.

Euphorbiaceae

SCN: pill-bearing spurge
Syn: *Euphorbia hirta* L.; *Euphorbia pilulifera* auct. non L.

OCN: asthma herb; garden euphorbia
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

As an expectorant, 2.0 g (Cook and Martin 1948; Powers et al. 1942); the emetic dose may be similar.

Notice

Diuretic (Johnson et al. 1999); *see* Appendix 2.

Adverse Events and Side Effects

May cause nausea and vomiting (Felter and Lloyd 1898; List and Hörhammer 1973).

Pharmacological Considerations

Traditional use and an animal study indicate that pill-bearing spurge is a diuretic (Johnson et al. 1999).

Pregnancy and Lactation

No information on the safety of pill-bearing spurge in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered single doses of 50 or 100 mg/kg of water or ethanol extracts of pill-bearing spurge daily, a time-dependent increase in urine output was observed. The water extract increased the urine excretion of sodium, potassium, and bicarbonate. In contrast, the ethanol extract increased the excretion of bicarbonate, decreased the loss of potassium, and had little effect on renal removal of sodium. The activity of pill-bearing spurge was noted as similar to the drug acetazolamide (Johnson et al. 1999).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

An ethnobotanical study indicated that pill-bearing spurge is used in Trinidad and Tobago to treat infertility (Lans 2007).

No information on the safety of pill-bearing spurge during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in chickens orally administered 2 g/kg of an aqueous extract of pill-bearing spurge. Parameters observed included liver enzyme levels and microscopic evaluation of livers and kidneys (Hashemi et al. 2008).

Short-Term Toxicity

In rats orally administered 10 g/kg of pill-bearing spurge aqueous extract daily for 14 days, leukocytosis, macrocytic hypochromic anemia, reduction in packed cell volume, and an elevation of liver enzyme levels (ALT and AST) were observed. By the end of the study, 20% of the animals in the pill-bearing spurge group had died (Adedapo et al. 2004).

Chelidonium majus L. — Papaveraceae

SCN: celandine
OCN: greater celandine

Part: herb

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (BfArM 2008).

Not for use in persons with biliary obstruction, having a history of liver disease, or taking substances contraindicated with liver disease (Benninger et al. 1999; BfArM 2008; Crijns et al. 2002; ESCOP 2003; Greving et al. 1998; Hardeman et al. 2008; Rifai et al. 2006; Stickel et al. 2003).

Not for use in excess of 2 to 4 weeks unless under the supervision of a qualified healthcare practitioner (BfArM 2008; ESCOP 2003; Mills and Bone 1999; Wichtl 2004).

Do not exceed recommended dose (ESCOP 2003).

Other Precautions

If signs of liver damage (yellowing of the skin or eyes, dark urine, abnormally colored stool, pain in the upper abdomen, nausea, loss of appetite, fatigue) are observed during celandine use, celandine use should be stopped, and appropriate medical attention should be sought (BfArM 2008).

Drug and Supplement Interactions

None known.

Standard Dose

The recommended dose is 125–700 mg of standardized hydroalcoholic extract (9–24 mg total alkaloids); 2–4 ml

of tincture three times daily; 1–2 ml of fluid extract three times daily (ESCOP 2003).

Notice

Berberine (0.011–0.25%) (Frohne and Pfänder 2000; Kursinszki et al. 2006; Osol and Farrar 1955; Sárközi et al. 2006; Tomè and Colombo 1995); *see* Appendix 1.

Editors' Note

Due to reported cases of liver toxicity, German regulatory authorities recommend that liver function values should be monitored if celandine is used for more than 4 weeks at a time at daily doses greater than 2.5 g or containing over 2.5 mg of alkaloids (calculated as chelidonin) (BfArM 2008; ESCOP 2003; Wichtl 2004).

Adverse Events and Side Effects

Cases of acute hepatitis, often cholestatic in nature, have been reported in persons taking celandine (Benninger et al. 1999; Crijns et al. 2002; Greving et al. 1998; Hardeman et al. 2008; Rifai et al. 2006; Stickel et al. 2003). None of the cases of hepatitis were fatal, and all were reversed on discontinuation of celandine. In some cases the patients were also taking pharmaceutical drugs that have been associated with cholestatic hepatitis (Huang and Liaw 1995; Kullak-Ublick and Meier 2000).

An herbal reference text notes that celandine infusions (hot water extracts) have significantly lower concentrations of alkaloids as compared to more recently available commercial extracts, and that the historical lack of adverse effects may be attributed to the lower alkaloid content in traditional preparations (Wichtl 2004).

Mild gastrointestinal disturbances, such as nausea, upset stomach, and diarrhea, have been reported as side effects of celandine (ESCOP 2003). Severe irritation of the digestive system has been reported in association with consumption of the fresh plant (Kingsbury 1964; Nelson et al. 2006).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of celandine in pregnancy or lactation was identified. In this work, the contraindications for use in pregnancy and lactation are based primarily on concerns regarding the cases of liver toxicity reported in association with celandine use, as the implications of these case reports, and possible mechanisms of liver toxicity, have yet to be fully understood.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A case series describes 10 incidences of acute hepatitis that were observed over a 2-year period. Cholestasis was observed in 5 of the 10 patients, and in 7 of the 10 cases, the hepatitis was characterized as drug-induced. No liver failure occurred in any of the patients, and cessation of celandine resulted in resolution of hepatitis. Use of celandine was from 1 to 9 months. Prescription and nonprescription drugs and herbal supplements were also being used in some cases, including thyroxine (2 patients), iodide (2 patients), estradiol (2 patients), and amitriptyline (1 patient) (Benninger et al. 1999). Cholestatic hepatitis has been associated with antithyroid medications, estradiol, and amitriptyline (Huang and Liaw 1995; Kullak-Ublick and Meier 2000; Larrey et al. 1988; Randeva et al. 2000).

Cholestatic hepatitis was reported in a 35-year-old woman who had been taking celandine for 4 months. The woman had been taking thyroxine for 5 years and took a course of roxithromycine in the month prior to the hepatitis (Greving et al. 1998). Severe cholestatic hepatitis was reported in a 39-year-old woman, with both incidences temporally related to the use of celandine. In both cases, the woman was taking or had recently finished taking either sulfamethoxazole or penicillin (Stickel et al. 2003).

Noncholestatic hepatitis was reported in a 28-year-old woman who had been taking celandine for 4 months (~4–8 mg of "active principle" per dose). The woman had been taking mestranol and chlormadinone acetate for several years, St. John's wort for 2 months, and had completed a course of tetracycline 6 months prior to the hepatitis (Greving et al. 1998).

Cholestatic hepatitis indicative of drug toxicity was reported in a 69-year-old man that had taken celandine capsules (about 2 daily, each containing 4 mg of chelidonin) (Stickel et al. 2003). A 58-year-old man experienced severe acute cholestatic hepatitis in association with use of a celandine and turmeric product (dose and duration of use not specified) (Rifai et al. 2006). A 42-year-old woman developed jaundice due to acute hepatitis after several weeks of

using celandine. Liver functions returned to normal within 2 months of withdrawal from celandine (Crijns et al. 2002). Acute hepatitis was reported in a 58-year-old woman after she began taking capsules of celandine, gentian, and turmeric (Hardeman et al. 2008).

Hemolytic anemia with kidney failure, liver cytolysis, and thrombocytopenia was reported in a 72-year-old woman who had occasionally consumed a tea of celandine (Pinto Garcia et al. 1990).

Overdose of celandine may cause abdominal pain, gastrointestinal cramps, urinary urgency, and hematuria (ESCOP 2003).

Contact dermatitis was reported in a 64-year-old woman who was using celandine juice topically (Etxenagusia et al. 2000).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No hepatoprotective activity was observed against carbon tetrachloride-induced liver toxicity in rats after animals were intraperitoneally administered 100 or 200 mg/kg of an aqueous extract of celandine (Sever Yilmaz et al. 2007).

Hepatoprotective, antitumor, and antigenotoxic activity was reported in mice with chemically induced liver tumors orally administered 0.1 ml daily (per 18 to 22 g animal) of an ethanol extract of celandine for 60 or 120 days (Biswas et al. 2008).

In Vitro Pharmacological Studies

Alkaloids isolated from celandine (chelerythrine, sanguinarine, berberine, and coptisine) had a significant inhibitory effect in mitochondrial respiration in mouse liver cells (Barreto et al. 2003).

IV. Pregnancy and Lactation

No information on the safety of celandine in pregnancy or lactation was identified.

V. Toxicity Studies

See *Sanguinaria canadensis* for additional toxicity studies on the compound sanguinarine.

Acute Toxicity

The LD_{50} of an intraperitoneally administered decoction of celandine in mice is 9.5 g/kg (Chang and But 1986). The LD_{50} of a subcutaneously administered extract of the alkaloids of celandine in mice is 300 mg/kg (Huang 1993).

The LD_{50} of intraperitoneally administered chelidonine in mice is 1.3 g/kg and in rats is 2 g/kg. Sublethal doses caused ptosis, tremor, sedation, and a decrease in body temperature (Jagiello-Wojtowicz et al. 1989).

Ingestion of 500 g of celandine can cause toxic effects in cattle and horses (Frohne and Pfänder 2000).

Subchronic Toxicity

No changes in liver enzymes were observed in pigs administered the compounds sanguinarine and chelerythrine (3:1 ratio) as 0.1 to 0.0002% of the diet for 90 days (Kosina et al. 2004).

Genotoxicity

DNA-damaging effects of the alkaloids chelidonine and sanguinarine were detected in the comet assay, with sanguinarine being active at a lower concentration than chelidonine (Philchenkov et al. 2008).

Cytotoxicity

In the brine shrimp lethality assay, the LC_{50} of chelidonine was 319 ppm, and for prototropine was 49 ppm. LC_{50} values for ethanol and aqueous extracts of celandine could not be determined at concentrations up to 1000 ppm (Saglam and Arar 2003).

Cytotoxic activity of an ethanolic celandine extract was observed in human lymphoblastoid cells treated with 10 or 50 µg/ml of the extract (Spiridonov et al. 2005).

The compounds chelidonine and sanguinarine induced apoptosis in human acute T-lymphoblastic leukemia MT-4 cells (Philchenkov et al. 2008).

Cytotoxicity tests in rat hepatocytes indicated that EC_{50} values for alkaloids isolated from celandine were as follows: 5 µg/ml for sanguinarine, 8 µg/ml for chelerythrine, 13 µg/ml for coptisine, 100 µg/ml for prototropine, and over 100 µg/ml for chelidonine (ESCOP 2003).

Chimaphila umbellata (L.) W.P.C. Barton

Pyrolaceae

SCN: pipsissewa
OCN: prince's pine

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of pipsissewa in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of pipsissewa in pregnancy or lactation was identified.

V. Toxicity Studies

The leaf of pipsissewa contains 18 to 22% of the compound arbutin (Shnyakina et al. 1981; Trubachev 1967). See *Arctostaphylos uva-ursi* Toxicity Studies for toxicity data on arbutin.

Chrysanthemum morifolium Ramat.

Asteraceae

SCN: chrysanthemum
Syn: *Chrysanthemum sinense* Sabine; *Dendranthema grandiflorum* (Ramat.) Kitam.; *Dendranthema morifolium* (Ramat.) Tzvelev

PN: *ju hua* (flower)
OCN: florist's chrysanthemum; mum
Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Persons highly sensitive to ragweed (*Ambrosia artemisiifolia*) may be sensitive to chrysanthemum.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Mild allergic skin reactions have been reported after ingestion of chrysanthemum (Bensky et al. 2004). Contact dermatitis has been reported after contact with fresh or dried chrysanthemum (Bensky et al. 2004; Frain-Bell et al. 1979; Goncalo et al. 1996; Sertoli et al. 1985; Sharma et al. 1989).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of chrysanthemum in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Mild allergic skin reactions have been reported after ingestion of chrysanthemum (Bensky et al. 2004).

Contact dermatitis to chrysanthemum has been reported after contact with the fresh or dried material (Bensky et al. 2004; Frain-Bell et al. 1979; Goncalo et al. 1996; Sertoli et al. 1985; Sharma et al. 1989). Airborne contact dermatitis has also been reported, primarily in workers in facilities that process chrysanthemums and other ornamental flowers (Sharma and Kaur 1989; Sharma et al. 1989).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of chrysanthemum during pregnancy or lactation was identified.

V. Toxicity Studies

Genotoxicity

Antimutagenic activity of flavonoid compounds from chrysanthemum has been observed in the Ames test for mutagenicity in *Salmonella typhimurium* strains treated with chemical mutagens (Miyazawa and Hisama 2003).

Chrysopogon zizanioides (L.) Roberty

Poaceae

SCN: vetiver
Syn: *Andropogon muricatus* Retz.; *Vetiveria zizanoides* (L.) Nash ex Small

AN: *ushira*
Part: root

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Caldecott 2006; Watt and Breyer-Brandwijk 1962).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Watt and Breyer-Brandwijk 1962); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

A text on Ayurvedic medicine indicates that vetiver should not be used during pregnancy (Caldecott 2006). Another reference reports that vetiver has been used as an abortifacient (Watt and Breyer-Brandwijk 1962). An ethnobotanical survey indicated that vetiver was one of a group of plants used to shorten labor and expel the placenta (Lans 2007).

No information on the safety of vetiver during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

An ethnobotanical survey of medicinal plants used for reproductive health in Trinidad and Tobago listed vetiver as one of a group of plants used to shorten labor and expel the placenta (Lans 2007).

A text on Ayurvedic medicine indicates that vetiver should not be used during pregnancy (Caldecott 2006). Another reference reports that vetiver has been used as an abortifacient, although no details are provided on dose, preparation, or whether the plant was used alone or in a formula (Watt and Breyer-Brandwijk 1962).

No information on the safety of vetiver during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Cichorium intybus L. — Asteraceae

SCN: chicory
AN: *kasni*

Part: roasted root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
Allergic skin reactions to chicory have been reported (Blumenthal et al. 1998), most likely due to the presence of sesquiterpene lactone compounds present in the fresh, unroasted plant material (Friis et al. 1975; Malarz et al. 2002; Pyrek 1985; Ross et al. 1993).

Animal studies have indicated that chicory root may modify glucose regulation (Kaur and Gupta 2002; Pushparaj et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of

this herb with a qualified healthcare practitioner prior to use.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of chicory in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A decrease in serum glucose levels with no change in serum insulin levels was observed in diabetic rats orally administered 125 mg/kg of an extract of whole chicory plant (Pushparaj et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of chicory in pregnancy or lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

No adverse effects, including clinical observations, changes in body weights, food consumption, clinical pathology, gross necropsy, and histology, were observed in rats orally administered up to 1 g/kg chicory root extract daily for 28 days. Based on the results of that study, the researchers indicated that the no-observed-adverse-effect level was 1 g/kg daily (Schmidt et al. 2007).

Genotoxicity

No mutagenic activity of a chicory root extract was observed in the Ames test for mutagenicity in *Salmonella* with or without metabolic activation (Schmidt et al. 2007).

Cinchona spp. Rubiaceae

Cinchona calisaya Wedd.
SCN: yellow cinchona
Syn: *Cinchona ledgeriana* Moens ex Trimen
OCN: calisaya; yellow quinine

***Cinchona officinalis* L.**
SCN: red cinchona
OCN: Jesuit's bark; Peruvian bark; red quinine

***Cinchona pubescens* Vahl**
SCN: red cinchona
OCN: red quinine
Part: bark

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Blaschek et al. 2006; Wichtl 2004).

Do not exceed recommended dose (Martindale and Reynolds 1996).

Other Precautions

The compound quinine may cause serious and potentially life-threatening hypersensitivity reactions in some individuals (Belkin 1967; BfR 2005; Brasic and Baltimore 2001; CFR 2011a; Howard et al. 2003).

Cinchona may cause gastrointestinal irritation; use with caution in persons with gastric or intestinal ulcers (Wichtl 2004).

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 1 to 4 g daily as a tea (Wichtl 2004).

Editors' Notes

Red and yellow cinchona are sources of the alkaloid quinine, which has been widely used as an antimalarial drug. Red and yellow cinchona typically contain 5–8% alkaloids (including quinine and related compounds), though may contain up to 15% (Bradley 1992; DAB 1987; McHale 1986; Wichtl 2004).

Red and yellow cinchona are regulated in the United States as allowable in carbonated beverages in certain salt forms as long as the content of quinine does not exceed 83 ppm and as long as the ingredient is identified on the label as "quinine" (CFR 2011b).

U.S. regulations for over-the-counter drugs require the following label for quinine and other *Cinchona* derivatives: Caution: Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur (CFR 2011c). In the United States, products containing quinine sulfate may not be marketed for use related to nocturnal leg cramps (CFR 2011a).

Adverse Events and Side Effects

Symptoms of "cinchonism," due to overdose of the compound quinine, include headache, nausea, distributed vision, tinnitus, delirium, abdominal pain, and diarrhea. Extreme reactions including blindness, deafness, convulsions, paralysis, collapse, and even death may occur in hypersensitive individuals (Gilman et al. 1985; Martindale and Reynolds 1996; Remington and Wood 1918).

The compound quinine has been reported to cause thrombotic thrombocytopenic purpura (a disorder that causes blood clots to form in small blood vessels and leads to a low platelet count) in sensitive individuals. This condition has been associated with use of quinine tablets and tonic water containing quinine. Individuals can become sensitized to cinchona alkaloids and develop sudden reactions after long-term use (Belkin 1967; Brasic and Baltimore 2001; Howard et al. 2003).

Allergic reactions to cinchona are relatively common (Wichtl 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

The compound quinine is reported to have been used as an abortifacient, although some sources indicate the compound is generally ineffective for this purpose and toxic to the mother (Dannenberg and Dorfman 1983). Based on this and related information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of red cinchona during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A review of elderly patients with lupus anticoagulant (LA) indicated that 73% were taking cinchona alkaloids. The frequencies of drug usage differed significantly from age- and sex-matched controls. Features suggestive of the antiphospholipid syndrome were observed in 5 patients. Repeat testing showed persistent LA activity in all but 2 of 5 patients in whom the relevant drug had been ceased (Bird et al. 1995).

The compound quinine has been reported to cause thrombotic thrombocytopenic purpura (a disorder that causes blood clots to form in small blood vessels and leads to a low platelet count) in sensitive individuals. This condition has been associated with use of quinine tablets and tonic water containing quinine (Belkin 1967; Brasic and Baltimore 2001; Howard et al. 2003).

Contact urticaria due to cinchona has been reported (Dooms-Goossens et al. 1986).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Photosensitizing activity of the compound quinine and derivatives has been reported (Spikes 1998; Waddell et al. 1997).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

The compound quinine is reported to have been used as an abortifacient, although some sources indicate the compound is generally ineffective for this purpose and is generally toxic to the mother (Dannenberg and Dorfman 1983).

The compound quinine is listed in FDA pregnancy category C, "Animal reproduction studies have shown an adverse effect on the fetus and there are no adequate and well-controlled studies in humans, but potential benefits may warrant use of the drug in pregnant women despite potential risks."

No information on the safety of red cinchona during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound quinine intraperitoneally administered in mice is 245 mg/kg (Carlson and Cretcher 1951).

Cinnamomum aromaticum Nees — Lauraceae

SCN: cassia
Syn: *Cinnamomum cassia* auct.
PN: *rou gui* (bark); *gui zhi* (twig)
OCN: Chinese cinnamon
Part: bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004; List and Hörhammer 1973).

Other Precautions

Use with caution in persons with sensitivity to balsam of Peru tree (Calnan 1976; Hoskins 1984; Pfutzner et al. 2003).

Drug and Supplement Interactions

None known.

Editors' Notes

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Several species of *Cinnamomum* are commonly traded under the name "cinnamon" (Leung and Foster 1996).

European authorities have raised concern over the coumarin content of cassia (BfR 2006; EFSA 2008). In the 1980s, coumarin was suspected to have genotoxic and carcinogenic effects, although more recent evidence suggests that coumarin is not genotoxic (Lake 1999; Sproll et al. 2008). As of 2008, the European Food Safety Authority indicated that the appropriate total daily intake (TDI) level of coumarin in foods was 0.1 mg/kg, and that intake of three times this amount for 1 to 2 weeks posed no concerns (EFSA 2008). The German Federal Institute for Risk Assessment (BfR) reviewed human clinical data from pharmaceutical use of coumarin and also concluded that 0.1 mg/kg was the acceptable TDI (BfR 2006). Others have questioned this TDI level since it is based on studies of an isolated compound and does not account for activity of other compounds in the whole plant or plant extract that may modify the toxicity of coumarin (Schmidt et al. 2007). The coumarin content of cassia is reported to range from 1250 to 1490 mg/kg, while in cassia essential oil, the coumarin content is 4370 mg/kg (Rychlik 2008).

Adverse Events and Side Effects

Allergic or sensitization reactions to cassia or compounds from cassia are relatively common. These reactions usually affect the skin or mucous membranes (Allen and Blozis 1988; Endo and Rees 2006; Lamey et al. 1990; Miller et al. 1992; Wright 2007).

Pharmacological Considerations

Human and animal studies indicated that cassia may modify glucose levels (Dugoua et al. 2007; Kim et al. 2006; Pham et al. 2007; Verspohl et al. 2005). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Occupational allergy to cassia and cassia essential oil has been reported and confirmed by patch testing (De Benito and Alzaga 1999; Steger et al. 2000).

Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that cassia should not be used during pregnancy (Bensky et al. 2004;

Chen and Chen 2004). In rats administered the compound cinnamaldehyde (5 to 250 mg/kg daily), an increase in fetal malformations was observed (Mantovani et al. 1989). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of cassia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No significant adverse events were reported in clinical trials with cassia at doses up to 6 g daily for 40 or 60 days (Hlebowicz et al. 2007; Khan et al. 2003).

Case Reports of Adverse Events

Overdoses (aqueous extracts of 18 g or more daily) of cassia have been associated with a sensation of abdominal tension, dysuria, red urine, burning urination, proteinuria, constipation, a sensation of heat in the chest, a thirst for cold beverages, dry and swollen eyes, flushed face, dizziness, blurred vision, and numbness of the tongue (Bensky et al. 2004).

The compound cinnamaldehyde, which comprises approximately 70 to 95% of cassia essential oil, can cause skin sensitization and irritation in sensitive persons. Reactions to cinnamaldehyde occur most commonly with prolonged oral exposure to products such as toothpaste, gum, or hard candies. Such cinnamon-flavored products have been found to be responsible for a number of cases of oral inflammation or lesions (Allen and Blozis 1988; Endo and Rees 2006; Lamey et al. 1990; Miller et al. 1992; Wright 2007). These include stomatitis (an inflammation of the mucous lining of any of the structures in the mouth), orofacial granulomatosis, erythematous patches, erythema multiforme, lichen planus, leukoplakia, varying degrees of superimposed keratosis or ulceration, and plasma cell gingivitis (Allen and Blozis 1988; Anil 2007; Cohen and Bhattacharyya 2000; Endo and Rees 2006, 2007; Lamey et al. 1990; Mihail 1992; Miller et al. 1992; Wright 2007). Some cases have been diagnosed as allergic in nature (Drake and Maibach 1976; Tremblay and Avon 2008). *See* Case reports of adverse events in *Cinnamomum verum* for more information on adverse events related to cinnamaldehyde.

Persons that took 36 g of powdered cassia (standard dose of powdered herb is 1–2 g) in a single dose experienced symptoms such as dizziness, blurred vision, rapid pulse, increased intraocular pressure, cough, decreased urine production, and thirst (Bensky et al. 2004; Zhu 1998).

Occupational allergy to cassia essential oil has been reported and confirmed by patch testing (De Benito and Alzaga 1999).

In workers occupationally exposed to cassia, skin prick tests and specific IgE tests indicated that 11% of 62 workers with high or low exposure to cassia were sensitized to this herb (Steger et al. 2000).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A review of randomized controlled studies on cassia in diabetes reported that two out of three studies showed that doses of 1 to 6 g daily reduced fasting blood glucose. The third study indicated no change on glucose levels after doses of 1.5 g daily (Dugoua et al. 2007). Studies published since that review indicated no effects on glucose at a dose of 3 g cassia daily, and a reduction in glucose at a dose of 6 g daily (Hlebowicz et al. 2007, 2009).

Cassia and balsam of Peru contain many similar allergenic compounds. Patch testing has demonstrated cross-reactivity in persons with allergies to these two species (Calnan 1976; Hoskins 1984; Pfutzner et al. 2003). Patch testing in a group of 118 patients allergic to balsam of Peru indicated that 14.5% of patients were allergic to cassia. Of 220 patients tested who were not allergic to balsam of Peru, only one tested positively to cassia (Niinimaki 1984).

In healthy volunteers orally administered 2.8 g (containing ~55 mg of oxalates) of cassia daily for 4 weeks, no significant changes in fasting plasma glucose were observed. No significant changes in urinary oxalate levels were observed at the end of the test period (Tang et al. 2008).

Animal Pharmacological Studies

In rats orally administered 5.29 mg/kg of a dried aqueous extract of cassia or 85.7 mg/kg of powdered cassia

(equivalent to the dose of cassia used in the extract), a decrease in blood glucose levels was observed in the glucose tolerance test but not in animals challenged with a glucose load (Verspohl et al. 2005).

A dose-dependent reduction in glucose levels was observed in diabetic mice orally administered 50, 100, 150, or 200 mg/kg of a cassia extract daily for 6 weeks (Kim et al. 2006). In diabetic rats orally administered 5, 10, or 20 mg/kg of the compound cinnamaldehyde daily for 45 days, a dose-dependent decrease in plasma glucose levels was observed (Subash Babu et al. 2007).

In Vitro Pharmacological Studies

Antiestrogenic effects of an ethanol extract of cassia were observed in a recombinant yeast system featuring a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

An extract of cassia decreased the dissolution of tetracycline hydrochloride (Miyazaki et al. 1977).

IV. Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that cassia should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of cassia during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intravenously administered decoction of cassia in mice is 18.48 g/kg (Chen and Chen 2004). The LD_{50} of orally administered cassia essential oil in rats is 2.8 ml/kg, while the dermal LD_{50} of the same product in rabbits is 0.32 ml/kg (Opdyke 1979).

The LD_{50} of the compound cinnamic acid orally administered to rats, mice, and guinea pigs could not be determined at doses up to 5 g/kg (Hoskins 1984).

The LD_{50} of the compound cinnamaldehyde in mice is 132 mg/kg after intravenous administration, 610 mg/kg after intraperitoneal administration, and 2225 mg/kg after oral administration (Zhu 1998).

Genotoxicity

No mutagenic activity of cassia essential oil was observed in the Ames test for mutagenicity in *Salmonella typhimurium* strain TA100 with or without activation by S9 (Park 2002; Sekizawa and Shibamoto 1982). Cassia essential oil tested positively in the *rec* assay with *Bacillus subtilis* (Sekizawa and Shibamoto 1982).

Cinnamomum camphora (L.) J. Presl — Lauraceae

SCN: camphor
Syn: *Camphora camphora* (L.) H. Karst, nom. illeg.; *Camphora officinalis* Nees; *Laurus camphora* L.

AN: *karpura*
Part: distillate of the wood

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Not for long-term use; do not exceed recommended dose (Manoguerra et al. 2006; McGuffin et al. 1997).

Not for use in children under 2 years of age (Bensky et al. 2004; Guilbert et al. 2007; Uc et al. 2000).

Other Precautions

Use with caution in small children (Bensky et al. 2004; Guilbert et al. 2007; Uc et al. 2000).

Camphor must be used with extreme caution if taken internally (Bensky et al. 2004; Chen and Chen 2004; Geller et al. 1984; Love et al. 2004; Manoguerra et al. 2006).

Drug and Supplement Interactions

None known.

Notice

Alkenylbenzenes (safrole 1.1–43%) (Stubbs et al. 2004); *see* Appendix 1.

Standard Dose

External Use

Products should contain 11% or less of the compound camphor (Love et al. 2004; Manoguerra et al. 2006).

Internal Use

The standard dose is 100 to 200 mg daily (Bensky et al. 2004; Chen and Chen 2004).

Editors' Notes

"Camphor" is the common name for *Cinnamomum camphora* and the name of the compound that gives this plant its distinctive smell. The compound camphor is frequently used in topical personal care products. The compound camphor comprises approximately 50% of camphor essential oil (Stubbs et al. 2004).

Use of camphor as a food additive in the United States is subject to a limitation that the finished food or beverage is safrole-free (CFR 2011). Dietary ingredients for use in dietary supplements, however, are specifically excluded from the federal food additive definition (U.S.C. 2010).

Adverse Events and Side Effects

Numerous cases of poisoning have been reported after accidental or intentional ingestion of products containing the compound camphor. Symptoms of poisoning, which generally begin soon after ingestion, include mucous membrane irritation, nausea, vomiting, generalized seizures, and abdominal pain. Other symptoms include central nervous system depression, headache, dizziness, confusion, anxiety, hallucinations, and twitching. Fatal cases of poisoning have been reported. Poisoning after topical use of products is relatively rare and occurred primarily in small children (Love et al. 2004; Manoguerra et al. 2006).

A review of cases of poisoning from the compound camphor indicated that patients ingesting less than 2 mg/kg were asymptomatic, while 5 to 10 mg/kg resulted in minor symptoms. A dose of 30 mg/kg is generally considered toxic, and severe symptoms are generally observed at 59 mg/kg. The average fatal dose has been reported as 199 mg/kg (Geller et al. 1984; Manoguerra et al. 2006).

Pharmacological Considerations

See Adverse Events and Side Effects.

Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that camphor should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

An animal study showed no adverse effects of the compound camphor at relatively high doses (Leuschner 1997).

No information on the safety of camphor during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Numerous cases of poisoning have been reported after accidental or intentional ingestion of products containing the compound camphor. Symptoms of poisoning, which generally begin soon after ingestion, include mucous membrane irritation, nausea, vomiting, abdominal pain, and generalized seizures. Other symptoms include central nervous system depression, headache, dizziness, confusion, anxiety, hallucinations, and twitching. Rare cases of hepatotoxicity have been reported. Some cases of poisoning have been fatal. Poisoning after topical use of products is relatively rare and occurred primarily in small children (Love et al. 2004; Manoguerra et al. 2006).

A review of cases of poisoning from the compound camphor indicated that patients ingesting less than 2 mg/kg were asymptomatic, while 5 to 10 mg/kg resulted in minor symptoms. A dose of 30 mg/kg is generally considered toxic, and severe symptoms are generally observed at 59 mg/kg. The average fatal dose has been reported as 199 mg/kg (Geller et al. 1984; Manoguerra et al. 2006).

Myocarditis (inflammation of the heart muscle) was reported in a 60-year-old man with a history of severe anemia. Symptoms developed after the man consumed 120 mg/kg of the compound camphor (Bhaya and Beniwal 2007).

Seizures were reported in a 4-month-old girl who had been treated topically on her abdomen with an unspecified amount of a topical product containing the compound camphor (Guilbert et al. 2007).

Hepatotoxicity was reported in a 2-month-old undernourished girl that had been topically administered "generous amounts" of a cold remedy containing the compound camphor three times daily for 5 days. The hepatotoxicity resolved after cessation of the cold remedy (Uc et al. 2000).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In studies with rats and rabbits, the compound D-camphor elicited no evidence of teratogenicity when administered orally at doses up to 1000 mg/kg daily in rats and 681 mg/kg daily in rabbits. The developmental no-observed-effect level for rats was above 1000 mg/kg and for rabbits was 681 mg/kg (Leuschner 1997).

No information on the safety of camphor during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of the compound camphor is 1800 mg/kg in guinea pigs, 2000 mg/kg in rabbits, and 800 mg/kg in dogs. The intraperitoneal LD_{50} of the compound camphor is 900 mg/kg in rats and 3000 mg/kg in mice. The subcutaneous LD_{50} of the compound camphor is 2200 mg/kg in mice (Wickstrom 1988).

Genotoxicity

No mutagenic activity of the compound camphor was observed in the *Salmonella*/microsome assay with *Salmonella* strains TA97a, TA98, TA100, and TA102 with or without metabolic activation (Gomes-Carneiro et al. 1998).

Cinnamomum verum J. Presl — Lauraceae

SCN: cinnamon
Syn: *Cinnamomum zeylanicum* Nees
AN: *tvak*

OCN: Ceylon cinnamon; true cinnamon
Part: bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chadha 1988; Mantovani et al. 1989; Wichtl 2004).

Other Precautions

Use with caution in persons with sensitivity to balsam of Peru (Calnan 1976; Hoskins 1984; Pfutzner et al. 2003).

Drug and Supplement Interactions

None known.

C

Editors' Notes

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Several species of *Cinnamomum* are commonly traded under the name "cinnamon" (Leung and Foster 1996).

Adverse Events and Side Effects

Allergic or sensitization reactions to cinnamon or compounds from cinnamon are relatively common. These reactions usually affect the skin or mucous membranes (Allen and Blozis 1988; Endo and Rees 2006; Lamey et al. 1990; Miller et al. 1992; Wright 2007).

Pharmacological Considerations

Animal studies have indicated that cinnamon may modify glucose levels (Kannappan et al. 2006; Verspohl et al. 2005). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

A reduction in the number of embryos was observed in mice fed diets containing cinnamon essential oil (Domaracky et al. 2007). In rats administered the compound cinnamaldehyde (5 to 250 mg/kg daily) on days 7 to 17 of pregnancy, an increase in fetal malformations was observed (Mantovani et al. 1989).

No information on the safety of cinnamon during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No side effects from cinnamon are expected at standard therapeutic doses (2–4 g daily). In overdose, cinnamon may excite the central nervous system causing increases in heart rate, peristalsis, respiration, and perspiration. The excitation is sometimes followed by sedation, with sleepiness (Wichtl 2004).

The compound cinnamaldehyde, which comprises approximately 55 to 75% of cinnamon essential oil, can cause skin sensitization and irritation in sensitive persons. Reactions to cinnamaldehyde occur most commonly with prolonged oral exposure to products such as toothpaste, gum, or hard candies. Such cinnamon-flavored products have been found to be responsible for a number of cases of oral inflammation or lesions (Allen and Blozis 1988; Endo and Rees 2006; Lamey et al. 1990; Miller et al. 1992; Wright 2007). These include stomatitis (an inflammation of the mucous lining of any of the structures in the mouth), orofacial granulomatosis, erythematous patches, erythema multiforme, lichen planus, leukoplakia, varying degrees of superimposed keratosis or ulceration, and plasma cell gingivitis (Allen and Blozis 1988; Anil 2007; Cohen and Bhattacharyya 2000; Endo and Rees 2006, 2007; Lamey et al. 1990; Mihail 1992; Miller et al. 1992; Wright 2007). Some cases have been diagnosed as allergic in nature (Drake and Maibach 1976; Tremblay and Avon 2008).

Cases of allergic contact dermatitis have been reported in persons that added powdered cinnamon to their coffee. In at least one of the cases, the patient held the coffee in his mouth to cool before swallowing, resulting in increased oral contact with cinnamon (De Rossi and Greenberg 1998).

Contact allergy to the compound cinnamal was confirmed in a patient with oral lichen planus (Hoskyn and Guin 2005).

Squamous cell carcinoma of the tongue was reported in a 24-year-old woman who chewed up to 5 packs daily of a sugarless gum flavored with cinnamon aldehydes, compounds that can incite irritation of oral mucosa (Westra et al. 1998). An oral leukoplakic lesion that was clinically thought to be a squamous cell carcinoma was reported in a patient that chewed cinnamon gum. The patient was found to be allergic to cinnamon (Mihail 1992).

Numerous cases of topical contact dermatitis from cinnamon, cinnamon essential oil, and compounds isolated from cinnamon have been reported and confirmed by patch testing (Farkas 1981; Garcia-Abujeta et al. 2005; Goh and Ng 1988; Hartmann and Hunzelmann 2004; Kern 1960; Kirton

1978; Ludera-Zimoch 1981; Sanchez-Perez and Garcia-Diez 1999). Some cases have been due to occupational exposure in bakers and restaurant workers (Ackermann et al. 2009; Fisher 1982; Nixon 1995).

Severe exacerbation of rosacea was reported in a 68-year-old woman with type 2 diabetes who had been taking a 500 mg capsule of cinnamon every other day for 1 week, and then one capsule daily for a second week (Campbell et al. 2008).

First and second degree burns were reported on the rear thigh of an 11-year-old male that had been carrying a vial of cinnamon essential oil in his back pants pocket. The vial broke, resulting in contact with a relatively large amount of cinnamon oil (Sparks 1985).

Oral burning, abdominal pain, and a single case of nausea were reported in 32 adolescent males that had sucked on toothpicks, hard candy, or their fingers that had been dipped in cinnamon essential oil (Perry et al. 1990).

Vomiting, diarrhea, dizziness, and loss of consciousness were reported in a child who ingested 60 ml of cinnamon essential oil (Pilapil 1989).

Self-inflicted bloody tears were reported in a woman who had been applying cinnamon bark wrapped in gauze to her eye for an unspecified amount of time (Awan et al. 2006).

Occupational asthma has been reported in workers regularly exposed to cinnamon dust (Uragoda 1984). In workers occupationally exposed to cinnamon dust, skin and eye irritation as well as hair loss have been reported and are likely due to the irritant nature of cinnamaldehyde (Calnan 1976; Uragoda 1984).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Cinnamon and balsam of Peru contain many similar allergenic compounds. Patch testing has demonstrated cross-reactivity in persons with allergies to these two species (Calnan 1976; Hoskins 1984; Pfutzner et al. 2003).

Among spice factory workers, pruritus and skin irritation were reported as common in persons working with spice powders, with cinnamon being noted as the most common irritant. Positive patch test reactions to cinnamaldehyde were found in 11 of 25 factory workers who had skin reactions, and skin prick testing elicited positive reactions in 6 workers (Meding 1993).

Animal Pharmacological Studies

In rats orally administered 0.2 or 2.0 ml (per 150–170 g animal) of an aqueous extract of cinnamon daily for 60 days and fed a high-fructose diet, blood glucose levels in the 2.0 ml dose group were similar to untreated animals fed a regular diet. Untreated animals fed a high-fructose diet had elevated blood glucose levels (Kannappan et al. 2006).

In rats orally administered 5.96 mg/kg of a dried aqueous extract of cinnamon, a decrease in blood glucose levels was observed in the glucose tolerance test but not in animals challenged with a glucose load (Verspohl et al. 2005).

In diabetic rats orally administered 5, 10, or 20 mg/kg of the compound cinnamaldehyde daily for 45 days, a dose dependent decrease in plasma glucose levels was observed (Subash Babu et al. 2007).

In maximization tests with guinea pigs, animals sensitized to cinnamaldehyde also reacted to cinnamyl alcohol and cinnamic acid. Animals sensitized to cinnamyl alcohol reacted to cinnamyl alcohol and cinnamaldehyde, but not to cinnamic acid. Cinnamic acid did not sensitize guinea pigs. Compared to the challenge concentration for cinnamaldehyde, a 15 times higher concentration of cinnamyl alcohol and a 25 times higher concentration of cinnamic acid were required to give positive reactions in animals sensitized to cinnamaldehyde (Weibel et al. 1989).

In Vitro Pharmacological Studies

Aqueous extracts of cinnamon provoked dose-related contractile responses of isolated guinea pig tracheal smooth muscle. The authors indicated that, based on that result, reactions to cinnamon experienced in spice factory workers exposed to cinnamon dust may be due to direct irritant reactions (Zuskin et al. 1988).

IV. Pregnancy and Lactation

In rats orally administered the compound cinnamaldehyde at doses of 5, 25, or 250 mg/kg on days 7 to 17 of pregnancy, the incidence of poor cranial ossification was increased in all treated groups, while reduced ossification of the tympanic bulla was increased in the 25 and 250 mg/kg groups. Increases in the incidences of dilated pelvis/reduced papilla in the kidney, dilated ureters, and abnormal sternebrae were detected in the 25 mg/kg group, which had the highest overall prevalence of minor abnormalities. Increases in the incidences of reduced cranial ossification, dilated ureters, and renal variants were observed at 5 mg/kg, a dose at which there was no detectable maternal toxicity (Mantovani et al. 1989).

In mice orally administered a diet containing 0.25% cinnamon essential oil for 2 weeks, a decrease in the number of nuclei and an alteration of the distribution of embryos was observed at gestational day 4 (Domaracky et al. 2007).

No information on the safety of cinnamon during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered ethanol extract of cinnamon in mice could not be determined at does up to 3 g/kg (Shah et al. 1998).

The oral LD_{50} of the compound cinnamaldehyde has been reported in different studies as 1.85 2.22, 3.35, or 3.4 g/kg in rats, 1.16 or 3.4 g/kg in guinea pigs, and 0.46 or 2.32 g/kg in mice (Hoskins 1984; Subash Babu et al. 2007).

The LD_{50} of the compound cinnamic acid orally administered in rats, mice, and guinea pigs could not be determined at doses up to 5 g/kg (Hoskins 1984).

Subchronic Toxicity

In mice orally administered 100 mg/kg of an ethanol extract of cinnamon daily for 90 days, no signs of mortality were observed. Hematological studies indicated a reduction in hemoglobin levels. Increases in reproductive organ weights, sperm motility, and sperm count were observed with no spermatotoxic effects (Shah et al. 1998).

Chronic Toxicity

In mice orally administered 100 mg per animal of cinnamon powder daily for 12 months, an increase in squamous papillomas and poorly differentiated carcinomas was observed. Similar results were observed for popularly consumed spices and foods such as chili peppers (*Capsicum annuum*) and large hairtail fish (*Trichiurus lepturus)* (Balachandran and Sivaramkrishnan 1995).

Genotoxicity

In the *Bacillus subtilis rec* assay with strains H17 *rec*$^+$ and M45 *rec*$^-$, no mutagenic activity of an ethanol extract of cinnamon was observed. Petroleum ether and chloroform extracts exhibited mutagenic activity that was not seen after metabolic activation by S9 mix (Ungsurungsie et al. 1984).

"Intermediate" mutagenic activity of an ethanol extract of cinnamon was observed in *Salmonella typhimurium* strain TA102 but not in TA98 (Mahmoud et al. 1992).

In the Ames test for mutagenicity and the *Escherichia coli* WP2 *uvrA* reversion test, no mutagenic activity of cinnamon essential oil was observed. The essential oil exhibited mutagenic activity in the *Bacillus subtilis rec* assay without S9 (Sekizawa and Shibamoto 1982).

SCN: bitter orange
PN: *zhi shi* (immature fruit); *zhi qiao* (nearly mature fruit)

OCN: bigarade; marmalade orange; Seville orange; sour orange
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: C

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

In human studies, the fruit juice of bitter orange has been shown to inhibit the drug metabolizing isoenzyme CYP3A4, leading to increased blood levels of certain drugs metabolized by CYP3A4. Human studies have confirmed interactions of the juice with cyclosporine, felodipine, dextromethorphan, and saquinavir (Di Marco et al. 2002; Edwards et al. 1999; Malhotra et al. 2001; Mouly et al. 2005). *See* Cytochrome P450 in Appendix 3.

Editors' Notes

Crude (minimally processed) dried bitter orange immature fruit and nearly mature fruit are used in traditional Chinese medicine. The content of synephrine in dried bitter orange fruit ranges from 0.012 to 0.25% (Rossato et al. 2011), and *p*-synephrine is reported to be the primary protoalkaloid present in bitter orange (Stohs et al. 2011). Extracts of the fruit with an increased concentration of synephrine (usually 4 to 6%) are also available in the marketplace (*see* next entry).

The interaction class established for this entry is based primarily on studies of bitter orange fruit juice, and on the fact that bergamottin, one of the furocoumarins in the juice

that are responsible for its interaction with numerous drugs (Baumgart 2004; Edwards et al. 1999; Malhotra et al. 2001; Messer et al. 2012), is also present in the fruit (Peroutka et al. 2007).

In addition, some furocoumarins are recognized to be phototoxic (Kavli and Volden 1984). However, no cases of phototoxicity in persons using bitter orange fruit have been reported, and two of the citrus furocoumarins, bergaptol and bergamottin, were not found to be phototoxic in vitro (Messer et al. 2012).

Adverse Events and Side Effects

Ingestion of "large amounts" of orange peel (bitter or sweet) has been reported to cause intestinal colic, convulsions, and even death in children (Leung and Foster 1996). A review of this reference and its sources, however, discloses that the reported death was limited to a single case recorded in 1833 that was attributed to "eating the rind of an orange," and that no additional details were provided on the other reported effects (Wood and Bache 1833). The current literature does not indicate any concern for such events at standard therapeutic doses.

Pharmacological Considerations

The juice of bitter orange fruit and extracts of whole bitter orange fruits have been shown to affect the metabolism of certain drugs in ways similar to, but not precisely the same as, grapefruit juice (Malhotra et al. 2001; Di Marco et al. 2002). Animal studies have found that decoctions of the fruit significantly decreased blood levels of the drug tacrolimus in rats, whereas an article described as the peel of the ripe fruit had no effect on the drug (Lin et al. 2011) and increased plasma concentrations of cyclosporine in swine (Hou et al. 2000).

Several studies have recorded poor binding affinity of *p*-synephrine to α- and β-1- and β-2-adrenoreceptors (Brown et al. 1988; Jordan et al. 1987; Ma et al. 2010), which provides a mechanistic explanation for the lack of observed effects on blood pressure and heart rate in numerous animal and human studies (Stohs et al. 2011).

Human studies have confirmed interactions of bitter orange juice with cyclosporine, felodipine, dextromethorphan, and saquinavir (Di Marco et al. 2002; Edwards et al. 1999; Malhotra et al. 2001; Mouly et al. 2005).

Pregnancy and Lactation

Information on the safety of bitter orange fruit during pregnancy is limited. One reference text on traditional Chinese medicine cites caution for both the immature and nearly mature fruit during pregnancy (Bensky et al. 2004), a concern not documented in other references.

No information on the safety of bitter orange fruit in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In healthy volunteers orally administered 240 ml of bitter orange fruit juice along with felodipine, a 73% increase in the area under the plasma time-concentration curve of felodipine was observed. The effects of bitter orange fruit juice were similar to that of grapefruit juice, in that the felodipine maximum concentration was augmented while the terminal elimination half-life was unchanged. Inactivation of intestinal CYP3A4 was the suggested mechanism of action (Malhotra et al. 2001).

In healthy volunteers orally administered 200 ml of bitter orange fruit juice or grapefruit juice, the bioavailability of orally administered dextromethorphan increased significantly with both juices, but only returned to half the baseline value after three days of washout. The results suggested that both juices are clinically significant inhibitors of intestinal CYP3A4 and P-glycoprotein (Di Marco et al. 2002).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Coadministration of cyclosporine (10 mg/kg) and an aqueous extract of crude bitter orange fruit in pigs increased the plasma concentration of cyclosporine by 64% (Hou et al. 2000).

In rats orally administered 1.5 mg/kg of tacrolimus (a substrate of CYP3A4) with or without 2 g/kg of a decoction of the unripe fruits or an article described as the ripe peel of bitter orange, a 72% decrease in the maximum plasma concentration of tacrolimus was observed in rats administered the decoction of the unripe fruits of bitter orange. No change in tacrolimus levels was observed in the rats administered a decoction of the ripe peels. A related in vitro study with the same plant materials indicated that the unripe fruit increased the activity of P-gp, a drug transport protein that transports drugs out of cells. For both studies, the decoctions of the unripe fruits and ripe peels were made by adding 25 g of plant material to 500 ml of water and cooking gently until 100 ml of liquid remained (Lin et al. 2011).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

p-Synephrine was measured to be 1000-fold less active than norepinephrine in binding to α-1- and α-2-adrenoreceptors in rat aorta (Brown et al. 1988). *p*-Synephrine was shown to act as a partial agonist in α-*1a-adrenoreceptors* in human embryonic kidney (HEK293) cells, giving a maximal response of 55% of the *m*-synephrine maximum (Ma et al. 2010). In addition, *p*-synephrine acted as an antagonist in α-2*a*- and α-2c-receptors in Chinese hamster ovary cells, but did not act as an agonist (Ma et al. 2010). *p*-Synephrine exhibited little or no β-1- and β-2-adrenoreceptor activation in guinea pig atria and trachea, and was 40,000-fold less potent than norepinephrine at binding to β-1- and β-2-adrenoreceptors (Jordan et al. 1987).

IV. Pregnancy and Lactation

Information on the safety of bitter orange fruit during pregnancy is limited. One reference text on traditional Chinese medicine cites caution for both the immature and nearly mature fruit during pregnancy (Bensky et al. 2004), a concern not documented in other references.

No information on the safety of bitter orange fruit during lactation was identified. Although this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an injection solution of immature bitter orange fruit administered intravenously in mice has been recorded as 72 g/kg, and intravenous injection administered to dogs did not produce any serious reactions at a dose of 21 g/kg (Zhu 1998).

Citrus × aurantium L. — Rutaceae

SCN: bitter orange
OCN: bigarade; marmalade orange; Seville orange; sour orange

Part: fruit concentrated extract (3–8% synephrine)

Quick Reference Summary

Safety Class: 2d*
Interaction Class: C†

Contraindications

Bitter orange fruit concentrated extract combined with caffeine or caffeine-containing herbs is not recommended for excessive or long-term use or for use by persons with heart irregularities, hypertension, insomnia, or anxiety (Haller 2005).

Other Precautions

None known.

Drug and Supplement Interactions

In human studies, the fruit juice of bitter orange has been shown to inhibit the drug metabolizing isoenzyme CYP3A4, leading to increased blood levels of certain drugs metabolized by CYP3A4 (Di Marco et al. 2002; Edwards et al. 1999; Malhotra et al. 2001; Mouly et al. 2005). *See* Editors' Notes below and Cytochrome P450 in Appendix 3.

Editors' Notes

Crude (minimally processed) dried bitter orange immature fruit and nearly mature fruit are used in traditional Chinese medicine (*see* previous entry). The content of synephrine in dried bitter orange fruit ranges from 0.012 to 0.25% (Rossato et al. 2011), and *p*-synephrine is reported to be the primary protoalkaloid present in bitter orange (Stohs et al. 2011a). Concentrated extracts of the fruit are also marketed, typically standardized to 4 or 6% *p*-synephrine (Bui et al. 2006; Calapai et al. 1999; Gurley et al. 2004; Hansen et al. 2006; Kubo et al. 2005; Nguyen et al. 2006).

Several of the articles referenced in this entry clearly state that the subject extract is derived from the whole fruit of bitter orange (Calapai et al. 1999; Firenzuoli et al. 2005; Min et al. 2005), while numerous others do not specifically identify the part of the plant from which the extract is derived (Bouchard et al. 2005; Bui et al. 2006; Colker et al. 1999; Gurley et al. 2004; Hansen et al. 2006; Nykamp et al. 2004). Some of the latter articles, however, provide *zhi shi*, which is the pinyin name for the dried immature fruit of this *Citrus* species, as a synonym for bitter orange or *Citrus aurantium* (Bui et al. 2006; Gurley et al. 2004; Hansen et al. 2006). Just one case report identifies bitter orange peel as an ingredient in a weight loss formula, apparently based on the product's labeling (Gange et al. 2006), and some studies refer to one particular brand of bitter orange fruit extract (Douds 1997; Haller et al. 2005). For purposes of this entry, it is assumed that ingredients reviewed in all references are actually extracted from whole bitter orange fruit rather than from the peel.

The interaction class established for this entry is based primarily on the fact that furocoumarins present in bitter orange fruit are known to be CYP3A4 inhibitors (Ishihara et al. 2011). In one study of a bitter orange fruit extract, however, no significant effects on the drug metabolizing enzyme CYP3A4 were observed, though it was also reported that the furocoumarin 6,7-dihydroxybergamottin, a known inhibitor of CYP3A4, was not detected in the tested extract (Gurley et al. 2004). No clinically relevant drug or supplement interactions are expected with bitter orange fruit concentrated extract in which the furocoumarins that are naturally occurring in the fruit are not present.

Furocoumarins are recognized to be phototoxic (Kavli and Volden 1984). However, no cases of phototoxicity in persons using bitter orange fruit extract have been reported, and two of the citrus furocoumarins, bergaptol and bergamottin, were not found to be phototoxic in vitro (Messer et al. 2012).

Health Canada's Natural Health Products Directorate (NHPD) has concluded that daily use by healthy adults of *p*-synephrine at up to 50 mg, or up to 40 mg in combination with up to 320 mg of caffeine, would generally result in a Type III risk classification. This classification is defined to mean that such use "is not likely to cause any adverse health consequences." On the other hand, NHPD determined that products that contain *p*-synephrine but lack certain cautionary statements, identified as "contraindicated in children, pregnancy, and breast-feeding, do not use if you are taking blood pressure medications (either hypertensives or antihypertensives), thyroid medications, sympathomimetics, or monoamine oxidase inhibitors," would be subject to a Type II risk classification (meaning "the use of, or exposure to, such a product may cause temporary adverse health consequences or where the probability of serious adverse health consequences is remote") (Marles 2011).

* No contraindications known when used without caffeine or caffeine-containing herbs.

† No clinically relevant drug or supplement interactions are expected with bitter orange fruit concentrated extract in which the furocoumarins that are naturally occurring in the fruit are not present.

Adverse Events and Side Effects

Adverse events, including stroke, variant angina, and myocardial infarction, have been reported in temporal association with consumption of bitter orange concentrated extracts in combination with caffeine or a caffeine-containing ingredient (Bouchard et al. 2005; Gange et al. 2006; Nasir et al. 2004; Nykamp et al. 2004). One of 16 reports of cardiovascular adverse reactions received by Health Canada between 1998 and 2004 and associated with products containing bitter orange or synephrine was related to a product that was reported to contain neither caffeine nor ephedrine, while the other reported products contained one or both of these alkaloids (Jordan et al. 2004). Instances of tachycardia were reported in a 52-year-old woman on two separate occasions, each on the same day that oral use of a dietary supplement containing 500 mg of an extract of *Citrus aurantium* standardized to 30 mg of synephrine was initiated; other ingredients, if any, were not disclosed (Firenzuoli 2005).

Pharmacological Considerations

Studies on the effects of bitter orange fruit concentrated extract on heart rate and blood pressure are conflicting. No increase in heart rate was associated with acute use of bitter orange fruit concentrated extract (containing 50 mg *p*-synephrine) at 75 minutes (Stohs et al. 2011b), though a significant increase was noted with a similar dose after 4 hours (Bui et al. 2006) and 6 hours (Haller et al. 2005). Similarly, one study showed a significant increase in blood pressure after use of bitter orange fruit concentrated extract (Bui et al. 2006), with others showing no such effect (Haller et al. 2005; Min et al. 2005; Stohs et al 2011b). Several studies have recorded poor binding affinity of *p*-synephrine to α and β-1- and β-2-adrenoreceptors (Brown et al. 1988; Jordan et al. 1987; Ma et al. 2010), which provides a mechanistic explanation for the lack of observed effects on blood pressure and heart rate in numerous animal and human studies (Stohs et al. 2011a).

Bitter orange fruit concentrated extract has been shown in one human trial to have no effect on the drug-metabolizing enzyme CYP3A4 (Gurley et al. 2004). Bitter orange juice (also known as Seville orange juice), however, has been shown to significantly inhibit the activity of CYP3A4 (Penzak et al. 2002). Research findings on the juice of bitter orange may not be relevant to products made from the fruit, as the two parts are distinct.

Bitter orange contains furocoumarins, compounds recognized to be phototoxic and to act as inhibitors of certain drug-metabolizing enzymes (Baumgart et al. 2005). However, no cases of phototoxicity in persons using bitter orange have been reported.

Pregnancy and Lactation

Information on the safety of bitter orange fruit concentrated extract in pregnancy is limited. A study of bitter orange fruit concentrated extract in pregnant rats showed no adverse effects on mothers or fetuses (Hansen et al. 2006). In a subsequent study, administration of oral doses of synephrine of up to 100 mg/kg body weight to pregnant rats for 20 days resulted in no developmental toxicity and no adverse effects on fetal development (Hansen et al. 2011).

No information on the safety of bitter orange fruit extract in lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for nursing women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No significant effects of bitter orange fruit concentrated extract (700 mg daily with 28 mg synephrine) were observed on CYP3A4 (Gurley et al. 2004).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse events were reported in a clinical trial of adults taking a supplement containing bitter orange fruit concentrated extract (975 mg with 58 mg synephrine), caffeine, and St. John's wort (*Hypericum perforatum*) for 6 weeks (Colker et al. 1999).

In a review of over 20 published and unpublished human studies, bitter orange extract alone (*p*-synephrine) or in combination with other herbal ingredients did not produce significant adverse events as an increase in heart rate or blood pressure, or alter electrocardiographic data, serum chemistry, blood cell counts or urinalysis (Stohs et al. 2012).

Case Reports of Adverse Events

A stroke was reported in a 38-year-old man with a one-week history of taking a supplement containing bitter orange fruit

concentrated extract (6–12 mg synephrine daily) and caffeine (200–400 mg daily) (Bouchard et al. 2005).

Two episodes of tachycardia were reported in a woman who took a dietary supplement for weight loss that contained bitter orange concentrated extract (30 mg synephrine daily); no additional information on the product formulation was provided in the case report. The episodes occurred on two separate days, 1 month apart, on which the woman initiated use of the extract (Firenzuoli et al. 2005).

An acute lateral-wall myocardial infarction was reported in a 55-year-old woman with a 1-year history of use of a weight loss product containing 300 mg *Citrus aurantium* (no other description provided) as well as 30 mg caffeine (misidentified as guararanine [sic]) and 30 mg green tea (no other description). The patient also reported a nearly 40-year tobacco-smoking habit (1½ packs per day), high caffeine intake from cola, coffee, and tea, and a preexisting heart murmur (Nykamp et al. 2004).

A 57-year-old man with a 35-day history of use of a weight loss product containing 125 mg of a combination of *Citrus aurantium* extract standardized to 5% synephrine and green tea leaf extract standardized to 50% epigallocatechin gallate, along with several other ingredients, presented with symptoms typical of variant angina involving the right coronary artery (Gange et al. 2006).

A previously healthy 22-year-old woman, who had recently resumed use of a combination product with numerous caffeine-containing ingredients along with standardized bitter orange extract, experienced a syncopal episode while running. An electrocardiogram revealed sinus tachycardia and QT prolongation (Nasir et al. 2004).

In the six-year period from 1998 to 2004, Health Canada received 16 reports of cardiovascular adverse reactions associated with products containing bitter orange or synephrine. One of these products was reported to contain neither caffeine nor ephedrine, while the others contained one or both of these alkaloids (Jordan et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No changes in the QT_c interval or blood pressure were observed after a single dose of bitter orange fruit concentrated extract (450 mg with 27 mg synephrine) (Min et al. 2005). No increases in systolic or diastolic blood pressure or heart rate occurred in fasting volunteers 45 minutes after oral consumption of bitter orange fruit concentrated extract containing 50 mg *p*-synephrine with or without the flavonoids naringin and hesperidin (Stohs et al 2011b).

Conversely, a single dose of bitter orange fruit concentrated extract containing 46.9 mg synephrine was reported to be associated with an increased heart rate of 11.4 ± 10.8 beats per minute after 6 hours, while blood pressure remained unchanged (Haller et al. 2005). In another study of a bitter orange fruit concentrated extract (900 mg with 54 mg synephrine), heart rate increased from pretreatment rate by 4.2 ± 4.5 beats per minute 4 hours after administration, and systolic and diastolic blood pressure increased by 7.3 ± 4.6 mm Hg and 2.6 ± 3.8 mm Hg, respectively (Bui et al. 2006).

Animal Pharmacological Studies

In rats administered 2.5 to 20 mg/kg bitter orange fruit concentrated extract daily (4 or 6% synephrine) for 7 or 15 days, mortality was observed in a dose-dependent manner in animals receiving extracts with either 4 or 6% synephrine. No differences in blood pressure were observed as compared to the control group (Calapai et al. 1999).

In rats administered bitter orange concentrated extract as 5% of the daily diet, adrenaline and dopamine were elevated, and heart weight was slightly lower, as compared to control animals (Kubo et al. 2005).

In Vitro Pharmacological Studies

p-Synephrine was measured to be 1,000-fold less active than norepinephrine in binding to α-1- and α-2-receptors in rat aorta (Brown et al. 1988). *p*-Synephrine was shown to act as a partial agonist in α-*1a-adrenoreceptors* in human embryonic kidney (HEK293) cells, giving a maximal response of 55% of the *m*-synephrine maximum (Ma et al. 2010). In addition, *p*-synephrine acted as an antagonist in α-*2a*- and α-2c-adrenoreceptors in Chinese hamster ovary cells, but did not act as an agonist (Ma et al. 2010). *p*-Synephrine exhibited little or no β-1- and β-2-adrenoreceptor activation in guinea pig atria and trachea, and was 40,000-fold less potent than norepinephrine at binding to β-1- and β-2-adrenoreceptors (Jordan et al. 1987).

IV. Pregnancy and Lactation

No teratogenic or other adverse effects were found in fetuses of rats administered up to 100 mg/kg daily by gavage of bitter orange concentrated extract (6% synephrine). In combination with caffeine (25 mg/kg), however, a decrease in the number of implanted eggs was observed (Hansen et al. 2006).

In a subsequent study, oral doses of synephrine of up to 100 mg/kg body weight (at least 20 times the normal equivalent human dose) given to pregnant rats for 20 days did not produce developmental toxicity. No adverse effects were observed with respect to fetal weight, embryo-lethality, or incidence of gross, visceral or skeletal abnormalities. In this study, administration was either as a natural constituent in a bitter orange extract standardized to 6% synephrine, or as relatively pure 90% synephrine extract (Hansen et al. 2011).

No information on the safety of bitter orange fruit concentrated extract during lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

Rats fed 10 g/kg bitter orange fruit concentrated extract daily for 14 days showed no mortality, although

clinical abnormalities were observed, including rough coat, decreased activity, congested breathing, dark material around the facial area, decreased defecation, salivation, soft stools and urine/fecal stain (Douds 1997).

Citrus × aurantifolia (Christm.) Swingle — Rutaceae

SCN: lime
OCN: key lime

Part: peel

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Photosensitizing (Opdyke 1979; Pomeranz and Karen 2007); *see* Appendix 2.

Adverse Events and Side Effects

Lime peel contains furanocoumarin compounds that can cause phytophotodermatitis (a nonimmunological phototoxic reaction of the skin) in sensitive individuals after topical exposure to lime peel followed by exposure to the sun (Opdyke 1979; Pomeranz and Karen 2007). Such reactions are not expected after oral consumption.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of lime in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Several cases of phytophotodermatitis have been reported after topical exposure to lime peel followed by exposure to the sun. Erythematous vesicles and bullae were observed on the hands of a 62-year-old man who had been picking limes (Schmidt 2007). Phytophotodermatitis with a painful, erythematous, blistering rash was observed in a 23-year-old woman who had prepared mojitos (cocktails that contain limes) during 2 days she spent at the beach (Pomeranz and Karen 2007). Cases of phytophotodermatitis have been reported in children after preparing lime juice (Mill et al. 2008).

Allergic reactions to lime peel have also been reported after topical exposure. Such was the case for a 52-year-old woman with a history of eczema and eyelid dermatitis who presented with angular cheilitis after having developed a habit of sucking on the limes in her gin and tonic for up to a minute after finishing the drink (Thomson et al. 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In sensitization tests with fragrance raw materials, several volunteers that tested positive to patch tests with a fragrance mix also tested positive to lime extract (Roesyanto-Mahadi et al. 1990). Lime essential oil demonstrated phototoxic activity in human patch tests (Opdyke 1979).

Animal Pharmacological Studies

In phototoxicity testing, lime essential oil processed by expression showed phototoxic effects in pigs and hairless mice, while the steam-distilled oil showed no such effects (Opdyke 1979).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of lime in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered lime essential oil in rats and rabbits could not be determined at doses up to 5 g/kg (Opdyke 1979).

Citrus × aurantium L. — Rutaceae

SCN: bitter orange
PN: *zhi shi* (immature fruit); *zhi qiao* (nearly mature fruit)

OCN: bigarade; marmalade orange; Seville orange; sour orange
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: C

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

In human studies, the fruit juice of bitter orange has been shown to inhibit the drug metabolizing isoenzyme CYP3A4, leading to increased blood levels of certain drugs metabolized by CYP3A4. Human studies have confirmed interactions of the juice with cyclosporine, felodipine, dextromethorphan, and saquinavir (Di Marco et al. 2002; Edwards et al. 1999; Malhotra et al. 2001; Mouly et al. 2005). *See* Cytochrome P450 in Appendix 3.

Editors' Notes

Three types of bitter orange fruit products are commercially available. The crude (minimally processed) dried immature fruit and nearly mature fruit are the products used in traditional Chinese medicine, and extracts of the fruit with an increased concentration of the compound synephrine (usually 4 to 6%) are also available (*see* next entry).

Synephrine, an alkaloid present in bitter orange, has a stimulant action on the nervous system. Synephrine affects α-adrenergic receptors and, to a lesser extent, β-adrenergic receptors, and it can raise blood pressure and have other effects on cardiac function that may be beneficial for selected patients when a proper dosage is administered (ILS 2004). Synephrine content in dried bitter orange fruit ranges from 0.012 to 0.25% (Rossato et al. 2011).

The interaction class established for this entry is based primarily on studies of bitter orange fruit juice, and on the fact that bergamottin, one of the furocoumarins in the juice that are responsible for its interaction with numerous drugs (Baumgart 2004; Edwards et al. 1999; Malhotra et al. 2001; Messer et al. 2012), is also present in the fruit (Peroutka et al. 2007).

In addition, some furocoumarins are recognized to be phototoxic (Kavli and Volden 1984). However, no cases of phototoxicity in persons using bitter orange fruit have been reported, and two of the citrus furocoumarins, bergaptol and bergamottin, were not found to be phototoxic in vitro (Messer et al. 2012).

Adverse Events and Side Effects

Ingestion of "large amounts" of orange peel (bitter or sweet) has been reported to cause intestinal colic, convulsions, and even death in children (Leung and Foster 1996). A review of this reference and its sources, however, discloses that the reported death was limited to a single case recorded in 1833 that was attributed to "eating the rind of an orange," and that no additional details were provided on the other reported effects (Wood and Bache 1833). The current literature does not indicate any concern for such events at standard therapeutic doses.

Pharmacological Considerations

The juice of bitter orange fruit and extracts of whole bitter orange fruits have been shown to affect the metabolism of certain drugs in ways similar to, but not precisely the same as, grapefruit juice (Malhotra et al. 2001; Di Marco et al. 2002). Animal studies have found that decoctions of the fruit significantly decreased blood levels of the drug tacrolimus in rats, whereas an article described as the peel of the ripe fruit had no effect on the drug (Lin et al. 2011) and increased plasma concentrations of cyclosporine in swine (Hou et al. 2000).

Human studies have confirmed interactions of bitter orange juice with cyclosporine, felodipine, dextromethorphan, and saquinavir (Di Marco et al. 2002; Edwards et al. 1999; Malhotra et al. 2001; Mouly et al. 2005).

Pregnancy and Lactation

Information on the safety of bitter orange fruit during pregnancy is limited. One reference text on traditional Chinese medicine cites caution for both the immature and nearly mature fruit during pregnancy (Bensky et al. 2004), a concern not documented in other references.

No information on the safety of bitter orange fruit in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In healthy volunteers orally administered 240 ml of bitter orange fruit juice along with felodipine, a 73% increase in the area under the plasma time-concentration curve of felodipine was observed. The effects of bitter orange fruit juice were similar to that of grapefruit juice, in that the felodipine maximum concentration was augmented while the terminal elimination half-life was unchanged. Inactivation of intestinal CYP3A4 was the suggested mechanism of action (Malhotra et al. 2001).

In healthy volunteers orally administered 200 ml of bitter orange fruit juice or grapefruit juice, the bioavailability of orally administered dextromethorphan increased significantly with both juices, but only returned to half the baseline value after three days of washout. The results suggested that both juices are clinically significant inhibitors of intestinal CYP3A4 and P-glycoprotein (Di Marco et al. 2002).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Coadministration of cyclosporine (10 mg/kg) and an aqueous extract of crude bitter orange fruit in pigs increased the plasma concentration of cyclosporine by 64% (Hou et al. 2000).

In rats orally administered 1.5 mg/kg of tacrolimus (a substrate of CYP3A4) with or without 2 g/kg of a decoction of the unripe fruits or an article described as the ripe peel of bitter orange, a 72% decrease in the maximum plasma concentration of tacrolimus was observed in rats administered the decoction of the unripe fruits of bitter orange. No change in tacrolimus levels was observed in the rats administered a decoction of the ripe peels. A related in vitro study with the same plant materials indicated that the unripe fruit increased the activity of P-gp, a drug transport protein that transports drugs out of cells. For both studies, the decoctions of the unripe fruits and ripe peels was made by adding 25 g of plant material to 500 ml of water and cooking gently until 100 ml of liquid remained (Lin et al. 2011).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Information on the safety of bitter orange fruit during pregnancy is limited. One reference text on traditional Chinese medicine cites caution for both the immature and nearly mature fruit during pregnancy (Bensky et al. 2004), a concern not documented in other references.

No information on the safety of bitter orange fruit during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an injection solution of immature bitter orange fruit administered intravenously in mice has been recorded as 72 g/kg, and intravenous injection administered to dogs did not produce any serious reactions at a dose of 21 g/kg (Zhu 1998).

Citrus × aurantium L. — Rutaceae

SCN: bitter orange
OCN: bigarade; marmalade orange; Seville orange; sour orange

Part: fruit concentrated extract (3–8% synephrine)

Quick Reference Summary

Safety Class: 2d*
Interaction Class: C†

Contraindications

Bitter orange fruit concentrated extract combined with caffeine or caffeine-containing herbs is not recommended for excessive or long-term use or for use by persons with heart irregularities, hypertension, insomnia, or anxiety (Haller 2005).

Other Precautions

None known.

Drug and Supplement Interactions

In human studies, the fruit juice of bitter orange has been shown to inhibit the drug metabolizing isoenzyme CYP3A4, leading to increased blood levels of certain drugs metabolized by CYP3A4 (Di Marco et al. 2002; Edwards et al. 1999; Malhotra et al. 2001; Mouly et al. 2005). *See* Editors' Notes below and Cytochrome P450 in Appendix 3.

Editors' Notes

Three types of bitter orange fruit products are commercially available. The crude (minimally processed) dried immature fruit and nearly mature fruit are the products used in traditional Chinese medicine (*see* previous entry), and extracts of the fruit with an increased concentration of the compound synephrine (usually 4–6%) are also available. This concentrated extract is marketed primarily as an ingredient in weight loss supplements.

* No contraindications known when used without caffeine or caffeine-containing herbs.

† No clinically relevant drug or supplement interactions are expected with bitter orange fruit concentrated extract in which the furocoumarins that are naturally-occurring in the fruit are not present.

Several of the articles referenced in this entry clearly state that the subject extract is derived from the whole fruit of bitter orange (Calapai et al. 1999; Firenzuoli et al. 2005; Min et al. 2005), while numerous others do not specifically identify the part of the plant from which the extract is derived (Bouchard et al. 2005; Bui et al. 2006; Colker et al. 1999; Gurley et al. 2004; Hansen et al. 2006; Nykamp et al. 2004). Some of the latter articles, however, provide *zhi shi*, which is the pinyin name for the dried immature fruit of this *Citrus* species, as a synonym for bitter orange or *Citrus aurantium* (Bui et al. 2006; Gurley et al. 2004; Hansen et al. 2006). Just one case report identifies bitter orange peel as an ingredient in a weight loss formula, apparently based on the product's labeling (Gange et al. 2006), and some studies refer to one particular brand of bitter orange fruit extract (Douds 1997; Haller et al. 2005). For purposes of this entry, it is assumed that ingredients reviewed in all references are actually extracted from whole bitter orange fruit rather than from the peel.

Synephrine, an alkaloid present in bitter orange fruit, has a stimulant action on the nervous system. Synephrine affects α-adrenergic receptors and, to a lesser extent, β-adrenergic receptors, and it can raise blood pressure and have other effects on cardiac function that may be beneficial for selected patients when a proper dosage is administered (ILS 2004). Synephrine content in dried bitter orange ranges from 0.012 to 0.25% (Rossato et al. 2011). Concentrated extracts of bitter orange fruit are typically standardized to 4 or 6% synephrine (Bui et al. 2006; Calapai et al. 1999; Gurley et al. 2004; Hansen et al. 2006; Kubo et al. 2005; Nguyen et al. 2006).

The interaction class established for this entry is based primarily on the fact that furocoumarins present in bitter orange fruit are known to be CYP3A4 inhibitors (Ishihara et al. 2011). In one study of a bitter orange fruit extract, however, no significant effects on the drug metabolizing enzyme CYP3A4 were observed, though it was also reported that the furocoumarin 6,7-dihydroxybergamottin, a known inhibitor of CYP3A4, was not detected in the tested extract (Gurley et al. 2004). No clinically relevant drug or supplement interactions are expected with bitter orange fruit concentrated extract in which the furocoumarins that are naturally-occurring in the fruit are not present.

Furocoumarins are recognized to be phototoxic (Kavli and Volden 1984). However, no cases of phototoxicity in persons using bitter orange fruit extract have been reported, and two of the citrus furocoumarins, bergaptol and bergamottin, were not found to be phototoxic in vitro (Messer et al. 2012).

Adverse Events and Side Effects

Adverse events, including stroke, variant angina, and myocardial infarction, have been reported in temporal association with consumption of bitter orange concentrated extracts in combination with caffeine or a caffeine-containing ingredient (Bouchard et al. 2005; Gange et al. 2006; Nasir et al. 2004; Nykamp et al. 2004). One of 16 reports of cardiovascular adverse reactions received by Health Canada between 1998 and 2004 and associated with products containing bitter orange or synephrine was related to a product that was reported to contain neither caffeine nor ephedrine, while the other reported products contained one or both of these alkaloids (Jordan et al. 2004). Instances of tachycardia were reported in a 52-year-old woman on two separate occasions, each on the same day that oral use of a dietary supplement containing 500 mg of an extract of *Citrus aurantium* standardized to 30 mg of synephrine was initiated; other ingredients, if any, were not disclosed (Firenzuoli 2005).

Pharmacological Considerations

Studies on the effects of bitter orange fruit concentrated extract on heart rate and blood pressure are conflicting. No increase in heart rate was associated with acute use of bitter orange fruit concentrated extract (containing 50 mg *p*-synephrine) at 75 minutes (Stohs et al. 2011), though a significant increase was noted with a similar dose after 4 hours (Bui et al. 2006) and 6 hours (Haller et al. 2005). Similarly, one study showed a significant increase in blood pressure after use of bitter orange fruit concentrated extract (Bui et al. 2006), with others showing no such effect (Haller et al. 2005; Min et al. 2005; Stohs et al 2011).

Bitter orange fruit concentrated extract has been shown in one human trial to have no effect on the drug-metabolizing enzyme CYP3A4 (Gurley et al. 2004). Bitter orange juice (also known as Seville orange juice), however, has been shown to significantly inhibit the activity of CYP3A4 (Penzak et al. 2002). Research findings on the juice of bitter orange may not be relevant to products made from the fruit, as the two parts are distinct.

Bitter orange contains furocoumarins, compounds recognized to be phototoxic and to act as inhibitors of certain drug-metabolizing enzymes (Baumgart et al. 2005). However, no cases of phototoxicity in persons using bitter orange have been reported.

Pregnancy and Lactation

Information on the safety of bitter orange fruit concentrated extract in pregnancy is limited. A study of bitter orange fruit concentrated extract in pregnant rats showed no adverse effects on mothers or fetuses (Hansen et al. 2006).

No information on the safety of bitter orange fruit extract in lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for nursing women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No significant effects of bitter orange fruit concentrated extract (700 mg daily with 28 mg synephrine) were observed on CYP3A4 (Gurley et al. 2004).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse events were reported in a clinical trial of adults taking a supplement containing bitter orange fruit concentrated extract (975 mg with 58 mg synephrine), caffeine, and St. John's wort (*Hypericum perforatum*) for 6 weeks (Colker et al. 1999).

Case Reports of Adverse Events

A stroke was reported in a 38-year-old man with a one-week history of taking a supplement containing bitter orange fruit concentrated extract (6–12 mg synephrine daily) and caffeine (200–400 mg daily) (Bouchard et al. 2005).

Two episodes of tachycardia were reported in a woman who took a dietary supplement for weight loss that contained bitter orange concentrated extract (30 mg synephrine daily); no additional information on the product formulation was provided in the case report. The episodes occurred on two separate days, 1 month apart, on which the woman initiated use of the extract (Firenzuoli et al. 2005).

An acute lateral-wall myocardial infarction was reported in a 55-year-old woman with a 1-year history of use of a weight loss product containing 300 mg *Citrus aurantium* (no other description provided) as well as 30 mg caffeine (misidentified as guararanine [sic]) and 30 mg green tea (no other description). The patient also reported a nearly 40-year tobacco-smoking habit (1½ packs per day), high caffeine intake from cola, coffee, and tea, and a preexisting heart murmur (Nykamp et al. 2004).

A 57-year-old man with a 35-day history of use of a weight loss product containing 125 mg of a combination of *Citrus aurantium* extract standardized to 5% synephrine and green tea leaf extract standardized to 50% epigallocatechin gallate, along with several other ingredients, presented with symptoms typical of variant angina involving the right coronary artery (Gange et al. 2006).

A previously healthy 22-year-old woman, who had recently resumed use of a combination product with numerous caffeine-containing ingredients along with standardized bitter orange extract, experienced a syncopal episode while running. An electrocardiogram revealed sinus tachycardia and QT prolongation (Nasir et al. 2004).

In the six-year period from 1998 to 2004, Health Canada received 16 reports of cardiovascular adverse reactions associated with products containing bitter orange or synephrine. One of these products was reported to contain neither caffeine nor ephedrine, while the others contained one or both of these alkaloids (Jordan et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No changes in the QT_c interval or blood pressure were observed after a single dose of bitter orange fruit concentrated extract (450 mg with 27 mg synephrine) (Min et al. 2005). No increases in systolic or diastolic blood pressure or heart rate occurred in fasting volunteers 45 minutes after oral consumption of bitter orange fruit concentrated extract containing 50 mg *p*-synephrine with or without the flavonoids naringin and hesperidin (Stohs et al 2011).

Conversely, a single dose of bitter orange fruit concentrated extract containing 46.9 mg synephrine was reported to be associated with increased heart rate of 11.4 ± 10.8 beats per minute after 6 hours, while blood pressure remained unchanged (Haller et al. 2005). In another study of a bitter orange fruit concentrated extract (900 mg with 54 mg synephrine), heart rate increased from pretreatment rate by 4.2 ± 4.5 beats per minute 4 hours after administration, and systolic and diastolic blood pressure increased by 7.3 ± 4.6 mm Hg and 2.6 ± 3.8 mm Hg, respectively (Bui et al. 2006).

Animal Pharmacological Studies

In rats administered 2.5 to 20 mg/kg bitter orange fruit concentrated extract daily (4 or 6% synephrine) for 7 or 15 days, mortality was observed in a dose-dependent manner in animals receiving extracts with either 4 or 6% synephrine. No differences in blood pressure were observed as compared to the control group (Calapai et al. 1999).

In rats administered bitter orange concentrated extract as 5% of the daily diet, adrenaline and dopamine were elevated, and heart weight was slightly lower, as compared to control animals (Kubo et al. 2005).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No teratogenic or other adverse effects were found in fetuses of rats administered up to 100 mg/kg daily by gavage of bitter orange concentrated extract (6% synephrine). In combination with caffeine (25 mg/kg), however, a decrease in the number of implanted eggs was observed (Hansen et al. 2006).

No information on the safety of bitter orange fruit concentrated extract during lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

Rats fed 10 g/kg bitter orange fruit concentrated extract daily for 14 days showed no mortality, although clinical abnormalities were observed, including rough coat, decreased activity, congested breathing, dark material around the facial area, decreased defecation, salivation, soft stools and urine/fecal stain (Douds 1997).

Citrus bergamia Risso & Poit. — Rutaceae

SCN: bergamot orange
Syn: *Citrus* × *aurantium* L. ssp. *bergamia* (Risso & Poit.) Wight & Arn. ex Engl.

Part: peel

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Photosensitizing (Dubertret et al. 1990; Freund 1916; Kejlova et al. 2007; Maibach and Marzulli 1986; Zaynoun et al. 1977a, 1977b); *see* Appendix 2.

Editors' Note

Bergamot orange peel contains the compound bergapten, a furanocoumarin that can cause photodermatitis after topical application followed by exposure to the sun (Dubertret et al. 1990; Freund 1916; Kejlova et al. 2007; Maibach and Marzulli 1986; Zaynoun et al. 1977a, 1977b). Such a reaction is not expected after oral ingestion of bergamot orange. Commercial processing can remove bergapten from bergamot orange products, and bergapten-free products are commercially available.

Adverse Events and Side Effects

Cases of dermatological reactions have been reported after topical application of products containing bergamot orange followed by exposure to the sun (Gruson and Chang 2002; Kaddu et al. 2001; Meyer 1970; Wang et al. 2002; Weisenseel and Woitalla 2005; Zacher and Ippen 1984).

Muscle cramping and twitching and blurred vision were reported in a man who drank approximately 4 liters of Earl Grey tea (black tea with bergamot orange essential oil) daily. Symptoms worsened with time and abated with cessation of Earl Grey (Finsterer 2002).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of bergamot orange in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Cases of photodermatitis have been reported in people topically exposed to bergamot orange essential oil, or products containing the oil, followed by exposure to sunlight (Cocks and Wilson 1998; Gruson and Chang 2002; Kaddu et al. 2001; Knott and Hofmann 2007; Wang et al. 2002; Weisenseel and Woitalla 2005).

A 44-year-old man with a history of drinking up to 4 liters of black tea daily developed muscle cramps and twitching, a tingling sensation of the limbs, and a feeling of pressure in the eyes associated with blurred vision with symptoms beginning 1 week after switching from black tea to Earl Grey tea (black tea with bergamot orange). Symptoms worsened with time and resolved after cessation of Earl Grey. The reporting author noted that the adverse effects of bergamot essential oil in this patient were likely due to the fact that the compound bergapten is a largely selective axolemmal potassium channel blocker that reduces potassium permeability at the nodes of Ranvier in a time-dependent manner, sometimes leading to hyperexcitability of the axonal membrane and phasic alterations of potassium currents, causing muscle twitching and cramping (Finsterer 2002).

Allergic contact dermatitis confirmed by patch testing was reported in two patients repeatedly exposed to perfumes or cosmetics containing bergamot orange (Zacher and Ippen 1984).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a study on factors that affect the phototoxic reaction of bergamot orange essential oil, the minimal effective concentrations of bergamot oil ranged from 1% to over 20%, showing some correlation with skin tone, with darker skins requiring a greater concentration of the essential oil to elicit a reaction after exposure to UVA light (Zaynoun et al. 1977b).

Animal Pharmacological Studies

In hairless albino mice treated topically with the compound bergapten at doses of 0 to 50 ppm, a dose-dependent relationship to time of tumor onset was observed and bergapten was reported to have phototumorigenic potential at the lowest tested dose of 5 ppm. The addition of UVA and UVB sunscreens to the treatment vehicle significantly reduced the tumorigenic effects (Young et al. 1990).

No papillomas were observed in mice with chemically initiated tumors subsequently treated topically with undiluted bergamot orange essential oil (Roe and Field 1965).

Studies comparing human, animal, and in vitro reactions to the compound bergapten have been used to develop phototoxicity tests (Girard et al. 1979; Gloxhuber 1970; Kejlova et al. 2007).

In Vitro Pharmacological Studies

Bergamot orange essential oil elicited a phototoxic reaction in human erythrocytes exposed to radiation sources rich in ultraviolet A or B (Placzek et al. 2007).

IV. Pregnancy and Lactation

No information on the safety of bergamot orange in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered bergamot orange essential oil in rats could not be determined at doses up to 10 g/kg (Opdyke 1979).

Genotoxicity

The compound bergapten was found to induce lethal and mutagenic photosensitization of bacteria, "dark"-induced frameshift mutagenesis in bacteria, and lethal and clastogenic effects on mammalian cells in tissue cultures (Ashwood-Smith et al. 1980).

Studies with bergapten and bergamot orange essential oil (containing equivalent amounts of bergapten) in *Saccharomyces cerevisiae* using solar simulated radiation (SSR) demonstrated that equal concentrations of bergapten alone or bergapten in bergamot orange essential oil have a similar influence on survival and on the induction of cytoplasmic *petite* mutations, reverse and forward mutations, mitotic gene conversion and genetically aberrant colonies including mitotic crossing-over. No reciprocity was found between SSR dose and bergapten concentration for cytotoxic, mutagenic, or recombinogenic effects. In the presence of chemical UVA or UVB filters, considerable protection against induction of genetic effects was observed (Averbeck et al. 1990).

No mutagenic effects of bergamot orange essential oil were observed in the *Bacillus subtilis rec* assay and *Salmonella*/microsome reversion assay with or without metabolic activation (Zani et al. 1991).

Citrus × limon (L.) Osbeck — Rutaceae

SCN: lemon
AN: *nimbuka*

Part: peel

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
Although lemon peel contains furanocoumarin compounds known to cause phototoxicity after topical application followed by exposure to the sun (Naganuma et al. 1985; Opdyke 1979; Zobel and Brown 1991), no case reports of phototoxicity were identified in the literature, and no such reaction is expected after ingestion.

Pregnancy and Lactation
No information on the safety of lemon in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
Allergic contact dermatitis due to lemon peel oil (among other products) was reported in perfume factory workers routinely exposed to essential oils and related compounds (Schubert 2006). A case of allergy to lemon peel essential oil has been reported and confirmed by patch testing (Audicana and Bernaola 1994).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

The compound oxypeucedanin, a furanocoumarin present in lemon peel essential oil, was found to elicit photopigmentation on colored guinea pig skin without preceding visible erythema. The phototoxic potency of oxypeucedanin was approximately one-quarter of that of the compound bergapten (Naganuma et al. 1985).

In Vitro Pharmacological Studies

Extracts of immature whole lemon fruit inhibited the drug-metabolizing isoenzymes CYP3A4 and CYP2C9 but did not cause significant inhibition of CYP2D6. The inhibition of CYP3A4 was similar to that of grapefruit (Fujita et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of lemon during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered lemon essential oil in rats could not be determined at doses up to 5 g /kg (Opdyke 1979).

Citrus reticulata Blanco

Rutaceae

SCN: tangerine
PN: *chen pi* (dried peel of mature fruit); *qing pi* (dried peel of green fruit)

OCN: mandarin; Mandarin orange; red tangerine
Part: peel

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Long-term use of tangerine peel is not recommended (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

An anaphylactic reaction to tangerine has been reported and confirmed by patch testing (Ebo et al. 2007). Contact dermatitis due to tangerine essential oil in a perfume has also been reported and confirmed by patch testing (Vilaplana 2002).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of tangerine in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An anaphylactic reaction to tangerine has been reported and confirmed by patch testing (Ebo et al. 2007). Contact dermatitis due to tangerine essential oil in a perfume has also been reported and confirmed by patch testing (Vilaplana 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of tangerine in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects of aged tangerine peel were reported after administration of a 50% decoction to dogs at doses of 3 ml/kg (Chen and Chen 2004).

In mice, the intravenous LD_{50} of the compound tangeretin is 780 mg/kg, while that of the compound hesperidin is 850 mg/kg (Chen and Chen 2004).

Clematis chinensis Osbeck

Ranunculaceae

SCN: Chinese clematis
PN: *wei ling xian* (root and rhizome)

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in pregnancy (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Editors' Note

The sap of Chinese clematis contains anemonin and protoanemonin, compounds that irritate the skin and mucous membranes (Bensky et al. 2004; Chang and But 1986; Kingsbury 1964; List and Hörhammer 1973; Nelson et al. 2006). These irritating principles are mostly lost on drying and lengthy storage in a dry environment (Bensky et al. 2004; List and Hörhammer 1973).

Adverse Events and Side Effects

No adverse effects have been observed with typical therapeutic use of the properly dried root (Bensky et al. 2004). Long-term or excessive use has been associated with adverse

events including gastrointestinal irritation, slowed heart rate, and dilated pupils (Bensky et al. 2004).

Topical application of the fresh herb may cause dermatitis (Bensky et al. 2004; Tan et al. 2008; Wang et al. 2001).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although one reference text on traditional Chinese medicine indicates that Chinese clematis should be used with caution in pregnancy (Chen and Chen 2004), another reference did not list any concern for use in pregnancy (Bensky et al. 2004). An animal study indicated that the alcohol extract of Chinese clematis had abortifacient activity in mice (Chen and Chen 2004). Information on dose and route of administration was not reported in the available English language translation. In traditional Chinese medicine, herbal products are typically extracted in water and used in formulas rather than single herbs, and thus the relevance of the above animal study to standard therapeutic use is not known.

No information on the safety of Chinese clematis in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No adverse effects have been observed with typical therapeutic use of the properly processed root. Long-term or excessive use (standard dose is a decoction of 6-9 g of the herb) has been associated with burning sensation, swelling, and ulcerations of the oral cavity, vomiting, abdominal pain, severe diarrhea, difficulty breathing, slowed heart rate, agitation, pale face, cold sweat, and dilated pupils. In severe cases, death was reported about 10 hours after ingestion (Bensky et al. 2004).

Topical application of large doses of Chinese clematis was associated with rash, blistering of the skin, and allergic dermatitis (Bensky et al. 2004). Pruritic erythema with depigmentation and hyperpigmentation was reported after topical application of fresh Chinese clematis (Tan et al. 2008). Severe contact dermatitis with a systemic reaction was reported after contact with fresh Chinese clematis (Wang et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Although one reference text on traditional Chinese medicine indicates that Chinese clematis should be used with caution in pregnancy (Chen and Chen 2004), another reference did not list any concern for use in pregnancy (Bensky et al. 2004). An animal study indicated that the alcohol extract of Chinese clematis had abortifacient activity in mice (Chen and Chen 2004). Information on dose and route of administration was not reported in the available English language translation. In traditional Chinese medicine, herbal products are typically extracted in water and used in formulas rather than single herbs, and thus the relevance of the above animal study to standard therapeutic use is not known.

No information on the safety of Chinese clematis in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally or intraperitoneally administered 50% ethanol extract of Chinese clematis in mice could not be determined at doses up to 50 g/kg (Yang and Chen 1997).

Short-Term Toxicity

In rats orally administered 5 or 10 g/kg of a 50% ethanol extract of Chinese clematis daily for 14 days, an increase in heart and liver wet weights were observed in animals administered the 10 g/kg dose. At the low dose, increased urinary output was observed, and at both doses, an increase in white blood cells and urinary protein and decrease in serum glutamic-pyruvic transaminase were observed (Yang and Chen 1997).

Cnicus benedictus L.

Asteraceae

SCN: blessed thistle
Syn: *Centaurea benedicta* (L.) L.

OCN: holy thistle
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as feverfew or *Echinacea* species) should exercise caution with blessed thistle, as allergic cross-reactivity is common to Asteraceae plants (Upton 2007; Zeller et al. 1985).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to blessed thistle have been reported (De Smet 1993). In animal studies, blessed thistle was a s ensitizer and showed cross-reactivity to other members of the Asteraceae family (Zeller et al. 1985).

High doses (more than 5.0 g per cup of tea) may irritate the stomach and cause vomiting (Roth et al. 1984).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Limited information on the safety of blessed thistle in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Sensitization testing in guinea pigs indicated that blessed thistle is a relatively strong sensitizer. In this testing, cross-reactivity to "a considerable number" of other plants in the Asteraceae family was observed (Zeller et al. 1985). Blessed thistle contains the compound cnicin, a sesquiterpene lactone. Such compounds are responsible for allergic contact dermatitis associated with a number of species of the Asteraceae family (Gordon 1999).

In Vitro Pharmacological Studies

Blessed thistle is reported to contain lithospermic acid, a compound with antigonadotropic activity (Graham and Noble 1955).

IV. Pregnancy and Lactation

Blessed thistle extract did not stimulate contractions in isolated guinea pig uterine tissue (Pilcher et al. 1916).

No information on the safety of blessed thistle during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound cnicin in mice is 1.6–3.2 µmol/kg (Müller and Schneider 1999).

Genotoxicity

An ethanolic extract of blessed thistle was not mutagenic in the Ames assay with *Salmonella typhimurium* with or without S9 mix (Schimmer et al. 1994).

Cnidium monnieri (L.) Cusson ex Juss.

Apiaceae

SCN: cnidium
PN: *she chuang zi* (seed)

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Cnidium should be used with caution by individuals with inflammation of the kidneys or a history of irritation of the kidneys (Yan et al. 2001).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of cnidium during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No adverse effects have been reported from ingestion of cnidium extracts. Ingestion of the coumarin fraction of cnidium has led to dry mouth, drowsiness, and mild gastric discomfort (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of cnidium in pregnancy or lactation was identified.

V. Toxicity Studies

Cytotoxicity

Coumarin compounds (osthol, imperatorin, bergapten, isopimpinellin, and xanthotoxin) isolated from a c nidium extract exhibited cytotoxic activity against human leukemia, cervical carcinoma, and colorectal carcinoma cells in vitro. The compound osthol showed the strongest cytotoxic activity on tumor cell lines. The compound imperatorin showed the highest sensitivity to human leukemia cells and the least cytotoxicity to normal peripheral blood mononuclear cells (Yang et al. 2003).

Codonopsis spp.

Campanulaceae

Codonopsis pilosula (Franch.) Nannf.
SCN: codonopsis
Syn: *Codonopsis silvestris* Kom.
PN: *dang shen* (root)
OCN: bellflower

Codonopsis tangshen Oliv.
SCN: codonopsis
PN: *dang shen* (root)
OCN: bellflower; Sichuan dang shen
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

No side effects are expected at standard therapeutic doses (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of codonopsis in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Doses of codonopsis over 63 g may cause discomfort in the left pectoral area or arrhythmia. These effects subside when the herb is discontinued (Bensky et al. 2004; Liang 1976). Other symptoms of overdose (aqueous extract of 30–60 g codonopsis) include visual impairment, throat pain, vertigo, disorientation, loss of balance, leg spasms, and loss of voice (Bensky et al. 2004). Codonopsis is reported to have a low toxicity, and no side effects are expected within the standard dose range (aqueous extract of 6–9 g daily) (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Administration of "large doses" (dose not specified in English language abstract) of codonopsis in rats was reported to cause a reduction in weight gain and serum triiodothyronine (T_3) levels, and an increase of reverse T_3 and thyrotropin-releasing hormone (TRH) levels (Chen et al. 1989).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of codonopsis in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered aqueous extract of codonopsis in mice is 79 g/kg (Chen and Chen 2004). No toxicity or fatalities were seen in mice orally administered up to 10 g/kg of the same extract (Chen and Chen 2004).

Short-Term Toxicity

No toxic effects were seen in rats subcutaneously administered an extract of codonopsis daily for 13 days (Wang 1983). No toxic effects or changes in serum glutamic-pyruvic transaminase levels were observed in mice intraperitoneally administered the same extract daily for 15 days (Wang 1983).

Coffea arabica L. — Rubiaceae

SCN: coffee
OCN: Arabian coffee

Part: roasted seed kernel

Quick Reference Summary

Safety Class: 1
Interaction Class: C*

Contraindications

None known.

Other Precautions

Coffee contains caffeine, a n ervous system stimulant. If taken in large amounts, coffee products containing caffeine can cause insomnia, nervousness, and the other well-known symptoms of excess caffeine intake (Donovan and DeVane 2001).

Due to the CNS stimulant effects of caffeine, use of caffeine-containing products is cautioned in persons with heart disorders, as excessive caffeine consumption may increase heart rate or exacerbate arrhythmias. Caution should also be observed in persons with psychological disorders, as caffeine may aggravate depression or induce anxiety (Brinker 2001).

Drug and Supplement Interactions

Use of caffeine with other central nervous system (CNS) stimulants, including bronchodilators or adrenergic drugs, may cause excessive central nervous system stimulation resulting in nervousness, irritability, insomnia, and possibly convulsions or cardiac arrhythmias (PDR 2006).

Caffeine is metabolized by the isoenzyme CYP1A2. Drugs that inhibit this isoenzyme (including fluvoxamine, ciprofloxacin, cimetidine, amiodarone, fluoroquinolones, furafylline, interferon, methoxsalen, and mibefradil) may slow the metabolism of caffeine. In persons drinking multiple cups of coffee daily, high levels of caffeine could accumulate (Carrillo and Benitez 2000).

Notice

Caffeine (1.5–2.5%) (Leung and Foster 1996; McCusker et al. 2003); *see* Appendix 1.

Diuretic (Carrillo and Benitez 2000; Maughan and Griffin 2003); *see* Appendix 2.

Editors' Note

An average 8 oz cup of coffee contains 75 to 130 mg caffeine. A shot of espresso contains 55 to 76 mg caffeine (McCusker et al. 2003). The caffeine content of a single type of coffee purchased from one store of an international coffee company on six different days was found to vary from 130 to 282 mg per 8 oz cup (McCusker et al. 2003).

The American Herbal Products Association has established a trade requirement (AHPA 2011) that dietary supplement products that contain caffeine, whether as a d irect ingredient or as a constituent of herbal ingredients, be labeled to disclose the presence of caffeine in the product and the quantity of added caffeine if greater than 25 mg; be formulated and labeled in a manner to recommend a maximum of 200 mg of caffeine per serving, not more often than every 3 to 4 hours; and bear the following or similar statement on the label of any dietary supplement that contains caffeine in sufficient quantity to warrant such labeling:

> *Too much caffeine may cause nervousness, irritability, sleeplessness, and, occasionally, rapid heartbeat. Not recommended for use by children under 18 years of age.*

See Appendix 1 for more specific details on this AHPA trade requirement.

Adverse Events and Side Effects

Overdose of coffee may result in restlessness, nervousness, excitement, insomnia, flushed face, frequent urination, stomach ache, nausea, tremors, talkativeness, periods of inexhaustibility, and irritability (Hughes et al. 1991).

Cessation of coffee may result in withdrawal symptoms including headache, drowsiness, fatigue, and irritability. Significant withdrawal symptoms can occur after 3 days of consuming as little as 100 mg caffeine (about one cup coffee) daily (Evans and Griffiths 1999; Juliano and Griffiths 2004).

Epidemiological studies have provided conflicting results on the association between coffee consumption and coronary heart disease risk. While some studies indicate no association, others indicate that drinking five cups of coffee or more daily increases the risk of coronary heart disease (Higdon and Frei 2006; Sofi et al. 2007).

The risk of heart attack has been shown to be higher in persons consuming five to ten cups of coffee daily as compared with those drinking two to three cups daily (Hammar et al. 2003; Palmer et al. 1995; Sesso et al. 1999; Tavani et al. 2001, 2004).

Consumption of boiled coffee has been associated with an increase in cholesterol levels, while no significant effects of filtered coffee have been observed (Jee et al. 2001).

Studies have generally indicated no association between coffee and risk of stroke (Adolfsson et al. 1977; Grobbee et al. 1990; Heyden et al. 1978).

* For caffeine-free preparations, no interactions are expected.

Contrary to earlier studies, more recent reviews and meta-analyses indicate no association between coffee and the risk of certain cancers, including pancreatic, bladder, ovarian, breast, prostate, and gastric cancer (Higdon and Frei 2006; Tavani and La Vecchia 2000).

Pharmacological Considerations

Coffee has been shown to cause an acute rise in blood pressure, although with chronic consumption the rise is minimal (1.2 mm Hg systolic, 0.49 mm Hg diastolic) (Geleijnse 2008; Noordzij et al. 2005; Nurminen et al. 1999).

Clinical trials and prospective studies have indicated no association between coffee and risk of irregular heart rhythms (Chelsky et al. 1990; Frost and Vestergaard 2005; Myers 1991; Wilhelmsen et al. 2002).

Coffee consumption has been associated with a slight decrease in calcium absorption. Studies have indicated no effect of coffee on bone mineral density and mixed results on coffee consumption and the risk of hip fracture in elderly persons (Barger-Lux and Heaney 1995; Hasling et al. 1992; Higdon and Frei 2006).

Coffee has been shown to strongly inhibit dietary iron absorption, though at only about half the inhibitory effect of black tea (Hurrell et al. 1999).

Pregnancy and Lactation

Pregnant women are advised to limit caffeine intake to less than 300 mg (about three cups of coffee) daily (PDR 2006; Sato et al. 1993). Lactating women are advised to limit consumption of caffeinated beverages to two to three cups daily (AAP 2001).

Studies of caffeine have indicated no adverse effects on pregnancy or fetal development at levels equivalent to three to four cups daily. At much higher doses (equivalent to 21 cups of coffee or more daily), no adverse effects on the fetus have been observed (Christian and Brent 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In healthy volunteers orally administered theophylline with or without two to seven cups of regular instant coffee during a 24-hour study period, blood levels of theophylline and caffeine were significantly higher in the coffee group. The half-life of theophylline was increased from 6.3 to 8.3 h, and the clearance of theophylline was reduced (Sato et al. 1993).

Case Reports of Suspected Drug or Supplement Interactions

In patients taking lithium, high coffee consumption and caffeine withdrawal have been associated with an increase in lithium tremors (Grandjean and Aubry 2009; Mester et al. 1995). A series of case reports and a related small trial indicated that coffee may inhibit intestinal absorption of thyroxine (T_4) (Benvenga et al. 2008).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of coffee may result in restlessness, nervousness, excitement, insomnia, flushed face, frequent urination, stomach ache, nausea, tremulousness, talkativeness, periods of inexhaustibility, irritability, and psychomotor agitation (Hughes et al. 1991).

Cessation of coffee may result in withdrawal symptoms including headache, drowsiness, fatigue, and irritability. Significant withdrawal symptoms can occur after 3 days of consuming as little as 100 mg caffeine (about one cup coffee) daily (Evans and Griffiths 1999; Juliano and Griffiths 2004).

Occupational asthma and allergy to roasted and green coffee have been reported in persons exposed to coffee dust (Diba and English 2002; Lemiere et al. 1996; Treudler et al. 1997). An anaphylactic reaction to coffee, with skin prick testing confirming caffeine as the responsible compound, has been reported (Infante et al. 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Epidemiological studies have provided conflicting results on the association between coffee consumption and coronary heart disease risk (Higdon and Frei 2006; Sofi et al. 2007). Case-control studies have found a 40 to 60% increased risk of coronary heart disease in people who consumed five or more cups of coffee daily, as compared to non-coffee drinkers (Greenland 1993; Kawachi et al. 1994). Prospective cohort studies, conversely, have generally not found a significant association between coffee consumption and coronary heart disease risk (Kawachi et al. 1994; Myers and Basinski 1992). The difference in results may be explained by the study methods. In case-control studies, the health history and related factors from individuals who have developed a disease are compared with a control population. A prospective cohort study follows a group over time (Coggon et al. 1997).

The risk of heart attack has been shown to be higher in persons consuming five to ten cups of coffee daily as compared with those drinking two to three cups daily (Hammar et al. 2003; Palmer et al. 1995; Sesso et al. 1999; Tavani et al. 2001, 2004). A case-control study identified an increased risk of cardiac arrest in patients with established coronary heart disease who drank ten cups of coffee or more daily (de

Vreede-Swagemakers et al. 1999), whereas a similar prospective study found no association between heavy (ten or more cups daily) coffee consumption and survival in persons who had survived a heart attack (Mukamal et al. 2004).

Clinical trials and prospective studies have indicated no association between coffee and risk of cardiac arrhythmias (Chelsky et al. 1990; Frost and Vestergaard 2005; Myers 1991; Wilhelmsen et al. 2002) and generally indicated no association between coffee and risk of stroke (Adolfsson et al. 1977; Grobbee et al. 1990; Heyden et al. 1978). One study, however, did show an increased risk of stroke in nonsmoking men with high blood pressure who consumed three cups of coffee or more daily (Hakim et al. 1998).

An acute rise in blood pressure, usually occurring 30 minutes to 4 hours after coffee consumption, has been observed in a number of studies with healthy volunteers (Nurminen et al. 1999). The blood-pressure raising effects may be more pronounced in persons with high blood pressure (Nurminen et al. 1999). With routine consumption of coffee, most individuals develop tolerance to the blood-pressure raising effect of coffee, while the tolerance is incomplete in some (James 1994; Lovallo et al. 2004). A meta-analysis of studies on the effects of chronic coffee consumption on blood pressure indicated that the average increase in blood pressure was small (1.2 mm Hg systolic, 0.49 mm Hg diastolic), with boiled coffee causing a greater increase than filtered coffee. In the studies reviewed, the average coffee intake was 450 to 1235 ml (225–798 mg caffeine) daily (Noordzij et al. 2005). Some epidemiological studies indicate an inverse, U-shaped relationship between blood pressure and coffee consumption, with low pressure shown in those who did not drink coffee and those who drank more than six or nine cups daily, as compared with those who drank one to two cups daily (Geleijnse 2008).

Unfiltered coffee (Turkish, French press, or boiled coffee) has been associated with an increase in serum cholesterol levels (total and LDL), while reviews indicate that filtered coffee results in very little increase in serum cholesterol levels (Jee et al. 2001). This effect has been attributed to the compounds cafestrol and kahweol that are present in unfiltered coffee (Urgert and Katan 1997).

In clinical and epidemiological studies, coffee has been associated with a dose-dependent increase in plasma total homocysteine levels (Bree et al. 2001; Husemoen et al. 2004; Mennen et al. 2002; Nygard et al. 1997; Stolzenberg-Solomon et al. 1999). Filtered coffee showed greater effects than unfiltered, with an 18% increase in homocysteine levels in persons drinking 34 oz of filtered coffee daily for 2 weeks, as compared to a 10% increase in persons drinking the same volume of unfiltered coffee (Urgert et al. 2000). A clinical trial in healthy volunteers showed that supplementation with 200 μg of folic acid daily prevented elevation of homocysteine levels caused by 2.5 cups coffee daily. Elevated total homocysteine levels have been associated with increased risk of cardiovascular disease such as coronary artery disease, stroke, and congestive heart failure (Mart-Carvajal et al. 2009).

Coffee has been shown to cause a slight decrease in the efficiency of calcium absorption, with an estimated 6 mg decrease in calcium balance per cup of coffee (Barger-Lux and Heaney 1995; Hasling et al. 1992). The majority of epidemiological studies indicate that coffee consumption is not associated with changes in bone mineral density (Higdon and Frei 2006). Epidemiological studies provide conflicting results on coffee consumption and the risk of hip fracture (Higdon and Frei 2006). Among five case-control studies, none found a relationship between coffee consumption and the risk of hip fracture (Cumming and Klineberg 1994; Johnell et al. 1995; Kanis et al. 1999; Nieves et al. 1992; Tavani et al. 1995). In cohort studies, three found no association between coffee consumption and the risk of hip fracture, while three other studies indicated an association in women drinking more than two to four cups of coffee daily (Cummings et al. 1995; Hernandez-Avila et al. 1991; Kiel et al. 1990).

Coffee has been shown to strongly inhibit dietary iron absorption, though at only about half the inhibitory effect of black tea (Hurrell et al. 1999).

While earlier case-control studies indicated an association between coffee consumption and increased incidences of pancreatic, bladder, and ovarian cancers, more recent, better-designed studies have not supported those findings (Higdon and Frei 2006). Prospective cohort studies generally indicate a lack of association between coffee consumption and pancreatic, bladder, ovarian, breast, prostate, and gastric cancer (Tavani and La Vecchia 2000). Reviews and meta-analyses indicate that coffee may decrease the risk of colorectal cancer (Giovannucci 1998; Tavani and La Vecchia 2004) and liver cancer (Higdon and Frei 2006).

Caffeine is a substrate of the drug-metabolizing isoenzyme CYP1A2 (Nordmark et al. 1999).

Animal Pharmacological Studies

Animal studies were identified but omitted due to the availability of human data.

In Vitro Pharmacological Studies

In vitro studies were identified but omitted due to the availability of human data.

IV. Pregnancy and Lactation

Caffeine is in the FDA pregnancy category C and has been shown to cross the placenta and achieve blood and tissue concentrations in the fetus. Excessive intake of caffeine by pregnant women has been associated with fetal arrhythmias. Pregnant women are advised to limit caffeine intake to less than 300 mg (approximately 3 cups of coffee) daily (PDR 2006; Sato et al. 1993).

Caffeine is listed as a "maternal medication usually compatible with breast-feeding" by the American Academy of Pediatrics Committee on Drugs. The committee noted that maternal consumption of caffeine may cause irritability and poor sleeping patterns in nursing infants, and that maternal consumption of caffeinated beverages should be limited to two to three cups daily (AAP 2001).

A review of reproductive and developmental toxicity studies of caffeine indicated that, at levels of 5 to 6 mg/kg of caffeine daily (about three or four cups of coffee), no adverse effects on pregnancy or fetal development are expected. The developmental toxicity no-observed-effect level (NOEL) of caffeine is 30 mg/kg daily (about 21 cups of coffee) and the reproductive toxicity NOEL is between 80 and 120 mg/kg daily (Christian and Brent 2001).

Epidemiological studies have indicated an association between high caffeine intake during pregnancy and an increased risk of spontaneous abortions. An analysis of these studies concluded that methodological flaws in many of these studies led to biased results and that a causal link between caffeine consumption and abortion cannot be confirmed (Signorello and McLaughlin 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of coffee essential oil orally administered in mice could not be determined at doses up to 5 g/kg (Viani 1988).

The LD_{50} of orally administered caffeine in rats is 335 mg/kg (Mills and Bone 2005). Other sources have more broadly estimated the oral LD_{50} of caffeine in rats to be between 261 and 383 mg/kg, or 200 and 400 mg/kg (NTP 1982; OECD 2004).

The lethal oral dose of caffeine in humans has been estimated as 5 to 10 g, equivalent to 50 to 100 cups of coffee (Stavric 1988).

Chronic Toxicity

In rats fed diets containing 6% regular or decaffeinated instant coffee for 2 years, the average coffee intake was 2.9 g/kg daily in males and 3.5 g/kg daily in females, a human equivalent of 70 to 80 cups of coffee daily. In all groups, the total number of neoplasms was either similar to or lower than the total in the control group. Body weights of coffee-treated groups were generally lower than body weights of controls and were inversely proportional to the caffeine content of the coffee samples. Food intake in treated rats was similar to or higher than that of control groups. Differences in blood chemistry and hematology were noted, but they were not considered to indicate toxic or ill effects, an interpretation substantiated by the histological findings. Plasma cholesterol levels in both sexes consistently showed a positive correlation with caffeine intake (Würzner et al. 1977a, 1977b).

In rats provided with coffee at dilutions of 25, 50, or 100% (intake at the 100% level was equivalent to human intake of 37 cups coffee by male rats and 67 cups coffee by female rats) as the sole source of fluid for up to 2 years, elevated levels of cholesterol were observed. A decrease in bone calcium and increase in serum calcium was observed after 1 year but returned to normal without change in treatment. Mean serum alkaline phosphatase, bilirubin, and blood urea nitrogen values were occasionally elevated. Treatment-related increases in relative weights of lungs, kidneys, liver, and epididymides were recorded. An increase in mortality was observed in females receiving 50 or 100% coffee. Levels of tumors were comparable in treatment and control groups (Palm et al. 1984).

In rats fed diets containing 0.5 to 5% instant coffee daily for 2 years, weight gain was impaired at the highest dose level. Liver and kidney hypertrophy were also observed at that dose level (Daubert 1967).

Genotoxicity

A review of genotoxicity studies on coffee indicated that mutagenic activity is seen in vitro with bacteria and fungi and in studies at high concentrations in mammalian cells in vitro. Mutagenic activity, however, is generally lacking when bacteria or mammalian cells are cultured with liver enzymes that provide metabolic activation. Animal studies indicate a lack of mutagenic activity of coffee and caffeine, with a number of studies showing antimutagenic activity of coffee (Nehlig and Debry 1994).

Coix lacryma-jobi L. — Poaceae

SCN: Job's tears
OCN: coix

PN: *yi yi ren* (seed)
Part: seed

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chen and Chen 2004; Tzeng et al. 2005).

Other Precautions

Job's tears should be used with caution in persons with spermatorrhea (frequent involuntary emission of the semen without copulation) and polyuria (passage of large volumes of urine) (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Editors' Note

Job's tears has traditionally been eaten as a food in China, India, and southeast Asia (Arber 2010; Simoons 1991).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that Job's tears may modify glucose regulation (Takahashi et al. 1986; Yeh et al. 2006). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Although two animal studies of Job's tears indicated a lack of adverse effects on fetal development (Shinoda et al. 2007; Tzeng et al. 2005), one of the studies using very large doses of Job's tears showed some loss of embryos but no adverse effects on fetal development (Tzeng et al. 2005).

Animal and in vitro studies have yielded conflicting data on the effects of Job's tears on uterine contractions. Inhibitory effects were observed on induced contractions in rats (Hsia et al. 2008), whereas studies in isolated rat uteri showed that different extracts induced, inhibited, or had no effects on uterine contractions (Hsia et al. 2008; Tzeng et al. 2005).

A reference text on traditional Chinese medicine indicates that Job's tears should not be used during pregnancy (Chen and Chen 2004).

No information on the safety of Job's tears during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

An inhibitory effect of Job's tears hulls on prostaglandin $F_{2\alpha}$-induced uterine contractions was observed in rats (Hsia et al. 2008).

A reduction in plasma glucose levels was observed in diabetic rats fed a diet containing 58% dehulled Job's tears daily for 4 weeks (Yeh et al. 2006). Hypoglycemic activity of Job's tears aqueous extract was observed in normal and diabetic mice after oral administration (Takahashi et al. 1986).

In Vitro Pharmacological Studies

In isolated rat uteri, an aqueous extract of Job's tears enhanced spontaneous uterine contractions. No effects of a methanol extract were observed (Tzeng et al. 2005). An

ethanol extract of Job's tears hull inhibited smooth muscle contraction in isolated rat uteri (Hsia et al. 2008).

Downregulation of progesterone biosynthesis was observed in rat granulosa cells treated with an extract of the bran of Job's tears (Hsia et al. 2006).

IV. Pregnancy and Lactation

In pregnant rats orally administered 1 g/kg of either aqueous or methanolic extracts of Job's tears on day 6 of pregnancy, an increase in fetal resorptions and postimplantation losses was observed in the group administered the water extract. No fetal malformations were observed in either group (Tzeng et al. 2005).

No adverse effects on fetal development were observed in rats fed diets containing up to 5% Job's tears during the full course of pregnancy. The authors concluded that the nontoxic dose level was over 3.5 g/kg daily for both mothers and pups (Shinoda et al. 2007).

No information on the safety of Job's tears during lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

No significant adverse changes in organ weights or blood chemistry were observed in rats orally administered aqueous extracts of whole Job's tears at doses of 0.5 to 2 g/kg daily for 14 days (Hayashi et al. 2009).

Cola spp.

Sterculiaceae

Cola acuminata (Pall.) Schott & Endl.
SCN: cola
OCN: abata cola; bissy nut; kola

***Cola nitida* (Vent.) A. Chev.**
SCN: cola
Syn: *Sterculia nitida* Vent.
OCN: ghanja cola; kola
Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: C*

Contraindications

None known.

Other Precautions

Cola contains caffeine, a nervous system stimulant. If taken in large amounts, cola products containing caffeine can cause insomnia, nervousness, and the other well-known symptoms of excess caffeine intake (Donovan and DeVane 2001).

Due to the central nervous system (CNS) stimulant effects of caffeine, use of caffeine-containing products is cautioned in persons with heart disorders, as excessive caffeine consumption may increase heart rate or exacerbate arrhythmias. Caution is also advised in psychological disorders, as caffeine may aggravate depression or induce anxiety (Brinker 2001).

* For caffeine-free preparations, no interactions are expected.

Drug and Supplement Interactions

Use of caffeine with other CNS stimulants, including bronchodilators or adrenergic drugs, may cause excessive central nervous system stimulation resulting in nervousness, irritability, insomnia, and possibly convulsions or cardiac arrhythmias (PDR 2006).

Notice

Caffeine (0.6–3.8%) (Atawodi et al. 2007; Leung and Foster 1996; Wichtl 2004); *see* Appendix 1.

Diuretic (Brunton et al. 2006); *see* Appendix 2.

Editors' Note

The American Herbal Products Association has established a trade requirement (AHPA 2011) that dietary supplement products that contain caffeine, whether as a direct ingredient or as a constituent of herbal ingredients, be labeled to disclose the presence of caffeine in the product and the quantity of added caffeine if greater than 25 mg; be formulated and labeled in a manner to recommend a maximum of 200 mg of caffeine per serving, not more often than every 3 to 4 hours; and bear the following or similar statement on the label of any dietary supplement that contains caffeine in sufficient quantity to warrant such labeling:

> *Too much caffeine may cause nervousness, irritability, sleeplessness, and, occasionally, rapid heartbeat. Not recommended for use by children under 18 years of age.*

See Appendix 1 for more specific details on this AHPA trade requirement.

Adverse Events and Side Effects

Habitual chewing of cola nuts may cause yellow pigmentation of the gums (Ashri and Gazi 1990), and excessive use may cause gastrointestinal complaints (Wichtl 2004).

Allergic reactions to cola have been reported (Speer 1976).

Pharmacological Considerations

See Other Precautions and Drug and Supplement Interactions above.

Pregnancy and Lactation

In a study of pregnant women who had consumed cola nuts during pregnancy, some association between cola use and infant head and chest circumference were observed (Abidoye et al. 1990), whereas an animal study showed no adverse effects on fetal development (Ajarem and Ahmad 1994). Pregnant women are advised to limit intake of caffeine to 300 mg daily (PDR 2006).

Caffeine is listed as a "Maternal Medication Usually Compatible with Breastfeeding" by the American Academy of Pediatrics Committee on Drugs with an indication that maternal consumption of caffeinated beverages should be limited to 150 mg daily (AAP 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Bright yellow pigmentation of the gums has been reported in persons who habitually chew on cola nuts (Ashri and Gazi 1990).

Cola nut has been listed as a common food allergen (Speer 1976).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In persons without malaria, administration of 35 g of cola nut was reported to cause malaria-like symptoms in a number of patients, including sleeplessness, lack of concentration, dizziness, and weakness (Alaribe et al. 2003).

Animal Pharmacological Studies

In mice intraperitoneally administered 2.5, 5, or 10 mg/kg of fresh cola nut extract, the 10 mg/kg dose depressed locomotor activities while the 5 mg/kg dose increased locomotor activity and the 2.5 mg/kg dose had no significant effects (Ajarem 1990).

An increase in arterial pressure was observed in rats fed diets containing 33 or 100% kola nuts daily for 7 days (Osim and Udia 1993).

In Vitro Pharmacological Studies

A methanol extract of cola showed a time-, dose-, and estrogen receptor-dependent stimulation of the *pS2* gene in estrogen receptor-positive human breast cancer cells (MCF-7), while an acetone extract showed no transcription stimulation of *pS2* (Fontenot et al. 2007).

In isolated rat hearts, application of an aqueous extract of *Cola nitida* subsp. *rubra* increased the heart metabolic rate at concentrations of 4 to 8 mg/l, while the rate decreased to control levels at 10 mg/l. In hearts treated with *Cola acuminata*, the heart metabolic rate increased after treatment with 4 to 10 mg/l with peak activity at 6 mg/l. Extracts of both species did not cause any change in heart metabolic rate after treatment with a concentration of 2 mg/l. Both extracts caused a dose-dependent increase followed by a decrease in heart rate (Chukwu et al. 2006).

IV. Pregnancy and Lactation

In a study of the effects of cola nut consumption during pregnancy on the anthropometric measurements of newborns, cola consumption was associated with a head circumference of 30 to 35 cm and was also associated with a difference in chest circumference. No correlation between cola nut consumption and birth weight was observed. Most mothers (76%) consumed between 13 and 91 g of cola nuts per week (Abidoye et al. 1990).

No adverse effects on development were reported in the offspring of pregnant mice provided up to 32 mg/l (equivalent to 10 mg/kg daily) of cola extract as the sole source of drinking water during the full course of pregnancy. In the 4-day-old pups, a decrease in body weight was observed as compared to the control group, but no differences in body weight were observed in pups of mothers that had been provided lower concentrations of cola extract (equivalent to 2.5 or 5 mg/kg daily) (Ajarem and Ahmad 1994).

Caffeine is in the FDA pregnancy category C and has been shown to cross the placenta and achieve blood and tissue concentrations in the fetus. Excessive intake of caffeine by pregnant women has been associated with fetal arrhythmias. Pregnant women are advised to limit caffeine intake to less than 300 mg daily (PDR 2006).

Caffeine is listed as a "Maternal Medication Usually Compatible with Breastfeeding" by the American Academy of Pediatrics Committee on Drugs. The Committee noted that maternal consumption of caffeine may cause irritability and poor sleeping patterns in nursing infants, and that maternal consumption of caffeinated beverages should not exceed 150 mg daily (AAP 2001).

Epidemiological studies have indicated an association between high caffeine intake during pregnancy and an increased risk of spontaneous abortions. An analysis concluded that methodological flaws in many of the studies led to biased results and that a causal link between caffeine consumption and abortion cannot yet be confirmed (Signorello and McLaughlin 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered caffeine in rats is 335 mg/kg (Mills and Bone 2005).

No adverse effects were reported in rats fed a diet of cola nuts (daily intake ~9.2 g; rats weighed ~210 g) (Osim and Udia 1993).

Subchronic Toxicity

In rats orally administered 57 mg/kg (equivalent to a human dose of 1 g/kg) of an aqueous extract of cola nut every other day for 18 weeks, a decrease in total body weight and an increase in absolute weights of liver, kidney, brain, and testis were observed. Total protein, RNA, and DNA of these organs were significantly depressed, and serum levels of total and conjugated bilirubin were significantly decreased (Ikegwuonu et al. 1981).

Collinsonia canadensis L.

Lamiaceae

SCN: stoneroot
OCN: citronella; horse balm; richweed

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Eclectic medical texts indicate that stoneroot was used to stop threatened abortions and to treat hemorrhoids in pregnant women (Ellingwood 1919; Felter and Lloyd 1898).

No information on the safety of stoneroot during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use during pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Doses over 2 to 4 grams may cause irritation of the kidneys and diarrhea (List and Hörhammer 1973).

Adverse Events and Side Effects

Allergic reactions to myrrh, including contact dermatitis and systemic allergic reactions, have been reported (Al-Suwaidan et al. 1998; Bensky et al. 2004; Bian and Pan 1987; Gallo et al. 1999; Lee and Lam 1993). Adverse events reported in one human study were giddiness, somnolence, mild fatigue, and abdominal discomfort (Sheir 2001).

Pharmacological Considerations

The bitter taste of myrrh may cause nausea and vomiting in persons with sensitive stomachs (Chen and Chen 2004).

Pregnancy and Lactation

In traditional Chinese medicine texts, myrrh is contraindicated in pregnancy (Bensky et al. 2004; Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No adverse effects of myrrh on fetal development were reported in an animal study (Massoud et al. 2000).

No information on the safety of myrrh during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal studies of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a human study of persons with schistosomiasis taking myrrh at doses of 10 mg/kg daily for 6 days, adverse events were transient and mild. The most frequently reported events were giddiness, somnolence, mild fatigue, and abdominal pain or discomfort. Myrrh had no significant effects on liver

functions, serum creatinine, or electrocardiographic findings, nor on liver and kidney functions (Sheir 2001).

No adverse events were reported in persons with *Fasciola* orally administered a resin and oil combination of myrrh at doses of 12 mg/kg daily for 6 days (Massoud 2001).

Case Reports of Adverse Events

Reports of allergic contact dermatitis to topical products containing myrrh have been confirmed by patch testing (Al-Suwaidan et al. 1998; Gallo et al. 1999; Lee and Lam 1993). Two cases of allergic reactions in persons orally administered Chinese herbal formulas containing myrrh have been reported. Myrrh was identified as the allergen in both cases (Bian and Pan 1987).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In traditional Chinese medicine texts, myrrh is contraindicated in pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No fetal abnormalities were observed in offspring of pregnant rats administered 50 to 200 mg/kg daily of a myrrh volatile oil and resin mixture on gestational days 6 to 15 (Massoud et al. 2000).

No information on the safety of myrrh during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered myrrh in mice could not be determined at doses up to 3 g/kg. No signs of toxicity were observed at that dose (Rao et al. 2001).

In goat kids orally administered 1 to 5 g/kg myrrh daily, grinding of teeth, salivation, soft feces, loss of appetite, jaundice, shortness of breath, ataxia, and recumbency were seen, and the animals died between days 5 and 16. Intestinal, hepatic, and renal toxicity were accompanied by anemia, leukopenia, increases in serum ALP activity and in concentrations of bilirubin, cholesterol, triglycerides and creatinine, and decreases in total protein and albumin. A dose of 0.25 g/kg was not toxic (Omer and Adam 1999).

Short-Term Toxicity

In rats administered myrrh at doses of 1000 mg/kg orally, 500 mg/kg intramuscularly, or 250 mg/kg intraperitoneally for 2 weeks, animals exhibited the following symptoms: depression, soft feces, jaundice, ruffled hair, hepatonephropathy, hemorrhagic myositis and patchy peritonitis (at the injection site), and death. These were accompanied by increases in serum ALP and ALT activities, bilirubin, and creatinine concentrations, and decreases in total protein and albumin levels, and macrocytic anemia and leukopenia. Doses of 500 mg/kg administered orally or 250 mg/kg administered intramuscularly were not lethal, and when given daily for 1 week the effects were less marked (Omer et al. 1999).

Subchronic Toxicity

No significant toxicity was observed in mice orally administered 100 mg/kg daily of myrrh for 90 days. At the end of the treatment period, the myrrh group had increased body weight gain and had increased weights of testes, epididymides, and seminal vesicles, although no spermatotoxic effects were found. An increase in red blood cell count and hemoglobin levels was seen (Rao et al. 2001).

Quick Reference Summary

Safety Class: 2b
Interaction Class: B

Contraindications

Not for use during pregnancy except under the supervision of a qualified healthcare practitioner (Chadha 1988).

Other Precautions

None known.

Drug and Supplement Interactions

Reductions in plasma concentrations of propanolol and diltiazem were observed after a single dose of guggulipid (Dalvi et al. 1994).

Notice

Uterine stimulant (Chadha 1988); *see* Appendix 2.

Editors' Notes

Many of the products on the U.S. market are standardized to contain specific levels of guggulsterones (Ulbricht et al. 2005; Urizar and Moore 2003). Preparations characterized on select guggulsterones may be expected to have different physiological effects than traditional preparations of the herb.

Guggulipid is a standardized extract of guggul (Sahni et al. 2005).

Adverse Events and Side Effects

Gastrointestinal upset, most commonly involving loose stools or diarrhea, has been reported as a side effect in human studies of guggul and guggul extracts (Kuppurajan et al. 1978; Malhotra and Ahuja 1971; Malhotra et al. 1977; Nityanand et al. 1989; Singh et al. 2007; Szapary et al. 2003). Such activity is generally seen at doses over 2 to 4 g (List and Hörhammer 1973).

Hypersensitivity drug rashes have been observed in human studies of orally administered guggul and guggul extracts (Gelfand et al. 2005; Satyavati 1991; Shanavaskhan and Binu 1997; Szapary et al. 2003). Allergic contact dermatitis to topical creams containing guggul was confirmed by patch testing (Kölönte et al. 2006; Salavert et al. 2007).

Pharmacological Considerations

Several human studies of guggul and guggulipid have indicated that guggul reduces platelet aggregation and increases serum fibrinolytic activity (Baldav et al. 1980; Bordia and Chuttani 1979; Gaur et al. 1997; Mester et al. 1979), although no reports of bleeding in humans is reported in the available literature, including multiple controlled trials (Ulbricht et al. 2005).

Pregnancy and Lactation

No adverse effects on fetal development have been observed in animal studies (CDIR 1986). An older study in rats indicated a reduction in fertility after repeated dosing of guggul (Amma et al. 1978). Uterine stimulant activity of guggul has been reported (Chadha 1988).

No information on the safety of guggul during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Reductions in plasma concentrations of orally administered propanolol and diltiazem were observed in healthy male volunteers administered a single oral 1 g dose of guggulipid (Dalvi et al. 1994).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal studies of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of clinical trials of gugulipid, guggulu A, and gum guggulu (Bordia and Chuttani 1979; Kuppurajan et al. 1978; Malhotra and Ahuja 1971; Singh et al. 1994; Szapary et al. 2002; Verma and Bordia 1988) indicated that several mild adverse events were reported during these trials, including rash, nausea, vomiting, eructation, hiccup, headache, loose stools, restlessness, and apprehension, although information regarding adverse events experienced during placebo administration was not always provided (Thompson Coon and Ernst 2003).

In a placebo-controlled double-blind human trial of guggulipid, 3% of the 3 g daily dose ("standard dose") group, 15% of the 6 g daily dose ("high dose") group, and none of the placebo group experienced a hypersensitivity drug rash judged by the investigators to be possibly related to the guggulipid. The skin reactions were associated with pruritus and all occurred within 48 hours of the initiation of therapy. Guggulipid was characterized by the investigators as generally well tolerated without statistically significant differences in rates of adverse events among the treatment groups. No significant changes in renal function, levels of liver-associated enzymes, electrolytes, or TSH levels were observed among any of the treatment groups. In the high dose group, a higher incidence of loose stools and diarrhea were reported than in the standard dose and placebo groups (Gelfand et al. 2005; Szapary et al. 2003).

Side effects reported in a human study of 100 mg daily of guggulipid for 24 weeks were headache, mild nausea, belching, and hiccups (Singh et al. 1994). Diarrhea was reported as a side effect in 12 to 15% of subjects in trials of guggul extract fractions. Anxiety and hiccups were also reported as side effects of these preparations (Malhotra and Ahuja 1971; Malhotra et al. 1977).

Unpurified guggul gum may cause itching or inflammation when applied topically. In early human studies of guggul, skin rashes, diarrhea, and irregular menstruation were reported as common side effects. Rashes were controlled by reducing the dose of guggul (Satyavati 1991; Shanavaskhan and Binu 1997).

No side effects were reported in some human studies of ethyl acetate fractions of guggul gum (Agarwal et al. 1986; Beg et al. 1996; Gopal et al. 1986).

Case Reports of Adverse Events

Reports of allergic contact dermatitis to topical creams containing guggul have been confirmed by patch testing. In one case, the patient was also sensitive to nickel and cobalt (Kölönte et al. 2006; Salavert et al. 2007). Cross-reactivity to abietic acid and balsam of Peru (*Myroxylon balsamum* var. *pereirae*) has been reported (Willis 1973).

Loose stools was reported in a man taking 3 g daily of guggulipid for 1 week. Prior to that week, the patient had been taking guggulipid at a dose of 550 mg daily for 5 months with no apparent side effects. Other drugs and supplements used daily were a nicotine patch, aspirin, and saw palmetto with lycopene (Sahni et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy subjects and subjects with coronary artery disease, administration of a petrol-soluble extract of guggul reduced the platelet adhesion index and increased serum fibrinolytic activity (Bordia and Chuttani 1979). Several other studies have indicated that guggulipid administration inhibits platelet aggregation and increases fibrinolysis (Baldav et al. 1980; Gaur et al. 1997; Mester et al. 1979). In theory, the risk of bleeding may increase, although there are no reports of bleeding in humans in the available literature, including multiple controlled trials (Ulbricht et al. 2005).

Animal Pharmacological Studies

An increase in serum triiodothyronine (T_3) and enhancement of the T_3/T_4 ratio were observed in mice orally administered a guggul extract at a dose of 0.2 g/kg daily for 15 days (Panda and Kar 1999). A ketosteroid isolated from guggul exhibited a strong thyroid-stimulatory action when administered to rats. Administration of 0.1 mg/kg caused an increase in iodine uptake by the thyroid and enhanced activities of thyroid peroxidase and protease (Tripathi et al. 1984).

In Vitro Pharmacological Studies

Guggulsterones activate the estrogen receptor-α isoform, progesterone receptor, and the pregnane X receptor with EC_{50} values in the low micromolar range. Guggulsterone-mediated activation of the pregnane X receptor induced the expression of CYP3A genes in both rodent and human hepatocytes (Brobst et al. 2004).

IV. Pregnancy and Lactation

A reduction in weights of the uterus, ovaries, and cervix as well as increases in sialic acid and glycogen levels in the uterus and ovaries were observed in rats orally administered guggul and the acid fraction of guggul at doses of 20 or 200 mg/kg daily for 7 days. The authors noted that such activity indicated an antifertility effect of this extract (Amma et al. 1978).

No teratogenic effects were observed in rats, monkeys, and dogs administered an ethyl acetate fraction of guggul (CDIR 1986).

Uterine stimulant activity of guggul has been reported (Chadha 1988).

No information on the safety of guggul during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally or intraperitoneally administered ethyl acetate fraction of guggul in mice could not be determined at doses up to 2 g/kg (Shanker and Singh 2001). The LD_{50} of orally administered guggul essential oil in mice is 1.7 g/kg (Bagi et al. 1985).

Short-Term Toxicity

In rats administered 250 mg/kg daily of a guggul petroleum ether fraction for 3 months, a 50% mortality rate was observed; a 20% morality rate was observed in the control group (Malhotra and Ahuja 1971).

Subchronic Toxicity

No mortality was observed in dogs administered 1 g daily of a guggul petroleum ether fraction for 3 months (Malhotra and Ahuja 1971).

Convallaria majalis L.

Liliaceae

SCN: lily-of-the-valley

Part: entire plant

Quick Reference Summary

Safety Class: 3
Interaction Class: B

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (List and Hörhammer 1973; Martindale and Reynolds 1996; Nelson et al. 2006; Roth et al. 1984; Wood and LaWall 1926).

Other Precautions

None known.

Drug and Supplement Interactions

Interaction considerations are the same as those for digoxin and other digitalis glycosides (Weiss and Fintelmann 2001).

Adverse Events and Side Effects

May cause nausea and vomiting (Felter and Lloyd 1898; Wood and LaWall 1926).

Ingestion of "large" amounts of lily-of-the-valley has been associated with changes in heart rhythms and rates. Pain in the oral cavity, nausea, emesis, abdominal pain, cramping, and diarrhea may also occur after ingestion (Nelson et al. 2006).

Pharmacological Considerations

Lily-of-the-valley has been reported to slow heart rate when given in "moderate doses" and to stop the heart at "toxic" doses (Wood and LaWall 1926).

Pregnancy and Lactation

No information on the safety of lily-of-the-valley during pregnancy or lactation was identified. While this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Dysrhythmia, heart block, hypotension, gastrointestinal distress, nausea, and vomiting were reported in four members of a family that ingested an unspecified amount of lily-of-the-valley leaves, having mistaken them for wild leeks (*Allium tricoccum*) (Edgerton 1989).

Ingestion of "large" amounts of lily-of-the-valley has been associated with dysrhythmia, sometimes accompanied by symptoms including sinus bradycardia, premature ventricular contractions, atrioventricular conduction defects, or ventricular tachydysrhythmias. Pain in the oral cavity, nausea, emesis, abdominal pain, cramping, and diarrhea may also occur after ingestion (Nelson et al. 2006).

Increased heart rate, restlessness, convulsions, and stupor were observed in a 2-year-old that had been mistakenly administered a teaspoon full of lily-of-the-valley fluid extract (Andrew 1898).

A review of lily-of-the-valley exposure cases reported to U.S. poison control centers over a 10-year period identified 2639 exposures to lily-of-the-valley and *Convallaria montana*, 93% of which were in children under 6 years of age. No fatalities were reported, and only 3 patients suffered major outcomes, with symptoms reported in 6% of all cases (Krenzelok et al. 1996).

Suspected lily-of-the-valley poisoning, with third degree atrioventricular block, bradycardia, vomiting, and lethargy, was reported in a dog that had been seen chewing on lily-of-the-valley leaves (Atkinson et al. 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of lily-of-the-valley during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Conyza canadensis (L.) Cronquist

Asteraceae

SCN: Canada fleabane
Syn: *Erigeron canadensis* L.

OCN: Canadian horseweed
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

In vitro studies have demonstrated some antiaggregatory effects of compounds from Canada fleabane on blood platelets (Olas et al. 2006; Saluk-Juszczak et al. 2007). The relevance of this in vitro data to human use is not known.

Pregnancy and Lactation

No information on the safety of Canada fleabane in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any

concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Polysaccharides from Canada fleabane have been observed to have dose-dependent antiaggregatory effects in ADP- and collagen-induced aggregation in human blood platelets (Olas et al. 2006; Saluk-Juszczak et al. 2007). The relevance of this in vitro data to human use is not known.

IV. Pregnancy and Lactation

No information on the use of Canada fleabane during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Coptis chinensis Franch. — Ranunculaceae

SCN: coptis
PN: *huang lian* (rhizome)

OCN: Chinese goldthread
Part: rhizome

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chan 1993; Jahnke et al. 2006; Yeung et al. 1990).

Other Precautions

Use of coptis during lactation is not recommended (Chan 1993).

Drug and Supplement Interactions

None known.

Notice

Berberine (4–7%) (Chang and But 1986); *see* Appendix 1.

Editors' Note

Most safety concerns reported for coptis are based on studies of the compound berberine and other alkaloids. Data regarding isolated compounds may not apply directly to products or extracts made from coptis.

Adverse Events and Side Effects

Hyperbilirubinemia was reported in an infant with G6PD deficiency (a hereditary enzyme deficiency, commonly called favism) who was administered coptis (Yeo and Tan 1996), although this may have been due to the G6PD condition (Kaplan and Hammerman 2002).

Texts on traditional Chinese medicine indicate that while coptis is regarded as relatively safe, adverse events reported in association with coptis include diarrhea, abdominal distention, reduction of red blood cells, heart palpitations, shortness of breath, dizziness, gastrointestinal discomfort, nausea, and vomiting (Bensky et al. 2004; Chen and Chen 2004).

Allergic reactions to coptis have been reported (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

The use of berberine-containing herbs is contraindicated or cautioned against in pregnancy in several contemporary texts on herbal safety (Brinker 2001; Mills and Bone 2005). These contraindications are based primarily on the uterine stimulant activity of the isolated compound berberine in excised mouse uteruses (Furuya 1957; Imaseki et al. 1961) and the potential ability of berberine to displace bilirubin and cause neonatal jaundice (Chan 1993). While definitive data confirming the safety of coptis during pregnancy is lacking, reproductive toxicity studies on the isolated compound berberine in mice and rats have shown no adverse effects on the fetus at doses equivalent to over 75 times the standard human dose (Jahnke et al. 2006; Price and George 2003).

Surveys and retrospective studies of coptis use during pregnancy in Taiwan indicate that coptis is commonly used by pregnant women (Chuang et al. 2006, 2007). One study indicated that no significant adverse effects on fetal growth were associated with coptis use (Chuang et al. 2006).

Some concerns exist for use of berberine-containing plants during pregnancy, including uterine stimulation (Furuya 1957; Imaseki et al. 1961), although no uterine stimulation was noted in rats administered high doses of berberine during pregnancy (Jahnke et al. 2006), and a study of berberine-containing herbal extracts on isolated uteri showed no correlation between uterine stimulation and berberine concentration (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of coptis monopreparations were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal studies of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An infant with glucose-6-phosphate dehydrogenase (G6PD) deficiency developed severe hyperbilirubinemia and transient bilirubin encephalopathy that the reporting authors indicated as being likely related to consumption of Chinese herbs, including coptis. The peak serum bilirubin was 562 µmol/l (Yeo and Tan 1996). A review of G6PD deficiency indicated that this condition is a potential source of severe neonatal hyperbilirubinemia and kernicterus (Kaplan and Hammerman 2002).

Texts on traditional Chinese medicine indicate that while coptis is regarded as relatively safe, adverse effects reported are transient diarrhea, abdominal distention, reduction of red blood cells, heart palpitations, shortness of breath, dizziness, tinnitus, vomiting, nausea, digestive tract discomfort, and allergic reaction. Details on the products used, doses, and durations of use were not reported (Bensky et al. 2004; Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Intraperitoneal administration of 0.02 mg/kg of the compound berberine daily for 1 week to adult rats resulted in a significant decrease in mean bilirubin serum protein binding due a displacement effect (Chan 1993).

In Vitro Pharmacological Studies

In vitro, an aqueous extract of coptis was found to displace bilirubin from serum protein binding as assessed by the peroxidase oxidation method. The authors indicated that coptis may increase the risk of brain damage by free bilirubin in jaundiced infants (Yeung et al. 1990).

The compound berberine was found to be 10 times more potent in vitro than phenylbutazone, a known displacer of bilirubin, and approximately 100 times more potent than papaverine (Chan 1993).

IV. Pregnancy and Lactation

In a retrospective survey of pregnant women in Taiwan taking two to three capsules of 300 to 500 mg of coptis daily during pregnancy, no significant adverse effects on fetal growth were observed. A statistically nonsignificant slight decrease in birth weight and increase in risk of low birth weight was reported in women who had taken coptis, especially in women who had taken more than 56 doses of coptis, as compared to a matched group of pregnant women who had not taken coptis (Chuang et al. 2006).

A survey regarding herb use during pregnancy in Taiwan indicated that 24% of women used at least one herbal product. Coptis was the third most commonly used herb, with 4% of women reporting use (Chuang et al. 2007).

A number of cases of kernicterus (brain damage caused by neonatal jaundice) were reported in south Asian countries in the 1970s and 1980s (Upton 2001). Coptis was a common ingredient in traditional formulas used in pregnant women and newborns. It has been shown in animal models to prevent bilirubin from binding to serum protein, an effect which was reported to increase the risk of brain damage by free bilirubin in jaundiced infants (Yeung et al. 1990). A review of traditional Chinese medicine use in cases of neonatal jaundice indicated that no association could be made between maternal use of Chinese goldthread during pregnancy and neonatal jaundice (Fok 2001).

In pregnant rats fed the compound berberine chloride dihydrate on gestational days (GD) 6 to 20, some reduction in maternal weight gain was observed, with a lowest-observed-adverse-effect level (LOAEL) of 530 mg/kg daily. Only a mild reduction in fetal weights was observed, and the LOAEL based on fetal weight reduction was 1000 mg/kg (Jahnke et al. 2006). Similarly, in mice administered berberine on GD 6 to 17 at doses up to 1155 mg/kg daily, the maternal LOAEL was determined to be 531 mg/kg daily, and the developmental toxicity level was 1000 mg/kg daily. In mice, 33% of the treated females died. Surviving animals had increased relative water intake, and average fetal body weight per litter decreased 5–6% with no change in live litter size (Jahnke et al. 2006).

Berberine has been shown to stimulate uterine contractions in both pregnant and nonpregnant mice (Furuya 1957; Imaseki et al. 1961). A study of various berberine-containing herbal extracts on isolated uteri, however, indicated that relaxation or stimulation of the uterus did not correlate with the concentration of berberine in the extract, suggesting that not all berberine-containing herbs will have the same effect on the uterus (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered berberine in mice is 329 mg/kg (Haginiwa and Harada 1962). The LD_{50} of orally administered berberine sulfate in rats is greater than 1000 mg/kg (Kowalewski et al. 1975).

Genotoxicity

No mutagenic activity of berberine was observed in *Salmonella typhimurium* TA100 and TA98 with or without metabolic activation by S9 mix. Berberine hydrochloride was weakly mutagenic to strain TA98 without S9 mix, but showed no mutagenic activity in TA100 without S9 mix (Nozaka et al. 1990).

No genotoxic, mutagenic, or recombinogenic activity of berberine with or without metabolic activation was observed in the SOS chromotest. Berberine did not induce significant cytotoxic, mutagenic, or recombinogenic effects during treatments performed under nongrowth conditions; however, in dividing cells, the alkaloid induced cytotoxic and cytostatic effects in proficient and repair-deficient strains of *Saccharomyces cerevisiae*. In dividing cells, the induction of frameshift and mitochondrial mutations, as well as crossing-over, indicated that berberine is not a potent mutagenic agent (Pasqual et al. 1993).

Coptis trifolia (L.) Salisb.

Ranunculaceae

SCN: American goldthread
Syn: *Coptis groenlandica* (Oeder) Fernald

OCN: canker root
Part: rhizome

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chan 1993; Jahnke et al. 2006).

Other Precautions

Use of American goldthread during lactation is not recommended (Chan 1993).

Drug and Supplement Interactions

None known.

Notice

Berberine (0.8%) (Felter and Lloyd 1898; Schultz 1884) *see* Appendix 1.

Editors' Note

Most safety concerns reported for American goldthread are based on studies of the compound berberine and other alkaloids. Data regarding isolated compounds may not apply directly to products or extracts made from American goldthread.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

The use of berberine-containing herbs is contraindicated or cautioned against in pregnancy in several contemporary texts on herbal safety (Brinker 2001; Mills and Bone 2005). These contraindications are based primarily on uterine stimulant activity of the isolated compound berberine in excised mouse uteruses (Furuya 1957; Imaseki et al. 1961) and the potential ability of berberine to displace bilirubin and cause neonatal jaundice (Chan 1993). While definitive data confirming the safety of American goldthread during pregnancy are lacking, several reproductive toxicity studies on the isolated compound berberine in mice and rats have shown no adverse effects on the fetus at doses equivalent to over 75 times the standard human dose (Jahnke et al. 2006; Price and George 2003).

Some concerns exist for use of berberine-containing plants during pregnancy, including uterine stimulation (Furuya 1957; Imaseki et al. 1961), although no uterine stimulation was noted in rats administered high doses of berberine during pregnancy (Jahnke et al. 2006). Moreover, a study of berberine-containing herbal extracts on isolated uteri showed no correlation between uterine stimulation and berberine concentration (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal studies of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Intraperitoneal administration of 0.02 mg/kg of the compound berberine daily for 1 week to adult rats resulted in a significant decrease in mean bilirubin serum protein binding due to a displacement effect (Chan 1993).

In Vitro Pharmacological Studies

The compound berberine was found to be 10 times more potent in vitro than phenylbutazone, a known displacer of bilirubin, and approximately 100 times more potent than papaverine (Chan 1993).

IV. Pregnancy and Lactation

In pregnant rats fed the compound berberine on gestational days (GD) 6 to 20, some reduction in maternal weight gain was observed, with a lowest-observed-adverse-effect level (LOAEL) of 530 mg/kg daily. Only a mild reduction in fetal weights was observed, and the LOAEL based on fetal weight reduction was 1000 mg/kg (Jahnke et al. 2006). Similarly, in mice administered berberine on GD 6 to 17 at doses up to 1155 mg/kg daily, the maternal LOAEL was determined to be 531 mg/kg daily, and the developmental toxicity level was 1000 mg/kg daily. In mice, 33% of the treated females died. Surviving animals had increased relative water intake, and average fetal body weight per litter decreased 5–6% with no change in live litter size (Jahnke et al. 2006).

Berberine has been shown to stimulate uterine contractions in both pregnant and nonpregnant mice (Furuya 1957; Imaseki et al. 1961). A study of various berberine-containing herbal extracts on isolated uteri, however, indicated that relaxation or stimulation of the uterus did not correlate with the concentration of berberine in the extract, suggesting that not all berberine-containing herbs will have the same effect on the uterus (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered berberine in mice is 329 mg/kg (Haginiwa and Harada 1962). The LD_{50} of orally administered berberine sulfate in rats is greater than 1000 mg/kg (Kowalewski et al. 1975).

Genotoxicity

No mutagenic activity of berberine was observed in *Salmonella typhimurium* TA100 and TA98 with or without metabolic activation by S9 mix. Berberine hydrochloride was weakly mutagenic to strain TA98 without S9 mix but showed no mutagenic activity in TA 100 without S9 mix (Nozaka et al. 1990).

No genotoxic, mutagenic, or recombinogenic activity of berberine with or without metabolic activation was observed in the SOS chromotest. Berberine did not induce significant cytotoxic, mutagenic, or recombinogenic effects during treatments performed under nongrowth conditions; however, in dividing cells, the alkaloid induced cytotoxic and cytostatic effects in proficient and repair-deficient strains of *Saccharomyces cerevisiae*. In dividing cells, the induction of frameshift and mitochondrial mutations, as well as crossing-over, indicated that berberine is not a potent mutagenic agent (Pasqual et al. 1993).

Cordia ecalyculata Vell.

Boraginaceae

SCN: chá-de-bugre
Syn: *Cordia salicifolia* Cham.

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of chá-de-bugre in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No effects on blood glucose were observed in diabetic rats orally administered an aqueous extract of chá-de-bugre daily for 13 days (Siqueira et al. 2006).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of chá-de-bugre during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered aqueous extract of chá-de-bugre in mice is 920 mg/kg whereas the oral LD_{50} could not be determined at doses up to 2 g/kg (Caparroz-Assef et al. 2005).

Subchronic Toxicity

No adverse effects, including changes in the body weight gain, organ weights, or biochemical and hematological parameters, were observed in mice orally administered up to 400 mg/kg aqueous extract of chá-de-bugre daily for 90 days (Caparroz-Assef et al. 2005).

Cordyceps sinensis (Berk.) Sacc.

Clavicipitaceae

SCN: cordyceps
PN: *dong chong xia cao* (fungal fruiting body and body of host larvae); *jinshuibao jiaonang*, *jinshuibao pian* (fermented Cs-4 mycelium)

OCN: Chinese caterpillar fungus
Part: fungal fruiting body and body of host larvae; mycelium

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known. *See* Clinical trials of drug or supplement interactions below for human studies demonstrating a lack of interaction with certain drugs.

Editors' Notes

Cordyceps is a fungus that parasitizes caterpillars (larvae) of the species *Hepialus armoricanus.* Commercially marketed cordyceps products include the fruiting body of the fungus with the body of the parasitized caterpillar, and products made from cultured strains of cordyceps mycelium (the nonreproductive portion of the fungus). The preparations Cs-4 and Cs-B_{414} that are the subject of several pharmacological studies are fermentation products from mycelial strains isolated from wild strains of cordyceps (Hockaday 2002).

Wild-collected cordyceps fruiting bodies (with body of host larva attached) have been reported to be adulterated with lead to increase the ingredient's weight, a practice that has led to contamination of cordyceps products and cases of lead poisoning (Wu et al. 1996). Such contamination is not a concern in products made from the mycelium or from cultivated cordyceps.

Adverse Events and Side Effects

A review of clinical trials of cordyceps and Cs-4 indicated that mild upper gastrointestinal tract discomfort has been reported (Zhu et al. 1998).

Pharmacological Considerations

Cordyceps and polysaccharide fractions of cordyceps have been shown to modify blood sugar levels in diabetic mice and rats, with the polysaccharide fraction having more marked effects than the whole extract (Balon et al. 2002; Li et al. 2006; Zhang et al. 2006; Zhao et al. 2002). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Limited information on the safety of cordyceps in pregnancy is available. One animal study of a cordyceps product in pregnancy indicated no adverse effects on maternal health or fetal development (Jing et al. 1987).

No information on the safety of cordyceps in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No adverse effects on cyclosporine A efficacy were observed when liver transplant patients taking cyclosporine A (5 mg/kg daily) were administered 3 g daily of cordyceps for 15 days. A significant reduction of cyclosporine A nephrotoxicity was reported (Xu et al. 1995).

No significant adverse events or interactions were reported in a study of Cs-4 in patients with chronic heart failure. Patients were administered 3 to 4 g daily of Cs-4 in addition to their standard prescription medication which included digoxin, hydrochlorothiazide, isosorbide dinitrate, furosemide, lanatoside, dopamine, and dobutamine (Zhang et al. 1995).

In elderly patients with acute infections, administration of 6 g daily of cordyceps reduced the toxicity of amikacin (400 mg daily for 6 days) with no apparent adverse effects on amikacin efficacy. Patients treated with cordyceps and amikacin had significantly lower levels of urinary *N*-acetyl-β-D-glucosaminidase as compared with those taking amikacin alone (Bao et al. 1994).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No adverse effects on methotrexate efficacy were observed in mice inoculated with melanoma cells orally administered 200 mg/kg daily of an aqueous extract of cordyceps with 15 mg/kg daily methotrexate (Nakamura et al. 2003).

Cordyceps reduced the nephrotoxic effects of cyclosporine A in rats, ameliorating glomerular and interstitial injuries. In the acute study, rats were administered 50 mg/kg cyclosporine A and 1000 mg/kg cordyceps daily for 15 days, while in the chronic study the animals received 30 mg/kg cyclosporine A and 500 mg/kg cordyceps daily for 3 months (Zhao and Li 1993).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical trials of cordyceps and Cs-4 indicated that adverse events reported in the trials were mild upper gastrointestinal tract discomfort, including nausea, dry mouth, and stomach discomfort (Zhu et al. 1998).

Case Reports of Adverse Events

Side effects associated with the use of cordyceps have been reported as headache, irritability, restlessness, edema, swelling of the face and extremities, nosebleeds, decreased volume of urine, and rapid pulse. Case details including exact product, dose, and duration of use were not available. (Chen and Chen 2004).

One case of constipation, abdominal distention, and decrease in peristalsis in a person taking cordyceps has been reported. Case details were not available (Bensky et al. 2004).

A systemic allergic reaction to Cs-4 has been reported (Xu 1992).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A polysaccharide-enriched preparation (10 mg/kg daily) of cordyceps and an aqueous extract of cordyceps (100 mg/kg daily) produced hypoglycemic effects on streptozotocin-induced diabetic rats, with the polysaccharide-enriched preparation producing greater effects than the aqueous extract (Zhang et al. 2006). A polysaccharide fraction of cordyceps (200 mg/kg daily) produced a hypoglycemic effect in alloxan-induced diabetic mice and streptozotocin-induced diabetic rats (Li et al. 2006).

Cs-4 lowered the fasting plasma levels of glucose and insulin, improving oral glucose tolerance and increasing the glucose-insulin index in rats (Zhao et al. 2002), and was observed to increase whole body insulin sensitivity in rats (Balon et al. 2002).

In Vitro Pharmacological Studies

The compound cordycepin has been shown to completely inhibit aggregation of human platelets induced by U46619 (a thromboxane A_2 analog) (Cho et al. 2006). Similarly, dose-dependent inhibition of collagen-induced human platelet aggregation by cordycepin in the presence of various concentrations of exogenous $CaCl_2$ has been observed (Cho et al. 2007).

The compound cordycepin produced apoptotic effects in OEC-M1, a human oral squamous cancer cell line (Wu et al. 2007).

IV. Pregnancy and Lactation

No adverse effects on pregnant rats or their fetuses were reported after pregnant rats were administered up to 5 g/kg cultured cordyceps mycelia on gestational days 6 to 16 (Jing et al. 1987).

No information on the safety of cordyceps during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered cordyceps in mice is 21 g/kg. Symptoms of overdose included generalized inhibition, followed by excitation, convulsions,

spasms, and respiratory depression (Chen and Chen 2004). Intraperitoneal administration of a macerate extract of cordyceps was lethal to some mice at a dose of 5 g/kg and was lethal to all treated mice at a dose of 30–50 g/kg (Zhu 1998). A macerate of cordyceps administered intravenously or subcutaneously had an inhibitory effect on mice and rabbits, with large doses inducing rapid respiration and pulse, then spasms resulting in death. The boiled extract was reported as nontoxic (Zhu 1998).

Cordyceps has been well tolerated in mice administered doses of 45 g/kg (route of administration not noted, likely oral) (Chen and Chen 2004).

Subchronic Toxicity

No significant changes in organ weights, blood parameters, or body weight were reported in rats administered 5 or 20 g/kg Cs-4 as part of the diet for 3 months (IMM 1996). No changes in blood parameters or liver or renal function were observed in dogs administered 3 g/kg Cs-4 as part of the diet for 3 months (IMM 1996).

No adverse effects were observed in rabbits orally administered Cs-B_{414} at a dose of 10 g/kg daily for 3 months. No changes in blood parameters, liver or renal function, and organ weights were observed, except an increase in the weight of the testes in treated males, which was associated with a significant increase in sperm count (Huang et al. 1987).

Genotoxicity

No genotoxic or mutagenic effects of Cs-B_{414} were observed in rabbits or in the Ames test with *Salmonella typhimurium* (Zhu et al. 1998).

Coriandrum sativum L. — Apiaceae

SCN: coriander (fruit)
AN: *dhanyaka*
PN: *yuan sui zi* (fruit)
OCN: Chinese parsley; culantro
Part: fruit (commonly known as "seed")

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to coriander fruit, including anaphylactic reactions, have been reported and confirmed by patch testing (Manzanedo et al. 2004).

Pharmacological Considerations

Coriander fruit has traditionally been used in the treatment of diabetes, and animal studies have demonstrated that it may modify glucose regulation (Aissaoui et al. 2008; Eddouks et al. 2002; Jabeen et al. 2009; Otoom et al. 2006; Srinivasan 2005). People with diabetes are advised to monitor their blood sugar closely and discuss the use of coriander fruit with a qualified healthcare practitioner prior to use.

Diuretic activity of coriander fruit has been observed in animal studies (Aissaoui et al. 2008; Jabeen et al. 2009).

Pregnancy and Lactation

In animal studies, no adverse effects of coriander fruit or oil on fetal development have been observed (Al-Said et al. 1987; Burdock and Carabin 2009; Vollmuth et al. 1990), although one study showed anti-implantation activity of a water extract of coriander fruit (Al-Said et al. 1987). The no-observed-adverse-effect level (NOAEL) of the oil for pregnant animals was estimated as 250 mg/kg daily and the NOAEL for fetuses was 500 mg/kg daily (Burdock and Carabin 2009; Vollmuth et al. 1990).

No information on the safety of coriander during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to coriander fruit, including anaphylactic reactions, have been reported and confirmed by patch testing (Manzanedo et al. 2004). Occupational protein contact dermatitis and occupational asthma from coriander exposure have been reported (Kanerva and Soini 2001; Sastre et al. 1996).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Coriander has traditionally been used in the treatment of diabetes (Eddouks et al. 2002; Otoom et al. 2006; Srinivasan 2005).

Animal Pharmacological Studies

Significant hypoglycemic activity of coriander fruit was observed in rats fed a diet containing 10% coriander seed daily for 90 days (Chithra and Leelamma 1999). An increase in insulin secretion was observed in diabetic mice fed a diet containing coriander fruit (62.5 g/kg approximate daily dose) and given drinking water containing coriander fruit (2.5 g/l) (Gray and Flatt 2007).

Dose-dependent diuretic activity of a coriander fruit extract was observed in rats intraperitoneally administered doses of 30 or 100 mg/kg, with the 30 mg/kg dose characterized as a mild diuretic and the 100 mg/kg dose reported as a "significant" diuretic, although the effects were less than that of furosemide, the control drug used in the study (Jabeen et al. 2009). Diuretic activity was observed in anesthetized rats administered a continuous intravenous infusion of an aqueous extract of coriander fruit at doses of 40

or 100 mg/kg for 2 h. Coriander fruit dose-dependently increased diuresis, excretion of electrolytes, and glomerular filtration rate but was less potent as a diuretic and saluretic than furosemide (Aissaoui et al. 2008).

A reduction in arterial blood pressure, partially blocked by atropine, was observed in anesthetized rats intravenously administered a water–methanol extract of coriander fruit (Jabeen et al. 2009).

In Vitro Pharmacological Studies

No adverse effects on immune function were observed in the plaque-forming cell and host-resistance assays in mice orally administered coriander oil at doses up to 1250 mg/kg daily for 5 days (Gaworski et al. 1994).

IV. Pregnancy and Lactation

In rats orally administered 250, 500, or 1000 mg/kg coriander essential oil daily 7 days prior to mating through 4 days after birth, at the highest dose a decrease in body weight and food consumption were observed along with a decrease in gestation index, length of gestation, and litter size. The only effect on offspring was a decrease in viability of pups at 1000 mg/kg/day. The authors of the study indicated that the maternal no-observed-adverse-effect level (NOAEL) of the oil was 250 mg/kg daily and the developmental NOAEL was 500 mg/kg daily (Burdock and Carabin 2009; Vollmuth et al. 1990).

In pregnant rats orally administered 250 or 500 mg/kg of an aqueous extract of fresh coriander fruit daily for at least 20 days, a dose-dependent anti-implantation effect was observed, but treatment failed to produce complete infertility. On the fifth day of treatment, a significant decrease in the serum progesterone level was noted. The investigators indicated this decrease might be responsible for the anti-implantation effects of the extract. No adverse effects on fetal development were observed, including changes in the weight or length of the fetuses, nor any changes in organs (Al-Said et al. 1987).

No information on the safety of coriander during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered water-methanol extract of coriander fruit in mice could not be determined at doses up to 10 g/kg (Jabeen et al. 2009). The LD_{50} of orally administered coriander essential oil in rats is 4.13 g/kg, whereas the dermal LD_{50} could not be determined at doses up to 5 g/kg in rabbits (Hart 1971).

Short-Term Toxicity

In rats orally administered 160, 400, or 1000 mg/kg coriander essential oil daily for 28 days, increases in absolute and relative kidney weights were observed in the high-dose group and in the mid-dose males. Absolute and relative liver weights were increased in the mid- and high-dose groups. Some histological changes were observed in the kidneys of high-dose males and in the livers of high-dose females. No treatment-related effects on survival, clinical observations, body weights, or food consumption were noted. The study suggested that the no-observed-effect level (NOEL) for coriander essential oil was 160 mg/kg daily for male rats and less than that for female rats (Letizia et al. 2003).

Genotoxicity

Some mutagenic activity of an ethanol extract of coriander fruit was observed in the Ames test in *Salmonella typhimurium* strains TA98 and TA100 (Mahmoud et al. 1992). In streptomycin-dependent strains of *S. typhimurium* TA98, some mutagenic activity of an alcohol extract of coriander was observed with but not without metabolic activation by S9 (Shashikanth and Hosono 1987). No mutagenic activity of hot water, methanol, or hexane extracts of coriander fruit was observed in the Ames test in *S. typhimurium* strains TA98 and TA100 with or without metabolic activation (Bersani et al. 1981; Higashimoto et al. 1993).

No genotoxic activity was observed in cultured rat embryo fibroblast cells treated with an alcohol extract of coriander (plant part not stated) in the comet assay with treatments up to 1020 mg (Heibatullah et al. 2008).

No clastogenic activity of coriander essential oil was observed in the chromosomal aberration test in vitro using a Chinese hamster fibroblast cell line treated with concentrations of the oil up to 0.125 mg/ml (Ishidate et al. 1984).

No genotoxic activity was observed in the yeast *Saccharomyces cerevisiae* treated with coriander essential oil (Bakkali et al. 2005).

Cornus officinalis Siebold & Zucc. — Cornaceae

SCN: Asiatic dogwood
Syn: *Macrocarpium officinale* (Siebold & Zucc.) Nakai
PN: *shan zhu yu* (fruit without seed)
OCN: Asiatic cornel; Asiatic cornelian cherry; Japanese cornel
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with painful or difficult urination (Bensky et al. 2004).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Asiatic dogwood in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Glucose-modulating activity was observed in diabetic rats administered an ether extract of Asiatic dogwood (Yamahara et al. 1981).

In Vitro Pharmacological Studies

No estrogenic or antiestrogenic activity of an ethanol extract of Asiatic dogwood was observed in a recombinant yeast system featuring a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of Asiatic dogwood in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

In mice, a study of anti-inflammatory activity utilized a dose of 5 g/kg of Asiatic dogwood with no adverse effects indicated (Chen and Chen 2004).

Genotoxicity

No mutagenic activity of water or methanol extracts of Asiatic dogwood were observed in the *Bacillus subtilis rec* assay or the Ames test with *Salmonella typhimurium* strains TA98 and TA100 with or without metabolic activation (Morimoto et al. 1982).

OCN: Chinese fumewort
Part: tuber

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Uterine stimulant (List and Hörhammer 1973); *see* Appendix 2.

Berberine (0.005–0.057%) (Ding et al. 2007; Zhang et al. 2009); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Allergic reactions to *Corydalis yanhusuo* have been reported (Bensky et al. 2004).

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that *Corydalis yanhusuo* should not be used in pregnancy (Bensky et al. 2004; Chen and Chen 2004), with one text making an exception for "exceptional circumstances" (Bensky et al. 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of *Corydalis yanhusuo* during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Although no adverse effects are expected at typical therapeutic doses, persons taking large doses (10–15 g) of *Corydalis yanhusuo* may develop drowsiness, dizziness, and abdominal distention (Bensky et al. 2004).

Allergic reactions to *Corydalis yanhusuo* have been reported, including drug fever, erythema, and pruritus, with nausea, dizziness, shortness of breath, and numbness of lips and extremities (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that *Corydalis yanhusuo* should not be used in pregnancy (Bensky et al. 2004; Chen and Chen 2004), with one text making an exception for "exceptional circumstances" (Bensky et al. 2004).

No information on the safety of *Corydalis yanhusuo* during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered *Corydalis yanhusuo* extract in mice was approximately 100 g/kg (Chen and Chen 2004). At this dose, side effects included decreased blood pressure, heart rate, and respiration along with sedation and tremor (Chen and Chen 2004).

The toxic dose of *Corydalis yanhusuo* in humans has been reported as 60–120 g. Symptoms of poisoning are reported to appear 1 to 4 hours after ingestion and include dizziness, facial pallor, drowsiness, weakness, dyspnea, spasms, shock, low blood pressure, and weak pulse. In severe cases of shock, tetanic convulsion and respiratory inhibition have been reported (Bensky et al. 2004).

Crataegus spp.

Rosaceae

Crataegus laevigata (Poir.) DC.
SCN: hawthorn
Syn: *Crataegus oxyacantha* auct.
OCN: English hawthorn; May tree; white thorn

Crataegus monogyna Jacq.
SCN: hawthorn
OCN: English hawthorn; one-seed hawthorn
Part: flower, leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

Some experience suggests that the dose of cardiac drugs may be reduced when hawthorn flower and leaf are taken concomitantly (Ammon and Haendel 1981; Bauer and Hölscher 1992; Blesken 1992; van Hellemont and Delfosse 1988). No interaction with digoxin was observed in a human study (Tankanow et al. 2003).

Adverse Events and Side Effects

In meta-analyses and systematic reviews of clinical trials, hawthorn flower and leaf extracts have been characterized as well tolerated in clinical trials, with few adverse events reported (Daniele et al. 2006; Pittler et al. 2003).

Pharmacological Considerations

A preliminary human study indicated a lack of interaction of an extract of dried flowering tops of hawthorn with low-dose insulin, metformin, gliclazide, ACE inhibitors, calcium channel blockers, β-blockers, and diuretics (Walker et al. 2006).

Pregnancy and Lactation

An animal study indicated no adverse effects of an ethanol extract of hawthorn leaf administered at a dose of 2.8 g/kg, noted as 56 times the human dose, daily on days 1–8 or 8–15 of gestation (Yao et al 2008). No adverse effects of hawthorn leaf and flower on pregnancy or fetal development have been observed in a limited number of additional animal studies (ESCOP 2003; Manolov and Daleva 1969).

No information on the safety of hawthorn leaf and flower during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Suspected Drug or Supplement Interactions

A clinical trial with eight healthy volunteers indicated that administration of 900 mg of hawthorn leaf and flower extract daily for 3 weeks had no effect on the pharmacokinetics of digoxin (Tankanow et al. 2003).

In a randomized trial of type 2 diabetes patients taking prescribed drugs, administration of 1200 mg daily of a 3:1 hawthorn leaf and flower extract for 16 weeks resulted in a moderate decrease in blood pressure with no adverse interactions reported. Prescription drugs being taken by the trial participants were hypoglycemic medications (low-dose insulin, metformin, gliclazide, and "others") and hypotensive medication (ACE inhibitors, calcium channel blockers, β-blockers, diuretics, and "others") (Walker et al. 2006).

Older studies indicated that hawthorn leaf and flower extracts could potentiate the effects of digitalis glycosides (Trunzler and Schuler 1962), or the coronary vasodilating effects of drugs such as caffeine, papaverine, adenosine, sodium nitrate, and epinephrine (Hahn et al. 1960). In the 1960s and 1970s, however, hawthorn leaf and flower extracts were often combined with conventional cardiac drugs including digitalis. Such combinations were reported to reduce the side effects of the drugs and sometimes allowed for a reduction in dose of the drug (Ammon and Haendel 1981; Bauer and Hölscher 1992; Blesken 1992; Upton 1999).

Case Reports of Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Coadministration of hawthorn leaf and flower extracts with barbiturates in mice resulted in significantly increased sleeping time as compared to barbiturates alone (Della Loggia et al. 1982).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A meta-analysis of hawthorn leaf and flower extract monopreparations, including 13 randomized, double-blind, and placebo-controlled clinical trials, indicated that adverse events reported were infrequent, mild, and transient. Adverse events reported in persons taking hawthorn included nausea, dizziness, and cardiac and gastrointestinal complaints. The number and nature of adverse events in placebo groups were not identified (Pittler et al. 2003).

A systematic review of adverse events in clinical trials, uncontrolled studies, observational studies, and case reports associated with hawthorn leaf and flower monopreparations, including 22 studies with a total of 7080 participants, concluded that hawthorn is generally well tolerated. Adverse events noted in the trials were similar in the hawthorn and placebo groups. The daily doses of hawthorn preparation in the clinical trials ranged from 160 to 1800 mg and the duration of treatment ranged from 3 to 24 weeks (Daniele et al. 2006).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In a study with rats orally administered 2.8 g/kg daily of an ethanol extract of hawthorn leaf on gestational days 1–8 or 8–15, examination of fetuses showed no adverse effects on fetal development. The dose used was calculated as 56 times the recommended human dose (Yao et al. 2008).

No adverse effects were observed in offspring of mice fed a flavonoid mixture obtained from the leaf of hawthorn at a dose of 100 mg/kg daily for 1 month (Manolov and Daleva 1969). No teratogenic effects were observed in pregnant rats and rabbits orally administered 1.6 g/kg of a hydroethanolic extract of hawthorn leaf and flower. The same study showed no postnatal toxicity in rats or their offspring (ESCOP 2003).

No information on the safety of hawthorn leaf and flower during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No signs of clinical toxicity or fatalities were observed in rats and mice orally administered up to 3000 mg/kg of hawthorn leaf and flower extract in a single dose (Schlegelmilch and Heywood 1994). No adverse effects were observed in rats orally administered 2.8 g/kg of an ethanol extract of hawthorn leaf daily for 8 days (Yao et al. 2008).

The LD_{50} of intraperitoneally administered hawthorn leaf and flower extract in rats is 750 mg/kg and in mice is 1170 mg/kg. Toxicity signs observed after intraperitoneal administration included sedation, piloerection, dyspnea, and tremor (Schlegelmilch and Heywood 1994). No adverse effects were observed in rats orally administered 2.8 g/kg of an ethanol extract of hawthorn leaf daily for 8 days (Yao et al. 2008).

Subchronic Toxicity

Administration of 300 mg/kg of hawthorn leaf and flower extract daily for 26 weeks to rats and dogs did not produce any signs of clinical toxicity (Schlegelmilch and Heywood 1994).

Genotoxicity and Mutagenicity

No evidence of mutagenicity or clastogenicity of extracts of hawthorn leaf and flower were observed using standard tests, including the Ames test, the mouse micronucleus assay, the mouse lymphoma test, and the human lymphoma test (Schlegelmilch and Heywood 1994).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

In the 1960s and 1970s, hawthorn fruit extracts were sometimes combined with conventional cardiac drugs, including digitalis, reportedly allowing for a reduction in dose of the drug (Ammon and Haendel 1981; Bauer and Hölscher 1992; Blesken 1992).

Editors' Note

Hawthorn fruit has been widely consumed as food, prepared as syrups and jams, and eaten fresh, and is considered to have a safety profile similar to commonly consumed fruits (Upton 1999).

Adverse Events and Side Effects

In meta-analyses and systematic reviews of clinical trials, hawthorn fruit extracts have been characterized as well tolerated in clinical trials with few adverse events reported (Daniele et al. 2006).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Chinese hawthorn fruit in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Suspected Drug or Supplement Interactions

In the 1960s and 1970s, hawthorn fruit extracts were sometimes combined with conventional cardiac drugs including digitalis. Such combinations were reported to reduce the side effects of the drugs and sometimes allowed for a reduction in dose of the drug (Ammon and Haendel 1981; Bauer and Hölscher 1992; Blesken 1992; Upton 1999).

Case Reports of Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal studies of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of adverse events in clinical trials and case reports associated with hawthorn monopreparations, including two trials of fruit extracts, concluded that hawthorn fruit extracts are generally well tolerated. Adverse events noted in the clinical trials were similar in the hawthorn fruit extracts and placebo groups. The duration of treatment was 8 or 10 weeks (Daniele et al. 2006).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of hawthorn fruit during pregnancy or lactation was identified.

V. Toxicity Studies

Hawthorn fruit has been widely consumed as food, eaten fresh, and prepared as syrups and jams, and is considered to have a safety profile similar to commonly consumed fruits (Upton 1999).

Crocus sativus L. — Iridaceae

SCN: saffron
AN: *kunkuma*
PN: *fan hong hua* (stigma)

OCN: Spanish saffron, true saffron
Part: stigma

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chadha

1988; Frohne and Pfänder 2000; List and Hörhammer 1973; Tang and Eisenbrand 1992).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Chadha 1988; Frohne and Pfänder 2000; List and Hörhammer 1973; Tang and Eisenbrand 1992; Wichtl 2004); *see* Appendix 2.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Overdose of saffron has been associated with vomiting, bleeding, vertigo, confusion, and yellowing of the skin and mucous membranes (mimicking jaundice) (Frank 1961; Wichtl 2004).

Pharmacological Considerations

Adverse effects have been associated with ingestion of 5 g of saffron stigmas (Frank 1961), although the standard dose in traditional Chinese medicine is an aqueous extract of 1.5 to 6 g (Bensky et al. 2004). The German Commission E lists the maximum daily dose as 1.5 g (Wichtl 2004). A human study indicated no adverse effects at doses up to 400 mg daily (Modaghegh et al. 2008). No risk is associated with consumption in standard food use quantities or in therapeutic dosage of less than 1.5 g per day (Wichtl 2004).

Pregnancy and Lactation

Saffron is reported to have a stimulating effect on the smooth muscles of the uterus (Wichtl 2004) and has been used as an abortifacient (Chadha 1988; Wichtl 2004). A reference text on traditional Chinese medicine indicates that saffron is contraindicated in pregnancy (Bensky et al. 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of saffron during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of saffron (maximum daily dose listed as 1.5 g) has been associated with vomiting, uterine bleeding, bloody diarrhea and urine, bleeding from the nose, lips, and eyelids, convulsions, intestinal colic, vertigo, confusion, and yellowing of the skin and mucous membranes (mimicking jaundice) (Bensky et al. 2004; Wichtl 2004).

Ingestion of 5 g of saffron in an attempted abortion resulted in severe purpura with black necrosis of the nose, thrombocytopenia, hypothrombinemia, uremia, and collapse (Frank 1961).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a safety evaluation of saffron in healthy volunteers, administration of 200 or 400 mg of saffron daily for 7 days did not cause any clinically important changes in hematological, biochemical, or electrocardiographic parameters. Observed changes regarded as not clinically significant included a decrease in standing systolic blood pressure and mean arterial pressure at the 400 mg dose, along with a slight decrease in red blood cells, hemoglobin, hematocrit, and platelets and an increase in sodium, blood urea nitrogen, and creatinine (Modaghegh et al. 2008).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An inhibitory effect on the calcium channel was observed in isolated guinea pig hearts treated with an aqueous-ethanol extract of saffron at concentrations of 1 or 5%, but not at 0.1 or 0.5% (Boskabady et al. 2008).

The compound crocetin demonstrated dose-dependent inhibition of platelet aggregation induced by ADP or collagen but not by arachidonic acid (Yang et al. 2008).

IV. Pregnancy and Lactation

In mice orally administered 100 mg/kg daily of a saffron extract on days 6 to 15 of pregnancy, a delay in bone ossification in the hip, metatarsus, metacarpus, fingers, and sternum was observed in fetuses excised on the 18th day of pregnancy. Decreased body weight of the fetuses, with no major congenital malformations, was observed (Golalipoor et al. 2006, 2008).

No information on the safety of saffron during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of saffron in rodents is reported as 20.7 g/kg (Nair et al. 1995). The LD_{50} of an ethanol extract of saffron in mice is reported as greater than 600 mg/kg (Nair et al. 1991).

The human lethal dose of saffron has been reported as 20 g (Wichtl 2004).

Short-Term Toxicity

In rats orally administered 0.35, 0.70, or 1.05 g/kg of an ethanol extract of saffron daily for 14 days, dose-dependent reductions in hemoglobin level, hematocrit, and total red blood cell count and an increase in total white blood cell count were observed. Dose-dependent increases in AST, ALT, urea, uric acid, and creatinine values were also seen. Microscopic observation revealed mild to severe hepatic and renal tissue injuries (Mohajeri et al. 2007).

Subchronic Toxicity

In rats subcutaneously administered 400 mg/kg of the compound crocin weekly for 13 weeks, acute tubular necrosis was found in all kidney samples from crocin-treated animals, and slight signs of nephrotoxicity were identified by biochemical analysis of the serum (Garcia-Olmo et al. 1999).

Genotoxicity

No mutagenic effects of ethyl acetate, methanol, or aqueous extracts of saffron were observed in the *Salmonella*/microsome assay using *S. typhimurium* strains TA98 and TA100 with or without metabolic activation (Yamamoto et al. 1982). No mutagenic effects of a 2:1 chloroform-methanol extract of saffron were observed in pig kidney cells or in trophoblastic placenta cells treated at concentrations of 100 mg/plate (Rockwell and Raw 1979).

Antimutagenic activity was observed in mice orally administered 20, 40, or 80 mg/kg of an aqueous extract of saffron three times in 5 days before administration of known mutagens (Premkumar et al. 2001, 2006). Antimutagenic effects of saffron were also observed in the mouse bone marrow micronucleus test with oral doses of 25, 50, and 100 mg/kg (Premkumar et al. 2003), and in the Ames test in *Salmonella typhimurium* strain TA98 (Abdullaev et al. 2003).

Cullen corylifolium (L.) Medik. — Fabaceae

SCN: psoralea
Syn: *Psoralea corylifolia* L.
AN: *bakuchi*
PN: *bu gu zhi* (fruit)
OCN: Malaytea scurfpea; scurfy pea
Part: seed

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chen et al. 2007).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Photosensitizing (Chang and But 1986; Innocenti et al. 1977; Maurice and Cream 1989); *see* Appendix 2.

Adverse Events and Side Effects

Allergic reactions of the skin have been reported after oral use of psoralea (Bensky et al. 2004).

Although psoralea contains compounds known to cause phototoxicity when applied externally (Epstein 1999; Innocenti et al. 1977), no phototoxic reactions from ingestion of psoralea have been reported in the Chinese literature (Bensky et al. 2004). A single case of phototoxicity after ingestion was identified in other literature, and the case involved long-term use of an excessive amount (30 g daily) of psoralea (Maurice and Cream 1989).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although one text on traditional Chinese medicine indicated that psoralea is sometimes used to prevent miscarriage (Bensky et al. 2004), another text indicates that psoralea should be used with caution during pregnancy (Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of psoralea during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Photosensitivity was reported in a 30-year-old man with vitiligo. The man had been drinking an infusion prepared from 30 g of powdered seed daily for approximately 6 months (Maurice and Cream 1989). Note that the 30 g in this case is a gross overdose; the standard dose in traditional Chinese medicine is 4.5 to 9 g, while in Ayurvedic medicine the standard dose is 1 to 3 g (Bensky et al. 2004; Kapoor 2001).

Acute cholestatic hepatitis was reported in a 44-year-old woman who drank an unspecified amount of psoralea with a cup of black tea every hour for 7 weeks (Nam et al. 2005).

A text on traditional Chinese medicine reports that no adverse effects of psoralea are expected within the normal dose range (decoction of 4.5–9 g) (Bensky et al. 2004). In overdose, psoralea has been associated with dizziness, general weakness, blurred vision, rapid breathing, and vomiting. Severe cases of overdose have been associated with vomiting of blood, loss of consciousness, and coma (Bensky et al. 2004).

Allergic reactions have been reported after use of oral and injected preparations of psoralea (Bensky et al. 2004; Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

The compounds psoralen and angelicin extracted from psoralea demonstrated photosensitizing activity after topical application to guinea pigs (Innocenti et al. 1977).

No changes in liver enzymes or hepatic CYP450 enzymes were observed in mice orally administered the compound isopsoralen daily for 6 days (Bickers et al. 1982).

A reduction in stress-induced increases in MAO-A and MAO-B was observed in mice orally administered 30 or 50 mg/kg of total furanocoumarins from psoralea daily for 21 days, and psoralea reduced biochemical changes induced by chronic mild stress (Chen et al. 2007).

No changes in uterine weight were observed in ovariectomized rats orally administered 25 or 50 mg/kg of a hydroethanolic extract of psoralea daily for 3 months. Rats in a control group administered 5 µg/kg estrogen daily had significantly higher uterine weights, suggesting a lack of estrogenic activity of psoralea (Tsai et al. 2007).

In Vitro Pharmacological Studies

The compounds psoralen and isopsoralen inhibited monoamine oxidase (MAO) activity in rat brain mitochondria, preferentially inhibiting MAO-A activity over MAO-B activity. This inhibition of enzyme activities was found to be dose-dependent and reversible. The IC_{50} values for MAO-A were 15.2 µ*M* for psoralen and 9.0 µ*M* for isopsoralen. The IC_{50} for MAO-B was 61.8 µ*M* for isopsoralen (Kong et al. 2001).

The compounds psoralen and isopsoralen were selective ER-α agonists in a HeLa cell assay. These compounds promoted proliferation of estrogen receptor-positive breast cancer cells (MCF-7). Other compounds in psoralea were ER-β agonists (Xin et al. 2010).

An ethanol extract of psoralea demonstrated estrogenic activity in a recombinant yeast system with both a human estrogen receptor expression plasmid and a reporter plasmid (Zhang et al. 2005).

Inhibition of platelet aggregation induced by arachidonic acid, collagen, and platelet-activating factor was observed in rabbit platelets treated with a methanol extract of psoralea (Tsai et al. 1996).

IV. Pregnancy and Lactation

Although one text on traditional Chinese medicine indicated that psoralea is sometimes used to prevent miscarriage (Bensky et al. 2004), another text indicates that psoralea should be used with caution during pregnancy (Chen and Chen 2004).

In rats subcutaneously administered 60 or 90 mg daily of nonsaponified fractions of psoralea, a reduction in fetal implantations and increase in resorptions was observed (Khan and Samad 1975).

No information on the safety of psoralea during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of psoralea essential oil in mice was 38 g/kg (Zhu 1998). The LD_{50} of compounds from psoralea orally administered to mice was 180 mg/kg for isopsoralen and 2.3 ml/kg for bakuchiol (Zhu 1998).

The LD_{50} of an ether-acetone fraction of the *n*-hexane extract of psoralea in mice could not be determined after oral administration of doses up to 400 mg/kg (Latha and Panikkar 1999).

In male rats orally administered a single dose of 10 g/kg of an ethanol extract of psoralea, a reduction of serum testosterone and FSH levels preceded degeneration of certain developing germ cells at 3 and 7 days after administration (Takizawa et al. 2004).

No adverse effects were observed in mice orally administered 50, 100, or 200 mg/kg of the compound isopsoralen daily for 3 days (Zhu 1998).

Subchronic Toxicity

In rats fed diets containing 0.375, 0.75, 1.5, or 3.0% of an ethanol extract of psoralea daily for 90 days, weights of the testes in the 1.5 and 3.0% groups and weights of the ovaries in the 3.0% group were significantly lower than controls. Histopathological examination revealed seminiferous tubular atrophy and Leydig cell atrophy in the testes, and epithelial cell atrophy in the seminal vesicles and prostate at the 1.5 and 3.0% level in males. In females, a decrease in the number of corpora lutea associated with necrotic follicles in the ovaries was observed at the 1.5 and 3.0% level (Takizawa et al. 2002). To clarify the pathogenetic targets for the testicular effects of psoralea, rats were fed a diet containing 3% psoralea extract for up to 12 weeks. Tubular degeneration associated with Leydig cell atrophy was observed along with a reduction of serum testosterone and FSH levels (Takizawa et al. 2004).

No changes in liver or kidney function, ECG, or histology of internal organs were observed in dogs orally administered 10 to 100 mg/kg of the compound isopsoralen daily for 14 days (Zhu 1998).

In mice orally administered up to 1 ml/kg of the compound bakuchiol daily for 1 to 4 weeks, progressive renal damage was observed but no pathological changes were reported in other organs (Zhu 1998).

Cuminum cyminum L. — Apiaceae

SCN: cumin
AN: *jiraka*

Part: fruit (commonly known as "seed")

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Cumin should be used with caution by individuals with inflammation of the kidneys or a history of irritation of the kidneys (Gachkar et al. 2007; Rong and Zi-Tao 2004).

Drug and Supplement Interactions

None known.

Editors' Note

Concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Allergic reactions, including anaphylactic reactions, to cumin have been reported (Anliker et al. 2002; Boxer et al. 1997; Stager et al. 1991).

Pharmacological Considerations

An animal study indicated that cumin increased plasma levels of the drug rifampicin (Sachin et al. 2007). Animal studies

suggested estrogenic activity of cumin seed (Al-Khamis et al. 1988; Malini and Vanithakumari 1987).

Pregnancy and Lactation

Animal studies have indicated that large doses of cumin have antifertility activity (Al-Khamis et al. 1988; Garg 1976).

No information on the safety of cumin in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

An increase in plasma levels of rifampicin was observed in mice orally administered 16 mg/kg of a water-ethanol extract of cumin with 40 mg/kg of rifampicin. The activity was attributed to a flavonoid glycoside and was hypothesized to be due to a permeation-enhancing effect of the glycoside (Sachin et al. 2007).

II. Adverse Events

Case Reports of Adverse Events

Anaphylactic reactions to cumin have been reported (Boxer et al. 1997). Persons with mugwort-spice syndrome have also tested positive to cumin (Anliker et al. 2002; Stager et al. 1991).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in bone loss was observed in ovariectomized rats with estrogen deficiency-induced osteoporosis orally administered 1 g/kg of a methanol extract of cumin daily for 10 weeks (Shirke et al. 2008).

In ovariectomized rats orally administered 10, 20, or 25 µg/kg of an acetone extract of cumin daily for 10 days, estrus was induced. In rats administered the 20 or 25 µg/kg doses, an increase in uterine weight and protein concentration in the endometrium were observed (Malini and Vanithakumari 1987).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In rats orally administered 250 or 500 mg/kg of an aqueous extract of cumin, mild abortifacient activity was observed when the extract was administered on gestational days 8 to 12. Cumin also increased the plasma levels of estradiol-17β at the proestrus and estrus stages of the estrus cycle (Al-Khamis et al. 1988).

In rats administered an alcohol extract of cumin, 100% antifertility activity was observed at a dose of 150 mg/kg (Garg 1976).

A survey of mothers in the United Arab Emirates indicated that cumin is one of the spices commonly used to soothe crying infants. Of 998 mothers surveyed, 33 reported using cumin to soothe their infants (Abdulrazzaq et al. 2009).

No information on the safety of cumin during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered ethanol extract of cumin could not be determined at doses up to 3 g/kg (Shah et al. 1989).

Short-Term Toxicity

In rats fed diets containing 2 or 10% cumin for 6 weeks, hematological changes were observed in the 10% group after 3 weeks of treatment. These changes included decreases in hemoglobin concentration, red blood cells, packed cell volume, and mean corpuscular hemoglobin concentration, and increases in white blood cells and lymphocytes. After 6 weeks of treatment, changes in erythrocytic series persisted, but the values for white blood cells and lymphocytes decreased. Impairment of growth and enterohepatonephropathy were also observed in the 10% group. No hematological changes were observed in the 2% group (Haroun et al. 2002).

Subchronic Toxicity

In rats orally administered 100 mg/kg of an ethanol extract of cumin daily for 90 days, 30% developed wounds and ulcers on the tail, 15% developed alopecia, and 25% of the animals had died by the end of the 90 days, as compared with 10% that died in the untreated control group. An increase in hemoglobin, and no change in organ weights, was observed (Shah et al. 1989).

Genotoxicity

No mutagenic activity of an aqueous extract of cumin was observed in *Salmonella typhimurium* strains (Sivaswamy et al. 1991). In the mouse micronucleus test, cumin exhibited dose-dependent inhibition of chemically induced genotoxicity (Abraham et al. 1998).

Curculigo orchioides Gaertn.

Hypoxidaceae

SCN: curculigo
PN: *xian mao* (rhizome)

OCN: golden eye grass
Part: rhizome

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Tarafder 1983).

Not for long-term use; do not exceed recommended dose (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Standard Dose

A decoction of 3 to 10 g (Bensky et al. 2004; Chen and Chen 2004); maximum dose is 12 g daily (Bensky et al. 2004).

Adverse Events and Side Effects

Large doses have been associated with cold sweating, numbness of the limbs, swollen tongue, agitation, and loss of consciousness (Bensky et al. 2004).

Pharmacological Considerations

An animal study indicated that curculigo may modify glucose regulation. People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a q ualified healthcare practitioner prior to use (Madhavan et al. 2007).

Animal studies have indicated that curculigo has immunomodulatory activity and may counteract the effects of immunosuppressant drugs (Bafna and Mishra 2006; Zhu 1998).

Conflicting results on estrogenic activity of curculigo have been reported in animal studies, with one study showing estrogenic activity (Vijayanarayana et al. 2007) and another study showing a lack of estrogenic activity (Cao et al. 2008).

Pregnancy and Lactation

An ethnobotanical survey in northern India indicated that curculigo was traditionally used as an abortifacient (Tarafder 1983). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of curculigo in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Large doses have been reported to cause side effects such as cold sweating, numbness of the limbs, swollen tongue, agitation, and loss of consciousness (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In mice with cyclophosphamide-induced immunosuppression, oral administration of 50 to 800 mg/kg methanol extract of curculigo daily for 13 days produced dose-dependent increases in humoral antibody titer, delayed-type hypersensitivity, and levels of white blood cells (Bafna and Mishra 2006).

In cyclophosphamide-induced immunosuppressed mice, oral administration of 10 or 20 g/kg of curculigo increased peritoneal macrophages and counteracted the immunosuppressive effect of cyclophosphamide (Zhu 1998).

In ovariectomized rats orally administered 300, 600, or 1200 mg/kg of an ethanol extract of curculigo daily for 7 days, increases in percentage vaginal cornification, uterine wet weight, uterine glycogen content, and proliferative changes in the uterine endometrium were observed, as compared to control (Vijayanarayana et al. 2007).

A reduction in bone loss with no effects on body weight or uterine weight was observed in ovariectomized rats intragastrically administered 0.5, 1.0, or 2.0 g/kg of curculigo extract daily for 12 weeks (Cao et al. 2008).

A reduction in blood glucose levels was observed in diabetic rats orally administered 0.5 or 1.0 g/kg of alcohol or aqueous extracts of curculigo daily for 21 days (Madhavan et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

An ethnobotanical survey of tribal peoples in Bihar, India, indicated that a paste of curculigo was traditionally used as an abortifacient (Tarafder 1983).

No information on the safety of curculigo during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered curculigo in mice could not be determined at doses up to 150 g/kg (Chen and Chen 2004).

Curcuma zedoaria (Christm.) Roscoe — Zingiberaceae

SCN: zedoary
AN: *karchura*
PN: *e zhu* (rhizome)
Part: rhizome

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004). Not for use in excessive menstruation (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Other species of *Curcuma* are used interchangeably as sources of *e zhu* (Bensky et al. 2004; Chen and Chen 2004; PPRC 2005).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Extracts of zedoary have inhibited platelet binding in vitro (Han et al. 1995). A text on traditional Chinese medicine indicates that zedoary should be used with caution in persons taking anticoagulant or antiplatelet drugs, although this concern is theoretical and no interactions have been documented (Chen and Chen 2004).

Pregnancy and Lactation

A text on traditional Chinese medicine indicates that zedoary should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information of the safety of zedoary in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed in human intestinal epithelial (Caco-2) cells treated with a methanol extract of zedoary. The 50% inhibitory concentration (IC_{50}) of the extract was 0.014 mg/ml (Hou et al. 2007). Extracts of zedoary inhibited the drug-metabolizing isoenzymes CYP1A1, CYP1A2, CYP2B1, CYP2B2, and CYP2E1 (Jeong et al. 2002).

An increase in activity of the drug transporter P-gp was observed in human intestinal epithelial (Caco-2) cells treated with a methanol extract of zedoary at a concentration of 0.1 mg/ml (Hou et al. 2008).

Inhibition of platelet-activating factor binding to rabbit platelets was observed after treatment of platelets with 200 µg/ml of the freeze-dried form of an aqueous extract of zedoary (Han et al. 1995).

IV. Pregnancy and Lactation

Texts on traditional Chinese medicine indicates that zedoary should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information of the safety of zedoary in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of zedoary in mice is 147 g/kg after oral administration and 55 g/kg after intramuscular injection (Chen and Chen 2004).

Short-Term Toxicity

In rats fed a high-protein flour prepared from zedoary, ingestion of 320 g/kg resulted in death of all animals by day 6. The author of that study noted that the traditional method of preparing zedoary in India involves prolonged washing in multiple changes of water, a process that removes most of the protein and other water-soluble nutrients (Latif et al. 1979).

In weanling rats fed 400 g/kg daily of dried zedoary, 40% of the animals died within 4 days. Day-old chicks fed 100 or 200 g/kg of the same dried zedoary had a decrease in body weight but survived the 20-day test period (Latif et al. 1979).

Genotoxicity

No genotoxic activity of a polysaccharide fraction of zedoary was observed in the Ames test for mutagenicity with or without metabolic activation with S9. No clastogenic activity of the same polysaccharide fraction was observed in micronucleus or chromosomal aberration assays performed using Chinese hamster lung fibroblast cells with or without metabolic activation (Kim et al. 2000).

Curcuma longa L.

Zingiberaceae

SCN: turmeric
Syn: *Curcuma domestica* Valeton
AN: *haridra*

PN: *jiang huang* (rhizome)
OCN: common turmeric; Indian saffron; yellow ginger
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Turmeric contains 0.3–5.4% of the compound curcumin (Leung and Foster 1996). Commercially available turmeric products include products with this normal percentage of curcumin and those modified to contain up to 95%

curcuminoids (including curcumin and other similar compounds). Products with modified concentrations of selected compounds may be expected to have different physiological effects than traditional preparations of the herb.

Adverse Events and Side Effects

Contact dermatitis has been reported in sensitive persons after topical application of turmeric products (Hata et al. 1997; Nath and Thappa 2007; Sakurane et al. 1999).

Turmeric and the compound curcumin have been generally well tolerated in human studies at doses up to 8 g daily. Adverse events reported included nausea and diarrhea (Hsu and Cheng 2007).

Pharmacological Considerations

Several references on herbal safety contraindicate the use of turmeric in persons with biliary tract obstruction (Brinker 2001; De Smet 1993; Mills and Bone 2005) due to reported bile-stimulating activity (De Smet 1993) observed in rats administered the compound curcumin (Bhat et al. 1984), and gallbladder contraction (50% contraction after 40 mg dose) observed in humans administered the compound curcumin (Rasyid et al. 2002). Such concerns are theoretical, and no clinical evidence for turmeric has been reported to support or refute these concerns.

In one study, a large dose (100 mg/kg) of the compound curcumin caused ulcers in rats but showed no ulcerogenic activity at a smaller dose (50 mg/kg) (Gupta et al. 1980); in other studies, curcumin exhibited potent antiulcer activity at a medium dose (80 mg/kg) (Sivalingam et al. 2007; Swarnakar et al. 2005). Extracts of turmeric have shown antiulcer activity in humans (3 g daily dose) and rats (500 mg/kg dose) (Prucksunand et al. 2001; Rafatullah et al. 1990).

Antiplatelet activity of turmeric and the compound curcumin has been reported in vitro but has not been confirmed in human or animal studies (Jantan et al. 2007; Shah et al. 1999; Srivastava 1989; Srivastava et al. 1995).

Pregnancy and Lactation

Although texts on traditional Chinese medicine contraindicate the use of turmeric rhizome in pregnancy (Bensky et al. 2004; Chen and Chen 2004), no adverse effects on reproduction in mice were observed at high doses (1 g/kg daily) of the compound curcumin in a two-generation study (Ganiger et al. 2007). Earlier studies on reproduction provided mixed results, with some indicating a decrease in implantation (An 1998; Chen 1988; Garg 1974) and other studies showing no adverse effects (Francis 2002; Govindarajan 1980; Vijayalaxmi 1980).

The compound curcumin and its metabolites have been shown to cross into breast milk (Singh et al. 1995, 1996).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical trials of turmeric and the compound curcumin indicated that turmeric and curcumin were generally safe and well tolerated at doses up to 8 g daily for 4 months. Adverse events reported in human pharmacological studies (see below) were primarily diarrhea or nausea, with other events reported as headache, rash and yellowish stool (Hsu and Cheng 2007).

Case Reports of Adverse Events

Kumkum, a turmeric-based paste applied topically, has been associated with cases of dermatitis (Nath and Thappa 2007). Cases of contact urticaria from the compounds curcumin and tetrahydrocurcumin have been reported (Fischer and Agner 2004; Lamb and Wilkinson 2003; Liddle et al. 2006; Thompson and Tan 2006). Contact dermatitis with positive patch test for turmeric was reported in a spice shop worker routinely exposed to spice powders (Goh and Ng 1987). Similarly, contact dermatitis was reported in a pasta factory worker exposed to curcumin food coloring (Kiec-Swierczynska and Krecisz 1998). Two cases of contact dermatitis were reported in individuals using a topical ointment containing turmeric. Patch testing of both individuals indicated a sensitivity to both turmeric and curcumin (Hata et al. 1997; Sakurane et al. 1999).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a dose escalation study of single doses of a standardized turmeric extract (95% curcuminoids), healthy volunteers were administered doses from 0.5 to 8 g. Tolerance was reported as excellent at all dose levels. Adverse events, including yellow stool, diarrhea, headache, and rash, were reported at doses of 1 g and above (Lao et al. 2006). In a dose

escalation study in patients with colorectal cancer, doses between 0.4 and 2.2 g of turmeric extract daily (36–180 mg curcumin) for up to 4 months were well tolerated, and dose-limiting toxicity was not observed. Ingestion of 440 mg of turmeric extract for 29 days was accompanied by a 59% decrease in lymphocytic glutathione *S*-transferase activity, but at higher dose levels that effect was not observed (Sharma et al. 2001). In a human safety study of turmeric essential oil, no effects on hematological, renal, or hepatic parameters were observed in healthy volunteers administered 1.8 ml of turmeric essential oil daily for 1 month and 3 ml daily for 2 months. One volunteer discontinued the study due to an allergic skin rash (Joshi et al. 2003).

Curcuminoids were reported as well tolerated at doses of 2 g daily for 7 weeks (Chainani-Wu et al. 2007), and curcumin was well tolerated at a dose of 2 g daily for 6 months (Hanai et al. 2006). A dose escalation study of curcumin at doses of 1 to 12 g daily in patients at high risk of selected cancers indicated that no toxicity was observed at doses up to 8 g daily for 3 months. The 12 g dose was reported as unacceptable to patients due to the bulky volume of the drug (Cheng et al. 2001).

Dose-dependent contraction of the gallbladder was observed in healthy volunteers administered 20, 40, or 80 mg of the compound curcumin, with higher doses causing greater contraction (Rasyid et al. 2002).

In patients with duodenal or gastric ulcers, administration of 3 g turmeric daily for 9 weeks resolved the ulcers in 75% of the patients (Prucksunand et al. 2001).

Turmeric paste has traditionally been applied topically to prevent unwanted hair growth in women (Rao and Kotagi 1984).

Animal Pharmacological Studies

Administration of the compound curcumin to rats at doses of 100 mg/kg daily for 6 days increased the formation of stomach ulcers, whereas doses of 50 mg/kg had no effect (Gupta et al. 1980). Conversely, an ethanolic extract of turmeric at a dose of 500 mg/kg was shown to have significant antiulcerogenic activity in rats subjected to stress or administered ulcer-causing compounds (Rafatullah et al. 1990).

Significant decreases in testis weight and serum testosterone were observed in rats subcutaneously administered 1 ml of a concentrated ethanol extract of turmeric (equivalent to 50 mg powder) daily for 10 days. No changes in liver, kidney, or spleen morphology were observed (Rao and Kotagi 1984).

In Vitro Pharmacological Studies

The compound curcumin exhibited significant antiplatelet activity in vitro, causing inhibition of arachidonic acid-, collagen- and ADP-induced platelet aggregation with IC_{50} values of 13.8, 22.4, and 16.8 μ*M*, respectively (Jantan et al. 2007). Inhibition of arachidonate-induced platelet aggregation was observed in human blood platelets treated with turmeric extract (Srivastava 1989). In a similar study, curcumin inhibited PAF- and AA-induced platelet aggregation, but not epinephrine-induced aggregation. Curcumin also inhibited the formation of thromboxane A_2 (TXA_2) by platelets at an IC_{50} value of 70 μ*M*, suggesting that curcumin-mediated preferential inhibition of PAF- and AA-induced platelet aggregation involves inhibitory effects on TXA_2 synthesis (Shah et al. 1999). In a third study, curcumin inhibited collagen- and AA-induced platelet aggregation and inhibited thromboxane B_2 production (Srivastava et al. 1995).

The compound ar-tumerone was shown to inhibit in vitro platelet aggregation induced by collagen or arachidonic acid but had no effect on platelet-activating factor or thrombin-induced platelet aggregation (Lee 2006).

In rat hepatocytes, the compound curcumin was cytoprotective at concentrations of 0.05 m*M*, whereas at 5 m*M* the observed protective effect on lipid peroxidation was accompanied with a tendency to increase cellular glutathione depletion and lactate dehydrogenase leakage (Donatus et al. 1990).

IV. Pregnancy and Lactation

In a two-generation reproductive study of mice fed a diet of 1500, 3000, or 10,000 ppm curcumin, no adverse effects were observed in parental animals or on reproduction. A small reduction in preweaning body weight gain of the F_2 pups was observed at the highest dose level. The no-observed-adverse-effect level (NOAEL) for reproductive toxicity of curcumin was determined to be 1043 mg/kg daily (Ganiger et al. 2007).

No significant effects on pregnancy rate, implantations, or embryo survival were observed in mice fed a diet of 0.5% turmeric or 0.015% curcumin for 12 weeks (Govindarajan 1980; Vijayalaxmi 1980). A reduction in implantations and litter size was observed in rabbits administered 100 or 200 mg/kg of turmeric daily during the first week of pregnancy. No teratogenic effects were observed (Garg 1974). No teratogenic or reproductive toxicity was observed in pups of mothers administered 50 mg/kg turmeric daily for 1 year (Francis 2002) or in rabbits administered 600 mg/kg curcumin daily from day 6 to 15 of pregnancy (Govindarajan 1980).

Abortions and prevention of implantation were reported in mice orally administered ethanol extracts of turmeric at very high doses of 15 g/kg (Chen 1988). The essential oil administered intravaginally, subcutaneously, or intraperitoneally produced similar antifertility effects (An 1998).

Texts on traditional Chinese medicine contraindicate the use of turmeric in pregnancy (Bensky et al. 2004; Chen and Chen 2004).

Administration of 4 g/kg turmeric or 0.4 g/kg curcumin for 2 or 3 weeks caused an increase in cytochrome P450 and cytochrome b5 levels in lactating mice and their pups (Singh et al. 1995). One other pharmacological study indicated that the active constituents and/or metabolites of turmeric cross into breast milk (Singh et al. 1996).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered turmeric oleoresin in mice and rats could not be determined at doses up to 10 g/kg (Francis 2002). No toxic effects were observed after rats, guinea pigs, and monkeys were administered 2.5 g/kg turmeric powder or 0.3 g/kg of an alcoholic turmeric extract (Shankar et al. 1980). No apparent toxicity of the compound curcumin was observed in rats administered doses up to 5 g/kg (Wahlstrom and Blennow 1978).

In the brine shrimp assay, no toxic effects of a turmeric ethanol extract were observed (Mahmoud et al. 1992).

Short-Term Toxicity

In mice and rats fed turmeric as 0, 1, or 5% of the diet or fed a turmeric ethanolic extract as 0, 0.05, or 0.25% for 14 days, mice were found to be more susceptible than rats to symptoms of hepatotoxicity observed in the study, with mice showing adverse effects at the 1% dose level after 14 days (Deshpande et al. 1998).

Histopathological changes were observed in the livers of mice administered whole turmeric at doses of 0.2, 1.0, or 5.0% of the diet or turmeric ethanolic extracts at doses of 0.05 or 0.25% of the diet for 14 days (Kandarkar et al. 1998).

A decrease in the levels of liver lipid peroxides were observed in mice administered 4 mg/kg (10% curcumin) daily of turmeric hydroalcoholic extract for 4 weeks. No toxic effects of the turmeric were observed (Miquel et al. 1995).

Subchronic Toxicity

In mice and rats fed turmeric as 0, 1, or 5% of the diet or fed a turmeric ethanolic extract as 0, 0.05, or 0.25% for 90 days, animals ingesting the highest dose of turmeric had symptoms of hepatotoxicity including focal necrosis or focal necrosis with regeneration (Deshpande et al. 1998).

In mice and rats administered turmeric oleoresin (79–85% curcumin) daily in food at doses of 0, 1000, 5000, 10,000, 25,000, or 50,000 ppm (equivalent to average daily doses of 50, 250, 480, 1300, or 2600 mg/kg in males and 60, 300, 550, 1450, or 2800 mg/kg in females) for 13 weeks, an increase in liver weights was observed at the 5000 ppm dose and above; no histopathological lesions were observed, nor were there any significant differences in hematology, clinical chemistry, or urinalysis parameters, although some animals were noted to have stained fur and discolored feces and urine (NTP 1993).

Dose-related increases in liver and thyroid weight were reported in pigs administered 60, 296, or 1551 mg/kg of turmeric oleoresin daily for 102 days. Inflammation of the bile duct, thyroid hyperplasia, and epithelial changes in the kidney and urinary bladder were observed in the two higher dose groups (Bille et al. 1985).

In mice administered 100 mg/kg daily of a concentrated turmeric extract for 90 days, a significant increase in heart, lung, and caudae epididymis weights were observed (Qureshi et al. 1992).

Chronic Toxicity

In mice and rats administered turmeric oleoresin (79–85% curcumin) daily in food at doses of 0, 1000, 5000, 10,000, 25,000, or 50,000 ppm (equivalent to average daily doses of 50, 250, 480, 1300, or 2600 mg/kg in males and 60, 300, 550, 1450, or 2800 mg/kg in females) for 2 years, an increase in liver weights was observed at the 10,000 ppm dose and above, but no toxic effects were observed. At the highest dose, decreased hematocrit values, hemoglobin concentration, and erythrocyte counts were significantly lower in rats. Also at that dose, increased incidences of ulcers and chronic inflammation were observed (NTP 1993).

Genotoxicity

No mutagenic effects of turmeric alcoholic extracts, turmeric oleoresin, or curcumin were observed in *Salmonella typhimurium* strains with or without metabolic activation or in the Ames test (Abraham and Kesavan 1984; Jensen 1982; Nagabhushan and Bhide 1986; NTP 1993; Shah and Netrawali 1988).

A single acute dose of 6 g/kg intraperitoneally administered turmeric methanolic extract in mice was reported to cause chromosomal damage (Jain et al. 1987). Changes in chromosome morphology were observed in hamster, mouse, and deer cell lines as well as in human lymphocyte cultures treated with an alcoholic turmeric extract (Goodpasture and Arrighi 1976). The compound curcumin was reported to induce DNA damage in human lymphocytes and gastric mucosa cells in vitro (Blasiak et al. 1999). No chromosomal aberrations were reported in rats fed a diet of up to 0.5% turmeric or mice fed a diet of 0.5% turmeric or 0.15% curcumin for 12 weeks (Vijayalaxmi 1980). Small but significant increases in sister chromatid exchanges and chromosomal aberrations were observed in cultured Chinese hamster ovary cells treated with turmeric oleoresin (NTP 1993).

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
Chinese dodder is used in traditional Chinese medicine to "calm the fetus" and is noted as an important herb for habitual or threatened miscarriage (Bensky et al. 2004; Chen and Chen 2004). An animal study indicated that compounds from Chinese dodder prevented miscarriage (Ma et al. 2008).

No information on the safety of Chinese dodder during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Nausea, vomiting, drowsiness, gastric bleeding, and clonic spasms have been reported in association with Chinese dodder use. Information on dose, duration, and relevant medical history were not available (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Chinese dodder is used in traditional Chinese medicine to "calm the fetus" and is noted as an important herb for habitual or threatened miscarriage (Bensky et al. 2004; Chen and Chen 2004).

Prevention of miscarriage was observed in pregnant rats orally administered the total flavones of Chinese dodder. Doses and days of administration were not specified in the English language abstract (Ma et al. 2008).

No information on the safety of Chinese dodder during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a subcutaneously administered ethanol extract of Chinese dodder in mice is 2.465 g/kg (Zhu 1998). The LD_{50} of orally administered Chinese dodder in mice could not be determined at doses up to 5 g/kg (Akbar et al. 1985). No toxic effects were observed in mice orally administered up to 40 g/kg of an ethanol extract of Chinese dodder (Zhu 1998).

Cyathula officinalis K.C. Kuan

Amaranthaceae

SCN: cyathula
PN: *chuan niu xi* (root)

Part: root

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Not for use in excessive menstruation (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Although contraindicated in excessive menstruation, a human clinical trial indicated a therapeutic effect of cyathula in patients with uterine bleeding (Chen and Chen 2004).

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that cyathula should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004). An animal study indicated decreased fertility and increased risk of miscarriage after treatment with cyathula (Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of cyathula during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that cyathula should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

In mice administered 250 to 500 mg/kg cyathula daily for 20 days, a decrease in egg fertilization and increase in the number of miscarriages were observed (Chen and Chen 2004).

No information on the safety of cyathula during lactation was identified.

V. Toxicity Studies

Genotoxicity

An aqueous extract of cyanthula inhibited chemically induced mutagenicity in the Ames assay (Niikawa et al. 1995).

Cymbopogon citratus (DC. ex Nees) Stapf — Poaceae

SCN: West Indian lemongrass
Syn: *Andropogon citratus* DC. ex Nees
AN: *bhutrina*

OCN: lemongrass; fever grass
Part: herb

Quick Reference Summary

Safety Class: 1

Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic contact dermatitis to West Indian lemongrass was reported after ingestion of an infusion in a person who had been repeatedly exposed to the essential oil (Bleasel et al. 2002).

Pharmacological Considerations

An animal study demonstrated that West Indian lemongrass may modify glucose regulation, although a human study indicated no effects on serum glucose levels (Adeneye and Agbaje 2007; Leite et al. 1986). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Among herbal references reporting on West Indian lemongrass use in different regions, a text on medicinal plants of the Caribbean indicated that West Indian lemongrass has been used as an abortifacient (Morton 1981). However, no other identified references indicated this use of West Indian lemongrass (Ayiku 1992; Blaschek et al. 2006; Teuscher et al. 2006), and no adverse effects on development were observed in mice administered West Indian lemongrass throughout pregnancy at doses equivalent to 10 to 20 times the standard human dose (Souza Formigoni et al. 1986).

Studies of the compound citral indicated that the developmental toxicity no-observed-adverse-effect level (NOAEL) in rats was approximately 60 mg/kg (Delgado et al. 1993). In rats exposed to citral vapor, no adverse effects on fetuses were observed up to or above levels that were toxic to the mothers (Gaworski et al. 1992). Studies of the compound β-myrcene indicated that the NOAEL for fertility and general reproductive performance was 300 mg/kg daily (Paumgartten et al. 1998), whereas that for developmental toxicity was 250 mg/kg (Delgado et al. 1993) and that for the compound citral was below 60 mg/kg (Delgado et al. 1993).

No information on the safety of West Indian lemongrass during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis was reported after ingestion of West Indian lemongrass tea by an aromatherapist. The reporting authors noted that persons working with essential oils should be aware of the sensitization potential of these products (Bleasel et al. 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered an infusion made from 2, 4, or 10 g of West Indian lemongrass daily for 2 weeks, no changes in serum glucose, urea, creatinine, cholesterol, triglycerides, lipids, total bilirubin, indirect bilirubin, GOT, GPT, alkaline phosphatase, total protein, albumin, LDH, or CPK were observed. Slight elevations of direct bilirubin and of amylase were observed in some of the volunteers, but without any clinical manifestation. At the 10 g dose, upset stomach was reported, while no adverse events were reported at the lower doses (Leite et al. 1986).

In an evaluation of fragrance sensitization, West Indian lemongrass essential oil elicited reactions in 1.6% of the 1600 fragrance-sensitive volunteers (Frosch et al. 2002).

In sensitization studies, no sensitization of West Indian lemongrass essential oil was observed at test concentrations of 4 or 5% in a petroleum base (Opdyke 1979). In a 48-hour closed patch test, no irritation was observed at a test concentration of 4%.

Animal Pharmacological Studies

A dose-dependent reduction in fasting plasma glucose levels was observed in healthy rats orally administered 125 to 500 mg/kg of an aqueous extract of West Indian lemongrass daily for 42 days (Adeneye and Agbaje 2007).

In the local lymph node assay in mice, weak dermal sensitization potential of West Indian lemongrass was observed (Lalko and Api 2006).

No phototoxic effects of undiluted West Indian lemongrass essential oil were observed in pigs or hairless mice (Opdyke 1979). Applied full strength to abraded rabbit skin, West Indian lemongrass essential oil was moderately irritating (Opdyke 1979).

In Vitro Pharmacological Studies

A reduction in cardiac rate, with no change in contractile force, was observed in isolated rat hearts treated with aqueous extracts of West Indian lemongrass (Gazola et al. 2004).

In human colon carcinoma cells (Caco-2) treated with an aqueous extract of West Indian lemongrass, mild induction of sulfoconjugation was detected in cells exposed to a 5% solution (Okamura and Tamura 2004).

IV. Pregnancy and Lactation

No adverse effects were observed in the offspring of mice orally administered 4 or 8 ml/kg of an aqueous extract of West Indian lemongrass (approximately 10 and 20 times the standard human dose) daily throughout gestation (Souza Formigoni et al. 1986).

A reference on medicinal plants of the Caribbean indicated that West Indian lemongrass has been used as an abortifacient. No information on dose or preparation used was listed (Morton 1981).

In rats orally administered the compound citral at doses of 60, 125, 250, 500, or 1000 mg/kg daily on days 6 to 15 of pregnancy, a transient decrease in weight gain and reduction in maternal body weight (minus uterine weight) was observed at the highest dose. A slight but statistically significant increase in the ratio of resorptions per implantations was observed at the 60 and 125 mg/kg doses. Signs of fetal growth retardation and a higher incidence of minor skeletal abnormalities were found in doses higher than 60 mg/kg. No increase in the frequency of visceral anomalies was found at any dose level, but an increase in fetal spleen weight was observed in doses higher than 125 mg/kg. The reporting authors indicated that the fetal no-observed-adverse-effect level was below 60 mg/kg (Delgado et al. 1993).

In rats exposed to the compound citral at concentrations of 0, 10, or 34 ppm as vapor or 68 ppm as an aerosol-vapor mixture for 6 hours daily on days 6 to 15 of pregnancy, exposure to 68 ppm was maternally toxic. At this dose level, reduced body weight gains, ocular opacity, breathing difficulty, nasal discharge, and salivation were observed. No maternal toxicity was seen at the lower vapor exposure levels. The number of corpora lutea, implantations, resorptions, fetal viability, litter size, and sex ratio were not adversely affected by citral at any exposure level tested, and no exposure-related malformations were observed. At a maternally toxic exposure level, a slight reduction in mean fetal body weight and a slight increase in the incidence of hypoplastic bones were noted (Gaworski et al. 1992).

In rats orally administered 0, 100, 300, or 500 mg/kg of the compound β-myrcene in pregnancy daily for 21 days prior to mating, during mating and pregnancy, and throughout the period of lactation up to postnatal day 21, no adverse effects on development were observed except at the highest dose. At the highest dose, increases in the resorption rate and frequency of fetal skeleton anomalies were observed. No sign of maternal toxicity and no increase in externally visible malformations were observed at any dose level. The authors concluded that the no-observed-adverse-effect level (NOAEL) for fertility and general reproductive performance is 300 mg/kg daily (Paumgartten et al. 1998).

In rats orally administered 0.25, 0.5, 1.0, or 1.5 g/kg of the compound β-myrcene beginning on day 15 of pregnancy through postnatal day 21, no adverse effects on offspring were seen at the lowest dose tested. At doses of 0.5 g/kg and higher, decreased birth weight, increased perinatal mortality, and delays in the day of appearance of landmarks of postnatal development were observed, and fertility was impaired in female offspring exposed to the two highest doses of β-myrcene. The authors concluded that the NOAEL for peri- and postnatal developmental toxicity is 0.250 g/kg (Delgado et al. 1993).

No information on the safety of West Indian lemongrass during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered West Indian lemongrass essential oil in rats is 3.25 g/kg (Fandohan et al. 2008). The LD_{50} of orally or topically administered West Indian lemongrass essential oil in rabbits could not be determined at doses up to 5 g/kg (Opdyke 1979).

The LD_{50} of an orally administered aqueous extract of West Indian lemongrass in rats could not be determined at doses up to 5 g/kg (Adeneye and Agbaje 2007). The LD_{50} of an orally administered alcohol extract of West Indian lemongrass in rats is 460 mg/kg (Lagarto Parra et al. 2001).

Short-Term Toxicity

In rats orally administered West Indian lemongrass essential oil at doses of 50, 500, 1000, 1500, 2000, or 3000 mg/kg daily for 14 days, no adverse effects were observed in animals treated with doses of 5 to 1500 mg/kg. At doses of 2000 or 3000 mg/kg, all animals died on the second day (Fandohan et al. 2008).

No adverse effects were observed in rats intragastrically administered 20 ml/kg of an aqueous extract of West Indian lemongrass daily for 6 weeks. A diuretic effect, similar to that of green tea, was noted (Mirza et al. 2001).

Genotoxicity

In the Ames test for mutagenicity in *Salmonella typhimurium* strains TA97a, TA98, TA100, and TA104 with or without metabolic activation by S9, some mutagenic activity of an aqueous extract of West Indian lemongrass was observed in TA104 without metabolic activation (Rivera et al. 1994). Conversely,

an ethanol extract of West Indian lemongrass was antimutagenic in *Salmonella typhimurium* strains TA98 and TA100 treated with mutagenic compounds (Vinitketkumnuen et al. 1994).

Cynanchum atratum Bunge

Asclepiadaceae

SCN: *Cynanchum atratum*
PN: *bai wei* (root and rhizome)

OCN: black-end swallowwort; swallowwort
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of *Cynanchum atratum* in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

In overdose (aqueous extract of 30–45 g), *Cynanchum atratum* has been associated with heart palpitations, nausea, vomiting, dizziness, headache, diarrhea, and salivation (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

The compound cynatroside B demonstrated antiacetylcholinesterase activity in mice (Lee et al. 2005). No information was identified on the concentration of cynatroside B in *Cynanchum atratum.*

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of *Cynanchum atratum* during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A decrease in serum glucose levels was observed in diabetic rats orally administered 500 mg/kg of a cyperus extract daily for 7 days (Raut and Gaikwad 2006).

In ovariectomized rats, two subcutaneous doses of 0.2 ml of cyperus essential oil administered at an interval of 6 hours resulted in complete keratinization of the vaginal epithelium within 48 h. After three doses of 0.3 ml each, white cells appeared among keratinized cells (Kilani et al. 2005).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of cyperus during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered cyperus alcohol extract in mice is 1.5 g/kg (Zhu 1998), whereas that of cyperus essential oil in rats is 0.29 ml/kg and that of the compound cyperone in rats is 1.5 g/kg (Chen and Chen 2004).

Short-Term Toxicity

No adverse effects were reported in rats fed diets containing 25% cyperus (duration of trial not specified in English language translation) (Chen and Chen 2004).

Cytisus scoparius (L.) Link

Fabaceae

SCN: Scotch broom
Syn: *Sarothamnus scoparius* (L.) Wimm. ex W.D.J. Koch; *Spartium scoparium* L.

OCN: broom; scoparium
Part: flowering top

Quick Reference Summary

Safety Class: 3
Interaction Class: B

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Felter and Lloyd 1898; Leung and Foster 1996; Martindale and Reynolds 1996; Williamson 2003).

Other Precautions

None known.

Drug and Supplement Interactions

Based on the presence of small amounts of tyramine, Scotch broom should not be taken with MAO inhibitors (Wichtl 2004). *Also see* Pharmacological Considerations for this entry.

Notice

Abortifacient (List and Hörhammer 1973); *see* Appendix 2.

Diuretic (Felter and Lloyd 1898; Wood and LaWall 1926) *see* Appendix 2.

Uterine stimulant (Seel 1949; Wolfes et al. 1936) ; *see* Appendix 2.

Adverse Events and Side Effects

Large doses of Scotch broom are reported to be emetic and cathartic, while smaller doses are reported to be diuretic (Felter and Lloyd 1898; Wood and LaWall 1926). A staggering gait, impaired vision, and profuse vomiting and sweating have been reported in association with Scotch broom use (Felter and Lloyd 1898).

Pharmacological Considerations

Scotch broom contains relatively small amounts (0.08–0.8%) of the compound tyramine (also found in many fermented foods), a monoamine compound that may accumulate and cause high blood pressure if MAO inhibitors are being taken. No cases of such an interaction from Scotch broom have been documented (Gresser et al. 1996; Schmalfuss and Heider 1931; Wichtl 2004).

The compound sparteine is antiarrhythmic, inhibiting the transport of sodium ions across cell membranes and reducing overstimulation of the conduction system of the heart (Wichtl 2004).

The compound sparteine is a s ubstrate of the drug-metabolizing isoenzyme CYP2D6 (Casarett et al. 2001; Zanger et al. 2004). Serum levels of sparteine may be altered by drugs or supplements that induce or inhibit CYP2D6.

Pregnancy and Lactation

In vitro studies have indicated that Scotch broom has a stimulating effect on the uterus (Seel 1949; Wolfes et al. 1936). The compound sparteine was the subject of human clinical trials as a labor inducer and was found to be as potent as oxytocin (Casarett et al. 2001).

No information on the safety of Scotch broom during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A staggering gait, impaired vision, and profuse vomiting and sweating have been reported in association with Scotch broom use. No details on dose or product were provided (Felter and Lloyd 1898).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In vitro studies have indicated that Scotch broom has a stimulating effect on the uterus (Seel 1949; Wolfes et al. 1936). The compound sparteine was the subject of human clinical trials as a labor inducer and was found to be as potent as oxytocin; however, it caused exaggerated responses in some women, including prolonged uterine contraction and abnormally rapid labor (Casarett et al. 2001).

No information on the safety of Scotch broom during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound sparteine orally administered to rats is approximately 430 mg/kg (Wink 1994).

Daemonorops draco (Willd.) Blume. Arecaceae

SCN: dragon's blood palm
PN: *xue jie* (resin)

Part: resin

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Not for internal use during menstruation (Bensky et al. 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to dragon's blood palm have been reported after ingestion and topical exposure (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that dragon's blood palm should not be used during pregnancy (Chen and Chen 2004) or should not be used internally during pregnancy (Bensky et al. 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of dragon's blood palm during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to dragon's blood palm have been reported after ingestion and topical exposure. Symptoms have included pruritis, skin wheals and eruptions, and angioneurotic edema of the hands and feet (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No additive effects on Δ^9-THC-induced inhibition of mouse motor performance was observed in mice intraperitoneally coadministered 10 or 100 mg/kg of dragon's blood palm and 10 mg/kg Δ^9-THC (Ford et al. 2001). This research was completed after reports of recreational use of *Cannabis sativa* in combination with dragon's blood palm (Ford et al. 2001).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that dragon's blood palm should not be used during pregnancy (Chen and Chen 2004) or should not be used internally during pregnancy (Bensky et al. 2004).

No information on the safety of dragon's blood palm during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Daucus carota L. ssp. *carota* — Apiaceae

SCN: wild carrot
OCN: Queen Ann's lace

Part: fruit (commonly known as "seed")

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Garg and Mathur 1972; Kaliwal et al. 1986; Kaliwal and Appaswamy Rao 1979; Kant et al. 1989; Sharma et al. 1976).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Felter and Lloyd 1898; Wood and LaWall 1918); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have indicated effects of wild carrot on estrus cycles and have shown weak estrogenic activity (Majumder et al. 1997; Sharma et al. 1976).

Pregnancy and Lactation

A number of studies on wild carrot have examined the effects of different extracts on implantation in pregnant or recently mated animals. Dose- and timing-related effects on implantation were observed in some studies, while other studies showed no effect on implantation (Garg and Mathur 1972; Kaliwal and Ahamed 1987; Kaliwal et al. 1986; Kaliwal and Appaswamy Rao 1979; Kant et al. 1989; Lal et al. 1986; Sharma et al. 1976). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of wild carrot in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

The fatty acid fraction of wild carrot arrested the normal estrus cycle and reduced the weight of ovaries in mice intraperitoneally administered 3 mg/kg of the fraction daily for 15 days. A similar arrest of the cycle was observed in mice intraperitoneally administered 3 or 10 mg/kg of a petroleum ether extract of wild carrot, but no effects of a 1 mg/kg dose were observed (Majumder et al. 1997).

In the 3-day uterotrophic bioassay in mice, a significant increase in wet uterine weights of mice was observed in animals treated with 60 or 120 mg per animal (average animal weight not stated) of an alcohol extract of wild carrot. In comparison to estradiol-17β, the activity was characterized as "extremely weak" (Sharma et al. 1976). In the 3-day antiestrogenic assay, the same extract and doses significantly inhibited the uterotrophic effect of estradiol-17β (Sharma et al. 1976).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In rats orally administered 100 mg/kg of fractions of a water extract, 50 mg/kg of fractions of an alcohol extract, or 20 mg/kg of fractions of a petroleum ether extract of wild carrot seed on days 1 to 7 of pregnancy, a reduction in pregnancies was observed with all fractions, although some fractions were more active than others. No adverse effects on development were observed in offspring that were born (Garg and Mathur 1972). A later study re-examining the most effective fractions and doses indicated no effects of these fractions on implantation (Kant et al. 1989).

In rats subcutaneously administered 0.006 ml/kg of a petroleum ether extract of wild carrot on days 1 to 7 of pregnancy, no implantation sites were observed on day 8 of pregnancy (Kaliwal et al. 1986).

In rats subcutaneously administered 0.06 ml/kg of a petroleum ether extract of wild carrot on days 1 to 7 of pregnancy, anti-implantation activity was observed in nearly all of the treated animals. Administration of progesterone blocked the activity of wild carrot seed (Kaliwal and Ahamed 1987). In rats treated subcutaneously with the same extract at the same dose on days 1 to 3, 1 to 5, 3 and 4, or day 3 of pregnancy, no anti-implantation activity was observed. In animals treated with 0.01 ml/kg, no anti-implantation activity was observed, while a dose of 0.02 to 0.04 ml/kg inhibited some implantation (Kaliwal and Appaswamy Rao 1979).

In rats administered an ethanol extract of wild carrot at doses of 50, 150, or 500 mg/kg on selected days after mating, the maximum inhibition of implantation (80%) was observed in animals treated with 500 mg/kg on days 4 to 6 or 1 to 7 after mating (Kant et al. 1989).

In rats orally administered 2 or 4.5 g/kg of wild carrot powder on days 1 to 10 of pregnancy, no anti-implantation effect was observed (Lal et al. 1986).

In mice orally administered 80 or 120 mg per animal (average animal weight not stated) of an alcohol extract of wild carrot, administration on days 4 to 6 after mating was effective in inhibiting implantation, while administration on days 8 to 10 after mating had no effect (Sharma et al. 1976).

In isolated rat uteri, a chloroform fraction of wild carrot seed inhibited spontaneous activity and oxytocin evoked activity. The activity was dose dependent and a concentration of 0.5 mg/ml of the extract produced a marked inhibition of oxytocin-induced activity (Dhar et al. 1975).

No information on the safety of wild carrot in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

In the brine shrimp lethality assay, the LD_{50} values of the major compounds from the methanol extract of wild carrot were 0.053 mg/ml for luteolin, 1 mg/ml for luteolin 3'-*O*-β-D-glucopyranoside, and 1 mg/ml for luteolin 4'-*O*-β-D-glucopyranoside (Kumarasamy et al. 2005).

Dendrobium nobile Lindl. — Orchidaceae

SCN: dendrobium
PN: *shi hu* (stem)

OCN: Chinese orchid
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Other species of *Dendrobium* are considered acceptable substitutes for *D. nobile*. They include *D. loddigesii*, *D. fimbriatum* var. *occulatum*, *D. chrysanthum*, and *D. officinale*, (Bensky et al. 2004; Chen and Chen 2004). Adulteration of dendrobium with species of *Pholidota* has been reported (Lau et al. 2001; Zhang et al. 2007).

Adverse Events and Side Effects

Gross overdose of dendrobium (standard dose is listed as decoction of 6–15 g) has been associated with seizures (Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of dendrobium in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Seizures have been reported in association with gross overdose of dendrobium (standard dose is a decoction of 6–15 g) (Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of dendrobium during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of dendrobium juice in mice could not be determined at doses up to 10 g/kg (route of administration not specified in English language abstract) (Jiang and Cheng 1999).

Genotoxicity

No mutagenic activity of dendrobium was observed in the Ames test for mutagenicity, a mouse myeloid cell micronucleus test, or a mouse teratospermia test (doses administered to mice not specified in English language abstract) (Jiang and Cheng 1999).

Extracts of dendrobium have shown antimutagenic activity in *Salmonella typhimurium* strains treated with mutagenic compounds (Miyazawa et al. 1997; Miyazawa et al. 1999).

Digitalis spp.

Scrophulariaceae

Digitalis purpurea L.
SCN: digitalis
OCN: foxglove; purple foxglove
Digitalis lanata Ehrh.
SCN: Grecian foxglove
OCN: digitalis
Part: leaf

Quick Reference Summary

Safety Class: 3
Interaction Class: C

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Hanzlik 1929; Hauptman and Kelly 1999; Maffe et al. 2009; Ramlakhan and Fletcher 2007; Withering 1785).

Other Precautions

None known.

Drug and Supplement Interactions

Interaction considerations are the same as those for digitoxin, digoxin, and other digitalis glycosides (Hauptman and Kelly 1999; Maffe et al. 2009; Vivo et al. 2008).

Editors' Notes

Grecian foxglove (*D. lanata*) contains the compound digoxin, which is not present in digitalis (*D. purpurea*). Digitalis contains digitoxin and gitoxin in the leaf and digitalin in the seed (Ramlakhan and Fletcher 2007). Grecian foxglove also contains lanatosides (Weiler and Zenk 1976).

U.S. regulations require that digitalis drugs be labeled in a manner which informs consumers of the inappropriateness of use as an antiobesity agent (CFR 2011).

Adverse Events and Side Effects

Cases of digitalis and Grecian foxglove poisoning have been reported after intentional self-poisoning or mistaking the leaves for other edible or medicinal species (Bain 1985; Cardano et al. 2002; Colls 1999; Dickstein and Kunkel 1980; Maffe et al. 2009; Slifman et al. 1998; Thierry et al. 2000). Symptoms of poisoning are similar to those from overdose of therapeutic cardiac glycosides such as digoxin and digitoxin. Symptoms include nausea, vomiting, changes in heartbeat and heart function, abdominal pain, diarrhea, dizziness, headache, confusion, delirium, hallucinations, changes in vision, shortness of breath, and chest pain (Ramlakhan and Fletcher 2007).

Pharmacological Considerations

Digitalis and Grecian foxglove have marked effects on heart function. As with digoxin, digitoxin, and other related compounds, the difference between the effective dose and the toxic dose is quite small (Hauptman and Kelly 1999; Withering 1785).

Pregnancy and Lactation

No information on the use of digitalis or Grecian foxglove during pregnancy or lactation was identified. Studies on the drug digoxin indicate that this compound readily crosses the placenta, and digoxin has been used to treat fetal arrhythmias (Chow et al. 1998; Joglar and Page 1999; Oudijk et al. 2002). Digoxin has also been shown to cross into breast milk, although the concentration is relatively low and the drug is considered compatible with breast-feeding (AAP 2001; Chow et al. 1998; Reinhardt et al. 1982). Safety has not been conclusively established for the use of this herb during pregnancy or lactation, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Digitalis or Grecian foxglove poisoning typically occurs after intentional self-poisoning or mistaking the leaves for other edible or medicinal species including borage (*Borago officinalis*), comfrey species (*Symphytum* spp.), and plantain species (*Plantago* spp.) (Bain 1985; Cardano et al. 2002; Colls 1999; Dickstein and Kunkel 1980; Maffe et al. 2009; Slifman et al. 1998; Thierry et al. 2000). Cases of poisoning result in nonspecific symptoms similar to those from overdose of therapeutic cardiac glycosides such as digoxin and digitoxin. Cardiovascular symptoms may include ECG changes, including ventricular premature contractions, sinus bradycardia or tachycardia, nonparoxysmal junctional tachycardia, atrioventricular (AV) dissociation, first-, second-, or third-degree AV block, and sinoatrial block or arrest. Other symptoms may include nausea or vomiting, abdominal pain, diarrhea, dizziness, headache, confusion, delirium, numbness, psychosis, visual and auditory hallucinations, somnolence, aphasia and seizures, blurred vision, photophobia, a predominance of yellow or green in the vision (xanthopsia), diplopia, transient blindness, palpitations, chest pain, and shortness of breath (Ramlakhan and Fletcher 2007).

Nausea and vomiting, abdominal pain, and cardiovascular shock with sinus bradycardia were reported in a 36-year-old female who ingested an unspecified amount of digitalis in an attempted suicide (Lacassie et al. 2000).

A family composed of father, mother, and daughter, respectively 62, 58, and 35 years of age, experienced persistent nausea, vomiting, lethargy, and intense weakness after having eaten potato dumplings containing digitalis leaves that had been mistaken for borage leaves in their garden. All three had marked sinus bradycardia and other electrocardiographic and biochemical aspects that were indicative of acute cardiac glycoside poisoning. No estimations on amount ingested were reported, but all three patients made a complete recovery. The reporting authors noted that the patients have since decided to purchase their produce from the market (Maffe et al. 2009).

Bradycardia and runs of second degree AV block, which rapidly progressed to a 3.5 s sinus pause, followed by sinus arrest, were reported in a 64-year-old man that ate "a whole *Digitalis purpurea* plant." The ingestion was believed to be with suicidal intention and was fatal despite treatment attempts (Ramlakhan and Fletcher 2007).

Poisonings by digitalis have been reported in a number of animals under human care, including cows, deer, ponies, minks, and turkeys (Corrigall et al. 1978; Parker 1951; Thomas et al. 1987; Wijnberg et al. 1999; Zimowski 1973).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of digitalis or Grecian foxglove during pregnancy or lactation was identified. Studies on the drug digoxin indicate that this compound readily crosses the placenta, and digoxin has been used to treat fetal arrhythmias (Chow et al. 1998; Joglar and Page 1999; Oudijk et al. 2002).

Digoxin has also been shown to cross into breast milk, although the concentration is relatively low and the drug is considered compatible with breast-feeding (AAP 2001; Chow et al. 1998; Reinhardt et al. 1982).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound digitoxin is 8.9 mg/kg in female rats and 15.4 mg/kg in male rats (Scott et al. 1971).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Editors' Note
Longan is commonly consumed as a fruit in Asian countries (Menzel and Waite 2005).

Adverse Events and Side Effects
Allergic reactions to longan have been reported (Bensky et al. 2004; Rank and Li 2007).

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of longan in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

None known.

Pharmacological Considerations

Animal studies have indicated that Chinese yam may modify glucose regulation (Chen and Chen 2004; Gao et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Allergic reactions to Chinese yam have been reported after ingestion and topical application (Bensky et al. 2004).

Pregnancy and Lactation

No information on the safety of Chinese yam in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to Chinese yam have been reported after ingestion and topical application. Symptoms following ingestion included maculopapular rashes over the whole body, itchy throat, pruritus, and a sensation of pressure in the chest (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In mice orally administered 30 g/kg of a decoction of Chinese yam daily for 10 days, blood glucose levels decreased by 10 to 30 mg/dl. The same extract and dose controlled the normally sharp increase of glucose following intraperitoneal administration of glucose (Chen and Chen 2004). An ethanol extract of Chinese yam orally administered to diabetic rats significantly reduced blood insulin and glucose levels (Gao et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of Chinese yam during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Dioscorea villosa L.

Dioscoreaceae

SCN: wild yam
OCN: China root; colic root; North American wild yam; rheumatism root

Part: rhizome

Quick Reference Summary

D

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Wild yam contains the compound diosgenin, commonly and mistakenly promoted as a natural source of progesterone. Diosgenin has been used as a precursor for the synthesis of progesterone, but the transformation required to form progesterone does not occur in the human body (Dentali 1996).

Adverse Events and Side Effects

"Large" doses of tincture (standard dose listed as 20–60 drops of tincture) are reported to cause vomiting, although smaller doses have been used to alleviate nausea and vomiting (Felter and Lloyd 1898).

An animal study indicated that inflammation of the liver and kidneys was observed in rats administered high doses (790 mg/kg daily) of a wild yam extract for 4 weeks. No inflammation was observed in rats administered the same dose for 2 weeks (Wojcikowski et al. 2008).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of wild yam in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered 50, 150, or 500 mg/kg of wild yam oleyl alcohol eluant extract daily for 4 days, observation of uterine and vaginal parameters indicated no estrogenic effects of the extract (Zava et al. 1998).

In a dermal irritation study in rabbits, no irritation was observed after topical application of a single dose of a 10% solution of wild yam oleyl alcohol eluant extract (Hooker 2004).

In Vitro Pharmacological Studies

No estrogenic activity of a hydroethanolic extract of wild yam was observed in estrogen receptor-positive (MCF-7) human breast cancer cells (Zava et al. 1998).

In normal kidney cells (NRK49F) and tubular epithelial cells (NRK52E), ethyl acetate, methanol, and water-methanol extracts of wild yam exhibited some toxicity. At concentrations of 5 to 50 µg/ml, induction of epithelial to mesenchymal transdifferentiation was observed (Wojcikowski et al. 2009).

IV. Pregnancy and Lactation

No information on the safety of wild yam in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally or dermally administered wild yam oleyl alcohol eluant extract in rats could not be determined at doses up to 2 g/kg (Hooker 2004).

Short-Term Toxicity

In rats orally administered 790 mg/kg wild yam hydroalcoholic extract daily for 28 days, an increase in fibrosis in the kidneys and inflammation in the liver was observed. No adverse effects on the kidneys or liver were observed in animals treated for 14 days (Wojcikowski et al. 2008).

In ovariectomized rats treated with a total of 500 mg of the compound diosgenin over a 45-day period (via an intraperitoneally implanted tricalcium phosphate drug delivery system), increases in body weight and spleen weight were observed along with a slight increase in wet adrenal weight. Histopathological evaluation of the adrenal gland revealed a decrease in the cortical and medullary adrenal areas (Benghuzzi et al. 2003).

In dermal toxicity testing, no adverse effects were observed in rats treated with 1 ml/kg of a 1, 3, or 10% concentration of wild yam oleyl alcohol eluant extract daily for 29 days (Hooker 2004).

Genotoxicity

In the Ames mutagenicity test with *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537, and TA1538, no mutagenic activity of an oleyl alcohol eluant extract of wild yam was observed with or without metabolic activation (Hooker 2004).

In the bone marrow micronucleus test in rats, no mutagenic activity of an oleyl alcohol eluant extract of wild yam was observed after the animals were administered two doses up to 2 g/kg (Hooker 2004).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to Sichuan teasel have been reported (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

In traditional Chinese medicine, Sichuan teasel is used to "calm the fetus," stop uterine bleeding during pregnancy, and prevent threatened miscarriage (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of Sichuan teasel in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to Sichuan teasel have been reported. Reactions included localized erythema, itching, and a sensation of heat or burning (Bensky et al. 2004; Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In traditional Chinese medicine, Sichuan teasel is used to "calm the fetus," to stop uterine bleeding during pregnancy, and to prevent threatened miscarriage (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of Sichuan teasel in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Drynaria fortunei (Kunze ex Mett.) J. Sm.

Polypodiaceae

SCN: drynaria
PN: *gu sui bu* (rhizome)

Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

In vitro studies have suggested estrogenic activity of drynaria extracts (Chang et al. 2003; Jeong et al. 2005).

Pregnancy and Lactation

No information on the safety of drynaria in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No adverse effects have been reported with use of drynaria at standard therapeutic doses (decoction of 9–21 g) (Bensky et al. 2004). Overdose of drynaria (a decoction of over 100 g) has been associated with dry mouth, excessive speech, fear, palpitations, and a manic-depressive type psychosis (Bensky et al. 2004; Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Proliferation of nontransformed osteoblastic cells (MC3T3-E1) induced by an extract of drynaria at concentrations of 30–100 µg/ml was eliminated by the estrogen antagonist tamoxifen (Jeong et al. 2005).

A methanol extract of drynaria exhibited proliferative activity in estrogen receptor-positive human breast cancer cells (MCF-7) and osteoblast-like cells (ROS 17/2.8) after treatment with concentrations of 100 µg/ml (Chang et al. 2003).

IV. Pregnancy and Lactation

No information on the use of drynaria during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Dryopteris filix-mas (L.) Schott — Aspidiaceae

SCN: male fern
Syn: *Aspidium filix-mas* (L.) Sw.

Part: rhizome

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Felter and Lloyd 1898; Maisch 1883; Weiss and Meuss 2001; Williamson 2003; Wood and LaWall 1918).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Symptoms of poisoning from male fern use include vomiting, diarrhea, vertigo, headache, tremors, cold sweats, difficulty breathing, cyanosis, convulsions, stupor, and mental disturbances. Poisonings have included disturbance of vision and sometimes blindness, which was permanent in several cases. Fatal cases of poisonings have been reported

(Felter and Lloyd 1898; Maisch 1883; Wood and LaWall 1918).

Pharmacological Considerations

Male fern was historically used in conjunction with castor oil. Castor oil is believed to increase absorption of the toxic compounds in male fern, and the concomitant use of these products is considered dangerous and is no longer recommended (Leung and Foster 1996; Wood and LaWall 1918).

Pregnancy and Lactation

Based on the toxicity of this species (Felter and Lloyd 1898; Wood and LaWall 1918), use of male fern in pregnancy or lactation is not recommended.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Symptoms of poisoning from male fern use include vomiting, diarrhea, vertigo, headache, tremors, cold sweats, difficulty breathing, cyanosis, convulsions, and mental disturbances. Some cases of poisonings included disturbance of vision and sometimes blindness, which was permanent in several cases. Cases of blindness were believed to be due to spasm of the retinal vessels and subsequent atrophy (Wood and LaWall 1918).

Cattle that grazed on male fern and a related species, *Dryopteris borreri,* down to the roots of the plant were found comatose and blind (Macleod and Greig 1978). Characteristics of *Dryopteris* poisonings in cattle are blindness, a desire to stand in water, and profound drowsiness, but with low rates of mortality (Macleod and Greig 1978).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Based on the toxicity of this species (Felter and Lloyd 1898; Maisch 1883; Wood and LaWall 1918), use of male fern in pregnancy or lactation is not recommended.

V. Toxicity Studies

No toxicity studies were identified.

SCN: *Echinacea pallida*
Syn: *Rudbeckia pallida* Nutt.
OCN: pale-flower echinacea; pale purple coneflower
Part: root, seed

Echinacea purpurea **(L.) Moench**
SCN: *Echinacea purpurea*
Syn: *Rudbeckia purpurea* L.
OCN: purple coneflower
Part: above-ground parts, root, seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Allergic reactions may occur in susceptible persons (Huntley et al. 2005). Reactions are most likely to products made from the flowers or flowering tops of *Echinacea* (Mills and Bone 2005; Upton and Graff 2004).

Drug and Supplement Interactions

None known.

Editors' Notes

The references cited in this entry are not always sufficiently specific to clearly identify a particular species of *Echinacea* or a specific plant part or preparation (Ang-Lee et al. 2001; Kemp and Franco 2002; Lee and Werth 2004; Logan and Ahmed 2003; Mullins and Heddle 2002; Soon and Crawford 2001). The relevance of such citations to all *Echinacea* species and preparations should therefore not be assumed.

In addition, some references are focused on just one of the three species addressed in this entry, while others review all three taxa. The unmodified generic name (i.e., *Echinacea*) is used here to indicate information that is relevant to all of the species.

Commission E reports for all *Echinacea* species that they are not to be used in systemic diseases such as tuberculosis, leukosis, collagenosis, multiple sclerosis, AIDS, HIV infections, and other autoimmune diseases (Blumenthal et al. 1998). Concerns regarding the use of *Echinacea* species in these conditions are theoretical, and definitive data supporting or refuting an association of *Echinacea* with autoimmune symptom exacerbation are lacking (Mills and Bone 2005; Upton and Graff 2004).

Allergic reactions to *Echinacea* products have been reported (*see* Adverse Events and Side Effects, below). Some authorities have suggested that the reactions may be due to the presence of *Echinacea* pollen in products, as allergies to pollens in the Asteraceae family are common. Ingestion of products made from the flowering top of *Echinacea* are thus more likely to result in allergic reactions than products made from the root and leaf (Mills and Bone 2005; Upton and Graff 2004).

Adverse Events and Side Effects

In clinical trials and reviews of clinical trials, *Echinacea* products have been noted as being well tolerated, with adverse events reported similar to those of placebo (Huntley et al. 2005). Allergic reactions to *Echinacea* species have been reported (Coeugniet and Elek 1987; George et al. 2006; Huntley et al. 2005; Kemp and Franco 2002; Lee and Werth 2004; Logan and Ahmed 2003; Moell 1951; Mullins 1998; Mullins and Heddle 2002; Röseler 1952; Soon and Crawford 2001).

Pharmacological Considerations

No drug or supplement interactions in humans have been reported in either case reports or clinical trials. Some sources (Ang-Lee et al. 2001; Izzo and Ernst 2001) indicate a theoretical concern for interactions with immunosuppressant drugs, although no clinical studies are available to support or refute this concern.

While several human studies of the effects of various parts and preparations of *Echinacea purpurea* on the CYP450 drug-metabolizing isoenzymes indicate a lack of effects or clinically insignificant effects (Gorski et al. 2004; Gurley et al. 2004; Heinrich et al. 2008), one study suggested that *Echinacea purpurea* induced the drug metabolizing isoenzyme CYP3A (Penzak et al. 2010).

Pregnancy and Lactation

Limited human data has not indicated any safety concerns for use of *Echinacea* species during pregnancy (Gallo et

al. 1998; Gallo et al. 1999; Perri et al. 2006; Tsui et al. 2001). Animal studies have given mixed results on the safety of *Echinacea purpurea* in pregnancy (Chow et al. 2006; Maass et al. 2005; Mengs et al. 2000).

No information on the safety of *Echinacea* spp. during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No changes in drug serum levels were observed in healthy volunteers orally administered 400 mg of lopinavir with 100 mg ritonavir twice daily with or without 1500 mg per day of a proprietary *Echinacea purpurea* extract (identified by the authors as an 8:1 extract of fresh *E. purpurea*, and by the manufacturer as derived from fresh root and flower) for 14 days. In the same study, the volunteers were administered 8 mg midazolam (a substrate of CYP3A) before and after *Echinacea purpurea* administration. A decrease in plasma levels ($AUC_{0-\infty}$) of midazolam was observed, suggesting induction of the drug metabolizing enzyme CYP3A. Lopinavir is a CYP3A substrate, thus a decrease in plasma levels of this drug might be expected. The lack of changes in lopinavir levels observed in this study was attributed to coadministration with ritonavir, a potent inducer of CYP3A (Penzak et al. 2010).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Coadministration of *Echinacea purpurea* root extract and melatonin to mice significantly reduced levels of mature, functional granulocyte progeny in the spleen and bone marrow as compared to either *Echinacea* or melatonin administered alone (Currier et al. 2001).

II. Adverse Events

Adverse Events Reported in Clinical Trials

Echinacea has been generally well tolerated in clinical trials, with most trials reporting similar incidences of adverse reactions for *Echinacea* and placebo (Huntley et al. 2005). One trial of fresh juice of *Echinacea purpurea* aerial parts in children showed a significantly higher incidence of rashes in children taking the *Echinacea* preparation than in children taking placebo (Taylor et al. 2003).

Case Reports of Adverse Events

Allergic reactions have been reported in persons taking *Echinacea* species, with events including anaphylaxis, asthma attacks, thrombotic thrombocytopenic purpura, leukopenia, abdominal pain, nausea, dysuria, arthralgia, myalgia, and dizziness (Coeugniet and Elek 1987; George et al. 2006; Huntley et al. 2005; Kemp and Franco 2002; Lee and Werth 2004; Logan and Ahmed 2003; Moell 1951; Mullins 1998; Mullins and Heddle 2002; Röseler 1952; Soon and Crawford 2001). Most case reports do not distinguish between the different species of *Echinacea*.

Clinical herbalists have reported differing information on the use of *Echinacea* species in autoimmune conditions. Exacerbation of symptoms has been reported in systemic lupus, ulcerative colitis (autoimmune etiology uncertain), glomerular nephritis, and multiple sclerosis. In "some" cases, effects reoccurred on rechallenge. In rheumatoid arthritis, treatment with *Echinacea* species for 10 days did not exacerbate the condition (Upton and Graff 2007). A survey of 25 medical herbalists indicated that 12 had used *Echinacea* species in persons with autoimmune conditions. Of these 12, 11 indicated a beneficial effect and 1 indicated a worsening of symptoms (Upton and Graff 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered 1600 mg *Echinacea purpurea* root daily for 8 days, no clinically significant changes in activity of tolbutamide (CYP2C9) or dextromethorphan (CYP2D6) were observed. *Echinacea purpurea* root reduced plasma levels of caffeine (CYP1A2 induction), while effects on midazolam (CYP3A4) were conflicting, with *Echinacea purpurea* root increasing midazolam systemic clearance (~34% increase) through an induction of hepatic CYP3A4 activity, while inhibiting intestinal CYP3A4 activity (Gorski et al. 2004). A review of drug interaction studies noted the effects of *Echinacea purpurea* root observed in this study pale in comparison to those reported by the same investigators for known CYP3A4 inhibitors (Gurley et al. 2012).

No significant effects on the drug-metabolizing isoenzymes CYP1A2 (caffeine), CYP2D6 (debrisoquine), CYP2E1 (chlorzoxazone), or CYP3A4 (midazolam) activity were observed in healthy volunteers orally administered 1600 mg of a whole plant extract of *Echinacea purpurea* (no additional description provided) daily for 28 days (Gurley et al. 2004).

Research was conducted on a proprietary *Echinacea purpurea* extract, identified as an 8:1 extract of fresh *E. purpurea* root and flower. In healthy volunteers orally administered 8 mg midazolam (a substrate of CYP3A) and 120 mg fexofenadine (a substrate of P-gp) before and after administration of 1500 mg per day of this extract for 14 days, a decrease in plasma levels ($AUC_{0-\infty}$) of midazolam was observed, suggesting induction of the drug metabolizing enzyme CYP3A.

No changes in blood levels of fexofenadine were observed, suggesting a lack of effect on the drug transporter protein P-glycoprotein (P-gp) (Penzak et al. 2010).

Echinacea purpurea root at a repeated daily dose of 1600 mg did not affect CYP2C9, using tolbutamide as a probe drug (Gorski et al. 2004); neither this dose of the root nor 800 mg of an *E. purpurea* extract (plant part not stated; containing 6.6 mg isobutylamides) affected CYP2D6 activity, using dextromethorphan and debrisoquine as probe drugs (Gorski et al. 2004; Gurley et al. 2008).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In vitro studies on the effect of *Echinacea purpurea* on CYP enzymes have given mixed results. Results from one study on the effects of a preparation of the aerial parts of *Echinacea purpurea* on CYP3A4 differed according to the model substrate used; one substrate (7-benzyloxy-4-trifluoromethylcoumarin) indicated induction, while the other (resorufin benzyl ether) indicated inhibition (Yale and Gulrich 2005). Another study showed significant inhibition by a "commercial grade extract" (no other description provided) of *Echinacea angustifolia* root (Budzinski et al. 2000).

A preparation of the aerial parts of *Echinacea purpurea* moderately inhibited CYP2C9 but did not influence CYP2D6 activity (Yale and Gulrich 2005).

In human liver cells, clinically relevant concentrations of an extract of fresh *Echinacea purpurea* herb (95%) and root (5%) or alkylamides isolated from *Echinacea purpurea* had no effect on expression of the transcription of the drug-metabolizing enzyme CYP3A4 (Modarai et al. 2009).

The effects of *Echinacea purpurea* on CYP enzymes have been shown to vary widely based on the alkylamide content of specific *Echinacea purpurea* preparations. Such variation in effects may explain the differing results obtained in the clinical studies (Modarai et al. 2007).

In male rats fed diets containing 50 mg/kg of *Echinacea purpurea* root extracted in 50% ethanol for 4 or 8 weeks, a reduction in the relative testicle size and changes in histology of the testicles were observed after 8 weeks of echinacea consumption (Skaudickas et al. 2004).

Exposure to extremely high concentrations (8 mg/ml) but not lower concentrations (0.8 mg/ml) of *Echinacea purpurea* root extract adversely affected the function of hamster gametes (Ondrizek et al. 1999).

IV. Pregnancy and Lactation

In a prospective study of women using *Echinacea* species products during pregnancy, no significant differences in minor malformations, neonatal complications, birth weight, or gestational age were observed in the *Echinacea* species group as compared to the control group (Gallo et al. 2000).

A survey of dietary supplement use by pregnant women in California indicated that *Echinacea* (species not specified) was the most commonly used supplement, with 8.9% of respondents reporting use during pregnancy (Tsui et al. 2001).

In pigs fed diets containing 1.2 or 3.6% dried aerial parts of *Echinacea purpurea* on days 85 to 110 of pregnancy and 0.5 or 1.5% on up to day 28 of lactation, no significant differences were found for growth performance, weight loss, blood picture, plasma enzymes, or colostrum composition. Performance of the sucking piglets was not impaired either during lactation or during a 4-week observation period after weaning (Maass et al. 2005). No embryotoxicity or adverse effects on postnatal development were observed in rats or rabbits fed up to 2700 mg/kg per day of an ethanol stabilized fresh juice preparation from *Echinacea purpurea* herb (Mengs et al. 2000).

In mice fed diets containing 45 mg/animal daily of an extract of *Echinacea purpurea* (plant part not stated; average animal weight not specified) from the beginning of pregnancy through days 10–14 of pregnancy, a reduction in number of fetuses per pregnancy was observed (Chow et al. 2006).

No information on the safety of *Echinacea* spp. during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intravenously administered polysaccharide fractions of *Echinacea purpurea* is reported to be between 1000 and 2500 mg/kg in mice (Lenk 1989). LD_{50} of intravenously administered *Echinacea purpurea* is 50 ml/kg in mice (Lang and Mengs 1976a, 1976b). Other studies with *Echinacea purpurea* indicated that no lethal dose of the expressed juice of the plant could be found in the highest physically possible oral and intravenous doses of 30,000 mg/kg (oral) and 10,000 mg/kg (intravenous) in mice (Mengs et al. 1991).

Short-Term Toxicity

Daily doses of 800 to 8000 mg/kg of the expressed juice of *Echinacea purpurea* for up to 4 weeks showed no toxic effects in rats (Mengs et al. 1991).

Genotoxicity

No carcinogenicity or mutagenicity was identified in in vitro assays (Kennelly 1985; Mengs et al. 1991; Schimmer et al. 1989).

Echinodorus macrophyllus (Knuth) Micheli

Alismataceae

SCN: chapéau de couro
OCN: water plantain

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

An animal study indicated immunosuppressive activity of chapéau de couro (Pinto et al. 2007).

Pregnancy and Lactation

No information on the safety of chapéau de couro in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In mice orally administered 0.5 or 5 mg/kg of an aqueous extract of chapéau de couro daily for 7 days, immunosuppressive activity was observed, including inhibition of B cell antibody production and delayed-type hypersensitivity mediated by T cells, reducing subcutaneous tissue leukocyte infiltration (Pinto et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of chapéau de couro during pregnancy or lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

In mice administered an aqueous extract of chapéau de couro in drinking water for 6 weeks with approximate intake of 3, 23, or 297 mg/kg of a lyophilized extract, or 2200 mg/kg of a crude extract daily, a decrease in body weight was observed in animals receiving the highest dose. Biochemical analysis of the plasma revealed some minor alterations indicating subclinical hepatic toxicity (da Costa Lopes et al. 2000).

Genotoxicity

No mutagenicity of an aqueous extract of chapéau de couro was observed in the *Salmonella*/microsome assay in strains TA97a, TA98, TA100, or TA102 with or without metabolic activation (da Costa Lopes et al. 2000).

In mice administered an aqueous extract of chapéau de couro in drinking water for 6 weeks with intake of 3, 23, or 297 mg/kg of a lyophilized extract, or 2200 mg/kg of a crude extract daily, no genotoxic effects on liver or blood cells were observed in the comet assay. DNA analyses of the kidney cells detected some genotoxic activity for the highest dose tested but not at lower doses (da Costa Lopes et al. 2000).

Pregnancy and Lactation

No information on the safety of eclipta in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A significant reduction in blood glucose levels was observed in diabetic rats orally administered 2 or 4 g/kg of a leaf suspension of eclipta daily for 60 days (Ananthi et al. 2003).

Examining the immunomodulatory effects of eclipta in mice, administration of doses from 100 to 500 mg/kg of a methanol extract of eclipta resulted in dose-dependent increases in the phagocytic index and antibody titer (Jayathirtha and Mishra 2004).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of eclipta during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} values for an aqueous extract of eclipta are 7841 mg/kg after oral administration, 303 mg/kg after intravenous administration, and 328 mg/kg after intraperitoneal administration (Qadri et al. 2001).

Elettaria cardamomum (L.) Maton var. *cardamomum* — Zingiberaceae

SCN: cardamom
Syn: *Amomum cardamomum* L.; *Elettaria cardamomum* L. var. *miniscula* Burkill; *Elettaria cardamomum* L. var. *minus* Watt

AN: *ela*
OCN: Mysore cardamom
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Contact and systemic contact-type dermatitis reactions to cardamom have been reported and confirmed by patch testing (Dooms-Goossens et al. 1990; Mobacken and Fregert 1975).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of cardamom in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Contact and systemic contact-type dermatitis reactions to cardamom have been reported and confirmed by patch testing (Dooms-Goossens et al. 1990; Mobacken and Fregert 1975). In spice factory workers with a history of skin symptoms, irritant patch test reactions were observed for cardamom in some workers (Meding 1993).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No irritant activity of 4% cardamom essential oil in petrolatum base was observed in 48-hour closed human patch tests (Opdyke 1979). In sensitization testing, no sensitization reactions were observed after testing with 4% cardamom essential oil in petrolatum base (Opdyke 1979).

Animal Pharmacological Studies

In an irritation test, no irritant effects were observed after cardamom essential oil was applied full strength to abraded or intact rabbit skin (Opdyke 1979).

In Vitro Pharmacological Studies

An extract of cardamom inhibited aggregation in human blood platelets treated with the agonists ADP, epinephrine, collagen, and calcium ionophore A 23187. No inhibition of aggregation was observed in platelets treated with ristocetin (Suneetha and Krishnakantha 2005).

IV. Pregnancy and Lactation

No information on the safety of cardamom in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered or topically applied cardamom essential oil in rats could not be determined at doses up to 5 g/kg (Opdyke 1979).

In mice orally administered 3 or 300 mg/kg daily for 7 days, microscopic evaluation indicated morphological perturbation of the heart along with inhibition of glyceraldehyde 3-phosphate dehydrogenase, and increases in the levels of thiobarbituric acid-reactive substances, succinate dehydrogenase, and catalase activity (El Malti et al. 2007).

Genotoxicity

No mutagenic activity of a cardamom aqueous extract was observed in the diploid yeast *Saccharomyces cerevisiae* strain D7 (Chughtai et al. 1998).

Eleutherococcus senticosus (Rupr. & Maxim.) Maxim. — Araliaceae

SCN: eleuthero
Syn: *Acanthopanax senticosus* (Rupr. & Maxim.) Harms
PN: *ci wu jia* (root and stem)
OCN: Siberian ginseng; Ussurian thorny pepperbush
Part: root, root bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Eleuthero has been reported to be adulterated with *Periploca sepium* (Martindale and Reynolds 1996), a botanical that contains cardioactive glycosides (Zhu 1998).

Adverse Events and Side Effects

A case of "hairy baby syndrome" was reported in association with a product labeled as "Siberian ginseng" (Koren et al. 1990). This product, however, was determined to be adulterated with *Periploca sepium* (Awang 1991).

Pharmacological Considerations

Insomnia has been rarely observed in association with clinical studies (De Smet 1993).

One source indicates that eleuthero should not be used in patients with high blood pressure (WHO 2002), based on the recommendation of two Russian studies published in the 1960s (Dalinger 1966; Lapchik 1967).

Pregnancy and Lactation

Basic animal studies have shown no adverse effects of eleuthero use during pregnancy or lactation (Curtze 1980; Davydov and Krikorian 2000; Farnsworth et al. 1985).

One reference contraindicates eleuthero during pregnancy, but the reason for this contraindication is not provided, with the reference citing animal studies that have shown no harm during pregnancy (WHO 2002).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Elevated serum digoxin levels were reported in a man taking eleuthero; the digoxin levels decreased and again increased when the man ceased and resumed consumption of eleuthero (McRae 1996). The elevated digoxin levels may have been due to an interference with the digoxin assay, especially since no toxic effects of elevated digoxin were observed (Brinker 2001). Others have questioned the botanical identity of the product the patient was taking, indicating that the product may have been adulterated with *Periploca sepium*, an herb that contains cardioactive glycosides (Zhu 1998).

Animal Trials of Drug or Supplement Interactions

Administration of eleuthero (40–320 mg/kg daily) and the barbiturate hexobarbital was shown to increase the sedative effects of hexobarbital (Medon et al. 1984).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical trials (over 4000 patients total) indicated that eleuthero was well tolerated with no significant adverse effects at doses of 2 to 16 ml daily of alcohol extract for up to 60 consecutive days (Farnsworth et al. 1985). Authors of two trials indicated that eleuthero should not be administered to persons with high blood pressure (over 180/90 mm Hg) (Dalinger 1966; Lapchik 1967), although no side effects of eleuthero were reported in these studies, which included more than 2100 participants. In studies on patients with atherosclerosis or with rheumatic heart disease, some adverse events were reported including insomnia, tachycardia, extra systole, hypertonia, headaches, pericardial pain, palpitations, and elevated blood pressure (Koshkareva and Kovinsky 1966; Mikunis et al. 1966).

Case Reports of Adverse Events

Use of eleuthero was reported in association with "ginseng abuse syndrome" (see *Panax ginseng* entry) (Siegel 1979). The study that included this information has been criticized for methodological flaws, notably, that no distinction

was made between the effects of Asian ginseng and eleuthero (Mills and Bone 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Administration of standardized eleuthero extract (970 mg daily) for 2 weeks had no significant effects on the drug-metabolizing isoenzymes CYP2D6 or CYP3A4 (Donovan et al. 2003).

Animal Pharmacological Studies

An aqueous extract of eleuthero administered intraperitoneally to mice lowered plasma sugar levels (Hikino et al. 1986).

No androgenic effects were observed in castrated rats administered eleuthero and testosterone for 7 days (Waller et al. 1992).

In Vitro Pharmacological Studies

Application of eleuthero extract (10%, v/v) to neonatal rat heart muscle cells (cardiomyocytes) resulted in a rapid cessation of heart beating due to calcium overload, although diluted extracts resulted in normal heart beating. Cardiotonic effects were observed when the same extract was applied to adult rat cardiomyocytes (Poindexter et al. 2006).

Animal and in vitro studies have indicated that consumption of eleuthero may cause some interference with certain digoxin immunoassays, falsely increasing serum digoxin levels in the FPIA assay or decreasing levels in the MEIA assay. No effects were observed in the EMIT, Randox, CLIA, or Tina-quant assays (Dasgupta and Reyes 2005; Dasgupta et al. 2003). Filtration of serum with activated charcoal prior to analysis increased the accuracy of test results (Dasgupta and Veras 2006).

IV. Pregnancy and Lactation

A case of neonatal androgenization was reported in the infant of a mother who had taken a product labeled as "Siberian ginseng" (an alternate common name for eleuthero) during her pregnancy (Koren et al. 1990). A subsequent analysis of this product revealed that the product was actually *Periploca sepium*, an herb that contains cardioactive glycosides (Awang 1991).

In two studies, eleuthero extracts (13.5 ml/kg or 10 mg/kg) administered for 9 or 16 days to pregnant rats showed no teratogenic effects (Curtze 1980; Davydov and Krikorian 2000). Likewise, no teratogenic effects were observed in sheep or mink after an ethanol extract of eleuthero was fed to pregnant animals (Farnsworth et al. 1985). No adverse effects were reported in minks fed eleuthero (10 ml/kg) on days 1 to 45 of lactation (Farnsworth et al. 1985).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered powdered eleuthero root in mice is 31 g/kg (Brekhman 1960, 1963). The LD_{50} of orally administered ethanolic extract of eleuthero in mice is 14.5 g/kg (Brekhman 1970).

Administration of a single oral dose of 3 g/kg of a freeze-dried aqueous extract of eleuthero to mice produced no deaths (Medon et al. 1981).

Subchronic Toxicity

No toxic effects were observed in rats fed 10 mg/kg daily of an ethanol extract of eleuthero for 2 months (Davydov and Krikorian 2000).

Chronic Toxicity

Rats administered 5 ml/kg daily of an ethanolic extract of eleuthero for 320 days showed no adverse reactions (Golotin et al. 1972).

Mice administered aqueous extracts of eleuthero for up to 96 days showed no significant difference in weight gain, liquid consumed, pathogenesis, or mortality, although mice that drank an extract with sugar exhibited aggressive behavior (Lewis et al. 1983).

Genotoxicity

No mutagenic or carcinogenic effects of eleuthero extracts were observed in bacterial mutagenicity assays or in rats (Hirosue et al. 1986).

Elymus repens (L.) Gould — Poaceae

SCN: couch grass
Syn: *Agropyron repens* (L.) P. Beauv.; *Elytrigia repens* (L.) Desv. ex B.D. Jackson; *Triticum repens* L.

OCN: dog grass; graminis; quack grass; triticum; twitch grass
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Notice
Diuretic (Mills and Bone 2005); *see* Appendix 2.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of couch grass in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of couch grass during pregnancy or lactation was identified.

V. Toxicity Studies

Genotoxicity
No mutagenic activity of a fluid extract (1:1, 20% ethanol) of couch grass was observed in the Ames test using *Salmonella typhimurium* strains TA98 and TA100 (Schimmer et al. 1994).

Epigaea repens L.

Ericaceae

SCN: trailing arbutus
OCN: gravel root

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Trailing arbutus has a chemical profile and traditional use similar to uva-ursi (*Arctostaphylos uva-ursi*), and these herbs have been considered as acceptable substitutes for each other (Felter and Lloyd 1898; Remington and Wood 1918).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of trailing arbutus in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of trailing arbutus during pregnancy or lactation was identified.

V. Toxicity Studies

See *Arctostaphylos uva-ursi* for a review of toxicity studies on the compound hydroquinone, which is hydrolyzed from the compound arbutin that is present in trailing arbutus (Felter and Lloyd 1898; Tanaka and Iwamoto 2002).

Epilobium angustifolium L. — Onagraceae

SCN: fireweed
Syn: *Chamaenerion angustifolium* (L.) Scop.; *Chamerion angustifolium* (L.) Holub

OCN: great willow herb
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of fireweed in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
In intact or testosterone-stimulated castrated male rats orally administered 40 mg/kg of hexane or water extracts or an ultrafiltration fraction daily for 20 days, the water extract caused a decrease in the weight of seminal vesicles in intact rats, and an increase in the weight of all accessory sexual organs in castrated rats. In intact rats, the ultrafiltration fraction exhibited the same but smaller effects than the water extract, with no effects observed in castrated rats. No effects on sexual organs were observed on rats administered the hexane extract (Hiermann and Bucar 1997).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the use of fireweed during pregnancy or lactation was identified.

V. Toxicity Studies
No toxicity studies were identified.

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
Compounds isolated from small-flower willow herb have been shown to inhibit 5α-reductase (Ducrey et al. 1997; Lesuisse et al. 1996).

IV. Pregnancy and Lactation
No information on the use of small-flower willow herb during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
The LD_{50} of an intraperitoneally administered ethanol extract of small-flower willow herb in rats is 200 mg/kg (Sharma et al. 1978).

No toxic effects were observed in rats orally administered up to 2 g/kg of a decoction of small-flower willow herb (Montalvo et al. 2003).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Some persons taking epimedium have experienced dry mouth, stomach discomfort, nausea, and vertigo, which were reported to abate without cessation of the herb (Bensky et al. 2004; Zhu 1998).

Pharmacological Considerations

Animal and in vitro studies have demonstrated estrogenic activity of epimedium (De Naeyer et al. 2005; Wang and Lou 2004; Yap et al. 2005, 2007; Zhang et al. 2005), although one study in menopausal women indicated a reduction in bone loss but no effects on estradiol levels (Zhang et al. 2007). In vitro, epimedium extracts have shown a greater affinity for estrogen receptor α than β (Shen et al. 2007).

Pregnancy and Lactation

No information on the safety of epimedium in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Some persons taking epimedium have experienced dry mouth, stomach discomfort, nausea, and vertigo, which were reported to abate without cessation of the herb (Bensky et al. 2004; Zhu 1998). Other adverse events that have been associated with epimedium use include vomiting, nosebleeds, and abdominal distention (Bensky et al. 2004). Details on products and doses associated with these adverse events were not reported in English language translations.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In late postmenopausal women, administration of epimedium-derived (*E. brevicornum*) phytoestrogen flavonoid

capsules (containing 60 mg icariin, 15 mg daidzein, and 3 mg genistein daily) for 2 years, a reduction in bone loss was observed without a detectable hyperplasia effect on the endometrium. Serum estradiol remained unchanged (Zhang et al. 2007).

Animal Pharmacological Studies

In male rats orally administered 500 mg of fractions of an ethanol extract of epimedium (*E. brevicornum*), an increase in estrogen receptor (ER)-α activity was observed (Yap et al. 2007).

In Vitro Pharmacological Studies

In estrogen receptor (ER)-α-positive breast cancer cells (MCF-7), 100 µg/ml of epimedium (*E. brevicornum*) inhibited the effects of tamoxifen. ER-α expression in the nucleus was observed with a low dose of epimedium (1 µg/ml), but higher doses (10 or 100 µg/ml) markedly reduced nuclear ER-α protein content (Yap et al. 2007).

In the modified MCF-7 cell proliferation assay, the compounds icaritin and desmethylicaritin, but not icariin, dose-dependently stimulated the proliferation of MCF-7/BUS cells. The estrogen receptor-regulated progesterone receptor and PS2 mRNA levels were increased by treatment with icaritin or desmethylicaritin (Wang and Lou 2004).

Epimedium (*E. brevicornum*) was reported to increase estrogen-responsive human breast cancer cell proliferation at low concentrations, and paradoxically cause profound inhibition of growth at higher concentrations (Yap et al. 2005).

In a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid, estrogenic activity of epimedium (*E. brevicornum*) was observed, with an EC_{50} of 100 µg/ml (Zhang et al. 2005).

Epimedium extracts demonstrated a greater affinity for ER-α than ER-β in human cells transfected with ER-α and ER-β (Shen et al. 2007).

An extract of the polyphenolic compounds from epimedium (*E. brevicornum*) exhibited estrogenic activity in estrogen-responsive bioassays, a yeast cell assay, and the Ishikawa Var-I assay (De Naeyer et al. 2005).

IV. Pregnancy and Lactation

No information on the safety of epimedium in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of epimedium extract in mice is 36 g/kg after intraperitoneal administration and 56.8 g/kg after intravenous administration (Chen and Chen 2004). The LD_{50} of flavonoids extracted from epimedium is 3 g/kg after intraperitoneal administration to mice (Leung and Foster 1996).

No adverse effects were observed in mice orally administered 450 g/kg of epimedium daily for 3 days (Chen and Chen 2004).

Equisetum hyemale L. — Equisetaceae

SCN: scouring rush
OCN: rough horsetail

PN: *mu zei* (above-ground parts)
Part: above-ground parts

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

Long-term use is not recommended (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Notice

Diuretic (Chen and Chen 2004; Perez Gutierrez et al. 1985); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that scouring rush should be used with caution in pregnant women (Bensky et al. 2004; Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of scouring rush in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Diuretic activity of a chloroform extract of horsetail was observed in mice. The effect of 50 mg/kg of horsetail was greater than that of the drugs hydrochlorothiazide, spironolactone, or furosemide (all 25 mg/kg) in relation to the urine output and excretion of sodium, potassium, and chloride (Perez Gutierrez et al. 1985).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that scouring rush should be used with caution in pregnant women (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of scouring rush during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Equisetum spp. Equisetaceae

Equisetum arvense L.
SCN: horsetail
OCN: field horsetail; shave grass; shavetail grass
Equisetum telmateia Ehrh.
SCN: giant horsetail
OCN: shave grass
Part: above-ground parts

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with kidney disease (Bradley 1992).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Felter and Lloyd 1898; Wichtl 2004); *see* Appendix 2.

Editors' Notes

The herb in powdered form is not recommended for children or for prolonged use due to the inorganic silica content (McGuffin et al. 1997), though decoctions contain mainly organic silica in colloidal form, so they are not problematic in this regard (Weiss and Meuss 1998). A review of horsetail states that toxicity has been reported after "eating large amounts of horsetail, which has occurred in children who have used the stems as blowguns or whistles," but does not cite the source of this information (Hamon and Awang 1992). Chewing fresh or dried horsetail may damage tooth enamel.

Adulteration of horsetail with *E. palustre*, which contains the potentially toxic alkaloid palustrin, is widely reported (Langhammer et al. 1972; Wichtl 2004), and hybrids of *E. arvense* and other *Equisetum* species have been reported, further challenging correct identification. The toxicity of palustrin-containing species in humans is not known, as poisonings have only been reported in grazing animals that have consumed large amounts of *Equisetum* species (Wichtl 2004).

Adverse Events and Side Effects

Low levels of sodium and potassium were reported in a woman with a history of hypertension who had been taking infusions of an unspecified amount of giant horsetail daily for approximately 6 months (Miro et al. 1996).

A reaction resembling seborrheic dermatitis, similar to that sometimes observed in association with nicotine, was reported in a man who had been in contact with fresh horsetail plants and then exposed to secondary tobacco smoke (Sudan 1985).

Allergic reaction to horsetail has been reported and confirmed by patch testing (Agustin-Ubide et al. 2004).

Pharmacological Considerations

An animal study demonstrated that horsetail may modify glucose regulation (Soleimani et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Animal studies and traditional use have indicated that horsetail has diuretic activity (Perez Gutierrez et al. 1985; Wichtl 2004).

Pregnancy and Lactation

No information on the safety of horsetail or giant horsetail in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Hyponatremia and hypokalemia were reported in an 84-year-old woman with a history of hypertension who had been taking infusions of giant horsetail (dose unspecified) for approximately 6 months (Miro et al. 1996).

A reaction resembling seborrheic dermatitis was reported in a man who had been in contact with fresh horsetail plants and then exposed to secondary tobacco smoke. A re-exposure to the plant elicited a more dramatic and rapid reaction. The reporting author indicated that nicotine present in horsetail was believed to be responsible for the reaction (Sudan 1985).

Allergic reaction to horsetail has been reported and confirmed by patch testing (Agustin-Ubide et al. 2004).

Multiple cases of cattle and horse poisoning by *Equisetum* species have been reported in the literature, with some reports indicating *E. arvense* as the causative species (Groh 1930; Hansen 1928; Hudson 1924; Jones 1901; Pammel 1921; Rapp 1954; Rich 1902). A review of these reports indicated that uncertainty in the identification of the species makes the reports difficult to interpret (Mills and Bone 2005). A 1904 study on the toxicity of various species of *Equisetum* in livestock indicated that *E. arvense* was nontoxic but that the botanically similar *E. palustre* demonstrated toxicity (Long 1924).

Symptoms of poisoning were observed in horses, but not in cattle, that ingested hay containing horsetail. The poisoning was treated successfully with injections of thiamine hydrochloride. Related in vitro testing indicated that horsetail destroyed thiamine by enzymatic activity (Henderson et al. 1952).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in blood glucose levels was observed in diabetic rats orally administered 50 mg/kg of a methanol extract of equisetum daily for 5 weeks (Soleimani et al. 2007).

In Vitro Pharmacological Studies

Inhibition of thrombin- but not ADP-induced aggregation was observed in rat platelets treated with aqueous extracts of horsetail, with an IC_{50} value of 6.75 mg/ml (Mekhfi et al. 2004).

IV. Pregnancy and Lactation

No information on the use of horsetail or giant horsetail during pregnancy or lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

In rats fed a 20% casein diet with or without cholesterol, the addition of 4% horsetail powder resulted in dermatitis of the neck, head, and back in 20 to 65% of the rats. The dermatitis resolved after the diet was changed to commercial pellets (Maeda et al. 1997).

No adverse effects on liver or kidney function were observed in voles fed diets containing increasing amounts of horsetail from 0.1 to 0.8 mg/kg daily (Jean and Bergeron 1986).

Subchronic Toxicity

No adverse effects were observed in rats intraperitoneally administered 50 mg/kg of a hydroalcoholic extract of horsetail daily for 8 weeks (Guilherme dos Santos et al. 2005).

Eriobotrya japonica (Thunb.) Lindley — Rosaceae

SCN: loquat
PN: *pi pa ye* (leaf)
Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Standard Dose
The standard dose is 4.5 to 15 g of dried leaf or 15 to 30 g of fresh leaf daily as a tea (Bensky et al. 2004; Chen and Chen 2004).

Notice
Cyanogenic glycosides (0.06% amygdalin) (Bensky et al. 2004; List and Hörhammer 1973); *see* Appendix 1.

Editors' Notes
The hairs naturally present on loquat leaf should be removed to avoid irritation of the mucous membranes that may aggravate a cough, causing edema and spasms of the larynx (Bensky et al. 2004; Tu 1988). While material imported from China has, as a rule, been properly processed with regard to this concern, added caution should be exercised when utilizing domestic sources.

Adverse Events and Side Effects
A case of severe muscular pain was reported after use of 2 liters daily of loquat tea for two weeks (Saliba et al. 2004).

Pharmacological Considerations
Animal studies have indicated that loquat may modify glucose regulation (Chen et al. 2008; De Tommasi et al. 1991; Li et al. 2007; Noreen et al. 1988; Roman-Ramos et al. 1991). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation
No information on the safety of loquat in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
Severe myalgia, particularly of the proximal muscles of the arms and legs, was observed in a 39-year-old man who had consumed approximately 2 liters of loquat tea daily for 2

weeks (amount of loquat used to make tea was not specified). The myalgia resolved after a reduction of the loquat dose (Saliba et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In normal and diabetic rabbits orally administered up to 200 mg/kg of an alcohol extract of loquat, a short-lived reduction in blood glucose was observed in healthy animals, but no significant effect was observed in diabetic animals (Noreen et al. 1988).

Compounds isolated from loquat exhibited hypoglycemic activity in diabetic mice and healthy rats (Chen et al. 2008; De Tommasi et al. 1991), with one compound showing activity after oral doses of 25 or 75 mg/kg (Chen et al. 2008).

A reduction in blood glucose levels was observed in healthy rabbits orally administered extracts of loquat (Roman-Ramos et al. 1991).

Hypoglycemic activity of an ethanol extract of loquat was observed in healthy and diabetic mice orally administered 15 to 60 g/kg. A 30 g/kg dose was reported to be more effective than 100 mg/kg of the drug phenformin. An extract of sesquiterpene compounds from loquat also lowered blood glucose at a dose of 30 g/kg (Li et al. 2007).

In Vitro Pharmacological Studies

An ethanol extract of loquat exhibited estrogenic activity in a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid (Kang et al. 2006; Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of loquat during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered ethanol extract of loquat in mice is 400.1 g/kg (Li et al. 2007).

No adverse effects were observed in rabbits orally administered up to 200 mg/kg of an alcohol extract of loquat (Noreen et al. 1988).

Eschscholzia californica Cham. — Papaveraceae

SCN: California poppy

Part: whole plant in flower

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Moore 2003).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

One text indicates that "large" doses may cause nausea. The standard dose listed in this text is 15 to 25 drops of tincture three times daily, or an infusion of 2 to 4 ounces of dried herb (Moore 2003).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Information on the safety of California poppy in pregnancy and lactation is limited. One contemporary herbal text indicates that California poppy should not be used during pregnancy (Moore 2003). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An aqueous extract of California poppy inhibited dopamine β-hydroxylase and monoamine oxidase (MAO-B) (Kleber et al. 1995).

An ethanol extract of California poppy was shown to bind to the serotonin 5-HT_{1A} and 5-HT_7 receptors at concentrations of 100 µg/ml (Gafner et al. 2006).

IV. Pregnancy and Lactation

One contemporary herbal text indicates that California poppy should not be used during pregnancy (Moore 2003). An ethnobotanical survey indicated that Native Americans of central California avoided use of California poppy during pregnancy and lactation (Bocek 1984). No other information on the safety of California poppy in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally and intraperitoneally administered aqueous-ethanolic extract of California poppy in mice could not be determined at doses up to 5 g/kg (Rolland et al. 2001).

Eucalyptus globulus Labill. — Myrtaceae

SCN: eucalyptus
OCN: blue gum; southern blue gum; Tasmanian blue gum

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (up to 11.0%) (De Smet 1992; Wichtl 2004); *see* Appendix 1.

Editors' Note

Eucalyptus leaf contains eucalyptus essential oil, which is the subject of a separate entry in this text (*see* next entry).

Adverse Events and Side Effects

Vocal cord dysfunction after exposure to eucalyptus leaf and allergic reaction to eucalyptus leaf have been reported (Galdi et al. 2003; Huggins et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of eucalyptus leaf in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

See eucalyptus leaf essential oil (next entry) for information on the safety of the essential oil in pregnancy and lactation.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Exacerbation of asthma was observed in a woman with asthma and rhinoconjunctivitis after ingestion of an infusion of eucalyptus leaf. Specific IgE were positive for eucalyptus pollens and negative for common aeroallergens (Galdi et al. 2003).

Vocal cord dysfunction after exposure to eucalyptus leaf and ammonia but not ammonia alone was observed in a woman undergoing inhalation challenges to identify agents that had been causing her respiratory distress. Negative skin prick test results, total IgE level, and negative IgE eucalyptus-specific antibodies support a nonimmunological mechanism (Huggins et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies of eucalyptus leaf were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies of eucalyptus leaf were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies of eucalyptus leaf were identified.

IV. Pregnancy and Lactation

No information on the safety of eucalyptus leaf during pregnancy or lactation was identified. *See Eucalyptus globulus* leaf essential oil (next entry).

V. Toxicity Studies

See Eucalyptus globulus leaf essential oil.

Eucalyptus globulus Labill. — Myrtaceae

SCN: eucalyptus
OCN: blue gum; southern blue gum; Tasmanian blue gum

Part: leaf essential oil

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for internal use in pregnancy except under the supervision of a qualified healthcare practitioner.

Do not exceed the recommended dose (Ruse 1998; Tibballs 1995).

Other Precautions

Eucalyptus essential oil is a h ighly concentrated product and should not be used on areas of the face, and especially the nose, in infants and young children.

Drug and Supplement Interactions

None known.

Standard Dose

The German standard dose for the compound eucalyptol is 200 mg three times daily (Juergens et al. 2003). This is equivalent to approximately 0.35 ml of eucalyptus essential oil.

Editors' Notes

Eucalyptus essential oil contains 70 to 80% of the compound eucalyptol (also called 1,8-cineole or 1,8-epoxy-*p*-menthane) (Chennoufi et al. 1980; De Vincenzi et al. 2002; HCPDG 2002; Leung and Foster 1996; Tyler et al. 1988). The oil must be free of other eucalyptus oils containing large amounts of phellandrene (Tyler et al. 1988).

Adverse Events and Side Effects

Cases of poisoning after ingestion of varying amounts of eucalyptus essential oil have been reported (Allan 1910; Anpalahan and Le Couteur 1998; Atkinson 1909; Benjamin 1906; Chun 1951; Craig 1953; Foggie 1911; Gurr and Scroggie 1965; Hindle 1994; Kirkness 1910; Myott 1906; Orr and Edin 1906; Owen 1885; Patel and Wiggins 1980; Sewell 1925; Spoerke et al. 1989; Taylor 1905; Webb and Pitt 1993; Wood 1900). Poisoning may affect the central nervous system (loss of consciousness, hypoventilation, depression of reflexes, and convulsions), the gastrointestinal system (abdominal pain, vomiting, and diarrhea), the respiratory system (respiratory depression, dyspnea, pneumonitis, and bronchospasm), and the cardiovascular system (low blood pressure, arrhythmia) (Craig 1953; Patel and Wiggins 1980; Tibballs 1995). Similar symptoms have been observed after topical application of eucalyptus essential oil (Darben et al. 1998).

Pharmacological Considerations

Older studies in rats indicate that eucalyptus essential oil administered subcutaneously or as an aerosol may increase the metabolism of pentobarbital (Jori and Briatico 1973).

Pregnancy and Lactation

One study in rats indicated no embryotoxicity or fetotoxicity in pregnant mice administered eucalyptus essential oil (Pages et al. 1990). In rats administered the compound eucalyptol during or after pregnancy, eucalyptol was shown to cross the placenta but was reported not to cross into breast milk (Jori and Briatico 1973).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Subcutaneous or aerosol administration of the compound eucalyptol to rats was shown to increase the metabolism of pentobarbital (Jori and Briatico 1973).

Reductions in duration of efficacy of pentobarbital, zoxazolamine, and amphetamine were seen in rats exposed to an aerosol of eucalyptus essential oil for 2 to 10 minutes daily for 4 days (Jori and Briatico 1973).

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a study of the compound eucalyptol at a dose of 200 mg three times daily in patients with bronchial asthma, side effects considered by the study physician to be possibly attributable to eucalyptol were heartburn and gastritis. These effects were experienced by 2 of 16 in the treatment group and none in the placebo group. No serious adverse events were reported, and no clinically relevant abnormalities in routine blood test parameters were observed (Juergens et al. 2003).

In Germany, eucalyptol is a licensed medicinal product sold in gut-soluble capsules and is reported to be well tolerated at a dose of 600 mg daily. Instructions for use indicate that this product should be taken with cold water about 20 minutes prior to eating to prevent epigastric pain (Juergens et al. 2003).

Case Reports of Adverse Events

Cases of poisoning after ingestion of varying amounts of eucalyptus essential oil have been reported (Allan 1910; Anpalahan and Le Couteur 1998; Atkinson 1909; Benjamin 1906; Chun 1951; Craig 1953; Foggie 1911; Gurr and Scroggie 1965; Hindle 1994; Kirkness 1910; Myott 1906; Orr and Edin 1906; Owen 1885; Patel and Wiggins 1980; Sewell 1925; Spoerke et al. 1989; Taylor 1905; Webb and Pitt 1993; Wood 1900). Poisoning affects the central nervous system (loss of consciousness, hypoventilation, depression of reflexes, and convulsions), the gastrointestinal system (abdominal pain, vomiting, and diarrhea), the respiratory system (respiratory depression, dyspnea, pneumonitis, and bronchospasm), and the cardiovascular system (low blood pressure, arrhythmia) (Craig 1953; Patel and Wiggins 1980; Tibballs 1995). Similar symptoms have been observed after topical application of eucalyptus essential oil (Darben et al. 1998).

Doses of eucalyptus oil causing poisoning vary widely, as a 15 ml dose administered to a 6-year-old resulted in slight drowsiness (Atkinson 1909), while approximately 4 ml given to a 10-year-old boy resulted in death (Foggie 1911), and 4 ml given to a 1-year-old girl resulted in severe poisoning with eventual recovery (Allan 1910). In adults, 10 ml led to poisoning with drowsiness and ataxia (Kirkness 1910), and 4 to 5 ml (Macpherson 1925) and 25 ml led to death (Myott 1906); however, severe poisonings were successfully treated in an adult who had ingested 120 to 220 ml (Gurr and Scroggie 1965), and in a 73-year-old woman who had ingested approximately 180 ml of eucalyptus essential oil (Anpalahan and Le Couteur 1998).

A review of cases of eucalyptus poisoning in children ages 5 months to 9 years categorized poisoning cases into five levels of severity, with information on doses of eucalyptus oil ingested by children (note that the doses are actual and not adjusted to ml/kg based on each child's weight): no effects (0.2 to 5.0 ml, mean 1.7 ml) with symptoms of sputtering or coughing after ingestion; minor poisoning (0.2 to 7.0 ml, mean 2.0 ml) with symptoms of ataxia, vomiting, abdominal pain, miosis; moderate poisoning (0.6 to 5.0 ml, mean 2.5 ml) with symptoms of depression of consciousness, Glasgow coma scale score of 8 to 14; major poisoning (7.5 ml) with symptoms of loss of consciousness, Glasgow coma scale score of 3 to 7 without hypoventiliation; life-threatening poisoning (no dose specified) with symptoms of unconsciousness with hypoventilation (Tibballs 1995). Older case reports indicate that children have recovered after ingestion of 14 and 24 ml of eucalyptus essential oil (Benjamin 1906; Sewell 1925). Tiballs (1995) provides information on the clinical management of the different levels of poisoning.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Ingestion or inhalation of the compound eucalyptol induces microsome mixed function oxidases in rats (Jori and Briatico 1973). Such activity may speed the clearance of certain drugs such as pentobarbital, aminopyrine, and amphetamine (Katzung 2007) and increase the toxicity of pyrrolizidine compounds (White et al. 1983).

In Vitro Pharmacological Studies

Eucalyptus essential oil weakly inhibited the drug-metabolizing isoenzymes CYP2C8, CYP2C19, and CYP3A4 in vitro with IC_{50} values over 100 µg/ml (Unger and Frank 2004).

Eucalyptus essential oil enhanced the penetration of 5-fluorouracil in excised human skin by a factor of 34 (Williams and Barry 1989).

IV. Pregnancy and Lactation

No embryotoxicity or fetotoxicity was observed in the offspring of pregnant mice subcutaneously administered 135 mg/kg daily eucalyptus essential oil on gestational days 6 to 15 (Pages et al. 1990).

In rats subcutaneously administered the compound eucalyptol on gestational days 10 to 14, the last 4 days of pregnancy, or on postnatal days 2 through 6, treatment enhanced microsomal enzyme activity of the mothers and induced enzyme activity in fetal livers, but did not induce microsomal activity of suckling newborn rats, suggesting that eucalyptol is able to cross the placenta but does not cross into breast milk (Jori and Briatico 1973).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered eucalyptol in rats has been reported as 1560 mg/kg (Brownlee 1940) and 2480 mg/kg (Jenner et al. 1964). Toxic effects at the 1560 mg/kg dose were rapid cyanosis, stupor, irregular breathing, extreme sensitivity to noise, convulsions, and death from respiratory failure (Brownlee 1940).

The estimated lethal dose in humans ranges from 0.05 to 0.5 ml/kg (Hindle 1994).

Short-Term Toxicity

In rats orally administered the compound eucalyptol via stomach tube at doses up to 1200 mg/kg 5 days per week or encapsulated and added to feed at doses up to 3342 mg/kg daily for 28 days, a dose-related decrease in weight gain and absence of a normal degree of hepatic centrilobular cytoplasmic vacuolization was observed in male rats. Dose-related lesions in the liver, kidneys, and parotid salivary glands were found at all dose levels in male rats fed encapsulated eucalyptol (Wolff 1987b).

In male rats administered 0, 500, or 1000 mg/kg of the compound eucalyptol daily for 28 days, statistically significant decreases in terminal body weight and increases in relative liver and kidney weights were found in both dose groups, whereas relative brain weight was increased only in the highest dose group. Minor focal infiltration of mononuclear cells in the liver was observed in all groups. In kidneys, a dose-related accumulation of eosinophilic protein droplets containing α2µ-globulin in the cytoplasm of proximal tubular epithelial cells was induced (Kristiansen and Madsen 1995).

In mice orally administered the compound eucalyptol via stomach tube at doses up to 1200 mg/kg 5 days per week or encapsulated and added to feed at doses up to 5607 mg/kg daily for 28 days, the liver weight/body weight ratio in males was increased at all but the lowest dose given in encapsulated form; likewise, the brain weight/body weight ratio was increased in females at the highest dose. Microscopic examination revealed a minimal hypertrophy of centrilobular hepatocytes in animals of both sexes fed the encapsulated compound, especially at the two highest dose levels (Wolff 1987a).

Commercial rutin derived from eucalyptus, but not purified rutin, caused the development of cataracts in rats orally administered the compound (Nakagawa et al. 1965).

Chronic Toxicity

Weak tumor-promoting activity was seen in mice treated topically once a week for 33 weeks with eucalyptus oil after application of the carcinogen 9,10-dimethyl-1,2-benzanthracene (DMBA). The tumor-promoting effect was less than that of orange or lemon essential oils (Roe and Field 1965).

Genotoxicity

No mutagenic effects of the compound eucalyptol were observed in *Salmonella typhimurium* strains TS97, TA98, TA100, TA102, TA1535, and TA1537 with or without metabolic activation (Gomes-Carneiro et al. 1998; Haworth et al. 1983). Eucalyptol was not active in *Bacillus subtilis* using the *rec* assay or in CHO K-1 cells using the SCE assay (Sasaki et al. 1989).

Eucommia ulmoides Oliv.

Eucommiaceae

SCN: eucommia
PN: *du zhong* (bark)

OCN: Chinese rubber tree; hardy rubber tree
Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions after extensive skin contact with eucommia have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Eucommia is one of the herbs most commonly used in traditional Chinese medicine to stabilize pregnancy and prevent miscarriage (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of eucommia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions after extensive skin contact with eucommia have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Eucommia is one of the herbs most commonly used in traditional Chinese medicine to stabilize pregnancy and prevent miscarriage (Bensky et al. 2004; Chen and Chen 2004).

In excised uteruses, eucommia dose-dependently relaxed chemically induced uterine stimulation and contraction. Processed eucommia was more active than unprocessed eucommia (Wang et al. 1989).

No information on the safety of eucommia during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of eucommia intravenously administered to mice is 574.1 g/kg (Chen and Chen 2004). No deaths were reported in mice intraperitoneally administered 500 g/kg of eucommia daily for 6 days (Chen and Chen 2004).

Short-Term Toxicity

No evidence of toxicity, as determined by clinical appearance, histopathology, and serum chemistry evaluation, was observed in rats orally administered 200, 600, or 1200 mg/kg of eucommia extract daily for 28 days (Lang et al. 2005).

Genotoxicity

In the mouse micronucleus and chromosomal aberration assays, mutagenic activity was observed in mice intraperitoneally administered an aqueous extract of eucommia at doses of 1 to 2 g/kg, with no mutagenic activity observed at a dose of 0.2 g/kg. A dose-dependent increase in the

incidence of chromosomal aberrations was observed at doses of 1 to 2 g/kg. In the micronucleus assay, an increase of polychromatic erythrocytes was observed at the 1 to 2 g/kg dose level (Yin et al. 1991).

In the Ames mutagenicity assay with *Salmonella typhimurium* strains TA98 or TA100, an extract of eucommia exhibited some mutagenic activity in TA100 with and without metabolic activation (Yin et al. 1991).

Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Bliss and Ramstad 1957a, 1957b; Bradley 1992).

Do not exceed recommended dose (Bradley 1992; Lyle 1932).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

A decoction of 0.3 to 1 g or 0.3 to 1 ml of tincture (Bradley 1992).

Adverse Events and Side Effects

Wahoo may cause nausea (Lyle 1932). A British reference text notes that "in excessive doses" wahoo is "relatively toxic" (Bradley 1992).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A British herbal reference text indicates that wahoo should not be used during pregnancy or lactation (Bradley 1992). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A British reference text notes that "in excessive doses" wahoo is "relatively toxic." The standard dose is reported as a decoction of 0.3 to 1 g or 0.3 to 1 ml of tincture (Bradley 1992).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A British herbal reference text indicates that wahoo should not be used during pregnancy or lactation (Bradley 1992).

V. Toxicity Studies

No toxicity studies were identified.

Eupatorium perfoliatum L. — Asteraceae

SCN: boneset
OCN: thoroughwort

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

The presence or absence of pyrrolizidine alkaloids (PAs), some of which may cause liver toxicity, in boneset has not been fully investigated. Although many species of the genus *Eupatorium* contain PAs, these compounds have not been confirmed in boneset, and several references indicate a lack of these compounds in boneset (Arzneimittelkommission 1990; De Smet 1993; Hensel et al. 2011; Leung and Foster 1996; Zhang et al. 2008).

Adverse Events and Side Effects

Boneset contains sesquiterpene lactones, compounds that may cause allergic contact dermatitis in sensitive individuals (Herz et al. 1977; Warshaw and Zug 1996).

"Large" doses (decoction of 5.5–7 g) of boneset may be emetic or cathartic (Felter and Lloyd 1898; Wood and LaWall 1926).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of boneset in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

Euphrasia spp.

Scrophulariaceae

Euphrasia rostkoviana F. Hayne
SCN: eyebright
Euphrasia stricta J.P. Wolff ex J.F. Lehm.
SCN: eyebright
Syn: *Euphrasia officinalis* L.
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (~12%) (Harkiss and Timmins 1973); *see* Appendix 1.

Editors' Note

Species of eyebright are difficult to distinguish botanically (Harkiss and Timmins 1973). *Euphrasia stricta*, *E. rostikoviana*, and hybrids or mixtures of these species are commonly accepted as eyebright (Wichtl 2004).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

An animal study indicated that eyebright may modify glucose regulation (Porchezhian et al. 2000). People with diabetes are advised to monitor their blood sugar closely and

discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of eyebright in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A hypoglycemic effect was observed in diabetic rats orally administered 600 mg/kg of an aqueous extract of eyebright. No significant hypoglycemic activity was observed in healthy rats (Porchezhian et al. 2000).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of eyebright during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in rats orally administered up to 6 g/kg of an aqueous extract of eyebright (Porchezhian et al. 2000).

Genotoxicity

No mutagenic activity of an ethanol extract of eyebright was observed in the Ames mutagenicity assay with *Salmonella typhimurium* strains TA98 and TA100 with or without metabolic activation by S9 (Schimmer et al. 1994).

Euryale ferox Salib. — Nymphaeaceae

SCN: euryale
AN: *makhanna*
PN: *qian shi* (seed)

OCN: foxnut; gorgon waterlily
Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions
Use with caution in persons with difficulty urinating or defecating (Bensky et al. 2004).

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of euryale in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions
Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events
Case Reports of Adverse Events
A case of allergic reaction to euryale, with tingling pruritus and localized urticaria-like papular rashes, was reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics
Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the use of euryale during pregnancy or lactation was identified.

V. Toxicity Studies
No toxicity studies were identified.

Euterpe oleracea Mart. — Arecaceae

SCN: açaí
OCN: assai palm; cabbage palm

Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Editors' Notes
The fruit of açaí is widely consumed as a food by people of the Amazon basin in South America (Brondízio et al. 2002; Janick and Paull 2008; Muñiz-Miret et al. 1996).

Cases of Chagas disease (a parasitic disease that can lead to heart and intestinal complications) have been

associated with açaí juice consumption in the Amazon (Nóbrega et al. 2009; Valente et al. 1999). Chagas disease is transmitted by several types of insects. Infections in the Amazon regions are believed to be due to triatomine bugs that, attracted by electrical lights, fell into the machine used to process the juice consumed by the patients (Valente et al. 1999). Use of properly cleaned machinery and fruit should prevent transmission of the disease.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of açaí in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of açaí during pregnancy or lactation was identified.

V. Toxicity Studies

Genotoxicity

Some mutagenic activity of açaí was observed in *Saccharomyces cerevisiae* yeast treated with high concentrations (5, 10, or 15%, w/v) of previously frozen açaí pulp. The mutagenic activity was similar to that of cashew apple (*Anacardium occidentale*), kiwi fruit (*Actinidia chinensis*), and strawberry (*Fragaria vesca*) (Spada et al. 2008).

Syn: *Eupatorium maculatum* L.
Eutrochium purpureum (L.) E.E. Lamont
SCN: Joe Pye; gravel root (root)
Syn: *Eupatorium purpureum* L.
OCN: Joe Pye weed; queen-of-the-meadow
Part: herb, rhizome, root

Quick Reference Summary

Safety Class: 2a, 2b, 2c
Interaction Class: A

Contraindications

For external use only (McGuffin et al. 1997).

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (De Smet 1993).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Pyrrolizidine alkaloids (Mills 1967; Smith and Culvenor 1981); *see* Appendix 1.

Editors' Notes

The American Herbal Products Association has established a trade requirement (AHPA 2011) that all products with botanical ingredients that contain toxic pyrrolizidine alkaloids, including *Eupatorium* species, are not offered for sale for internal use and display the following cautionary label: "For external use only. Do not apply to broken or abraded skin. Do not use when nursing."

The presence or absence of pyrrolizidine alkaloids (PAs), some of which may cause liver toxicity, in Joe Pye has not been fully investigated. Although many species of the genus *Eupatorium* contain PAs, these compounds have not been confirmed in Joe Pye. The one reference that indicates the presence of these compounds is a dissertation from the 1960s that lists Joe Pye as "probably" containing the compound echinatine in the aerial parts, and echinatine and trachelanthamine in the root (Mills 1967; Smith and Culvenor 1981). In 1983, Joe Pye was listed as a PA-containing plant "the toxicity of which has not been, or has been insufficiently, investigated" (Danninger et al. 1983; INCHEM 1988). Echinatine is an unsaturated PA, which is the type that has been associated with liver toxicity, as compared with trachelanthamine, a saturated PA which is the type considered nontoxic.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Joe Pye in pregnancy or lactation was identified. Based on the probable presence of pyrrolizidine alkaloid compounds, use of Joe Pye during pregnancy or lactation is not recommended.

Evernia spp.

Usneaceae

Evernia furfuracea (L.) W. Mann
SCN: tree moss
Evernia prunastri (L.) Ach.
SCN: oak moss
Part: thallus

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

May contain thujone (CFR 2011; Furia and Bellanca 1971); *see* Appendix 1.

Editors' Notes

Although some research indicated the presence of the compound thujone in oak moss (Gavin and Tabacchi 1975; Stoll and Scherrer 1937), a review of the chemistry of oak moss indicated that the presence of thujone in oak moss is questionable, and that more recent investigation has not confirmed the presence of the compound (Joulain and Tabacchi 2009).

The hot alcohol extract of *Evernia* produces a toxic ethyl ester and is therefore not for internal use (Furia and Bellanca 1971).

Use of oak moss as a food additive in the United States is subject to a limitation that the finished food or beverage is thujone-free (CFR 2011). Dietary ingredients for use in dietary supplements, however, are specifically excluded from the federal food additive definition. (U.S.C. 2010).

Adverse Events and Side Effects

Allergic reactions to oak moss as a fragrance ingredient have been reported (Goncalo 1987; Johansen et al. 2002; Schnuch et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of oak moss or tree moss in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Oak moss is a common ingredient in perfumes and is included in the standard fragrance mix used to screen for fragrance allergies (Johansen et al. 2002). Of 59,298 persons that tested positively to fragrance mix between 1996 and 2002, 29.9% had reactions to oak moss (Schnuch et al. 2004). In persons with allergic reactions to *Frullania*, many also tested positive to oak moss (Goncalo 1987).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No irritation was observed in healthy volunteers treated with 10% oak moss concrete in petrolatum in a 48-hour closed patch test (Opdyke 1979). No sensitization was observed in healthy volunteers treated topically with a 10% oak moss concrete in petrolatum (Opdyke 1979).

Animal Pharmacological Studies

In irritation tests, no irritation was observed after oak moss concrete was applied undiluted to the backs of hairless mice or pigs or to intact or abraded rabbit skin for 24 hours under occlusion (Opdyke 1979).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of oak moss or tree moss during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered oak moss concrete in rats is 2.9 g/kg; the dermal LD_{50} of the same product tested in rabbits could not be determined at doses up to 5 g/kg (Opdyke 1979).

Ferula foetida **(Bunge) Regel**
SCN: asafetida (oleo gum resin)
AN: *hingu*
OCN: asafoetida (oleo gum resin); devil's dung (oleo gum resin); giant fennel
Part: oleo gum resin from rhizomes and roots

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Keshri et al. 1999, 2004; Madari and Jacobs 2004).

Not for use in infants (Kelly et al. 1984).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Felter and Lloyd 1898); *see* Appendix 2.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Methemoglobinemia (a disorder characterized by a higher than normal level of methemoglobin in the blood) was reported in a 5-week-old after ingestion of glycerited asafetida. A related in vitro study showed activity of asafetida in infant but not adult hemoglobin (Kelly et al. 1984).

Side effects reported from excessive consumption include swollen lips, gastric burning, belching, flatulence and diarrhea, burning urination, headaches, and dizziness. Details on products, dose, and duration associated with these effects were not available (De Smet 1992; Roth et al. 1984).

Doses of 50 to 100 mg of asafetida have been reported to cause convulsions in persons suffering from nervousness (Roth et al. 1984).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Animal studies have indicated anti-implantation activity of asafetida (Keshri et al. 1999, 2004). An Eclectic medical text lists asafetida as an emmenagogue (Felter and Lloyd 1898). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of asafetida during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse effects were observed in healthy volunteers administered 3 g of asafetida with 100 g of butter on bread (Bordia and Arora 1975).

Case Reports of Adverse Events

Methemoglobinemia (a disorder characterized by a higher than normal level of methemoglobin in the blood) was diagnosed in a 5-week-old boy who had been administered glycerited asafetida (dose unspecified). An in vitro study conducted by the reporting physicians indicated that asafetida had an oxidizing effect on infant hemoglobin but not on adult hemoglobin (Kelly et al. 1984).

Side effects reported from excessive consumption include swollen lips, gastric burning, belching, flatulence and diarrhea, burning urination, headaches, and dizziness. Details on products, dose, and duration were not available (De Smet 1992; Roth et al. 1984).

Doses of 50 to 100 mg of asafetida have been reported to cause convulsions in persons suffering from nervousness (Roth et al. 1984).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Dose-dependent anti-implantation activity was observed in rats orally administered 200 to 400 mg/kg of extracts of asafetida on days 1 to 10 of pregnancy. Pregnancy was prevented in 80% of rats administered 400 mg/kg of a methanol extract and in 100% of rats administered 400 mg/kg of the extract in a polyvinyl pyrrolidone 1:2 complex (Keshri et al. 1999).

Anti-implantation activity of asafetida was observed in rats orally administered 400 mg/kg of a methanol extract of asafetida daily on days 1 through 7 of pregnancy (Keshri et al. 2004).

Asafetida is listed as an ingredient in ancient Persian abortifacient formulas, along with other botanicals (Madari and Jacobs 2004).

No information on the safety of asafetida during lactation was identified.

V. Toxicity Studies

Genotoxicity

Weak induction of sister-chromatid exchanges in the spermatogonia was observed after oral administration of 0.5 or 1 g/kg asafetida to mice (Abraham and Kesavan 1984).

No genotoxic activity of an aqueous extract of asafetida was observed in *Drosophila* treated with concentrations of 0.25 or 0.5% (Abraham and Kesavan 1985).

Antimutagenic activity of asafetida has been reported (Soni et al. 1997; Soudamini et al. 1995).

Filipendula ulmaria (L.) Maxim. — Rosaceae

SCN: meadowsweet
Syn: *Spiraea ulmaria* L.
OCN: queen-of-the-meadow
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use in persons with sensitivity to aspirin or other salicylate-containing drugs is cautioned (ESCOP 2003; Mills and Bone 2005; Wichtl 2004).

Use in persons with G6PD deficiency is cautioned (Mills and Bone 2005).

Drug and Supplement Interactions

None known.

Notice

Salicylates (up to 0.5%) (Hansel et al. 1993; Meier 1987; Meier et al. 1987; Thieme 1965); *see* Appendix 1.

Tannins (10–15%) (Hansel et al. 1993; Haslam et al. 1989; Okuda et al. 1993); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Meadowsweet flower has been reported to contain "heparin-like compounds" bound to plant proteins. In animal studies, injections of these compounds showed anticoagulant and fibrinolytic activity (Kudriashov et al. 1990, 1991). The relevance of those data to oral use of meadowsweet in humans is not known.

Pregnancy and Lactation

A study on isolated animal uteri indicated that meadowsweet increased the tone and force of uterine contractions (Barnaulov et al. 1978). The relevance of such in vitro studies to human use is not known.

No information on the safety of meadowsweet during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Heparin-like compounds bound to plant proteins were reportedly identified in meadowsweet flower. Intramuscular and intravenous administration of the compounds in animals enhanced anticoagulant and fibrinolytic activity. The activity was neutralized by protamine sulfate (Kudriashov et al. 1990, 1991).

IV. Pregnancy and Lactation

After treatment with an aqueous extract of meadowsweet, an increase in the tone and force of contractions was observed in smooth muscle sections of the uterine horns of rats, cats, and guinea pigs (Barnaulov et al. 1978). The relevance of such in vitro studies to human use is not known.

No information on the safety of meadowsweet during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an ethanol extract of meadowsweet in rabbits is 1770 mg/kg after intraperitoneal administration and 75.7 mg/kg after intravenous administration (Barnaulov et al. 1977).

The LD_{50} of a 1:20 meadowsweet decoction intraperitoneally administered to mice is 1050 mg/kg in females and 535 mg/kg in males. The LD_{50} of the decoction in rabbits is 141.5 mg/kg after intravenous administration (Barnaulov et al. 1977).

No adverse effects on liver function were observed in rabbits treated with different extracts of meadowsweet (extracts, doses, and duration of treatment not specified in available English translations) (Barnaulov et al. 1979).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Notice

Alkenylbenzenes (estragole as 5–10% of essential oil) (ESCOP 2003); *see* Appendix 1.

Adverse Events and Side Effects

A case series of premature thelarche (isolated breast development with no other clinical signs of sexual maturation), with elevated estradiol levels, was reported in four girls ages 5 months to 5 years who had been administered two to three cups of fennel tea daily for 4 months to 2 years (Turkyilmaz et al. 2008).

A case series of methemoglobinemia with respiratory distress, cyanosis, and tachycardia, was reported in four infants, 7 to 9 months old, that had been fed purées of fennel (part and dose used not specified). High nitrate levels in the products administered were believed to be responsible for the methemoglobinemia (Murone et al. 2005).

Allergic reactions to fennel are rare but have been reported (Bensky et al. 2004; De Smet 1992; Ottolenghi et al. 1995). Human studies have indicated an association between birch–mugwort–celery syndrome and fennel allergy (Jensen-Jarolim et al. 1997; Stager et al. 1991).

Pharmacological Considerations

Animal studies and human case reports have indicated estrogenic activity of fennel (Malini et al. 1985; Turkyilmaz et al. 2008).

An animal study indicated that the absorption of ciprofloxin was reduced with coadministration of fennel (Zhu et al. 1999).

Pregnancy and Lactation

Fennel seed is one of the most commonly used botanicals by nursing mothers, and it is also given to colicky infants. Although case reports and in vitro studies indicate some estrogenic activity of fennel, considering the widespread use and relative lack of adverse events reported, the editors of this text believe that fennel tea is safe for use during pregnancy and lactation. Fennel essential oil and alcohol extracts of fennel, however, should not be used during pregnancy or lactation (Wichtl 2004).

A review of the safety of fennel indicated that, while fennel essential oil, like many other essential oils, has been reported to cause excitation of the uterus, this effect is not likely to occur with therapeutic doses of fennel. The review also indicated that no cases of successfully self-induced abortions from fennel or fennel essential oil have been reported (De Smet 1992).

A risk-benefit analysis of fennel in infants, regarding concern for carcinogenicity of the compound estragole, concluded that, based on available clinical and epidemiological data, any cancer risk is negligible and fennel seed is safe for use in infants (Iten and Saller 2004).

Also see Adverse Events and Side Effects for this entry.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

In rats orally administered ciprofloxin with or without 2 g/kg of an aqueous extract of fennel, decreases in the maximum plasma concentration, area under the curve, and urinary recovery of ciprofloxin were observed after coadministration with fennel. The volume of distribution and terminal elimination half-life of ciprofloxin were increased (Zhu et al. 1999).

An increase in pentobarbital-induced sleeping time was observed in mice intraperitoneally administered 50 mg/kg of fennel essential oil (Marcus and Lichtenstein 1982).

II. Adverse Events

Case Reports of Adverse Events

A case series of premature thelarche (isolated breast development with no other clinical signs of sexual maturation) was reported in four girls ages 5 months to 5 years who had been administered two to three cups of fennel tea daily for 4 months to 2 years. Age-specific serum estradiol levels were 15 to 20 times higher than normal. All of the girls had been breast-fed for their first 9 months, and none had a history of prolonged drug intake that would account for the elevation in hormone levels. After cessation of administration, premature thelarche resolved within 3 to 6 months and hormone levels decreased to the normal range (Turkyilmaz et al. 2008).

A case series of methemoglobinemia with respiratory distress, cyanosis, and tachycardia was reported in four infants, 7 to 9 months old, that had been fed purées of fennel (part and dose used not specified). Purées administered to two of the infants were analyzed for nitrate content and found to contain high (2550 mg/kg) levels of nitrates. In two cases, the purées were combined with carrot, a vegetable that is high in nitrates. Nitrates are the most common cause of acquired methemoglobinemia (Murone et al. 2005).

Rare cases of allergic reaction to fennel have been reported (Bensky et al. 2004; De Smet 1992; Ottolenghi et al. 1995). Allergic reactions are reported to have been associated with symptoms such as shortness of breath, facial pallor, low blood pressure, excessive sweating, accelerated pulse, and impaired consciousness (Bensky et al. 2004).

In patch testing of persons with birch-mugwort-celery syndrome, cross-sensitivity to fennel was relatively high as compared to other allergens tested (Jensen-Jarolim et al. 1997; Stager et al. 1991).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a study of women with idiopathic hirsutism (excessive male pattern hair growth in women with normal levels of serum androgens), involving topical application of a cream containing 1 or 2% fennel ethanol extract daily for 8 or 12 weeks, a dose-dependent reduction in hair diameter was observed. The authors of the article indicated that estrogenic activity of fennel was responsible for this reduction (Javidnia et al. 2003).

Animal Pharmacological Studies

In rats orally administered an acetone extract of fennel at doses of 0.5 to 2.5 mg/kg daily for 14 days, dose-dependent induction of the estrus cycle and increased weights of mammary glands, endometrium, cervix, and vagina were observed in females. In males, a decrease in total protein concentration in the testes and vas deferens and an increase in the seminal vesicles and prostate gland were observed after doses of 1.5 or 2.5 mg/kg (Malini et al. 1985).

A decrease in the weight of testes, epididymis, seminal vesicle, ventral prostate, and vas deferens was observed in male rats orally administered 250 or 500 mg/kg of fennel aqueous extract daily for 60 days. A decrease in sperm motility was also observed along with a decrease in fertility (Agarwal et al. 2006).

Antithrombotic activity was observed in mice orally administered 30 mg/kg fennel essential oil daily for 5 days. At that dose, prevention of paralysis induced by collagen-epinephrine injection was observed and did not cause any prohemorrhagic side effects (Tognolini et al. 2007).

No effects on blood glucose levels were observed in diabetic mice intraperitoneally administered fixed oil of fennel daily for 7 days (Ozbek et al. 2003).

In Vitro Pharmacological Studies

Fennel essential oil inhibited platelet aggregation induced by arachidonic acid, ADP, thromboxane A_2, and U46619 in guinea pig and rat plasma (Tognolini et al. 2006). The compound anethole, the main component of fennel essential oil, inhibited platelet aggregation induced by arachidonic acid, collagen, ADP, and U46619, and prevented thrombin-induced clot retraction in guinea pig plasma (Tognolini et al. 2007).

Studies on the effects of fennel methanol extracts on the activity of the human drug-metabolizing isoenzyme CYP3A4 have shown differing results, with one study indicating significant inhibition (Subehan et al. 2006, 2007) and another study showing no activity (Usia et al. 2006). No significant effects of a methanol extract of fennel seed were observed on the human drug-metabolizing isoenzyme CYP2D6 (Subehan et al. 2006; Usia et al. 2006).

IV. Pregnancy and Lactation

German authorities have indicated that while fennel essential oil and alcohol extracts should not be taken during pregnancy, water-based extracts of fennel are regarded as safe (Wichtl 2004).

A review of the safety of fennel indicated that, while fennel essential oil, like many other essential oils, has been reported to cause excitation of the gravid uterus, this effect has not been verified and is not likely to occur with therapeutic doses of fennel. The review also indicated that no cases of successfully self-induced abortions from fennel or fennel essential oil have been reported (De Smet 1992).

An in vitro test using limb bud cells from day 13 rat embryos indicated some evidence of toxicity of fennel essential oil to fetal cells but no evidence of teratogenicity. After 5 days of incubation in concentrations of 0.93 mg/ml and above, a significant reduction in the number of stained differentiated foci were observed. This reduction was thought to be due to cell loss rather than to a decrease in cell differentiation (Ostad et al. 2004).

The compound *trans*-anethole, isolated from fennel essential oil, exhibited dose-dependent anti-implantation activity in rats administered doses of 50 to 80 mg/kg on days 1 to 10 of pregnancy. At the 80 mg/kg dose level, administration on days 1 and 2 of pregnancy did not cause any changes in fertility, while with the same dose administered on days 3 to 5 of pregnancy, no implantation occurred. The same dose administered on days 6 to 10 of pregnancy caused a reduction in the number of pregnancies. No malformations were observed in any of the animals born from treated mothers (Dhar 1995).

In isolated rat uteri, treatment with fennel essential oil reduced the intensity of contractions induced by oxytocin and prostaglandin E_2. The oil also reduced the frequency of contractions induced by prostaglandin E_2 but not by oxytocin (Ostad et al. 2001).

A risk-benefit analysis on the use of fennel tea as a colic remedy for infants indicated that studies regarding carcinogenicity of the compound estragole in animal studies were difficult to interpret, as direct translation of animal experimental data to humans is problematic for numerous reasons. The analysis concluded that, based on available clinical and epidemiological data, any cancer risk is negligible and fennel seed is safe for use in infants (Iten and Saller 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered fennel oil in rats is 3.8 ml/kg, whereas that of bitter fennel oil is 5.42 ml/kg (Opdyke 1979). The dermal LD_{50} of fennel oil and bitter fennel oil in rabbits could not be determined at doses up to 5 ml/kg (Opdyke 1979). The LD_{50} of an ethanol extract of fennel orally administered in mice and rats could not be determined at doses up 3 g/kg (Shah et al. 1991; Tanira et al. 1996).

The LD_{50} of orally administered fennel essential oil in rats has also been reported as 1.3 mg/kg (Ostad et al. 2001). In mice, the intraperitoneal LD_{50} of fennel essential oil is 1.04 ml/kg whereas the oral LD_{50} is 5.52 ml/kg (Ozbek et al. 2003, 2006).

Subchronic Toxicity

No adverse morphological, hematological, or spermatogenic changes were observed in mice orally administered 100 mg/kg of an aqueous extract of fennel daily for 90 days (Shah et al. 1991).

Genotoxicity

Some mutagenic activity of a fennel extract was observed in *Salmonella typhimurium* strains TA98 and TA102 (Mahmoud et al. 1992). Fennel essential oil exhibited mutagenic activity in the Ames test with *Salmonella typhimurium* strains TA98 and TA100, with activity potentiated by metabolic activation with S13 (Marcus and Lichtenstein 1982).

No mutagenic activity of aqueous and methanolic extracts of fennel were observed in the Ames test for mutagenicity in *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation (Morimoto et al. 1982; Yamamoto et al. 1982). No mutagenic activity of the same extract was found in the *Bacillus subtilis rec* assay (Morimoto et al. 1982).

In the *Bacillus subtilis* DNA-repair test, sweet fennel essential oil showed some mutagenic activity, while in the chromosomal aberration test in Chinese hamster fibroblast cells (Sekizawa and Shibamoto 1982), fennel essential oil showed no mutagenic activity (Ishidate et al. 1984).

Forsythia suspensa (Thunb.) Vahl

Oleaceae

SCN: forsythia
PN: *lian qiao* (fruit)

OCN: goldenbells
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (List and Hörhammer 1973; Roth et al. 1984).

Other Precautions

Use with caution in persons with diarrhea (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (List and Hörhammer 1973; Roth et al. 1984); *see* Appendix 2.

Adverse Events and Side Effects

A case of photodermatitis after topical application of forsythia has been reported (Bensky et al. 2004).

Pharmacological Considerations

An in vitro study indicated antiplatelet activity of forsythia. The applicability of the data to human use is not known (Iwakami et al. 1992).

Pregnancy and Lactation

Although forsythia has been reported as an emmenagogue (List and Hörhammer 1973; Roth et al. 1984), no cautions for use during pregnancy are listed in the traditional Chinese medicine literature.

No information on the safety of forsythia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A case of photodermatitis was reported after topical application of a f ormula containing forsythia. Forsythia was determined to be the causative agent (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Antiplatelet activity of an aqueous extract of forsythia was observed in rabbit platelets (Iwakami et al. 1992).

Inhibition of the drug-metabolizing isoenzyme CYP3A4 and very weak induction of CYP2E1 were observed in rats orally administered an extract of forsythia daily for 6 days. Dose and type of extract were not specified in the English language abstract (Yan et al. 2003).

IV. Pregnancy and Lactation

Although forsythia has been reported as an emmenagogue (List and Hörhammer 1973; Roth et al. 1984), no cautions for use during pregnancy are listed in the traditional Chinese medicine literature.

No information on the safety of forsythia during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of forsythia in mice is 172.2 g/kg after oral administration and 20.96 g/kg after intraperitoneal administration (type of extract not specified in available English language translation) (Chen and Chen 2004).

Genotoxicity

In chromosomal aberration and micronucleus assays in mice, an aqueous extract of forsythia tested positively for mutagenic activity (Yin et al. 1991).

Fouquieria splendens Engelm.

Fouquieriaceae

SCN: ocotillo

Part: stem

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Moore 1990).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

A reference text on medicinal plants of the southwestern United States indicates that ocotillo is not recommended for use in pregnancy (Moore 1990). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of ocotillo during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A reference text on medicinal plants of the southwestern United States indicates that ocotillo is not recommended for use in pregnancy (Moore 1990). No details on this concern are provided.

No information on the safety of ocotillo during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Frangula alnus Mill.

Rhamnaceae

SCN: frangula
Syn: *Rhamnus frangula* L.

OCN: alder buckthorn; buckthorn
Part: bark

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Bradley 1992; Chadha 1988; Wichtl 2004).

Contraindicated with intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (i.e., appendicitis, colitis, Crohn's disease, irritable bowel syndrome, and melanosis coli) (Bradley 1992; De Smet 1993; Wichtl 2004).

Not for long-term use in excess of 8 consecutive days (Bradley 1992; De Smet 1993; Leung and Foster 1996; Weiss and Meuss 2001; Wichtl 2004).

Not for use in children younger than 12 years of age (Bradley 1992; De Smet 1993).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations below.

Notice

Stimulant laxative (Bradley 1992; ESCOP 2003; Felter and Lloyd 1898; Leung and Foster 1996; Weiss and Meuss 2001; Wichtl 2004); *see* Appendix 2.

Standard Dose

The individually correct dose is the smallest dose necessary to produce a comfortable, soft stool (ESCOP 2003). Typically, this is 2 g (a scant teaspoon) infused as tea (Wichtl 2004).

Editors' Notes

The bark of frangula must be aged for 1 to 2 years prior to use to destroy emetic compounds (De Smet 1993; Weiss and Meuss 2001).

The American Herbal Products Association has established a t rade requirement (AHPA 2011) that products containing this herb in sufficient quantity to warrant such labeling bear the following label statement:

NOTICE: Do not use this product if you have abdominal pain or diarrhea. Consult a health care provider prior to use if you are pregnant or nursing. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use.

Adverse Events and Side Effects

Discoloration of the urine by frangula metabolites may occur but is not clinically significant. Abdominal spasms and pain have been reported (ESCOP 2003).

Pharmacological Considerations

Concomitant use of frangula is cautioned with antiarrhythmic drugs and botanicals containing cardiac glycosides, as long-term use of frangula as a laxative can cause potassium loss, leading to increased toxicity of these drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Concomitant internal use of frangula is cautioned with thiazide diuretics, corticosteroids, and licorice, as long-term use of frangula as a laxative may increase the potassium loss induced by these drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Use of stimulant laxatives, such as frangula, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

While most stimulant laxatives have traditionally been contraindicated in pregnancy due to concerns regarding stimulation of the uterus, a number of stimulant laxatives, including frangula, have shown a lack of adverse effects on pregnancy or the fetus when used according to the recommended dosage schedule (De Smet 1993; ESCOP 2003). Thus, these laxatives are now considered appropriate for use during pregnancy (De Smet 1993; ESCOP 2003; Prather 2004). Due to the potential genotoxicity of certain anthraquinones, however, it is recommended that use of certain anthranoid laxatives, including frangula, should be avoided in the first trimester of pregnancy or used under professional supervision (ESCOP 2003).

No information on the safety of frangula during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

While most stimulant laxatives have traditionally been contraindicated in pregnancy due to concerns regarding stimulation of the uterus, a number of stimulant laxatives, including frangula, have shown a lack of adverse effects on pregnancy or the fetus when used according to the recommended dosage schedule (De Smet 1993; ESCOP 2003). Thus, these laxatives are now considered appropriate for use during pregnancy (De Smet 1993; ESCOP 2003; Prather 2004). Due to the potential genotoxicity of certain anthraquinones, however, it is recommended that use of certain anthranoid laxatives, including frangula, should be avoided in the first trimester of pregnancy or used under professional supervision (ESCOP 2003).

Several herbal texts caution against the use of anthraquinone-containing botanicals in pregnancy due to mutagenic activity of some anthraquinone compounds, but these texts also note that animal tests of various anthraquinones show no teratogenic or embryotoxic activity (Brinker 2001; De Smet 1993; ESCOP 2003).

No information on the safety of frangula during lactation was identified.

V. Toxicity Studies

Genotoxicity

Dose-dependent genotoxic activity of an alcohol extract of frangula was observed in the *Salmonella* microsome mutagen test and the DNA repair test of primary rat hepatocytes (Helmholz et al. 1993).

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Bradley 1992; Chadha 1988; Wichtl 2004).

Contraindicated with intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (i.e., appendicitis, colitis, Crohn's disease, irritable bowel syndrome, and melanosis coli) (Bradley 1992; De Smet 1993; Martindale and Reynolds 1996; Wichtl 2004).

Not for use in children younger than 12 years of age (Bradley 1992; De Smet 1993).

Not for use in excess of 8 days unless under the supervision of a qualified healthcare practitioner (Bradley 1992; Chadha 1988; De Smet 1993; Leung and Foster 1996; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations below.

Standard Dose

The individually correct dose is the smallest dose necessary to produce a comfortable, soft stool (ESCOP 2003). Typical adult dosages of cascara sagrada bark or preparations provide the equivalent of 0.6 to 2 g o f the bark (Osol and Farrar 1955). An infusion made from 1.5 to 2 g of bark in 150 ml of water is also used (Hansel et al. 1994).

Notice

Stimulant laxative (Bradley 1992; Chadha 1988; De Smet 1993; ESCOP 2003; Felter and Lloyd 1898; Leung and Foster 1996; List and Hörhammer 1973; Martindale and Reynolds 1996; Wichtl 2004; Williamson 2003); *see* Appendix 2.

Editors' Notes

The American Herbal Products Association h as established a t rade requirement (AHPA 2011) that products containing this herb in sufficient quantity to warrant such labeling bear the following label statement:

> NOTICE: Do not use this product if you have abdominal pain or diarrhea. Consult a health care provider prior to use if you are pregnant or nursing. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use.

The bark of cascara sagrada must be aged for 1 year or heat-treated prior to use (De Smet 1993; Wichtl 2004).

Adverse Events and Side Effects

Discoloration of the urine by cascara sagrada metabolites may occur but is not clinically significant. Abdominal spasms and pain have been reported (ESCOP 2003).

One case of cholestatic hepatitis was reported in association with cascara sagrada use, although the patient was taking other medications that could have caused the hepatitis (Nadir et al. 2000). Occupational asthma due to cascara sagrada exposure has been confirmed (Giavina-Bianchi et al. 1997).

Pharmacological Considerations

Concomitant use of cascara sagrada is cautioned with antiarrhythmic drugs and botanicals containing cardiac glycosides, as long-term use of cascara sagrada as a laxative can cause potassium loss, leading to increased toxicity of these drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003; Mills and Bone 2005).

Concomitant internal use of cascara sagrada is cautioned with thiazide diuretics, corticosteroids, and licorice, and long-term use of cascara sagrada as a laxative may increase the potassium loss induced by these drugs and botanicals (Brinker 2001; ESCOP 2003; Mills and Bone 2005).

Use of stimulant laxatives, such as cascara sagrada, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; Mills and Bone 2005).

Pregnancy and Lactation

While most stimulant laxatives have traditionally been contraindicated in pregnancy due to concerns regarding stimulation of the uterus, a number of stimulant laxatives, including cascara sagrada, have shown a lack of adverse effects on pregnancy or the fetus when used according to the recommended dosage schedule (De Smet 1993; ESCOP 2003). Thus, these laxatives are now considered appropriate for use during pregnancy (De Smet 1993; ESCOP 2003; Prather 2004). Due to the potential genotoxicity of certain anthraquinones, however, it is recommended that use of certain anthranoid laxatives, including cascara sagrada, should be avoided in the first trimester of pregnancy or used under professional supervision (ESCOP 2003).

In one large prospective study, a statistical association between cascara sagrada use in pregnancy and an increased number of benign tumors in infants was reported, although the significance of that association is not known (Heinonen et al. 1977).

The American Academy of Pediatrics lists cascara sagrada as being compatible with breast-feeding (AAP 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 48-year-old man developed cholestatic hepatitis, complicated by portal hypertension, after having taken single 425 mg capsules of aged cascara sagrada three times daily for 3 days. Other medications included amitriptyline, cimetidine, and baclofen (Nadir et al. 2000). A*mitriptyline* has been associated with rare but severe incidences of *hepatotoxicity, notably, cholestatic injury* (Saeian and Rajender-Reddy 2003; Wen et al. 2008).

A case of IgE-mediated occupational asthma and rhinitis, confirmed by skin testing, was reported in a pharmacy worker (Giavina-Bianchi et al. 1997).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No induction of aberrant crypt foci (considered putative preneoplastic lesions) or increase in incidence of chemically induced aberrant crypt foci were observed in rats fed diets containing up to 0.1% anthraquinone glycosides from cascara sagrada for 56 days (Mereto et al. 1996).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In a prospective study on maternal drug use in pregnancy, 53 of 50,282 mothers took cascara sagrada during the first trimester of pregnancy, and 188 took cascara sagrada anytime in pregnancy. An association between cascara sagrada use and benign tumors in infants was observed in the statistical analyses, although the significance of this association is not known (Heinonen et al. 1977).

The American Academy of Pediatrics lists cascara sagrada as being compatible with breast-feeding (AAP 2001).

V. Toxicity Studies

No toxicity studies on cascara sagrada were identified.

Oleaceae

SCN: white ash

Part: bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Moerman 1998; Rousseau 1947).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Ethnobotanical references indicate that white ash was traditionally used as an abortifacient (Moerman 1998; Rousseau 1947). No modern data were identified to support or refute this activity. Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Fraxinus excelsior L.

Oleaceae

SCN: European ash

Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

No cautions for use of European ash are reported in historical medical texts and articles (Bentley and Trimen 1880; Hayes 1853).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of European ash in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of European ash during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Fritillaria spp.

Liliaceae

Fritillaria cirrhosa D. Don
SCN: Sichuan fritillary
PN: *chuan bei mu* (bulb)
OCN: tendril-leaf fritillary

Fritillaria thunbergii Miq.
SCN: Zhejiang fritillary
PN: *zhe bei mu* (bulb)
Part: bulb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Other species of *Fritillaria* are considered acceptable substitutes for the species listed above. These include *F. unibracteata*, *F. przewalskii*, and *F. delavayi*. Many other species of *Fritillaria* are used locally, including *F. hupehensis*, *F. anhuiensis*, *F. monantha*, *F. karelinii*, *F. maximowiczii*, and *F. davidii* (Bensky et al. 2004).

Adulteration with several species has been reported, including *Bolbostemma paniculatum*, *Tulipa edulis*, *Cremastra appendiculata*, and the highly toxic *Iphigenia indica* (Bensky et al. 2004).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Sichuan fritillary or Zhejiang fritillary in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Alkaloids isolated from Sichuan fritillary or Zhejiang fritillary have shown antihypertensive and anticholinergic activity (Li et al. 2006).

IV. Pregnancy and Lactation

No information on the safety of Sichuan fritillary or Zhejiang fritillary during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an extract of Sichuan fritillary orally administered in mice could not be determined at doses up to 8 g/kg (Chen and Chen 2004).

The LD_{50} of the compound peiminine, isolated from Zhejiang fritillary and intravenously administered, is 11 mg/kg in rabbits and 9 mg/kg in cats (Chen and Chen 2004).

Fucus vesiculosus L. — Fucaceae

SCN: bladderwrack
OCN: dyer's fucus; red fucus; rockwrack

Part: thallus

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with hyperthyroidism (Bradley 2006; Weiss and Meuss 2001).

Other Precautions

None known.

Drug and Supplement Interactions

None known, although use with thyroid medications should be under the supervision of a qualified healthcare practitioner (Bradley 2006).

Other drugs should be taken 1 hour prior to consumption of bladderwrack or several hours after consumption, as mucilaginous plants such as bladderwrack may slow the absorption of orally administered drugs (Brinker 2001; De Smet 1993; Mills and Bone 2005).

Editors' Notes

A number of seaweeds have been found to contain heavy metal residues (Almela et al. 2006; Rose et al. 2007). Total arsenic has been measured in bladderwrack at levels ranging from 20 to 40 mg/kg (Almela et al. 2006), though the inorganic form of arsenic is reported at much lower levels of 0.2–1.8 mg/kg (Almela et al. 2006). Evidence about the negative impact of inorganic arsenic on fetal health and infant

development is emerging (EFSA 2009). Caution is therefore recommended in pregnancy and for young children.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Bladderwrack contains the element iodine (0.03–0.2% dry weight) (Bradley 2006; Chapman 1970; Wichtl 2004). A number of cautions related to the use of bladderwrack in persons with thyroid conditions are listed in the European literature. These cautions are based primarily on the presence of iodine. Reference texts note that iodine idiosyncrasy, hyperthyroidism, and thyrotoxicosis have been indicated as possible side effects after long-term, uncontrolled use of bladderwrack (Wichtl 2004), and excessive consumption of iodine can lead to goiter (Baker 2004; Pennington 1990). No data exist to support or refute the clinical relevance of these concerns to bladderwrack use.

Pregnancy and Lactation

Although iodine is an essential nutrient that is required for proper prenatal development, infants are reported to be particularly sensitive to the effects of iodine (Baker 2004), and cases of infant goiter after maternal use of iodine during pregnancy or lactation have been reported (Pennington 1990). *Also see* Editors' Notes for this entry.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Kidney toxicity was diagnosed in a woman who had been taking a bladderwrack supplement found to contain high levels (21.3 mg/kg) of arsenic. The woman had been taking 1.2 g of the supplement daily for 3 months and presented with polydipsia, polyuria, proteinuria, and acute kidney injury. A renal biopsy revealed tubular degeneration and lymphomonocytic infiltration, which were attributed to the effects of arsenic (Conz et al. 1998).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a pilot study in three premenopausal women with abnormal menstrual cycling patterns and/or menstrual-related disease histories, intake of bladderwrack was associated with increases in menstrual cycle lengths, ranging from an increase of 5.5 to 14 days. Bladderwrack was taken in doses of 0.7 g daily for two menstrual cycles and 1.4 g daily for two additional cycles. Hormone testing in one woman indicated a reduction in 17β-estradiol and an increase in progesterone (Skibola 2004).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Dose-dependent anticoagulant activity of fucoidan fractions from bladderwrack was observed in human platelet-rich plasma treated with concentrations of 5, 10, and 50 µg/ml (Durig et al. 1997).

IV. Pregnancy and Lactation

Infants are reported to be particularly sensitive to the effects of iodine (Baker 2004), and cases of infant goiter after maternal use of iodine during pregnancy or lactation have been reported (Pennington 1990).

Also see Editors' Notes for this entry.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered bladderwrack extracts in rats is between 1 and 2 g/kg for a 33% ethanol extract and could not be determined at doses up to 2 g/kg for a 60% ethanol extract. In mice, the oral LD_{50} values are between 1 and 2 g/kg for a 33% ethanol extract and approximately 0.75 g/kg for a 60% ethanol extract. After intraperitoneal administration, the LD_{50} values for a 33% ethanol extract are 0.25 g/kg for female rats, between 1 and 2 g/kg for male rats, and between 0.15 and 0.2 g/kg in mice. For a 60% ethanol extract, the LD_{50} values are 0.5 g/kg in female rats, over 0.5 g/kg in male rats, and 0.25 to 0.5 g/kg in mice (Zaragoza et al. 2008).

Short-Term Toxicity

No signs of toxicity, including relevant changes in organ weights or serum parameters, were observed in rats orally administered 200 or 750 mg/kg of a hydroethanolic extract of bladderwrack daily for 28 days (Zaragoza et al. 2008).

Genotoxicity

No genotoxic activity of an aqueous extract of bladderwrack was observed in chromosome aberration and comet assays in human lymphocytes treated with concentrations of 0.25, 0.5, or 1.0 mg/ml (Leite-Silva et al. 2007).

Galium odoratum (L.) Scop. — Rubiaceae

SCN: sweet woodruff
Syn: *Asperula odorata* L.

OCN: sweet-scented bedstraw; woodruff
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Ingestion of sweet woodruff extracts has been associated with headaches in some individuals (Roth et al. 1984).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of sweet woodruff in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

V. Toxicity Studies

Acute Toxicity
The LD_{50} of an intraperitoneally administered ethanol extract of cleavers in rats is 1 g/kg (Sharma et al. 1978).

In toxicity assays in brine shrimp and fruit flies, the water fraction of a methanol extract of cleavers showed no toxicity, whereas the ethyl acetate fraction produced over 80% lethality in both types of organisms (McChesney and Adams 1985).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Adverse Events and Side Effects

Although one reference text notes that rare side effects, including dryness of the mouth, throat, and nasal area, itchiness, upset stomach, nosebleed, and bloody stools, have been recorded after 3 to 6 months of continuous use of reishi (Leung and Foster 1996), clinical trials and dose-ranging studies have indicated that reishi extracts are generally well tolerated at doses of 5.4 g daily for 3 months (Chen et al. 2006; Gao et al. 2002, 2003, 2004a; Noguchi et al. 2008).

Allergic reactions to reishi are rare but have been reported (Bensky et al. 2004; Leung and Foster 1996).

Fulminant hepatitis was reported in two patients who had been taking water extracts of reishi for several months and recently switched to a powdered reishi preparation (Wanmuang et al. 2007; Yuen et al. 2004).

Pharmacological Considerations

Human and animal studies have provided differing results on the effects of reishi on platelet aggregation. Inhibition of platelet aggregation was observed in healthy persons and persons with atherosclerosis after 3 g daily of reishi for 2 weeks (Tao and Feng 1990), whereas no antiplatelet activity was observed in HIV-positive patients given 900 mg reishi daily (Gau et al. 1990), suggesting that the activity could be dose related. Compounds isolated from reishi have demonstrated antiplatelet activity in vitro (Kawagishi et al. 1993; Mongold et al. 1993). Although no interactions have been reported, reishi should be used with caution in persons taking anticoagulant or antiplatelet medications (Upton 2000).

Human and animal studies have indicated immunomodulating effects of reishi, suggesting that reishi should be used with caution in persons taking immune-suppressant medications (Chen et al. 2006; Gao et al. 2003, 2005; Lin 2005; Upton 2000; Zhu et al. 2007).

Human and animal studies have shown that reishi may modify glucose levels (Gao et al. 2004b; Kimura et al. 1988; Zhang and Lin 2004). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of reishi in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A reishi extract comprised of polysaccharide fractions was reported as well tolerated in patients with type 2 diabetes, advanced-stage cancer, or coronary heart disease, at doses of 5.4 g daily for 12 weeks (Gao et al. 2002, 2004a, 2004b,

2005), with minor adverse events, primarily nausea and diarrhea, reported in one study (Gao et al. 2002).

Case Reports of Adverse Events

A 47-year-old woman with a history of schizophrenia developed fatal fulminant hepatitis after having taken 400 mg of powdered reishi daily for 2 months. She was also taking lithium, perphenazine, and trihexyphenidyl long-term. The woman had previously consumed an extract made from boiled reishi slices (dose not specified) for several years with no adverse effects. The reporting physicians indicated that the reaction could have been idiosyncratic (Wanmuang et al. 2007).

Fulminant hepatitis was diagnosed in a 78-year-old woman who had been taking felodipine, calcium supplements, multivitamins, and reishi. The woman had been taking an extract made from boiled reishi slices (dose not specified) for at least 1 year, and began taking a powdered reishi product (dose not specified) 4 weeks before the onset of symptoms (Yuen et al. 2004).

In rare cases, side effects from reishi have been reported, including dry mouth and nose, itchiness, upset stomach, nausea, vertigo, nosebleeds, constipation or diarrhea, and bloody stool. Products and doses taken were not specified, and one reference noted that such effects were associated with 3 to 6 months of reishi use (Bensky et al. 2004; Leung and Foster 1996).

Allergic reactions to reishi have been reported, primarily after intramuscular administration of reishi extracts (Bensky et al. 2004; Leung and Foster 1996). An instance of skin rash was observed following the consumption of reishi wine (Leung and Foster 1996).

Chronic watery diarrhea and pseudoparasitosis were observed in a 49-year-old man with non-Hodgkin's lymphoma who took reishi (product, dose, and duration not specified). Spores from reishi were mistakenly identified as parasites. The report indicates that the man had a 6-month history of diarrhea and that loose stools were observed several days after beginning reishi, although it is unclear if the reishi was suspected as the cause of the 6 months of diarrhea or if the reishi was thought to worsen existing diarrhea. The man was also taking drugs (not specified) for tuberculosis (Wanachiwanawin et al. 2006).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Inhibition of first and second phase platelet aggregation was observed in blood taken from healthy volunteers or patients with atherosclerotic disease, who had ingested 3 g of a water soluble extract of reishi daily for 2 weeks (Tao and Feng 1990). No antiplatelet activity of reishi extract was observed in HIV-positive hemophiliac patients treated with 0.9 g (containing 1.35 mg of adenosine) daily (Gau et al. 1990).

No adverse effects, including evidence of liver, renal, or DNA toxicity, were observed in healthy volunteers orally administered 1.44 g daily of a reishi preparation (equivalent to 13.2 g fresh reishi) for 4 weeks (Wachtel-Galor et al. 2004).

Good treatment tolerance and no major adverse events were reported in a dose-ranging study of reishi in men with lower urinary tract symptoms orally administered 0.6, 6, or 60 mg reishi daily for 8 weeks (Noguchi et al. 2008).

A reduction in mean fasting and stimulated glycosylated hemoglobin was observed in patients with type 2 diabetes orally administered 5.4 g of polysaccharide fractions of reishi daily for 12 weeks (Gao et al. 2004b).

No adverse effects were observed in a safety study of reishi in healthy volunteers orally administered 2 g of reishi extract daily for 10 days. No significant changes in hematological, cardiac, or urinary parameters were observed. Blood tests for immunological activity indicated no obvious changes in CD4, CD8, and CD19, with some elevation of CD56 cell counts (Wicks et al. 2007).

In an open-label study in patients with colorectal cancer, ingestion of 5.4 g of reishi daily for 12 weeks produced immune modulating effects. Treatment with reishi tended to increase mitogenic reactivity to phytohemagglutinin, counts of CD3, CD4, CD8, and CD56 lymphocytes, plasma concentrations of interleukin (IL)-2, IL-6, and interferon (IFN)-gamma, and NK activity, whereas plasma concentrations of IL-1 and tumor necrosis factor (TNF)-alpha were decreased. For all of these parameters, no statistical significance was observed when a comparison was conducted between baseline and treatment values. The changes of IL-1 were correlated with those for IL-6, IFN-gamma, CD3, CD4, CD8, and NK activity, and the IL-2 changes were correlated with those for IL-6, CD8, and NK activity (Chen et al. 2006).

In patients with advanced-stage cancer treated with 5.4 g of polysaccharide fractions of reishi daily for 12 weeks, increases in the mean plasma concentrations of IL-2, IL-6, and IFN-gamma were observed. Levels of IL-1 and TNF were decreased. A marked variability was observed in the numbers of each lymphocyte subset at baseline. The mean absolute number of CD56 cells was increased after treatment, and a marginal increase in the numbers of CD3, CD4, and CD8 was observed as compared to baseline, with the CD4:CD8 T cell ratios unchanged. PHA responses were enhanced in most patients, and the mean NK activity increased (Gao et al. 2003).

Animal Pharmacological Studies

In castrated rats, administration of a methanol extract of reishi inhibited testosterone-induced growth of the ventral prostate (Fujita et al. 2005).

A dose-dependent hypoglycemic effect was observed in healthy mice intraperitoneally administered reishi polysaccharides at doses of 25, 50, or 100 mg/kg (Zhang and Lin 2004).

A reduction in blood glucose levels with no elevation of blood insulin was observed in rats orally administered 50 mg per animal (200–250 g average weight) of an aqueous extract of reishi (Kimura et al. 1988).

In mice with immune suppression induced by cyclophosphamide, intraperitoneal administration of 2.5, 25, or 250 mg/kg of reishi polysaccharides daily for 7 days enhanced the function of immunological effector cells. The 2.5 mg/kg dose accelerated recovery of bone marrow cells, red blood cells, white blood cells, splenic natural killer cells, and natural killer T cells, and enhanced T and B cell proliferation responses, cytotoxic T lymphocyte activity, and NK cell and lymphokine activated killer cell activity (Zhu et al. 2007).

Dose-dependent inhibition of the drug-metabolizing isoenzymes CYP2E1, CYP1A2, and CYP3A was observed in rats with immune hepatic injury administered 50 or 200 mg/kg of reishi polysaccharides (Wang et al. 2007).

The compound ganoderol B suppressed testosterone-induced regrowth of the ventral prostate in rats (Liu et al. 2007).

In Vitro Pharmacological Studies

A review of the immunomodulating effects of reishi polysaccharides in vivo and in vitro demonstrated that the polysaccharides promote the function of antigen-presenting cells, mononuclear phagocytes, humoral immunity, and cellular immunity (Tahvonen et al. 2005).

Estrogen receptor (ER)-modulating activity of reishi was observed in human breast cancer cells (MCF-7). Reishi down-regulated the expression of ER-α in ER-positive (MCF-7) cells but did not effect the expression of ER-β in ER-positive and ER-negative (MDA-MB-231) cells. Additionally, reishi inhibited estrogen-dependent and constitutive transactivation activity of the ER through an estrogen response element in a reporter gene assay (Jiang et al. 2006).

Differing effects on viability of peripheral blood mononuclear cells from healthy adults and children and from children undergoing chemotherapy were observed after treatment with either of two crude extracts (solvents not specified) of reishi or polysaccharides isolated from reishi (Gill and Rieder 2008).

The compound ganoderol B inhibited androgen-induced growth of human prostate adenocarcinoma cells (LNCaP) (Liu et al. 2007).

The compound ganodermic acid S inhibited collagen-induced platelet aggregation in human platelets (Mongold et al. 1993). Inhibition of platelet aggregation was observed after application of the adenosine derivative 5′-deoxy-5′-methylsulfinyladenosine from reishi (50 µg/ml) (Kawagishi et al. 1993).

Tested with a variety of antimicrobial drugs, reishi showed antagonistic activity with ampicillin and cefazolin against *Proteus vulgaris*, but no antagonistic effects were observed with the drugs oxytetracycline or chloramphenicol, or in tested species of *Bacillus*, *Staphylococcus*, *Escherichia*, *Klebsiella*, or *Salmonella* (Yoon et al. 1994).

IV. Pregnancy and Lactation

No information on the safety of reishi in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of an aqueous extract or polysaccharide fraction of reishi could not be determined at doses up to 5 g/kg in mice (Kim et al. 1986).

The LD_{50} of intraperitoneally administered extracts of reishi have been reported to range from 3.42 to 38.3 g/kg, with effects dependent on the type of extract administered (Leung and Foster 1996).

Short-Term Toxicity

No changes in hematological parameters or organ weights were observed in mice orally administered 5 g/kg of an aqueous extract of reishi daily for 30 days (Kim et al. 1986).

No adverse effects were observed in mice orally administered a dose equivalent to 925.9 mg/kg of reishi freeze-dried extract daily for 14 days (Chiu et al. 2000).

No signs of toxicity were observed in mice orally administered an extract of reishi equivalent to 1.8 g/kg daily for 20 days (Leung and Foster 1996).

Genotoxicity

No genotoxic activity of reishi was observed in the comet assay in lymphocytes of mice orally administered single doses of an extract of reishi equivalent to 220 g of reishi (Chiu et al. 2000).

In the comet assay with human lymphocytes, reishi extract exhibited genoprotective activity at a concentration of 0.0001% but induced DNA damage at concentrations of 0.001% (w/v) and above (Wachtel-Galor et al. 2005).

Garcinia cambogia (Gaertn.) Desr.

Clusiaceae

SCN: garcinia
OCN: brindall berry; Malabar tamarind

Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Much of the research on garcinia is focused on a standardized extract referred to as HCA-SX, a garcinia extract that contains 60% of the compound hydroxycitric acid (HCA) (Soni et al. 2004). Garcinia fruit rind naturally contains approximately 16 to 26% HCA (Antony et al. 1998; Jayaprakasha and Sakariah 1998).

Adverse Events and Side Effects

Cases of liver toxicity have been reported in patients taking weight-loss products containing garcinia and other botanical and mineral ingredients (Actis et al. 2007; Dara et al. 2008; Jones and Andrews 2007; Shim and Saab 2009; Stevens et al. 2005). The relationship between these cases and garcinia is not clear (Stohs et al. 2009).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Multigeneration animal studies have indicated no adverse effects of HCA-SX on pregnancy or fetal development (Deshmukh 2008a, 2008b).

No information on the safety of garcinia in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Cases of liver toxicity have been reported in patients taking weight-loss products containing garcinia and other botanical and mineral ingredients (Actis et al. 2007; Dara et al. 2008; Jones and Andrews 2007; Shim and Saab 2009; Stevens et al. 2005). The relationship between these cases and garcinia is not clear (Stohs et al. 2009).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In overweight subjects, no changes in serum testosterone, estrone, and estradiol levels were observed after ingestion of 1667 mg daily of garcinia extract (1000 mg HCA daily) (Hayamizu et al. 2008).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In a two-generation reproductive toxicity study, rats were fed diets containing 1000, 3000, or 10,000 ppm HCA-SX for 10 weeks prior to mating, during mating, and, for females, through gestation and lactation, across two generations. No changes were observed in reproductive performance as evaluated by sexual maturity, fertility and mating, gestation, parturition, litter properties, lactation, and development of the offspring. HCA-SX exposure did not affect feed consumption or body weight at any of the exposure levels (Deshmukh 2008b). Animals from the second generation (F2b) of the study were fed diets containing 1000, 3000, or 10,000 ppm HCA-SX until sexual maturity, at

which time they were mated. Pregnant rats were continued on the same diet. A slight lowering of maternal body weight gain during the gestation period was observed in the group receiving 10,000 ppm HCA-SX. No evidence of maternal toxicity or adverse effects on fetal development were observed (Deshmukh 2008a).

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of garcinia extract (60% HCA) in rats could not be determined at doses up to 5 g/kg (Ohia et al. 2002).

The dermal LD_{50} of garcinia extract (60% HCA) in rabbits could not be determined at doses up to 2 g/kg (Ohia et al. 2002).

G

Short-Term Toxicity

In female rats fed diets containing 7.3% garcinia extract HCA-SX (41% HCA) for 2 or 4 weeks, no changes in reproductive hormones were observed (Kiyose et al. 2006a).

Subchronic Toxicity

In rats fed diets containing 0.2, 2, or 5% of a garcinia extract HCA-SX (60% HCA) for 90 days, an advancing age-induced marginal increase in hepatic lipid peroxidation was observed as compared to control animals. No differences were observed in hematology, clinical chemistry, histopathological evaluation, hepatic DNA fragmentation, or testicular lipid peroxidation. Relative organ weights, including liver, testis, and brain, were comparable to the control group (Shara et al. 2003, 2004).

In obese rats fed diets containing 0.5, 2.4, 4.9, or 7.3% (77, 388, 778, or 1244 mg/kg body weight HCA) garcinia extract for 92 days, animals on the 4.9% or higher diets had testicular atrophy and toxicity (Saito et al. 2005). The design of this study has been questioned for accuracy as a test of testicular toxicity (Burdock et al. 2005).

In male rats fed diets containing 4.9% garcinia extract HCA-SX (41% HCA) for 2 or 4 weeks, a decrease in the serum level of inhibin B and increase in follicle-stimulating hormone was observed. The level of testis meiosis-activating sterol was statistically lower in the testes of rats on the garcinia diet as compared to control (Kiyose et al. 2006b).

In male rats orally administered 100 or 200 mg/kg of an ethanol extract of garcinia seed 6 days per week for 6 weeks, changes in the testes were observed along with an increase in sperm counts (Oluyemi et al. 2007).

Genotoxicity

In the micronucleus test with HCA intraperitoneally administered to mice at doses of 20, 100, 500, 2,500, or 12,500 µmol/kg, HCA was found to increase the number of micronucleated polychromatic erythrocytes (Lee and Lee 2007). A commentary on this study noted that the route of administration (intraperitoneal instead of oral) and the use of DMSO as part of the treatment but not the control group were likely to produce results different than those seen after oral use of HCA (Lau et al. 2008).

No mutagenic activity of the compound (–)-hydroxycitric acid (HCA) was observed in the Ames test for mutagenicity with or without metabolic activation, or in the chromosomal aberration test (Aujoulat 2003; Lee and Lee 2007).

Gardenia jasminoides J. Ellis

Rubiaceae

SCN: gardenia
Syn: *Gardenia augusta* Merr.
PN: *zhi zi* (fruit)

OCN: Cape jasmine
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic skin reactions to gardenia have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of gardenia in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic skin reactions to gardenia have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic mice, administration of 200 or 400 mg/kg of the compound geniposide caused a dose-dependent decrease in blood glucose and insulin levels in diabetic mice (Wu et al. 2009).

The compounds geniposide and genipin isolated from gardenia and intravenously administered to mice prolonged the time required for thrombotic occlusion induced by photochemical reaction in the mouse femoral artery (Suzuki et al. 2001).

In Vitro Pharmacological Studies

The compounds geniposide and genipin isolated from gardenia inhibited collagen-induced but did not inhibit arachidonate-induced platelet aggregation in mouse platelets (Suzuki et al. 2001).

IV. Pregnancy and Lactation

No information on the safety of gardenia in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered alcohol extract of gardenia in mice is 107.4 g/kg (Chen and Chen 2004). The LD_{50} of subcutaneously administered water extract of gardenia in mice is 31.79 g/kg (Zhu 1998).

The LD_{50} of the compound genipin in mice is 237 mg/kg after oral administration, 190 mg/kg after intraperitoneal administration, and 153 mg/kg after intravenous administration (Chen and Chen 2004; Zhu 1998).

The LD_{50} of the compound geniposide in mice is 3 g/kg after oral, intraperitoneal, or intravenous administration (Chen and Chen 2004).

Chronic Toxicity

No carcinogenic activity of the food colorant gardenia blue was observed in rats fed diets containing 2.5 or 5% gardenia blue for 2 years (Imazawa et al. 2000).

Genotoxicity

Mutagenicity tests, including the Ames assay, *rec* assay, and sister-chromatid exchange test, were completed on gardenia yellow, a food colorant derived from ethanol extracts of gardenia, and its components, crocetin, gentiobiose, geniposide, and genipin. Gardenia yellow and its components were found not to be mutagenic in the Ames assay. Gardenia yellow and genipin caused damage of DNA in the *rec* assay. Gardenia yellow and genipin induced sister-chromatid exchanges. Genipin induced a significant increase of tetraploids at all doses tested. Subsequent analysis of a gardenia yellow preparation indicated that genipin was not observed (Ozaki et al. 2002).

No mutagenic or clastogenic activity of the compound crocin was observed in the Ames assay, chromosomal aberration assay, *tk*(+/–) gene forward mutation assay, or comet assay. Post-treatment with crocin dose-dependently suppressed H_2O_2-induced DNA damage (Choi et al. 2008).

The compound crocetin inhibited chemically induced genotoxicity and neoplastic transformation in mouse C3H10T1/2 cells in vitro (Chang et al. 1996).

Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Rare cases of allergic reactions to gastrodia have been reported, including urticaria, purpura, vertigo, acute renal failure, and anaphylactic shock (Bensky et al. 2004). Rash, eczema and hair loss have been reported, even in association with aqueous preparations of as little as 10 g of gastrodia (Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of gastrodia in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Case Reports of Adverse Events

Rare cases of allergic reactions to gastrodia have been reported, including urticaria, purpura, vertigo, acute renal failure, and anaphylactic shock (Bensky et al. 2004). Rash, eczema and hair loss have been reported in association with gastrodia use, and side effects are reported to occur even at doses of as little as 10 g as an aqueous preparation (Chen and Chen 2004).

Very large doses (aqueous extracts of 80 g within 3 h) have been reported to cause poisoning, with symptoms including flushing and hot sensation of the face, general weakness, headache, dizziness, visual disturbance, loss of muscle coordination, and loss of consciousness (Bensky et al. 2004). Overdose of gastrodia (standard dose listed as an aqueous extract of 3–10 g) is characterized by headache, nausea, vomiting, facial flushing, drowsiness, and delayed response to light (Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Antiplatelet activity of several compounds isolated from gastrodia was observed in platelet-rich plasma from rats (Pyo et al. 2004).

IV. Pregnancy and Lactation

No information on the safety of gastrodia during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered aqueous extract of gastrodia in mice is 51.4 to 61.4 g/kg (Zhu 1998).

The LD_{50} of the compound gastrodin in mice is 1000 mg/kg after oral administration and 337 mg/kg after intravenous administration (Chen and Chen 2004).

In rabbits intraperitoneally administered 12 g/kg of the compound gastrodin, lethargy, reduced deep-tendon

reflexes, loss of appetite, and tachycardia were observed (Chen and Chen 2004).

Subchronic Toxicity

No changes in serum chemistry, liver or kidney function tests, or blood lipids were observed in dogs orally administered 75 mg/kg of the compound gastrodin daily for 60 days, or in mice orally administered 375 mg/kg of the compound *p*-hydroxybenzyl alcohol or 250 mg/kg of the compound gastrodin daily for 60 days (Zhu 1998).

Gaultheria procumbens L.

Ericaceae

SCN: wintergreen
OCN: checkerberry; teaberry

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Salicylates (0.5–1.0% in the leaf, 98% in the essential oil) (Chyka et al. 2007; Ribnicky et al. 2003; Williamson 2003); *see* Appendix 1.

Adverse Events and Side Effects

Cases of salicylate poisoning have been reported in persons that accidentally (typically children) or intentionally (typically persons attempting to self-poison) ingested wintergreen essential oil (Chan 1996a; Chyka et al. 2007; Stevenson 1937). Common features of salicylate poisoning include nausea, vomiting, tinnitus, deafness, sweating, hyperventilation, respiratory alkalosis, and metabolic acidosis (Chyka et al. 2007).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A review of reproductive and developmental toxicity studies of the compound methyl salicylate reported that the no-observed-adverse-effect level for reproductive toxicity was 75 to 100 mg/kg daily, similar to that of salicylic acid (Belsito et al. 2007).

No information on the safety of wintergreen in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 1937 case report and review of the literature identified 43 cases of wintergreen oil poisoning, almost half of which were in young children that drank bottles of wintergreen oil (Stevenson 1937). A more recent review of cases of methyl salicylate poisoning from wintergreen reported to the American poison control centers between 1985 and 2003 identified 11 cases. The review reports wintergreen oil intake in terms of estimated salicylate intake associated with the poisonings and provides a conversion factor of 1.4 for an aspirin equivalent dose of wintergreen oil. The smallest amount of wintergreen oil reported to cause toxicity was the equivalent of 346 mg/kg of salicylates; the lowest lethal dose of salicylates reported was 432 mg/kg in a 2.5-year-old, although a 1-year-old survived a 486 mg/kg dose with symptoms of severe toxicity. This review also includes evidence-based guidelines for out-of-hospital management of salicylate poisoning (Chyka et al. 2007). Another review indicated that 30 ml of wintergreen oil can be lethal in adults, although doses of 6 ml have been lethal in some adults, and doses of 4 ml are lethal to children (Botma et al. 2001).

Common features of salicylate poisoning include nausea, vomiting, tinnitus, deafness, sweating, hyperventilation, respiratory alkalosis, and metabolic acidosis. Uncommon features of poisoning include coma, fever, hypo- or hyperglycemia, gastrointestinal bleeding, seizures, fluid retention, pulmonary edema, respiratory distress syndrome, cerebral edema, and renal failure (Botma et al. 2001; Chan 1996b; Chyka et al. 2007; Proudfoot 1983).

Laryngeal edema, vomiting, irritability, lethargy, and tachypnea were reported in an 18-month-old who had accidentally ingested an unspecified amount of wintergreen essential oil. Serum salicylate levels at the time of hospital admission (~12 hours after initial ingestion) were 4.8 mmol/l (Botma et al. 2001).

Topical application of products containing the compound methyl salicylate has led to poisonings in some individuals (Chyka et al. 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed after treatment with an ethanol extract of wintergreen. No effects on CYP19 were observed (Scott et al. 2006).

IV. Pregnancy and Lactation

A review of reproductive and developmental toxicity studies of methyl salicylate indicated that, under conditions of sufficient exposure, there is a pattern of embryotoxicity and teratogenesis that is similar to that caused by comparable doses of salicylic acid. The abnormalities included neural tube defects and malformations of the skeleton and viscera. Studies of orally administered methyl salicylate indicated that the no-observed-adverse-effect level (NOAEL) for reproductive toxicity is 75–100 mg/kg daily, which is a level consistent with data from subchronic and chronic toxicity studies and is also consistent with the reproductive NOAEL for salicylic acid, which has been reported as 80 mg/kg daily (Belsito et al. 2007).

No information on the safety of wintergreen during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of the compound methyl salicylate (which comprises 97 to 99% of wintergreen essential oil) is 1110 mg/kg in mice, 887 or 1250 mg/kg in rats, 1060 mg/kg in guinea pigs, 1300 or 2800 mg/kg in rabbits, and 2100 mg/kg in dogs (FAO/WHO 1967). The adult human oral LD_{50} is estimated at 500 mg/kg (FAO/WHO 1967).

Subchronic Toxicity

In dogs orally administered 50, 100, 250, 500, 800, or 1200 mg/kg methyl salicylate for up to 10 weeks, no adverse effects were noted in animals receiving 250 mg/kg or less, but an increasing dose-dependent fatty metamorphosis of the liver was observed at higher test levels (Webb and Hansen 1963).

In rats fed diets containing 0.1, 0.5, or 1.0% methyl salicylate for 17 weeks, both sexes showed a significant reduction in growth rate at the 1.0% level, but histological examination of the major organs revealed no abnormality. In a related experiment, in rats fed a diet containing 2% methyl salicylate for up to 10 weeks, bone growth was reduced and excessive density of bone with reduced chondroclastic and osteoclastic activity was observed (Webb and Hansen 1963).

Chronic Toxicity

In rats fed diets containing 0.1, 0.5, 1.0, or 2.0% methyl salicylate for 2 years, animals fed the highest dose did not survive past 49 weeks. At the 1% level, growth rates were considerably reduced and enlargement of male testes and female hearts and kidneys were noted. Excess cancellous bone formation was seen at the 2.0, 1.0, and 0.5% levels (Webb and Hansen 1963). Another 2-year feeding study revealed no adverse effects, including bone changes, at dietary levels up to 0.21% of methyl salicylate (Packman et al. 1961).

In dogs orally administered 0, 50, 150, and 250 mg/kg methyl salicylate daily for 2 years, some growth retardation and liver enlargement were noted at the 150 and 250 mg/kg level, and histology revealed enlarged hepatic parenchymal cells (Webb and Hansen 1963).

Genotoxicity

In the *Bacillus subtilis rec* assay, no mutagenic activity of methyl salicylate was observed. In the Ames test for mutagenicity, one study indicated no mutagenic activity; another study indicated no mutagenic activity with S9 from rats, mice, or guinea pigs but some mutagenic activity with S9 from hamsters (Lapczynski et al. 2007). No mutagenic activity was observed in the chromosomal aberration test in a Chinese hamster fibroblast cell line (Lapczynski et al. 2007).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known

Other Precautions

When taken as a bulk-forming laxative, agar should not be used in persons with bowel obstruction or with abnormal esophageal or intestinal narrowing.

Take with at least 250 ml (8 oz.) of liquid (CFR 2011a).

Drug and Supplement Interactions

Other drugs or supplements should be taken 1 hour prior to consumption of agar or several hours after consumption, as agar may reduce the absorption of certain drugs and supplements due to the mucilage content and the increased speed of passage through the intestines (Bradley 1992; Brinker 2001); *see* Mucilages in Appendix 3.

Standard Dose

The standard dose is 4 to 16 g taken once or twice daily (Martindale and Reynolds 1996).

Notice

Bulk-forming laxative (CFR 2011a); *see* Appendix 2.

Mucilages; *see* Appendix 3.

Editors' Notes

Specific labeling is required in the United States for all over-the-counter drug products containing agar (CFR 2011a); *see* Bulk-forming laxatives in Appendix 2.

Concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Agar is commonly used as a thickening agent in foods and is identified as generally recognized as safe by the U.S. FDA in limited quantities for certain specified uses, including in baked goods, confections, and soft candy (CFR 2011b). Although an associated regulation states that other uses in foods would require a food additive regulation (CFR 2011c), dietary ingredients for use in dietary supplements are specifically excluded from the federal food additive definition (U.S.C. 2010).

Adverse Events and Side Effects

Blockages in the small intestine have occurred after ingestion of agar with insufficient quantities of liquids (Osada et al. 2008).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although animal studies have indicated that very large doses (0.5 or 1 g/kg) of agar have led to postimplantation losses in pregnant rats (Premakumara et al. 1995, 1996; Ratnasooriya et al. 1994), agar is commonly used as a thickening agent in foods and is believed to be safe at standard food and therapeutic levels.

No information on the safety of agar during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Small bowel obstruction due to primary small bowel bezoars was seen in a 70-year-old woman who had ingested "a large amount" of highly concentrated agar dissolved in boiling water 2 days earlier (Osada et al. 2008).

An allergic reaction to agar, including nasal and asthmatic symptoms, was reported in a bakery worker who routinely used a product containing agar. Skin and sniff testing confirmed agar as the allergen (Criep and Riley 1951).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In pregnant rats orally administered 1 g/kg of an agar extract on days 7 and 8 of pregnancy, an 89% postimplantation loss rate was observed, resulting in fetal death between days 9 and 14 of pregnancy (Premakumara et al. 1995).

The hexane fraction of a methanol-dichloromethane extract of agar exhibited antifertility activity in rats orally administered the compound on days 1 through 7 of pregnancy (Premakumara et al. 1996).

Dose-dependent increases in resorption sites and increases in postimplantation losses were observed in rats orally administered 0.5 or 1 g/kg daily of a methanol-dichloromethane extract of agar on days 1 through 7 of pregnancy. Postimplantation losses of 44% were observed after the 0.5 g/kg dose and 98% after the 1 g/kg dose (Ratnasooriya et al. 1994).

No information on the safety of agar during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Genista tinctoria L. — Fabaceae

SCN: dyer's broom
OCN: dyer's greenwood

Part: flower, herb

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Casarett et al. 2001; McGuffin et al. 1997; Wichtl 2004).

Not for use in persons with high blood pressure (Wichtl 2004).

Other Precautions

Exceeding the standard dose may cause diarrhea (Wichtl 2004).

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 1 to 2 g as a tea (Wichtl 2004).

Notice

Emetic (Williamson 2003); *see* Appendix 2.

Editors' Note

Although one reference text lists dyer's broom as "toxic" (Roth et al. 1984), this concern is not substantiated by other

texts (List and Hörhammer 1973; Madaus 1976; Wichtl 2004; Williamson 2003).

Adverse Events and Side Effects

Dyer's broom has been reported to cause nausea and vomiting (Williamson 2003). Diarrhea has been associated with excessive use of dyer's broom (Wichtl 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of dyer's broom in pregnancy or lactation was identified, although constituents found in dyer's broom are similar to the compound sparteine, a uterine stimulant, found in *Cytisus scoparius* (Casarett et al. 2001; McGuffin et al. 1997; Wichtl 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Gentiana lutea L. — Gentianaceae

SCN: gentian
OCN: yellow gentian

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with gastrointestinal irritation (Felter and Lloyd 1898), and duodenal ulcers (Bradley 1992).

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (India 1987); *see* Appendix 2.

Editors' Notes

Multiple cases of misidentification of *Veratrum* species as gentian by individuals collecting for home use have been reported in the literature. *Veratrum* species produce adverse cardiovascular and gastrointestinal effects after consumption (Festa et al. 1996; Garnier et al. 1982, 1985; Grobosch et al. 2008; Zagler et al. 2005).

Adverse Events and Side Effects

The German Standard License label states that headaches may occasionally occur in persons sensitive to bitter substances (Wichtl 2004).

Gentian may cause gastrointestinal irritation. Irritating qualities are maximized in tincture form and minimized as a tea (McGuffin et al. 1997).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Gentian has been used as an emmenagogue in the Unani tradition of medicine in India (India 1987), although such activity has not been reported in any literature from Europe where gentian is commonly used.

No information on the use of gentian during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Among 205 patients that took an average of 576 mg of a dry hydroethanolic extract of gentian (equivalent to 2.9 g of dried root) daily for 15 days, 2.4% reported minor adverse events including flatulence, stomach cramps, nausea, and headache (Wegener 1998).

Case Reports of Adverse Events

No case reports of adverse events associated with gentian use were identified.

Multiple cases of misidentification of *Veratrum* species as gentian by individuals collecting for home use have been reported in the literature. *Veratrum* species are botanically similar to and grow in similar habitats to gentian and produce adverse cardiovascular and gastrointestinal effects after consumption (Festa et al. 1996; Garnier et al. 1982, 1985; Grobosch et al. 2008; Zagler et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Some induction of the drug-metabolizing isoenzyme CYP1A2 and the drug transporter protein MDR1 were observed in LS180 (human colon carcinoma) cells treated with an ethanolic extract of gentian (Brandin et al. 2007).

IV. Pregnancy and Lactation

Gentian has been used as an emmenagogue in the Unani tradition of medicine in India (India 1987), although such activity has not been reported in any literature from Europe where gentian is commonly used.

No information on the use of gentian during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered ethanol extract of gentian (bitterness value 200 Ph. Helv. Units/g) in mice is 25 ml/kg (Leslie 1978).

No signs of toxicity were observed in rabbits treated with 12.6 mg/animal of gentian extract daily for 3 d ays. Aside from slightly lower erythrocyte levels as compared to the control group, no abnormal serum parameters were observed (Chibanguza et al. 1984).

No signs of toxicity were observed in mice intraperitoneally administered 250 or 500 mg/kg of a methanol extract of gentian (Ozturk et al. 2002).

Genotoxicity

Weak mutagenic activity of gentian and compounds isolated from gentian were observed in the Ames test for mutagenicity in *Salmonella typhimurium* strains TA97, TA98, TA100, and TA2637 with metabolic activation by S9 (Göggelmann and Schimmer 1986; Hänsel et al. 1993; Matsushima et al. 1985; Morimoto et al. 1983). Compounds believed to be responsible for the mutagenic activity were noted as being structurally similar to quercetin, a compound that has mutagenic activity in vitro but is regarded as safe in humans (ESCOP 2003; Harwood et al. 2007).

Gentiana macrophylla Pall.

Gentianaceae

SCN: large-leaf gentian
PN: *qin jiao* (root)

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

See Editors' Note.

Drug and Supplement Interactions

None known.

Editors' Note

The concerns stated for *Gentiana lutea* (*see* previous entry), though not specified in available references, may also be relevant to this species (McGuffin et al. 1997).

Adverse Events and Side Effects

Large-leaf gentian may cause drowsiness or sedation (Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of large-leaf gentian in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Oral administration of 100 mg of the compound gentianine daily to mice for 4 to 13 days resulted in severe nausea and vomiting (Zhu 1998).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of large-leaf gentian during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound gentianine in mice is 480 mg/kg after oral administration, 350 mg/kg after intraperitoneal administration, and 250 to 300 mg/kg after intravenous administration (Chen and Chen 2004). The LD_{50} of the compound gentianadine is 1250 mg/kg after oral administration (Chang and But 1986).

Gentiana scabra Bunge — Gentianaceae

SCN: scabrous gentian
PN: *long dan cao* (root and rhizome)

Part: root and rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

See Editors' Note.

Drug and Supplement Interactions

None known.

Editors' Note

The concerns stated for *Gentiana lutea* (*see* previous entries), though not specified in available references, may also be relevant to this species (McGuffin et al. 1997).

Adverse Events and Side Effects

When administered after meals or in excessive dosage, scabrous gentian may cause impairment of digestive function and, occasionally, headache, flushing of the face, and vertigo (Bensky et al. 2004; Chang and But 1986; Chen and Chen 2004).

Pharmacological Considerations

Scabrous gentian may cause drowsiness or sedation (Chen and Chen 2004).

Pregnancy and Lactation

No information on the safety of scabrous gentian in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

In high doses (aqueous extract of 30 g as a single dose), abdominal pain, nausea, vomiting, vertigo, impaired consciousness, and stiff neck have been reported (Bensky et al. 2004).

In a case of overdose, a 150 g dose resulted in the previously listed symptoms within 30 minutes of ingestion. Emergency treatment was necessary, and the patient fully recovered in 2 days (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound 2-hydroxy-3-methoxybenzoic acid glucose ester isolated from large-leaved gentian was found to be a potent antagonist of platelet-activating factor (Huh et al. 1998).

IV. Pregnancy and Lactation

No information on the safety of scabrous gentian during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound gentianine in mice is 460 mg/kg after oral administration, 500 mg/kg after subcutaneous administration, and 250 to 300 mg/kg after intravenous administration (Chen and Chen 2004).

Ginkgo biloba L.

Ginkgoaceae

SCN: ginkgo
PN: *yin xing ye* (leaf); *yin guo ye* (leaf); *bai guo ye* (leaf)

OCN: maidenhair tree
Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: B

Contraindications

None known.

Other Precautions

Use in persons with coagulation disorders should be under the supervision of a qualified healthcare practitioner (Bent et al. 2005; Kudolo et al. 2002).

Patients undergoing surgery are advised to stop ginkgo leaf 7 days prior to surgery (Bebbington et al. 2005; Destro et al. 2005; Fessenden et al. 2001; Yagmur et al. 2005).

Drug and Supplement Interactions

Concomitant use with anticoagulants should be under the supervision of a qualified healthcare practitioner (Bent et al. 2005; Kudolo et al. 2002).

Ginkgo leaf may lower plasma concentrations of nifedipine (Smith et al. 2001).

Concomitant use with MAO inhibitors should be under the supervision of a qualified healthcare practitioner (Rojas et al. 2004; Woerdenbag and Van Beek 1997).

Editors' Notes

Ginkgo leaf preparations are generally sold either as a tincture, for which no side effects have been recorded, or as a highly concentrated extract. Ginkgo leaf extracts (concentrated to 24% flavonol glycosides and 6% terpene lactones; referred to herinafter as "24/6") are among the most actively studied botanicals. With over 5 million prescriptions per year reported in Germany alone, only occasional side effects, such as headaches and gastrointestinal upset, have been reported (Hobbs 1991).

Ginkgo leaf contains ginkgolic acids (urushiol type alkylphenols), compounds that are related to those found in poison ivy (*Toxicodendron radicans*) and associated with contact allergies, especially dermatitis. Ginkgolic acids are found in relatively high concentrations in ginkgo seed coats and in low concentrations in the leaf (Blumenthal 1997).

Adverse Events and Side Effects

Reviews and meta-analyses of clinical trials have shown that ginkgo leaf is generally well tolerated, with adverse events similar to those of placebo (Birks and Grimley Evans 2006; DeFeudis 1991; Ernst 2002; Hilton and Stuart 2004; Kleijnen and Knipschild 1992a; Pittler and Ernst 2000; Woerdenbag and Van Beek 1997; Zeng et al. 2005).

Case reports of adverse events associated with ginkgo leaf use include abnormal bleeding (several cases post-surgically) (Bebbington et al. 2005; Benjamin et al. 2001; Castellote Varona and Atienza Morales 2005; Destro et al. 2005; Evans 2000; Farnsworth et al. 1975; Fessenden et al. 2001; Gilbert 1997; Hauser et al. 2002; MacVie and Harney 2005; Matthews 1998; Meisel et al. 2003; Miller and Freeman 2002; Purroy Garcia et al. 2002; Rosenblatt and Mindel 1997; Rowin and Lewis 1996; Schneider et al. 2002; Smolinske 1999; Yagmur et al. 2005) and cases of skin eruptions (Chiu et al. 2002; Pennisi 2006).

Pharmacological Considerations

Although a series of case reports have correlated ginkgo leaf extract use with incidences of abnormal bleeding (Bent et al. 2005), controlled human studies have yielded mixed results on the effects of ginkgo leaf on bleeding. In patients with type 2 diabetes, ginkgo leaf extract has been shown to decrease platelet function by inhibiting platelet aggregation (Kudolo et al. 2002). However, no significant modifications of bleeding time, platelet function, or coagulation factors were observed in healthy male volunteers administered up to 480 mg daily of ginkgo leaf extract (Bal Dit Sollier et al. 2003; Beckert et al. 2007; Kohler et al. 2004).

Human studies have shown a lack of interactions with a number of drugs, including warfarin, clopidogrel, aspirin, ticlopidine, digoxin, talinolol, lopinavir, ritonavir, voriconazole, bupropion, diazepam, donepezil, and fexofenadine (Aruna and Naidu 2007; Engelsen et al. 2002; Fan et al. 2009; Gardner et al. 2007; Kim et al. 2010; Lei et al. 2009a, 2009b; Lu et al. 2006; Mauro et al. 2003; Robertson et al. 2008; Wolf 2006; Yasui-Furukori et al. 2004; Zuo et al. 2010).

A number of human studies have examined the effects of ginkgo leaf preparations on the CYP450 drug-metabolizing isoenzymes. Ginkgo leaf extract has been shown to induce CYP2C19 (Yin et al. 2004). Effects on CYP3A4 have been mixed, with most studies showing no effect and others suggesting induction or inhibition (Gurley et al. 2002, 2005; Markowitz et al. 2003a; Robertson et al. 2008; Uchida et al. 2006). Studies have shown no activity to slight induction of CYP2E1 and CYP2C9 (Gurley et al. 2002, 2005; Mohutsky et al. 2006; Uchida et al. 2006; Yin et al. 2004) and no activity on CYP2D6 or CYP1A2 (Gurley et al. 2002, 2005; Markowitz et al. 2003b).

Pregnancy and Lactation

Information on the safety of ginkgo leaf during pregnancy and lactation is limited. Animal studies on the use

of ginkgo leaf during pregnancy have provided conflicting results. One study showed decreased fetal weights from mother rats fed doses of 7 or 14 mg/kg daily of ginkgo leaf extract. In the same study, no adverse effects on fetal development were reported at a lower dose (Pinto et al. 2007). Other studies indicated no adverse effects on mothers or offspring at doses up to 1600 mg/kg daily in rabbits and 900 mg/kg daily in rats (Blaschek et al. 2002; DeFeudis 1991; Li et al. 2003).

No information on the safety of gingko leaf during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Trials with nifedipine yielded conflicting results, with significantly lower nifedipine plasma levels reported after ingestion of 120 mg ginkgo (no additional information given) for 18 days (Smith et al. 2001), but an increase in plasma nifedipine levels was reported after a single dose of 240 mg of a ginkgo leaf extract standardized to 24% flavonol glycosides and 6% terpene lactones (Yoshioka et al. 2004).

In healthy volunteers orally administered six ginkgo tablets (each containing the equivalent of 2 g of ginkgo leaf) daily for 7 days, then administered ginkgo with 25 mg warfarin daily, no significant changes in plasma levels of warfarin were observed. No changes were observed in platelet aggregation or international normalized ratio (INR) of prothrombin time (Jiang et al. 2005, 2006). Another study in patients stabilized on warfarin indicated no effects of 100 mg of standardized (24/6) ginkgo extract daily for 4 weeks on INR values (Engelsen et al. 2002).

In healthy volunteers orally administered single doses of 120 mg ginkgo (no specific product description stated) with 100 mg cilostazol or with 75 mg clopidogrel, platelet inhibition with the combination of ginkgo and clopidogrel or cilostazol was not significantly different as compared with clopidogrel or cilostazol alone. With the combination of ginkgo and cilostazol, prolongation of bleeding time was observed as compared to either product alone, although no changes were found in clotting time or platelet count (Aruna and Naidu 2007).

In healthy volunteers orally administered 500 mg aspirin with or without 240 mg standardized ginkgo leaf extract daily for 1 week, no significant differences were observed in bleeding time or agonist-induced platelet aggregation during treatment with ginkgo and aspirin as compared to aspirin alone (Wolf 2006). In adults with peripheral artery disease or risk factors for cardiovascular disease, who were administered 325 mg aspirin alone or with 300 mg of the same ginkgo leaf extract daily for 4 weeks, no significant changes in platelet function analysis, platelet aggregation, or bleeding or bruising episodes were observed (Gardner et al. 2007).

In healthy volunteers orally administered single doses of 250 mg ticlopidine with or without 80 mg standardized (24/6) ginkgo leaf extract, no changes in plasma levels of ticlopidine were observed. Bleeding times were not prolonged with gingko, and coadministration was not associated with additional antiplatelet effects compared with ticlopidine alone (Kim et al. 2010). Similarly, no changes in ticlopidine plasma levels were observed after ticlopidine was administered to healthy volunteers before or after 120 mg ginkgo leaf extract daily for 3 days (Lu et al. 2006).

In healthy volunteers orally administered 0.5 mg digoxin before or after 240 mg of standardized (24/6) ginkgo leaf extract daily for 2 weeks, no changes in serum levels of digoxin were observed (Mauro et al. 2003).

In healthy volunteers orally administered 100 mg talinolol with a single dose of 120 mg ginkgo leaf extract, no changes in plasma levels of talinolol were observed. After repeated dosing for 14 days with 360 mg of the same ginkgo leaf extract daily, plasma levels of talinolol were increased. Talinolol is a substrate of the drug transporter protein P-gp (Fan et al. 2009).

In healthy volunteers administered a lopinavir (400 mg) and ritonavir (100 mg) combination to steady state, the addition of 240 mg ginkgo leaf extract (analyzed as containing 29.2% flavonol glycosides and 5.1% terpene lactones) daily for 2 weeks had no effects on plasma levels of either of the drugs (Robertson et al. 2008).

No significant changes in plasma levels of bupropion were observed in healthy volunteers orally administered 150 mg bupropion before or during administration of 240 mg standardized (24/6) ginkgo leaf extract daily for 14 days (Lei et al. 2009a).

No significant changes in voriconazole plasma levels were observed in healthy volunteers (including both extensive and poor metabolizers of CYP2C19) orally administered 200 mg of voriconazole before or after 240 mg standardized (24/6) ginkgo leaf extract daily for 12 days (Lei et al. 2009b).

No significant changes in plasma levels of diazepam (a CYP2C19 substrate) were observed in healthy volunteers orally administered 10 mg diazepam before or during treatment with 240 mg ginkgo leaf extract daily for 28 days (Zuo et al. 2010).

A study of Alzheimer's patients taking donepezil with 90 mg/day of ginkgo leaf extract for 30 days showed no significant impact on plasma concentration of donepezil (Yasui-Furukori et al. 2004).

Case Reports of Suspected Drug or Supplement Interactions

Several cases of suspected drug interactions have been reported in the literature. Coma was reported in a woman taking trazodone (40 mg daily) concomitantly with standardized (24/6) ginkgo leaf extract (160 mg daily) for two days (Galluzzi et al. 2000). Fatal intracerebral mass bleeding was reported in a patient four weeks after introduction of 600 mg ibuprofen daily. This was in addition to ongoing daily use of 180 mg of a concentrated extract of ginkgo leaf for at least 30 months (Meisel et al. 2003). A breakthrough seizure was reported in a patient taking phenytoin and valproic acid (unspecified doses) and multiple herbal supplements with ginkgo (unspecified dose) (Kupiec and Raj 2005).

Animal Trials of Drug or Supplement Interactions

A ginkgo leaf decoction has been shown to reduce plasma concentrations of orally, but not intravenously, administered cyclosporine in rats (Yang et al. 2006). Similarly, when coadministered in rats with phenobarbital, a ginkgo leaf extract (24.2% flavonol glycosides and 9.2% terpene lactones) was shown to significantly reduce plasma concentrations of phenobarbital and sleeping time induced by phenobarbital (Kubota et al. 2004). Studies in rats with the same ginkgo leaf extract indicated significant reduction in the hypotensive effect of nicardipine (Kubota et al. 2003; Shinozuka et al. 2002). Coadministration of standardized (24/6) ginkgo leaf extract and amikacin to rats resulted in an earlier onset and more significant amikacin-induced ototoxicity (Miman et al. 2002). The applicability of these animal data to humans is unknown.

In rats with induced pulmonary embolism given 20 mg/kg ginkgo leaf extract (24.74% flavonol glycosides and 7.55% terpene lactones) with 25 mg/kg cilostazol, no significant effects on the bleeding time, prothrombin time, and activated partial thromboplastin time were observed as compared to cilostazol alone. Survival was improved in the group that received both ginkgo and cilostazol, suggesting that ginkgo may potentiate the antiplatelet effect of cilostazol without the prolongation of bleeding time or coagulation time (Ryu et al. 2009).

II. Adverse Events

Adverse Events Reported in Clinical Trials

Reviews and meta-analyses of clinical trials with ginkgo leaf extract have shown that no serious side effects were reported in any trials and, if present, side effects were not significantly different from those in patients treated with placebo (Birks and Grimley Evans 2006; DeFeudis 1991; Ernst 2002; Hilton and Stuart 2004; Kleijnen and Knipschild 1992a; Pittler and Ernst 2000; Woerdenbag and Van Beek 1997; Zeng et al. 2005).

Case Reports of Adverse Events

Ginkgo leaf preparations have been associated with a number of cases of abnormal bleeding, including cerebral hemorrhages (Benjamin et al. 2001; Castellote Varona and Atienza Morales 2005; Matthews 1998; Meisel et al. 2003; Purroy Garcia et al. 2002; Smolinske 1999), hematomas (Evans 2000; Gilbert 1997; Hauser et al. 2002; Miller and Freeman 2002; Rowin and Lewis 1996), intraocular bleeding (Farnsworth et al. 1975; Hauser et al. 2002; MacVie and Harney 2005; Rosenblatt and Mindel 1997; Schneider et al. 2002), and postsurgical bleeding (Bebbington et al. 2005; Destro et al. 2005; Fessenden et al. 2001; Yagmur et al. 2005). Spontaneous bleeding was reported in a patient with a history of bleeding who was taking ginkgo leaf extract reported to be standardized to 27% flavonol glycosides and 10% terpene lactones, 75 mg per day for the previous 6 months, along with aspirin, vitamins A, C, D, E, and folic acid (Bent et al. 2005).

A review of all spontaneous reports from 1982 to 1988 of adverse events associated with the most established concentrated ginkgo extract concluded that side effects are rare and that "tolerance was generally excellent" (DeFeudis 1991).

Recurrent seizures in two patients with well-controlled epilepsy were associated with use of "*Ginkgo biloba*," presumably consisting of leaf extracts, for 12 days to two weeks (Granger 2001). A review of gingko hypothesized that the compound ginkgotoxin (4′-*O*-methylpyridoxine) may be responsible for lowering seizure threshold by inhibiting synthesis of vitamin B_6 (Leistner and Drewke 2010).

Cases of skin eruptions have been reported in persons taking ginkgo leaf products (Chiu et al. 2002; Pennisi 2006).

Two sisters with no significant prior psychiatric history, but with a significant paternal history of paranoid schizophrenia, were reported to experience manic episodes after taking a ginkgo product of at least twice the recommended dosage for about two years. After discontinuation of ginkgo and stabilization on medication, the sisters were reported to have relapses while not taking ginkgo (Lamonaca et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Study results on the influence of ginkgo on platelet aggregation are mixed. No effects on hemostasis, coagulation, bleeding time, platelet function, or fibrinolysis were observed after administration of 120, 240, or 480 mg daily of ginkgo leaf standardized extract to healthy volunteers for 14 days (Bal Dit Sollier et al. 2003). No changes in platelet aggregation or blood coagulation were observed in healthy volunteers administered 240 mg standardized ginkgo leaf extract daily for 7 days (Kohler et al. 2004). A significant reduction in platelet aggregation was observed in type 2 diabetes patients after 3 months of daily administration of 120 mg standardized ginkgo leaf extract, whereas with the

same treatment in healthy volunteers a significant reduction in collagen-induced but no change in PAF-mediated platelet aggregation was observed (Kudolo et al. 2002). Other studies indicate that ginkgo is believed to have antiplatelet activity via platelet-activating factor (PAF) antagonism (Braquet 1986; Braquet et al. 1987). PAF is primarily involved with pathological thrombosis formation and therefore may not affect normal mechanisms of platelet aggregation and thus have no effect on bleeding time (Mills and Bone 2005). The extent of the effect of ginkgo on the PAF pathway at the standard therapeutic dose has been debated (Braquet 1993; DeFeudis 1991; Skogh 1998).

In healthy volunteers orally administered ginkgo capsules at the manufacturer's recommended dose (amount not specified) daily for two weeks, no effects on platelet function or other hematological parameters were observed, including prothrombin time, partial thromboplastin time, thrombin time, bleeding time, the collagen/epinephrine assay, or the collagen/adenosine diphosphate assay. Aspirin (325 mg daily) was used as a positive control and markedly inhibited platelet function (Beckert et al. 2007).

A reduction in blood viscosity was observed in healthy volunteers orally administered 80 mg standardized ginkgo leaf extract daily for 6 months (Galduróz et al. 2007).

Human study results on the effects of ginkgo on CYP2C9 are mixed, with one trial of standardized (24/6) ginkgo leaf extract in extensive CYP2C9 metabolizers showing slight but significant induction (Uchida et al. 2006) and another trial with the same extract showing no effect (Mohutsky et al. 2006). Ginkgo has been shown to significantly induce CYP2C19 (Yin et al. 2004). Ginkgo leaf extracts showed no significant effect on CYP2E1 in two studies (Gurley et al. 2002, 2005b) and significant induction of CYP2E1 in another study (Yin et al. 2004). No effect of ginkgo has been observed in CYP2D6 (Gurley et al. 2002, 2005b; Markowitz et al. 2003a) or CYP1A2 (Gurley et al. 2002, 2005b).

Several human studies on the effects of ginkgo leaf extracts on CYP3A4 activity have shown no effect on CYP3A4 metabolism (Gurley et al. 2002, 2005; Markowitz et al. 2003a), although one trial of extensive CYP2C9 metabolizers showed a significant inhibition of CYP3A4 (Uchida et al. 2006).

In healthy volunteers orally administered single doses of midazolam and fexofenadine before and after 240 mg per day for 28 days of a gingko leaf extract analyzed as containing 29.2% flavonol glycosides and 5.1% terpene lactones, a significant decrease (~30%) in plasma levels of midazolam were observed, suggesting induction of the drug-metabolizing isoenzyme CYP3A4. Plasma levels of fexofenadine were unchanged (Robertson et al. 2008).

In healthy volunteers orally administered flurbiprofen after three doses of 120 mg standardized (24/6) ginkgo leaf extract in a 24-hour period, no significant changes in plasma levels of flurbiprofen were observed. These results suggest a lack of activity of ginkgo on the drug-metabolizing isoenzyme CYP2C9 (Greenblatt et al. 2006).

A study on the effects of ginkgo on monoamine oxidase (MAO) activity in humans indicated that 60 mg of a standardized ginkgo leaf extract did not affect MAO activity and that MAO inhibitory compounds in ginkgo did not cross the blood-brain barrier (Fowler et al. 2000).

Animal Pharmacological Studies

A decrease in monoamine oxidase (MAO) activity was observed in mice orally administered 50 mg/kg of a standardized ginkgo leaf extract daily for 7 months (Pardon et al. 2000). Similar inhibition was observed in mice intraperitoneally administered a standardized ginkgo leaf extract at a dose of 20 to 100 mg/kg for 7 days (Wu and Zhu 1999), and in mice orally administered 10 mg/kg of standardized ginkgo leaf extract for 17 days (Rojas et al. 2004). A fourth study, however, showed no effect on MAO activity in mice orally administered 25 to 100 mg/kg of a standardized ginkgo leaf extract daily for 5 days (Porsolt et al. 2000).

Other animal studies were identified but omitted due to availability of human data.

In Vitro Pharmacological Studies

In vitro studies were identified but omitted due to availability of human data.

IV. Pregnancy and Lactation

Oral administration of standardized ginkgo leaf extract to rats (up to 1600 mg/kg daily) and rabbits (up to 900 mg/kg daily) did not produce any signs of teratogenicity or embryotoxicity (Blaschek et al. 2002; DeFeudis 1991). Fetuses of pregnant rats fed 7 or 14 mg/kg daily ginkgo leaf extract during pregnancy were shown to have a lower birth weight as compared to control, while treatment with 3.5 mg/kg ginkgo had no adverse effects on fetuses. No signs of toxicity were observed in mothers fed ginkgo at any of the dose levels (Pinto et al. 2007). Standardized (24/6) ginkgo leaf extracts administered to pregnant rats at doses of 100 or 300 mg/kg daily for 5 days increased the number of hippocampal neurons of fetuses. No adverse effects in the fetuses or the mothers were noted (Li et al. 2003).

Ginkgo extract and ginkgo extract fractions with high levels of ginkgolic acids demonstrated embryotoxic effects when injected into recently fertilized chicken eggs (Floissac and Chopin 1999). Toxic effects were noted to be dose dependent. A significant effect of ginkgolic acids was observed in the LD_{50} values for ginkgo extract fractions, with LD_{50} ranging from 250 mg/egg (1% ginkgolic acid, 16% biflavones), to 1.8 mg/egg (16% ginkgolic acid, 6.7% biflavones) and 3.5 mg/egg (58% ginkgolic acid, 0.02% biflavones) (Baron-Ruppert and Luepke 2001).

One study of pregnant women taking herbal remedies reported to have identified the highly toxic alkaloid colchicine in a commercial ginkgo preparation (Petty et al. 2001). Colchicine, however, has never been previously detected in ginkgo extracts, and studies following the report of colchicine failed to identify the compound in other commercial preparations (Bone 2002; Li et al. 2002a, 2002b).

Direct treatment of hamster oocytes with high concentrations of gingko (0.1 and 1 mg/ml) extract significantly reduced penetration by sperm and the integrity of sperm DNA. The relevance of this study to humans taking ginkgo supplements is doubtful (Ondrizek et al. 1999).

No relevant information on the safety of ginkgo leaf during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered standardized ginkgo leaf extract in mice is 7.7 g/kg. The intraperitoneal LD_{50} is 1.9 g/kg in mice and 2.1 g/kg in rats (Blaschek et al. 2002).

An extract of ginkgo leaf with relatively high levels (~30%) of alkylphenols produced immunotoxic effects after subplantar injection in mice (Koch et al. 2000).

Subacute Toxicity

In rats and mice, ginkgo administered orally did not produce any signs of organ damage or impairment of hepatic or renal function when administered for over 27 weeks in doses ranging from 100 to 1600 mg/kg (Salvador 1995).

Ginkgo biloba L. — Ginkgoaceae

SCN: ginkgo
PN: *yin xing* (seed); *bai guo* (seed); *yin guo* (seed)
OCN: maidenhair tree
Part: seed

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Do not exceed recommended dose (Bensky et al. 2004; Chang and But 1986; Leung and Foster 1996).

Other Precautions

Eating raw ginkgo seed may cause toxic reactions such as nausea, vomiting, seizures, and other symptoms of central nervous system disturbances (Chen and Chen 2004; Leung and Foster 1996), and even cooked seed should be eaten only in small amounts (Leung and Foster 1996). These concerns are not associated with the seed administered in decoction (Bensky et al. 2004).

Not recommended for long-term use (Bensky et al. 2004; Chang and But 1986; Leung and Foster 1996).

Ginkgo seed should be used with caution in pregnancy (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Standard Dose

Prepared: 1.5 to 9 g daily (Bensky et al. 2004; Chen and Chen 2004). Unprocessed raw ginkgo seed is generally not used due to its toxicity (Chen and Chen 2004).

Editors' Notes

Safety concerns for ginkgo seed are largely dependent on whether the seed is consumed in raw or cooked form. Consumption of cooked ginkgo seed is well documented (Chadha 1988; Leung and Foster 1996), although case reports of adverse effects from consumption of large amounts of the cooked seed have been reported (Hasegawa et al. 2006; Kajiyama 2002; Miwa 2001). One source advises a limit of no more than 10 boiled or roasted seeds daily (Leung and Foster 1996). The seed is considered toxic if eaten raw and has been reported to cause death in children (Chadha 1988; Leung and Foster 1996). Toxic reactions are not known to occur, however, when ginkgo seed is administered in decoction (Bensky et al. 2004).

Ginkgolic acids are urushiol type alkylphenols, related to compounds in poison ivy (*Rhus toxicodendron*), and are associated with contact allergic responses, especially dermatitis. Ginkgolic acids are found in relatively high concentrations in ginkgo seed coats and in lower concentrations in ginkgo leaf (Blumenthal 1997).

Adverse Events and Side Effects

Adverse reactions, including seizures, have been reported in individuals who have consumed large numbers of raw or cooked ginkgo seeds (Hasegawa et al. 2006; Kajiyama et al. 2002; Miwa 2001), though are not associated with decoctions of the seed (Bensky et al. 2004). Symptoms of overdosage, described as including hyperthermia, nausea, vomiting, shortness of breath, abdominal pain, diarrhea, restlessness, convulsions, and loss of consciousness, among other symptoms, can appear 1 to 12 hours after consuming the seeds, and are associated with doses of 7 to 150 seeds in children and 40 to 300 seeds in adults (Bensky et al. 2004; Chen and Chen 2004). It is also reported that death may occur due to respiratory and circulatory failure 1 to 2 days following gross overdose in the absence of emergency treatment (Bensky et al. 2004; Chen and Chen 2004). The number of ginkgo seeds eaten in reported fatalities ranges from 15 to 574 (Kajiyama et al. 2002).

Contact with ginkgo fruit pulp has been associated with contact dermatitis in a number of individuals (Nakamura 1985; Tomb et al. 1988).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A text on traditional Chinese medicine indicates that ginkgo seed should be used with caution during pregnancy (Chen and Chen 2004).

No information on the safety of gingko seed during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of suspected drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Several cases of convulsions and vomiting have been reported in association with consumption of cooked ginkgo seeds, especially in Japan where cooked ginkgo seed is used as food. A 34-year-old woman experienced two episodes of convulsions and vomited several times after eating 70–80 microwaved ginkgo seeds (Miwa 2001). A 2-year-old presented with vomiting, diarrhea, irritability, and a symmetrical generalized clonic seizure from consumption of 50–60 roasted ginkgo seeds (Kajiyama et al. 2002). A 2-year-old boy experienced vomiting and afebrile convulsions after eating a large number of roasted ginkgo seeds (Hasegawa et al. 2006). In each of these cases, onset of symptoms occurred several hours after consumption of the ginkgo.

Other symptoms of overdose of ginkgo seed may include abdominal pain, dyspnea, and other symptoms related to central nervous system disturbances (Bensky et al. 2004; Chen and Chen 2004). The compound 4′-*O*-methylpyridoxine, a neurotoxin that can cause vitamin B_6 deficiency symptoms, is believed to be responsible for the toxic effects of ginkgo seed (Wada et al. 1985). Although the seed is recognized to be toxic in large amounts, cooked ginkgo seed is a food item commonly eaten throughout Japan, Korea, and China. The number of seeds that can be eaten safely in a single meal has not been defined, and fatalities have been reported from consumption of from 15 to 574 seeds (Kajiyama et al. 2002), with overdose in children reported from as few as seven seeds (Chen and Chen 2004).

Contact with ginkgo fruit pulp has been associated with contact dermatitis in a number of individuals (Nakamura 1985; Tomb et al. 1988).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A text on traditional Chinese medicine indicates that ginkgo seed should be used with caution during pregnancy (Chen and Chen 2004).

No information on the safety of gingko seed during lactation was identified.

V. Toxicity Studies

Mice fed a "gross overdose" of ginkgo seed for 60 days were observed to have weight loss, poor appetite, liver damage, and glomerulonephritis, and some animals died. Intravenous administration of ginkgo seed extract caused an increase followed by a decrease in blood pressure, dyspnea, seizures, and death (Anonymous 1989, 1995). Decoctions of the seed are recognized as nontoxic (Bensky et al. 2004; Chen and Chen 2004).

SCN: glehnia
PN: *bei sha shen* (root)
OCN: beach silvertop
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
Although furanocoumarins, compounds that can cause photosensitivity after contact with skin, have been identified in glehnia (Mizukami et al. 1993), no cases of photosensitivity have been reported.

Pregnancy and Lactation
No information on the safety of glehnia in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: B

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bradley 1992; Strandberg et al. 2001, 2002).

Not for use in persons with hypertension, liver disorders, edema, severe kidney insufficiency, low blood potassium, heart disease with edema, or congestive heart failure (Bensky et al. 2004; Bradley 1992; De Smet 1993; Mills and Bone 2005).

Not for prolonged use or in high doses except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Bradley 1992; Chadha 1988; Martindale and Reynolds 1996).

Other Precautions

None known.

Drug and Supplement Interactions

No interactions are expected at standard therapeutic doses. At higher doses or with long-term use, licorice may potentiate potassium depletion of high-ceiling loop diuretics and thiazide diuretics, stimulant laxatives (Mills and Bone 2005), and corticosteroids such as prednisolone (Cheng et al. 2004; De Smet 1993), and may potentiate the action of cardiac glycosides such as digoxin (Kelly 1990).

One reference indicated a theoretical concern that licorice may counteract the effects of oral contraceptives (Mills and Bone 2005).

Editors' Notes

The contraindications and precautions listed above apply to products that contain the compound glycyrrhizin and not to deglycyrrhizinated licorice (DGL) products.

Licorice contains approximately 1 to 7% of the compound glycyrrhizin (Kondo et al. 2007). Many commercial products are standardized to 12% glycyrrhizin, and the European Pharmacopoeia specifies that licorice root should contain a minimum of 4% glycyrrhizin (Council of Europe 2001).

Standard Dose

The standard dose is 1 to 5 g, three times daily for up to 6 weeks, though French regulation limits daily consumption to 5 g for direct consumption or 8 g as a tea; reduction in sodium and increase in potassium intakes are recommended (De Smet 1993; Mitchell et al. 1991).

In traditional Chinese medicine texts, the standard dose is listed as 1.5 to 10 g daily of sliced licorice root prepared as a decoction or infusion (Bensky et al. 2004; Chen and Chen 2004).

Adverse Events and Side Effects

No case reports of adverse effects have been reported in persons using licorice within the recommended dose (less than 50 g daily) and treatment period (less than 6 weeks) (WHO 1999).

In highly sensitive individuals, a daily intake of 100 mg glycyrrhizin (approximately 50 g licorice sweets) may produce adverse effects, and most individuals that consume 400 mg experience adverse effects (Størmer et al. 1993). A 12-week trial of the compound glycyrrhizin in women indicated that a dose of 2 mg/kg glycyrrhizin daily, equivalent to approximately 6 g of licorice daily, was the no-observed-adverse-effect level (NOAEL) of the compound (van Gelderen et al. 2000).

The mineralocorticoid effects of licorice are well documented (*see* Human pharmacological studies) (Stewart et al. 1987). Licorice may cause reversible potassium depletion and sodium retention when consumed in therapeutic dosages over a prolonged period (Bensky et al. 2004; Bradley 1992; Martindale and Reynolds 1996). Most cases of adverse events associated with licorice have been reported in persons consuming excessive amounts of licorice candies. Overdoses of licorice have been associated with temporary paralysis, loss of vision, sodium and fluid retention, hypertension, and decreased serum levels of aldosterone. Licorice-related potassium depletion has resulted in symptoms such as tachycardia, rhabdomyolysis, myopathy, and hypokalemic paralysis. These effects are attributed primarily to the action of the compound glycyrrhizin (Isbrucker and Burdock 2006). Preparations of licorice without this compound, deglycyrrhizinated licorice (DGL), are available.

Pharmacological Considerations

Deglycyrrhizinated licorice (DGL) is usually free of adverse effects (Martindale and Reynolds 1996).

Pregnancy and Lactation

Two retrospective epidemiological studies on licorice consumption by pregnant women suggested that heavy licorice consumption was associated with earlier births (Strandberg et al. 2001, 2002). Another epidemiological study indicated that heavy consumption (over 500 mg daily) of licorice candies by pregnant women was associated with adverse effects on cognitive and psychiatric development in children (Räikkönen et al. 2009).

In animal studies, doses of the compounds glycyrrhizin or glycyrrhetic acid over 100 mg/kg were associated with some adverse developmental effects in the fetus, although no adverse effects were observed at lower doses (FDRL 1971; Hundertmark et al. 2002; Mantovani et al. 1988).

No information on the safety of licorice during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Coadministration of glycyrrhizin (50 mg orally) and prednisolone (0.096 mg/kg intravenously) significantly decreased the clearance of and increased the plasma concentrations of prednisolone (Cheng et al. 2004).

Estrogens may react with the mineralocorticoid receptor or inhibit 11β-hydroxysteroid dehydrogenase activity, exacerbating the effects of licorice (Clyburn and DiPette 1995).

Case Reports of Suspected Drug or Supplement Interactions

A case of neuromuscular paralysis due to low potassium was reported in a woman taking excessive amounts of both the diuretic furosemide (60–150 mg per day, three times per week) and licorice (40–60 g daily) (Famularo et al. 1999).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Adverse events reported in clinical trials are consistent with the known pharmacological effects of licorice, including sodium and fluid retention, increased blood pressure, and decreased serum levels of potassium and aldosterone. Such events have been associated with doses of licorice containing high levels (greater than 2 mg/kg) of the compound glycyrrhizin, and are not common with products containing 2 mg/kg or less of glycyrrhizin (Isbrucker and Burdock 2006).

Case Reports of Adverse Events

No case reports of adverse effects have been reported in persons using licorice within the recommended dose (less than 50 g daily) and treatment period (less than 6 weeks) (WHO 1999).

Adverse events associated with licorice consumption are primarily related to the mineralocorticoid effects (*see* Human pharmacological studies), with symptoms such as sodium and fluid retention, increased blood pressure, and decreased serum levels of potassium (hypokalemia) and aldosterone. Multiple forms of licorice products have been associated with adverse events, including licorice candies, teas, and capsules. Most reports of adverse events are associated with ingestion of at least 35 g per day of licorice candies.

One case of cardiac arrest was reported in a patient with licorice-induced hypokalemia (Bannister et al. 1977). Multiple cases of hypertension (Beretta-Piccoli et al. 1985; Brouwers and van der Meulen 2001; Conn et al. 1968; Cugini et al. 1983; Cuspidi et al. 1981; Dellow et al. 1999; Janse et al. 2005; Pozzoli et al. 1980; Takeda et al. 1979; Wash and Bernard 1975) and one case of hypertension encephalopathy (van den Bosch et al. 2005) have been reported.

Various effects of licorice-induced hypokalemia have been reported, including hypokalemia-induced ventricular tachycardia or ventricular fibrillation (Eriksson et al. 1999; Gerritsen et al. 2009; Harris 2000; van den Bosch et al. 2005), hypokalemic rhabdomyolysis (breakdown of muscle fibers) (Barrella et al. 1997; Piette et al. 1984), hypokalemic myopathy (nonfunctioning muscle fibers) (Famularo et al. 1999; Hussain 2003; Ishikawa et al. 1999; Shintani et al. 1992; Yoshida and Takayama 2003), and hypokalemic paralysis (Cheng et al. 2004; Cumming et al. 1980; de Rohan Chabot et al. 1984; Elinav and Chajek-Shaul 2003; Famularo et al. 1999; Lin et al. 2003; Yasue et al. 2007). In one reported case, a woman had generalized edema and sodium retention without elevated blood pressure, suggesting that hypokalemia is not always associated with blood pressure changes (Negro et al. 2000). One case of myopathy was associated with renal tubular damage in an anorexic individual (Ishikawa et al. 1999).

Other related conditions reported in case reports include mineralocorticoid excess (Doeker and Andler 1999; Hamidon and Jeyabalan 2006) and pseudoaldosteronism (Colloredo et al. 1987; Gomez Fernandez et al. 1981; Kageyama et al. 1997).

One case of vestibular neuronitis (swelling of the inner ear, causing vertigo) (Belhadj-Tahar et al. 2003) was reported. Ischemia with a blood vessel blockage was reported in a

hypokalemic patient who had consumed licorice regularly for over 10 years (Lozano et al. 2000).

A case series of five patients with transient visual loss observed over a 10-year period was reported. All of the patients had consumed significant amounts of licorice prior to the visual loss. Potential other causes of the loss were noted, including significant coffee consumption in three of the patients and histories of ischemia or migraine headaches in two of the patients (Dobbins and Saul 2000).

One case of occupational asthma was reported in an herbalist exposed to licorice powder. The allergy was IgE-mediated and confirmed by inhalation challenges (Cartier et al. 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

The compound glycyrrhetinic acid has been shown to inhibit the enzyme 11β-hydroxysteroid dehydrogenase, leading to a decreased conversion of cortisol to cortisone (Stewart et al. 1987). Cortisol has the same affinity for the mineralocorticoid receptors as aldosterone, increasing the mineralocorticoid effects in the body. Such an increase in effect may lead to a syndrome known as pseudoaldosteronism, with symptoms such as sodium and fluid retention, increased blood pressure, and decreased serum levels of potassium and aldosterone (Sigurjonsdottir et al. 2006).

A review of case reports and human studies of licorice indicated significant variability in individual susceptibility to the compound glycyrrhizin. In highly sensitive individuals, a daily intake of 100 mg glycyrrhizin (~50 g licorice sweets) may produce adverse effects, and most individuals that consume 400 mg experience adverse effects (Størmer et al. 1993).

Administration of 100 or 200 g daily of licorice (0.7 or 1.4 g glycyrrhizin) for 1 to 4 weeks has been shown to significantly decrease plasma renin secretion and inhibit the renin-angiotensin-aldosterone system (RAAS) (Epstein et al. 1977).

A human study of 50 to 200 g of licorice daily for 2 or 4 weeks showed a dose-response relationship for blood pressure, with licorice significantly raising blood pressure, even at the 50 g dose (including 75 mg glycyrrhetinic acid). Variation in individual sensitivity was observed, with responses following a normal distribution curve (Sigurjonsdottir et al. 2001). A trial of 100 g daily of licorice (including 150 mg glycyrrhetinic acid) for 4 weeks indicated that patients with hypertension are more sensitive to inhibition of 11β-hydroxysteroid dehydrogenase than persons with regular blood pressure (Sigurjonsdottir et al. 2003). In a similar trial, men were shown to be more sensitive to inhibition of 11β-hydroxysteroid dehydrogenase than women (Sigurjonsdottir et al. 2006).

A reduction in serum potassium and renin and an increase in body weight were observed in persons taking 5 or 11 g of licorice daily (380 or 814 mg of glycyrrhizin). Several of the study participants withdrew due to hypertension, edema, or headaches, although some participants had possibly contributing factors, including a family history of hypertension or concomitant use of oral contraceptives. Doses of 1.4 or 2.8 g of licorice were not associated with any significant physiological changes or study withdrawals (Bernardi et al. 1994).

Testing of varied doses (0–4 mg/kg) of the compound glycyrrhizin for 12 weeks in women to determine a no-observable-adverse-effect level (NOAEL) for blood pressure and potassium effects suggested that 2 mg/kg glycyrrhizin was the NOAEL. This level is approximately equivalent to 6 g of licorice daily (van Gelderen et al. 2000).

The results of one small clinical trial (7 men studied) indicated a significant reduction of serum testosterone levels after 4 days of administration of 7 g daily of a licorice preparation (0.5 g glycyrrhizin, equivalent to ~10 g daily of licorice root) (Armanini et al. 1999). Replications of that trial using the compound glycyrrhizin resulted in a nonsignificant decrease of testosterone (Josephs et al. 2001). The discrepancy in results between the studies is believed to be caused by the method used for testosterone analysis, with the first study measuring testosterone in serum (total hormone level) and the second measuring testosterone in saliva (free hormone level) (Isbrucker and Burdock 2006). A repeat of the original methodology provided similar results to the earlier study (Armanini et al. 2003).

A trial in women showed that serum testosterone was significantly decreased during the luteal phase of the menstrual cycle after administration of 3.5 g licorice (containing 0.26 g glycyrrhizic acid) daily for two menstrual cycles (Armanini et al. 2004).

Administration of 3.5 g daily of licorice (containing 0.26 g glycyrrhizic acid) to healthy women for 2 months significantly increased urinary levels of parathyroid hormone (PTH), vitamin D, and calcium (Armanini et al. 2002).

Animal Pharmacological Studies

Animal pharmacological studies were identified but omitted due to presence of human data.

In Vitro Pharmacological Studies

In vitro pharmacological studies were identified but omitted due to presence of human data.

IV. Pregnancy and Lactation

Two retrospective epidemiological studies on licorice consumption by pregnant women (total 1144 women) suggested that heavy licorice consumption (≥500 mg/week glycyrrhizin) was correlated with earlier births. Heavy consumption reduced the mean gestational period by 2.5 days (Strandberg et al. 2001, 2002).

A study on cognitive and psychiatric outcomes in children based on maternal consumption of licorice during

pregnancy suggested some adverse effects associated with high levels of licorice candy consumption. The study populations were sorted based on whether the mothers had low (0–249 mg) or high (>500 mg) rates of licorice candy intake during pregnancy. Children of mothers with a high licorice candy intake had decrements in verbal and visuospatial abilities and narrative memory, and increases in rule-breaking, aggression, and attention problems. The authors indicated that results of this study are consistent with recognized effects of glucocorticoid drugs (Räikkönen et al. 2009).

Doses of licorice in excess of those normally recommended (3–15 g daily) may affect blood pressure (*see* Human pharmacological studies) and should be avoided by women with preeclampsia (a condition during pregnancy that includes hypertension) (Mills and Bone 2005).

No teratogenic effects were observed in mice, rats, hamsters, and rabbits administered the compound ammoniated glycyrrhizin at doses up to 1000 mg/kg daily starting on the sixth day of gestation (continuing for 10, 10, 5, or 13 days, respectively) (FDRL 1971).

Renal tissue abnormalities were observed in fetuses of some rats fed 100 or 250 mg/kg of the compound disodium glycyrrhizin on days 0 to 20 of gestation. Skeletal abnormalities were observed in fetuses of the two highest dose groups, although the authors noted that similar abnormalities were observed in control groups. No adverse effects were observed in rats fed 10 mg/kg disodium glycyrrhizin under the same protocol (Mantovani et al. 1988).

A study on the effects of glycyrrhetic acid on rat fetal lung development found moderately but significantly reduced levels of 11β-hydroxysteroid dehydrogenase in the lungs of fetuses of rats fed 1000 mg/kg daily glycyrrhetic acid on days 13 through 17, 19, or 21, of pregnancy or postpartum day 1. Fetuses of rats fed lower doses (up to 100 mg/kg) showed no adverse effects (Hundertmark et al. 2002).

No information on the safety of licorice during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered licorice extract (53% glycyrrhizin) is 18 g/kg in male rats and 14.2 g/kg in female rats. In mice, the LD_{50} is greater than 7.5 g/kg (Komiyama et al. 1977).

Subchronic Toxicity

Mice administered the compound glycyrrhizin at amounts of 0.6 or 1.25% of drinking water (~880 or 1830 mg/kg glycyrrhizin daily) died within 10 weeks of treatment (Kobuke et al. 1985).

Chronic Toxicity

No significant changes in body weight, clinical chemistry, or histology were observed in rats fed 100, 300, or 1000 mg/kg glycyrrhetinic acid daily for 1 year. Serum potassium and chloride levels were slightly reduced at the highest dose. In dogs fed the same doses, animals receiving 1000 mg/kg displayed a decrease in weight gain and increases in serum levels of alkaline phosphatase and alanine aminotransferase (Kelloff et al. 1994).

Mice administered the compound glycyrrhizin at amounts up to 0.15% of drinking water (~220 mg/kg glycyrrhizin daily) for 96 weeks did not develop tumors (Kobuke et al. 1985).

G

Gossypium spp. — Malvaceae

Gossypium herbaceum L.
SCN: Levant cotton
AN: *karpasa*
OCN: *algodao*

Gossypium hirsutum L.
SCN: cotton
Part: root bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Conway and Slocumb 1979; Felter and Lloyd 1898; Randel et al. 1992).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Chadha 1988; Conway and Slocumb 1979; De Smet 1993; Felter and Lloyd 1898; Moore 1978); *see* Appendix 2.
Uterine stimulant (Chadha 1988; Felter and Lloyd 1898; List and Hörhammer 1973; Williamson 2003); *see* Appendix 2.
Diuretic (Felter and Lloyd 1898); *see* Appendix 2.

Editors' Notes

Cotton and Levant cotton contain the compound gossypol, found primarily in the seed but also present in lesser amounts in the root bark. Gossypol content in the root and root bark reportedly ranges from 0.16 to 5.1% (Royce et al. 1941; Stipanovic et al. 2006; Wang 1987). Gossypol was widely researched as a male contraceptive. *See* Pharmacological Considerations for more information.

Adverse Events and Side Effects

See Pharmacological Considerations.

Pharmacological Considerations

The compound gossypol has been widely investigated as a potential male contraceptive, with a number of human and animal studies showing a significant reduction or complete elimination of sperm in the semen. Research on gossypol as a contraceptive was stopped for two reasons. First, the compound was found to produce chronic or permanent infertility in 25 to 50% of trial participants. Secondly, some clinical trials in China indicated that gossypol produced or exacerbated hypokalemia (low levels of potassium), although this effect was generally not observed in studies outside of China. More recent animal studies have indicated a possible mechanism of action for the hypokalemia (Coutinho 2002; Qian and Wang 1984; Waites et al. 1998).

Pregnancy and Lactation

Cotton and Levant cotton root barks have traditionally been used as abortifacients (Conway and Slocumb 1979; Felter and Lloyd 1898; Moore 1978). A number of animal studies have indicated that the compound gossypol has embryotoxic activity, while other studies have indicated no such activity and a lack of teratogenic effects (Li et al. 1989; Qian and Wang 1984; Randel et al. 1992; Sein 1986; Lin et al. 1985). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of cotton root bark during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

The compound gossypol has been shown to have antifertility activity in men at doses of 0.3 mg/kg. Doses in clinical trials generally range between 7.5 and 15 mg daily. After clinical trials, approximately 60% of men regained fertility by 16 weeks after the end of the trial, whereas azoospermia (lack of sperm in the semen) persisted in about 19% of men (Coutinho 2002). Human studies have indicated that gossypol has no significant effects on hormone levels (De Smet 1993; Qian and Wang 1984).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Cotton and Levant cotton root barks have traditionally been used as abortifacients (Conway and Slocumb 1979; Felter and Lloyd 1898; Moore 1978). An Eclectic medical text reported that cotton acts as an emmenagogue and parturient (Felter and Lloyd 1898).

A reproductive toxicity review indicated that animal studies of the compound gossypol demonstrated no teratogenic activity or abortifacient activity of the compound (Randel et al. 1992). No teratogenicity or embryotoxicity of gossypol was reported in studies with rats and rabbits at 5 to 30 times the clinical dose (Qian and Wang 1984). No teratogenic effects were observed in rats orally administered 40 mg/kg of gossypol (Beaudoin 1985).

Administration of the compound gossypol to rats on days 0 to 8 of pregnancy inhibited ovum implantation and maintenance of pregnancy (Lin et al. 1985).

In mice orally administered 60 or 120 mg/kg of gossypol acetic acid daily on days 6 to 13 of pregnancy, an increase in fetal resorptions and late fetal deaths was observed (Li et al. 1989).

In mice orally administered 50 or 75 mg/kg of gossypol acetic acid daily on days 1 to 15 of pregnancy, a dose-dependent embryotoxic effect was observed. No abnormalities were observed in surviving fetuses (Sein 1986).

No information on the safety of cotton root bark during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of the compound gossypol has been reported as 2400 to 3340 mg/kg in rats, 500 to 950 mg/kg in mice, 360 to 600 mg/kg in rabbits, 280 to 300 mg/kg in guinea pigs, and 500 mg/kg in pigs (Qian and Wang 1984).

Short-Term Toxicity

In rats orally administered 0.4, 2, or 4 ml/kg of a fluid extract of Levant cotton root daily for 30 days, no toxicity was observed at the lowest dose (equivalent to the human therapeutic dose). Dose-dependent changes in weight gain, hematological values, and biochemical blood analyses at the two higher doses were indicative of systemic toxicity (Mello et al. 2008).

Genotoxicity

No mutagenic activity of the compound gossypol was observed in the Ames test for mutagenicity (Li et al. 1989).

Grifola frondosa (Dicks.: Fr.) Gray — Polyporaceae

SCN: maitake
Syn: *Polyporus frondosus* (Dicks.: Fr.) Fr.

OCN: dancing mushroom; hen-of-the-woods
Part: fruiting body, mycelium

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Maitake is commonly consumed as a food (Zhuang and Wasser 2004).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that maitake may modify glucose regulation (Cui et al. 2009; Han and Liu 2009; Hong et al. 2007; Horio and Ohtsuru 2001; Kubo et al. 1994; Lo et al. 2008; Preuss et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of maitake in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a phase I/II dose escalation trial in postmenopausal women with a history of breast cancer, an extract of maitake was administered at doses of 0.5, 1.5, 3, or 5 mg/kg twice daily for 3 weeks. No dose-limiting toxicity was encountered. Nausea and joint swelling were reported in one patient and rash and pruritus in another. Increasing doses of maitake increased certain immunologic parameters and depressed others, and the dose-response curves for many endpoints were non-monotonic, with intermediate doses having either immune enhancing or immune suppressant effects compared with both high and low doses (Deng et al. 2009).

Animal Pharmacological Studies

In diabetic mice orally administered 150 or 450 mg/kg of alpha-glucan from maitake, a decrease in fasting plasma glucose levels was observed (Hong et al. 2007).

A reduction in fasting blood glucose levels was observed in diabetic rats fed diets containing 20 percent maitake for 100 days (Horio and Ohtsuru 2001).

A reduction in blood glucose levels was observed in diabetic mice orally administered 1 g of maitake powder. When extracts of maitake were tested, an ethanol extract had hypoglycemic activity, but no activity was observed from an aqueous extract (Kubo et al. 1994).

Oral administration of 1 g daily of maitake fruiting body extract or mycelium extract for 15 days attenuated diabetes-induced changes in blood glucose levels (Lo et al. 2008).

Improved glucose sensitivity was observed in spontaneously hypertensive rats fed diets containing a maitake extract fraction (Preuss et al. 2007).

A reduction in blood glucose levels was observed in diabetic mice orally administered a vanadium-rich extract of maitake daily for 20 days (Cui et al. 2009; Han and Liu 2009).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of maitake during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in rats orally administered single doses of 0.5 or 2 g/kg of powdered maitake (Koike et al. 2003).

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Grindelia species accumulate selenium when growing in soils with a high selenium content. No adverse effects related to selenium accumulated in grindelia have been reported in humans, although adverse effects have been reported in grazing animals that have ingested significant amounts of selenium-containing plants (Frankenberger and Benson 1994).

Adverse Events and Side Effects

High doses can produce kidney and stomach irritation (Felter and Lloyd 1898; Remington and Wood 1918).

Pharmacological Considerations

One Eclectic medical text indicates that overdose of grindelia is toxic and may cause paralysis of the respiratory muscles (Ellingwood 1919). Grindelia is reported to have cardiotonic and cardiac depressant activity (BHP 1976; Culbreth 1927).

Pregnancy and Lactation

Although no information on the safety of grindelia in pregnancy or lactation was identified, the editors of this text recommend that use of grindelia during pregnancy be short term and with caution.

Gymnema sylvestre (Retz.) R. Br. ex Schult.

Asclepiadaceae

SCN: gymnema
AN: *meshashiringi*

Part: leaf

Quick Reference Summary

Safety Class 1
Interaction Class A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Compounds from gymnema temporarily suppress the sensation of sweetness from certain sugars (i.e., sucrose) and other substances with sweet tastes (i.e., saccharin) (Singh et al. 2008). This effect has traditionally been experienced by persons chewing the leaf (Yeh et al. 2003).

Pharmacological Considerations

Human and animal studies have demonstrated that gymnema may modify glucose regulation (Baskaran et al. 1990; Gholap and Kar 2005; Shanmugasundaram et al. 1990; Spasov et al. 2008). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of gymnema in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Reductions in blood glucose levels were observed in patients with type 1 diabetes orally administered 400 mg of a g ymnema extract daily for 10 to 12 months and in patients with type 2 diabetes orally administered 400 mg of a gymnema extract daily for 18 to 20 months (Baskaran et al. 1990; Shanmugasundaram et al. 1990).

Animal Pharmacological Studies

A reduction in blood glucose levels was observed in mice with high blood glucose levels intraperitoneally administered 6.7, 13.4, or 26.8 mg/kg of gymnemic acids (Gholap and Kar 2005).

No significant changes in blood sugar levels were observed in healthy or diabetic rats orally administered gymnema aqueous extract as a single dose of 1000 mg/kg or as a repeated dose of 30 mg/kg daily for four weeks (Galletto et al. 2004).

A reduction in fasting blood glucose levels was observed in diabetic rats orally administered the compound conduritol A i solated from the stem of gymnema (Wei et al. 2008).

In Vitro Pharmacological Studies

A concentration-dependent stimulation of insulin secretion was observed in isolated human islets and the MIN6 β-cell line after treatment with varying amounts of gymnema extract (Liu et al. 2009).

IV. Pregnancy and Lactation

No information on the use of gymnema during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of water and ethanol extracts of gymnema intraperitoneally administered to mice was 375 mg/kg (Bhakuni and Dhar 1971).

Chronic Toxicity

In rats fed diets containing 0.01, 0.10, or 1.0% gymnema for 52 weeks, no exposure-related changes in body-weight, in the food consumption, in the hematological parameters, or in the serum biochemical examinations were recognized. No histopathological alterations were seen (Ogawa et al. 2004).

Hamamelis virginiana L.

Hamamelidaceae

SCN: witch hazel

Part: bark, leaf

Quick Reference Summary

Safety Class: 1

Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (10% bark, 3–10% leaf) (Leung and Foster 1996; Touriño et al. 2008; Wichtl 2004); *see* Appendix 1.

Editors' Note

Witch hazel water is a steam distillate and does not contain tannins (Leung and Foster 1996).

Adverse Events and Side Effects

In sensitive individuals, witch hazel may cause irritation of the stomach (Wichtl 2004).

Allergic contact dermatitis from witch hazel has been reported (Granlund 1994).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of witch hazel in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Witch hazel ointment was reported as generally well tolerated in an observational study in children (age 27 days to 11 years) with minor skin injuries (Wolff and Kieser 2007).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In patients with allergy to chamomile, patch testing with cosmetic and herbal product ingredients indicated that witch hazel tincture was a sensitizing agent (Paulsen et al. 2008).

Among 1032 patients selected from patch testing clinics, none had positive reactions to patch testing with a 25% witch hazel extract (Bruynzeel et al. 1992).

Allergic contact dermatitis from witch hazel has been reported (Granlund 1994).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of witch hazel during pregnancy or lactation was identified.

V. Toxicity Studies

Chronic Toxicity

In rats subcutaneously administered 10 mg daily of a freeze-dried extract of witch hazel leaf weekly for 78 weeks, 3 of 15 male rats and 0 of 15 female rats developed malignant mesenchymoma. This rate of tumors was not considered significant (Kapadia et al. 1978).

No carcinogenic activity of witch hazel water was observed in 2-year carcinogenicity tests. Rats were administered a dose of 0.6 ml and mice were administered 0.2 ml (Haseman and Clark 1990).

Genotoxicity

No mutagenic activity of witch hazel water was reported in mutagenicity assays with Chinese hamster ovary cells with or without metabolic activation, nor in the mouse lymphoma cell forward mutation assay (Galloway et al. 1987; McGregor et al. 1988; Tennant et al. 1987).

Harpagophytum procumbens (Burch.) DC. ex Meisn.

Pedaliaceae

SCN: devil's claw

Part: secondary tuber

Quick Reference Summary

Safety Class: 1

Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with gastric or duodenal ulcers (Bradley 1992; ESCOP 2003; Hänsel et al. 1993; Weiss 1991).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Systematic reviews of clinical trials of devil's claw have reported that devil's claw is generally well tolerated and that adverse effects associated with devil's claw are mild, with gastrointestinal complaints and allergic reactions reported in a small number of trial participants (Brien et al. 2006; Denner 2007; Gagnier et al. 2004; Vlachojannis et al. 2008).

Pharmacological Considerations

Although devil's claw has been studied for anti-inflammatory activity, notably in patients with arthritis, studies have indicated that devil's claw does not affect the biosynthesis of prostanoids, and thus is not expected to produce the adverse effects associated with nonsteroidal anti-inflammatory and glucocorticoid drugs (ESCOP 2003; Loew et al. 1996; Moussard et al. 1992; Whitehouse et al. 1983).

While some references contraindicate devil's claw in persons with gastric or duodenal ulcers, one herbal

reference text noted that these contraindications were theoretical in nature, and based on the bitter tonic activity of the herb. The same text notes that bitters should be used with caution in persons with esophageal reflux or hyperacidity (Mills and Bone 2005).

Pregnancy and Lactation

In South Africa, devil's claw has traditionally been administered to pregnant women in low doses (250 mg, three times daily) for pain relief during pregnancy. A reduced dose is used during the postpartum period (Watt and Breyer-Brandwijk 1962).

In vitro studies have indicated that devil's claw caused contractions of the uterus. The authors of the study noted that this activity was consistent with traditional use for induction or acceleration of labor, or for expulsion of retained placentas (Mahomed and Ojewole 2006). Another in vitro study indicated that some mouse embryos incubated in a solution containing devil's claw had misshapen tails but were otherwise normal (Yokoyama et al. 2005).

No information on the safety of devil's claw during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

A case of purpura was reported in a patient taking warfarin and devil's claw. The type of devil's claw preparation and dose and duration of the drug and herb were not specified (Shaw et al. 1997).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of the safety of devil's claw preparations for osteoarthritic and low back pain included 28 clinical trials with a total of 6892 patients. The review included both double-blind and observational studies with doses of 2 to 27 g (most studies used 4.5 g) daily of devil's claw aqueous or ethanol extracts for durations of 3 to 54 weeks. In the double-blind studies, incidences of adverse events with devil's claw were less than or equal to those reported in placebo groups. In the observational studies, adverse events were reported in 3% of participants and were primarily gastrointestinal complaints and allergies. Allergic reactions to devil's claw were characterized as rare (Vlachojannis et al. 2008). Other systematic reviews have reported similar findings (Brien et al. 2006; Denner 2007; Gagnier et al. 2004).

Case Reports of Adverse Events

An allergic reaction to devil's claw, confirmed by provocation testing, was reported in a worker routinely exposed to devil's claw (Altmeyer et al. 1991).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Moderate inhibition of the drug-metabolizing isoenzymes CYP2C8, CYP2C9, CYP2C19, and CYP3A4 were observed in baculovirus-infected insect cells treated with a hydroalcoholic extract of devil's claw. The same extract caused mild inhibition of CYP1A2 and CYP2D6 (Unger and Frank 2004). Conversely, in another study, no effects on human CYP3A4 were observed (Budzinski et al. 2000).

An extract of devil's claw dose-dependently inhibited lipopolysaccharide-induced synthesis of TNF-α in stimulated primary human monocytes. The compounds harpagide and harpagoside had no effect on LPS-induced TNF-α release (Fiebich et al. 2001).

IV. Pregnancy and Lactation

Increases in the baseline tone and spontaneous, rhythmic, myogenic contractions of estrogen-dominated rat uterine muscle strips were observed after treatment with an aqueous extract of devil's claw. Effective concentrations were 10 to 800 µg/ml. The authors noted that the activity was consistent with traditional use for induction or acceleration of labor, or for expulsion of retained placentas (Mahomed and Ojewole 2006).

Devil's claw has traditionally been administered to pregnant women at doses of approximately 250 mg three times daily for pain relief during pregnancy. A reduced dose is used during the postpartum period (Watt and Breyer-Brandwijk 1962).

In mice embryos cultured from days 11 to 13 of gestation in a solution containing devil's claw, no effects on heartbeat, crown-rump length, embryo weight, or the total number of somites were observed, although short or curly

tail was associated with devil's claw treatment (Yokoyama et al. 2005).

No information on the safety of devil's claw during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered devil's claw could not be determined at doses up to 13.5 g/kg (Whitehouse et al. 1983). The LD_{50} of a 10% aqueous solution of devil's claw orally administered in mice is 220 ml/kg (Capresse 1980).

The LD_{50} of an intravenously administered purified extract of devil's claw (85% harpagoside) in mice is 511 mg/kg (Erdös et al. 1978), whereas that of pure harpagoside intraperitoneally administered to mice is 1 g/kg (Van Haelen et al. 1983).

Short-Term Toxicity

No adverse effects, including changes in hematology or gross pathology, were observed in mice orally administered 7.5 g/kg of devil's claw daily for 21 days (Whitehouse et al. 1983).

Hedeoma pulegioides (L.) Pers. — Lamiaceae

SCN: American pennyroyal

Part: herb

Quick Reference Summary

Safety Class: 2b, 2c
Interaction Class: A

Contraindications

Not for use during pregnancy or lactation (De Smet 1992; Sleckman et al. 1983).

Other Precautions

Not recommended for use in persons with liver or kidney disease (Gordon et al. 1982; Mizutani et al. 1987; Speijers 2001; Sztajnkrycer et al. 2003).

Not recommended for use in children or infants (Bakerink et al. 1996).

Drug and Supplement Interactions

None known.

Editors' Notes

American pennyroyal and European pennyroyal (*Mentha pulegium*) are historically interchangeable as sources for pennyroyal oil (De Smet 1992). American pennyroyal is reported to contain less of the toxic compound pulegone (0.0017–0.0057% of dried leaf) than European pennyroyal (0.8–1.9%) (Furia and Bellanca 1971; List and Hörhammer 1973; Lorenzo et al. 2002; Sleckman et al. 1983).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although animal or other studies on the use of American pennyroyal during pregnancy are lacking, the presence of the potentially toxic compound pulegone (*see* Toxicity Studies in *Mentha pulegium* herb and essential oil entries) suggests that American pennyroyal should not be taken during pregnancy (Sleckman et al. 1983).

No information on the safety of American pennyroyal during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Although animal or other studies on the use of American pennyroyal during pregnancy are lacking, the presence of the potentially toxic compound pulegone (*see* Toxicity Studies in entries for *Mentha pulegium* herb and essential oil) suggests that American pennyroyal should not be taken during pregnancy (De Smet 1992).

No information on the safety of American pennyroyal during lactation was identified.

V. Toxicity Studies

See Mentha pulegium herb and essential oil Toxicity Studies for information on the toxicity of the compound pulegone.

Helianthus annuus L. — Asteraceae

SCN: sunflower

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to sunflower seed, including anaphylactic reactions, have been reported (Asero et al. 2004; Duran et al. 1997; Fremont et al. 2002; Iwaya et al. 1994; Palma-Carlos et al. 2005).

Cases of bezoars (masses trapped in the gastrointestinal tract) have been reported in persons, primarily children, who have eaten "large" amounts of unshelled sunflower seeds (Bakr et al. 2006; Dent and Levine 1989; Lowry and Shah 2001; Melchreit et al. 1984; Sawnani and McFarlane-Ferreira 2003; Tsou et al. 1997).

A case of black hairy tongue was reported in a man who orally dehulled and consumed sunflower seeds nightly for 2 years (Pipili et al. 2008).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of sunflower during pregnancy or lactation was identified. Based on the widespread use of sunflower as a food and the seed oil as a cooking oil, no adverse effects are expected.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of suspected drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to sunflower, including anaphylactic reactions, have been reported and confirmed by skin prick tests and immunoblotting (Asero et al. 2004; Duran et al. 1997; Fremont et al. 2002; Iwaya et al. 1994; Palma-Carlos et al. 2005).

Numerous cases of rectal sunflower seed bezoars (a mass trapped in the gastrointestinal tract) have been reported in persons, primarily children, who have eaten "large" amounts of unshelled sunflower seeds (Bakr et al. 2006; Dent and Levine 1989; Lowry and Shah 2001; Melchreit et al. 1984; Sawnani and McFarlane-Ferreira 2003; Tsou et al. 1997).

Occupational asthma due to inhalation of sunflower dust was reported in a worker exposed to sunflower (Vandenplas et al. 1998).

Black hairy tongue, a benign hyperplasia of the surface of the tongue, was observed in a man who ate sunflower seeds for approximately 2 hours every night while watching television. The man removed the hulls by cracking the seeds with his teeth, and spitting out the hulls while keeping the kernels in his mouth. The tongue returned to normal after cessation of sunflower seed ingestion, nightly brushing of the tongue, and treatment with 40% urea solution (Pipili et al. 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of sunflower during pregnancy or lactation was identified.

V. Toxicity Studies

Subchronic Toxicity

No adverse effects, including changes in kidney function, serum chemistry, or organ weights, were observed in rats fed diets with sunflower protein isolates at amounts up to 13 g/kg daily for 90 days (Hoernicke et al. 1988).

Genotoxicity

Inconclusive results on the genotoxicity of sunflower seed oil were obtained in the *Drosophila* somatic mutation and recombination test (Rojas-Molina et al. 2005).

Clastogenic activity of a water extract of thermally stressed sunflower oil (heated to 180–220°C) was observed in human lymphocytes (Indart et al. 2007).

Hemidesmus indicus (L.) W.T. Aiton

Asclepiadaceae

SCN: *Hemidesmus indicus*
Syn: *Periploca indica* L.
AN: *sariva*

OCN: East Indian sarsaparilla
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of *Hemidesmus indicus* in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An ethanol extract of *Hemidesmus indicus* was found to reduce the toxicity of gentamicin to hair cells in organotypic cultures without affecting the uptake of gentamicin. The effective concentrations ranged from 25 to 100 µg/ml (Previati et al. 2007).

In sheep red blood cells, an ethanol extract of *Hemidesmus indicus* was found to suppress cell-mediated and humoral components of the immune system (Atal et al. 1986).

An aqueous extract of *Hemidesmus indicus* inhibited TNF-α and interleukin-8 in human peripheral blood mononuclear cells (Jain and Basal 2003).

IV. Pregnancy and Lactation

No information on the safety of *Hemidesmus indicus* during pregnancy or lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

In rats fed diets containing 25% *Hemidesmus indicus* for 14 days, diffuse hydropic degeneration and focal hepatocellular necrosis were observed in the livers (Arseculeratne et al. 1985). Conversely, a number of studies have demonstrated a hepatoprotective effect of alcohol extracts of *Hemidesmus indicus* administered at doses of 100 to 500 mg/kg for up to 30 days (Baheti et al. 2006; Prabakan et al. 2000; Saravanan and Nalini 2007a, 2007b, 2007c, 2008).

Syn: *Anemone hepatica* L.; *Hepatica americana* (DC.) Ker Gawl.
OCN: American liverleaf; round-lobe hepatica
Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Blumenthal et al. 1998; Moerman 1998).

Other Precautions

In large doses, irritation of the kidneys and urinary tract may be caused by the compound protoanemonin (Blumenthal et al. 1998).

Drug and Supplement Interactions

None known.

Editors' Notes

Liverwort, like several other species in the Ranunculaceae family, contains protoanemonin, a strongly irritating vesicant oil (Muhe 1947; Turner 1984). Protoanemonin, however, has a solubility of about 1% in water (Windholz 1983). Although the fresh herb can cause subepidermal blistering of the skin, the compound and the related concern are destroyed on drying (Epstein 1990; List and Hörhammer 1973; Mitchell 1979).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Ethnobotanical records indicate that liverwort was traditionally used as a contraceptive, to treat side or abdominal pain during pregnancy, to treat amenorrhea, and to induce labor in middle-aged women. Information on typical doses and durations used was not reported (Moerman 1998). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of liverwort during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Hibiscus sabdariffa L. — Malvaceae

SCN: hibiscus
AN: *ambashthaki*

OCN: roselle
Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Hibiscus may increase the elimination rate of acetaminophen without affecting the plasma levels or other parameters of acetaminophen. Investigators suggested that acetaminophen should be taken at least 3 h ours before or after the ingestion of hibiscus (Kolawole and Maduenyi 2004).

A human study indicated that hibiscus has mixed effects on the urinary excretion of diclofenac, with excretion increased in some patients and reduced in others (Fakeye et al. 2007). Another human study indicated that hibiscus juice may reduce the bioavailability of chloroquine, with effects of hibiscus similar to those of lemonade and a tamarind beverage. Investigators recommended not taking

chloroquine tablets with acidic beverages (Mahmoud et al. 1994).

Pregnancy and Lactation

No adverse effects of large doses of hibiscus on pregnancy or fetal development were observed in several animal studies. In animals administered very large doses (1.5 or 3 g/kg) of hibiscus during pregnancy or lactation, a decrease in maternal food and water intake and associated delay in puberty in offspring were observed (Iyare and Adegoke 2008a, 2008b; Iyare and Iyare 2008).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

An increase in the elimination rate of acetaminophen was observed in healthy volunteers orally administered 1 liter of sweetened aqueous extract of hibiscus (made from 30 g of hibiscus/liter) 1.5 hours prior to oral administration of acetaminophen (1000 mg). No changes in the maximum plasma concentration, time to maximum concentration, or area under the time-concentration curve were observed. The authors of the study indicated that acetaminophen should be taken at least 3 hours before the ingestion of hibiscus so that the therapeutic activity of acetaminophen will not be shortened (Kolawole and Maduenyi 2004).

Changes in urinary excretion of diclofenac were observed in healthy volunteers pretreated with 300 ml of an aqueous hibiscus extract (containing 8.18 mg anthocyanins) daily for 3 days. Urinary excretion was increased in some volunteers and decreased in others (Fakeye et al. 2007).

A reduction in serum levels of chloroquine was observed in healthy volunteers orally administered 600 mg chloroquine with 300 ml of a juice made from hibiscus (amount of plant material used was not specified). The effects of hibiscus were similar to those of lemonade and a tamarind beverage, with the acidity of all beverages believed to be the cause of reduced absorption. The authors of the study recommended not taking chloroquine tablets with acidic beverages (Mahmoud et al. 1994).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a tolerability study in hypertensive patients, an infusion prepared from 10 g hibiscus taken daily for 4 weeks was well tolerated (Herrera-Arellano et al. 2004).

Animal Pharmacological Studies

Intraperitoneal administration of 100, 200, or 400 mg/kg of an aqueous extract of hibiscus reduced the spontaneous motor activity and increased the duration of pentobarbital-induced sleeping time in mice (Amos et al. 2003).

A reduction in blood glucose after rice starch and or sucrose challenges was observed in rats orally administered 0.5 g/animal (344–442 g average animal weight) of hibiscus extract. No significant changes in blood glucose levels were observed when hibiscus was administered outside of the challenge tests (Preuss et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

An aqueous extract of hibiscus dose-dependently inhibited the rate and amplitude of uterine contractions in rats after intra-arterial injection of 1, 5, 10, 50, or 100 mg/kg. The uterine response to hibiscus was not affected by administration of either atropine or propranolol. At the 500 mg/kg dose, hibiscus produced a slight reduction of contraction amplitude in oxytocin-precontracted uteruses (Fouda et al. 2007).

In rats provided with drinking water containing an aqueous extract of hibiscus at a concentration that provided doses equivalent to 1.5 or 3.0 g/kg extract daily throughout pregnancy, a decrease in maternal food and fluid intake was observed; in offspring, an increase in postnatal weight gain and delay in onset of puberty were observed (Iyare and Adegoke 2008c). A follow-up study indicated that the delay in puberty onset in the offspring was associated with elevated maternal plasma levels of sodium and corticosterone during pregnancy (Iyare and Adegoke 2008b).

In rats provided with drinking water containing 0.6 or 1.8 g/100 ml of aqueous extract of hibiscus throughout pregnancy and through postnatal day 20, no adverse effects on early postnatal growth of offspring were observed (Iyare and Iyare 2008).

In lactating rats provided with drinking water containing 0.6 or 1.8 g/100 ml of aqueous extract of hibiscus

throughout lactation (21 days), a decrease in maternal food and fluid intake was observed along with increased postnatal weight gain and delayed onset of puberty in the offspring (Iyare and Adegoke 2008a).

V. Toxicity Studies

Acute Toxicity

The LD_{50} in rats was 5 g/kg of an orally administered hibiscus aqueous extract prepared from dried hibiscus calyx and described as yielding 22% of the dry plant material (Onyenekwe et al. 1999; Orisakwe et al. 2004). The LD_{50} of an intraperitoneally administered aqueous extract of hibiscus could not be determined at doses up to 5 g/kg (Amos et al. 2003).

Subchronic Toxicity

No changes in testicular weights were observed in rats orally administered 1.15, 2.30, or 4.60 g/kg of an aqueous extract of hibiscus daily for 12 weeks. A decrease in the epididymal sperm counts and disintegration of sperm cells were observed in the 4.6 g/kg group. Distortion of tubules and a disruption of normal epithelial organization were observed in the 1.15 g/kg group, and hyperplasia of the testes with thickening of the basement membrane was observed in the 2.3 g/kg group (Orisakwe et al. 2004).

In rats orally administered 300 or 2000 mg/kg (~10,000 and 66,000 times the average human dose) of an aqueous, aqueous-ethanolic, or ethanolic extract of hibiscus daily for 90 days, all animals at the 2000 mg/kg dose had severe diarrhea by day 3. By day 8, all in the ethanol extract group had died, and by day 28 all from the aqueous-ethanolic extract group had died. In the 300 mg/kg group, animals developed mild diarrhea, all of the animals in the aqueous-ethanolic extract group died by day 40, and 80% of the animals in the aqueous extract group died by day 60. No mortality was observed in the animals in the ethanol extract group (Fakeye et al. 2009).

In rats orally administered 1, 3, 5, 10, or 15 doses of 250 mg/kg each of a hydromethanolic extract of hibiscus daily, serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels were increased in all the treatments, as compared to the control group. Serum levels of alkaline phosphatase and lactate dehydrogenase were not significantly affected. In the group that received 15 doses, serum levels of albumin were elevated. Histopathological studies indicated no pathological changes in livers or hearts in any of the treatment groups (Akindahunsi and Olaleye 2003).

Genotoxicity

No chromosomal aberrations were observed in lymphocytes of rats that had been intraperitoneally administered up to 200 mg/kg, twice at a 24-hour interval, of a hydroethanolic extract of hibiscus (Sowemimo et al. 2007).

Mutagenic activity of a food colorant derived from hibiscus was observed in the Ames assay in *Salmonella typhimurium* strains TA98 and TA100 with or without activation by S9. The compounds responsible for the mutagenic activity were identified as kaempferol and/or quercetin (Takeda and Yasui 1985). Although quercetin has been shown to have mutagenic activity in vitro, in vivo tests indicate a lack of mutagenicity in animals (Harwood et al. 2007).

Hoodia gordonii (Masson) Sweet ex Decne — Apocynaceae

SCN: *Hoodia gordonii*
Syn: *Stapelia gordonii* Masson

Part: fleshy stem

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Editors' Note
Numerous cases of adulteration of *Hoodia gordonii* with *Opuntia* species and *Caralluma fimbriata have been reported (Avula et al. 2007; Rumalla et al. 2008).*

Adverse Events and Side Effects
None known.

Pharmacological Considerations
An in vitro study indicated that *Hoodia gordonii* inhibited the drug-metabolizing isoenzyme CYP3A4 but had no effects on other CYP450 isoenzymes (Madgula et al. 2008). The relevance of those data to human use is not known.

Pregnancy and Lactation
No information on the safety of *Hoodia gordonii* in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
A report on adverse events associated with natural health products in Italy from the Italian Pharmacovigilance System indicated that one case of acute hepatitis was reported in a person taking a *Hoodia gordonii* product along with other products including deanol, acetoaminobenzoate, iodocasein, metformin, triiodoacetic acid, and furosemide. Details on the *Hoodia gordonii* product, dose, and duration taken and the patient medical history were not provided (Menniti-Ippolito et al. 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed in human liver microsomes treated with a steroidal glycoside compound (P57) from *Hoodia gordonii*, with a 50% inhibitory concentration (IC_{50}) of 45 µ*M*. No effects on the activity of CYP1A2, CYP2C9, or CYP2D6 were observed (Madgula et al. 2008).

In human colon cancer epithelial cells (Caco-2), the compound P57 exhibited a higher transport in the secretory direction than in the absorptive direction, and efflux was inhibited by selective inhibitors of multidrug resistance-associated proteins MRP1/MRP2 (MK-571) and P-gp (Madgula et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of *Hoodia gordonii* in pregnancy or lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

No adverse effects were observed in rats fed a diet containing 2% of an aqueous homogenate of dried *Hoodia gordonii* daily for 3 weeks (Tulp et al. 2001).

Hordeum vulgare L.

Poaceae

SCN: barley
AN: *yava*

PN: *mai ya* (dried germinated ripe seed)
Part: sprouted seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to barley, including anaphylactic reactions, have been reported (Bonadonna et al. 1999; Curioni et al. 1999; Gutgesell and Fuchs 1995).

Pharmacological Considerations

Human and animal studies have demonstrated that barley may modify glucose regulation (Chang and But 1986; Chen and Chen 2004). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of sprouted barley in pregnancy was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant women, safety has not been conclusively established.

Sprouted barley is used in large doses (typically 30–60 g, sometimes up to 120 g daily) to reduce or stop lactation. However, small doses (up to 9 g) are considered to promote lactation (Bensky et al. 2004; Chen and Chen 2004). Large doses of sprouted barley should not be used by women who are lactating and wish to continue to do so.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions after consumption of beer containing barley have been reported. The reactions included anaphylactic reactions, generalized urticaria with angioedema, and contact dermatitis. Skin-prick testing confirmed barley as the causative agent (Bonadonna et al. 1999; Curioni et al. 1999; Gutgesell and Fuchs 1995).

Occupational asthma and contact dermatitis due to barley grain dust has been reported in workers routinely exposed to barley dust (Cronin 1979; Pereira et al. 1998; Vidal and Gonzalez-Quintela 1995; Yap et al. 1994).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Oral administration of an aqueous extract of barley was reported to lower blood sugar in humans. Dose and duration of use were not specified in English language translations (Chang and But 1986; Chen and Chen 2004).

Animal Pharmacological Studies

Oral administration of an aqueous extract of barley was reported to lower blood sugar in rabbits. Dose and duration of use were not specified in English language translations (Chang and But 1986; Chen and Chen 2004; Donard and Labbe 1932).

In Vitro Pharmacological Studies

No relevant in vitro studies were identified.

IV. Pregnancy and Lactation

No information on the safety of sprouted barley in pregnancy was identified. While this review did not identify any concerns for pregnant women, safety has not been conclusively established.

Sprouted barley is used in large doses (typically 30–60 g, sometimes up to 120 g daily) to reduce or stop lactation (Bensky et al. 2004; Chen and Chen 2004). Unless this is the desired effect, sprouted barley is contraindicated in lactation. However, small doses (up to 9 g) are considered to promote lactation (Bensky et al. 2004; Chen and Chen 2004).

V. Toxicity Studies

No toxicity studies were identified.

Humulus lupulus L. — Cannabinaceae

SCN: hops

Part: strobilus

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to hops have been reported, primarily in farm or brewery workers regularly exposed to fresh or dried hops (Estrada et al. 2002; Godnic-Cvar et al. 1999; Gora et al. 2004a, 2004b; Newmark 1978; Pradalier et al. 2002; Spiewak and Dutkiewicz 2002; Spiewak et al. 2001).

Pharmacological Considerations

Hops contains the compound 8-prenylnaringenin (8-PN), which has been shown to have selective estrogen receptor-modulating activity in animals and in vitro studies (Chadwick et al. 2006; Milligan et al. 1999, 2002; Zanoli and Zavatti 2008).

Animal studies provide conflicting results on the effects of hops on sedative-induced sleeping time. Some studies showed that extracts of hops can prolong sleeping time induced by pentobarbital and ketamine (Schiller et al. 2006; Zanoli et al. 2005), whereas another study suggested that hops causes a decrease in the hypnotic effect of pentobarbital (Raskovic et al. 2007).

Pregnancy and Lactation

No information on the safety of hops in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Intraperitoneal administration of alcoholic extracts of the Magnum variety of hops at doses of 10 ml/kg (1:2 extract) to mice, one day to several hours prior to receiving 25 mg/kg cocaine, almost completely suppressed the action of cocaine compared to controls. Other varieties (Aroma and wild genotypes) administered according to the same regimen also decreased the cocaine-induced locomotor activity of mice, but to a lesser extent (Horvat et al. 2007).

Ethanol extracts of Magnum and Aroma varieties of hops, intraperitoneally administered to mice at doses of 10 ml/kg four times in 24 hours prior to administration of pentobarbital (40 mg/kg) or diazepam (3 mg/kg), suppressed the hypnotic action of the drugs. No effects on pentobarbital and diazepam were observed after administration of the same extract of a wild genotype of hops (Raskovic et al. 2007). A CO_2 extract of hops, orally administered to rats, produced a dose-dependent increase in pentobarbital-induced sleeping time beginning at a dose of 10 mg/kg. A dose of 5 mg/kg had no effect on sleeping time (Zanoli et al. 2005). Ethanol and CO_2 extracts of the hops variety Perle 99, administered at doses of 200 mg/kg, increased the ketamine-induced sleeping time. Sleeping time was not affected by a dose of 100 mg/kg (Schiller et al. 2006).

A significant increase in analgesic activity was observed in mice intraperitoneally administered an alcoholic extract of hops at doses of 10 ml/kg (1:2 extract), one day to several hours prior to receiving 80 mg/kg paracetamol (Horvat et al. 2007).

II. Adverse Events

Case Reports of Adverse Events

Occupational asthma, contact and airborne dermatitis, and anaphylactic reactions to fresh and dried hops have been reported in farm and brewery workers (Estrada et al. 2002; Godnic-Cvar et al. 1999; Gora et al. 2004a, 2004b; Newmark 1978; Pradalier et al. 2002; Spiewak and Dutkiewicz 2002; Spiewak et al. 2001). Hops was 1 of 10 antigens that provoked anaphylaxis in a skin prick test series of 79 food antigens in patients with a diagnosis of idiopathic anaphylaxis (Stricker et al. 1986).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Single oral doses of 50, 250, or 750 mg of the compound 8-PN were well tolerated in postmenopausal women (Rad et al. 2006).

Animal Pharmacological Studies

In rats, the compound 8-PN was shown to have estrogenic activity in reproductive tissue about 20,000-fold weaker compared to 17β-estradiol (Schaefer et al. 2003). Doses of 0.67 to 18 mg/kg of 8-PN daily administered subcutaneously to mice for 28 days completely inhibited ovariectomy-induced bone loss while exhibiting minimal, dose-independent, trophic effects on uterus and endometrium (Humpel et al. 2005).

Five dogs, four of which were greyhounds, developed hyperthermia, restlessness, panting, vomiting, signs of abdominal pain, and seizures after ingestion of spent hops, and four of the five dogs died despite aggressive therapeutic measures (Duncan et al. 1997).

Lupulones, notably the compound colupulone, induced the drug-metabolizing isoenzyme CYP3A in mice (Mannering et al. 1992).

In Vitro Pharmacological Studies

A methanol extract of hops showed significant competitive binding to estrogen receptors alpha (ERα) and beta (ERβ), exhibited estrogenic activity in cultured endometrial cells, induced alkaline phosphatase activity, upregulated presenelin-2 (an estrogen-inducible gene) in S30 breast cancer cells, and upregulated progesterone receptor mRNA. For estrogen receptor binding, IC_{50} (the concentration that provided 50% inhibition) was 30 μg/ml for ERα and 27 μg/ml for ERβ, while for alkaline phosphatase the IC_{50} was 13 μg/ml (Liu et al. 2001).

A fraction of a CO_2 extract of hops showed an estrogenic potential equivalent to that of red clover. The extract demonstrated competitive ER binding, activation of transiently transfected ERE-luciferase, and alkaline phosphatase enzyme induction (Overk et al. 2005).

A hydroethanolic extract of hops bound to estrogen receptors in the estrogen receptor (ER)-positive human breast cancer cell line MCF-7. The same extract did not bind to progesterone receptors in the human breast cancer cell line T-47D (Zava et al. 1998). The extract stimulated the proliferation of T-47D (ER positive) cells but had no effect on MDA486 (ER negative) cells (Zava et al. 1998). An extract of hops was shown to have growth-inhibitory activity on estrogen receptor-positive breast cancer cell lines MCF-7 and T-47D (Dixon-Shanies and Shaikh 1999).

Binding and transcription studies with 8-PN demonstrated that the compound bound to both receptors, with a more than twofold preference for ERα over ERβ. 8-PN was shown to be 10-fold more potent than coumestrol and 100-fold stronger than genistein but 70 times weaker than 17β-estradiol (Schaefer et al. 2003). A similar study indicated that 8-PN exhibited a slight preference for ERβ over ERα (Milligan et al. 2000). The compound 8-PN was shown to have proliferative activity in MCF-7 cells (Effenberger et al. 2005).

IV. Pregnancy and Lactation

No information on the safety of hops during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered ethanolic extract of hops in mice is 3.5 g/kg and in rats is 2.7 g/kg. The LD_{50} of an orally administered ethanol extract of hops in mice is 2.7 g/kg and in rats is 0.415 g/kg (Hansel and Wagener 1967). The LD_{50} of orally administered lupulone in mice is 525 mg/kg (Hansel and Wagener 1967).

No adverse effects were observed in rats orally administered a single dose of 2 g/kg of hops polyphenols (Nagasako-Akazome et al. 2007).

Short-Term Toxicity

No signs of toxicity were observed in rats subcutaneously administered 30 mg/kg of the compound 8-PN daily for 2 weeks (Miyamoto et al. 1998).

No adverse effects on major organ functions or protein, lipid, or carbohydrate metabolism were observed in rats orally administered the compound xanthohumol ad libitum in drinking water at a concentration of 0.0005 *M* for 28 days (Vanhoecke et al. 2005).

In mice administered a diet containing 2 or 4% lupulone for 40 days, leukocytic infiltration into the lungs and some cases of bronchopneumonia were observed (Chin and Anderson 1950).

Subchronic Toxicity

No adverse effects on blood chemistry, organ weights, or histology were observed in rats orally administered hops polyphenols at doses up to 2 g/kg daily for 90 days (Nagasako-Akazome et al. 2007).

Oral administration of the compounds hexahydroisohumulone at doses of 10, 25, 35, or 50 mg/kg or tetrahydroisohumulone at doses of 25, 50, or 100 mg/kg daily for 14 weeks to beagle dogs showed that the compounds were generally well tolerated. At the high dose levels, both compounds induced vomiting, and much of the material administered was excreted in the feces. The no-observed-adverse-effect level (NOAEL) was 50 mg/kg for hexahydroisohumulone and 100 mg/kg for tetrahydroisohumulone (Chappel et al. 1998).

Genotoxicity

A slight mutagenic effect of hops polyphenols was observed at concentrations of 5000 µg/plate in the Ames test in the absence of S9 mix for TA98 and in the presence of S9 mix for TA1537. No mutagenic activity of the same extract was observed in the micronucleus test (Nagasako-Akazome et al. 2007).

Cytotoxicity

Flavonoids isolated from hops were shown to have cytotoxic effects at high concentrations (at or above 10−4 *M*) (Effenberger et al. 2005).

Hydrangea arborescens L.

Hydrangeaceae

SCN: hydrangea
OCN: seven barks; wild hydrangea

Part: root

Quick Reference Summary

H

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known

Drug and Supplement Interactions

None known.

Notice

Cyanogenic glycosides (hydrangin, ~1–3%) (Bondurant 1887; Cook and Martin 1948; Palmer 1963); *see* Appendix 1.

Editors' Note

The flower and leaf of hydrangea are reported to have caused toxic symptoms in humans. This is assumed to be due to the cyanogenic glycoside hydrangin, which is also reported to be found in the root (Bondurant 1887; Leung and Foster 1996; List and Hörhammer 1973).

Adverse Events and Side Effects

Allergic contact dermatitis to *Hydrangea* species has been reported, primarily in agricultural workers (Avenel-Audran et al. 2000; Bruynzeel 1986, 1991; De Rooij et al. 2006; Kuligowski et al. 1992; Meijer et al. 1990; Rademaker 2003).

Overdose of hydrangea (standard dose listed as 2 g) has been reported to cause dizziness and a sense of oppression of the chest (Felter and Lloyd 1898; Powers et al. 1942).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of hydrangea in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis to *Hydrangea* species has been reported, primarily in agricultural workers (Avenel-Audran et al. 2000; Bruynzeel 1986, 1991; De Rooij et al. 2006; Kuligowski et al. 1992; Meijer et al. 1990; Rademaker 2003).

Overdose of hydrangea has been reported to cause dizziness and a sense of oppression of the chest (Felter and Lloyd 1898).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of hydrangea during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Hydrastis canadensis L.

Ranunculaceae

SCN: goldenseal
OCN: yellow puccoon; yellow root

Part: rhizome, root

Quick Reference Summary

Safety Class: 2b
Interaction Class: C

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bradley 1992; List and Hörhammer 1973; Mills and Bone 2005).

Other Precautions

Use of goldenseal during lactation is not recommended (Mills and Bone 2005).

Drug and Supplement Interactions

Goldenseal may slow the metabolism of drugs metabolized by the drug-metabolizing isoenzymes CYP3A4 and CYP2D6 (Gurley et al. 2005, 2008a, 2008b). *See* Appendix 3.

Notice

Berberine (0.5–6%) (Upton 2001); *see* Appendix 1.

Editors' Notes

Most safety concerns reported for goldenseal are based on studies of the compound berberine and other alkaloids. Data regarding isolated compounds may not apply directly to products or extracts made from the whole rhizome and root. Berberine has been shown to exhibit a number of bioactivities including cytotoxicity in cancer cell lines (Kettmann et al. 2004; Kim et al. 2005; Orfila et al. 2000) and topoisomerase I and II inhibition (Kim et al. 1998; Mantena et al. 2006).

Studies have indicated that the antimicrobial action of berberine may be potentiated by nonantimicrobial compounds found in berberine-containing plants, indicating a synergistic action of compounds (Stermitz et al. 2000).

Adverse Events and Side Effects

No cases of adverse events associated with the use of goldenseal were identified.

Pharmacological Considerations

Human studies have shown that goldenseal may inhibit drug-metabolizing isoenzymes CYP3A4 and CYP2D6, slowing the clearance of drugs metabolized by these enzymes and increasing plasma levels of these drugs (Gurley et al. 2005, 2008a, 2008b). *See* Cytochrome CYP450 in Appendix 3.

Pregnancy and Lactation

Goldenseal is contraindicated in pregnancy in several contemporary texts on herbal safety (Brinker 2001; Mills et al. 2006; Mills and Bone 2005). These contraindications are based primarily on uterine stimulant activity of the isolated compound berberine in excised mouse uteruses (Furuya 1957; Imaseki et al. 1961) and the potential ability of berberine to displace bilirubin and cause neonatal jaundice (Chan 1993). Although definitive data confirming the safety of goldenseal during pregnancy is lacking, several reproductive toxicity studies of goldenseal and the isolated compound berberine in mice and rats have shown no adverse effects on the fetus at doses equivalent to over 45 times the standard human dose (Jahnke et al. 2006; NTP 2002; Price 2003; Yao et al. 2005).

Some concerns exist for use of berberine-containing plants during pregnancy, including uterine stimulation (Furuya 1957; Imaseki et al. 1961), although no adverse effects were observed in rats administered high doses of goldenseal during pregnancy (Yao et al. 2005).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No effects on digoxin were observed after oral administration of 3210 mg daily of goldenseal for 14 days (Gurley et al. 2007). No effects on indinavir were observed after administration of 2280 mg daily of goldenseal for 14 days (Sandhu et al. 2003).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

The compound berberine has been shown to significantly prolong pentobarbital-induced sleeping time in rats (Janbaz and Gilani 2000).

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse events were reported in the identified clinical trials of goldenseal (Gurley et al. 2005; Gurley et al. 2007).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Significant inhibition of the drug-metabolizing isoenzymes CYP2D6 and CYP3A4/5 was observed after oral administration of goldenseal for 14 (3210 or 3960 mg daily) or 28 days (2700 mg daily). No effect was observed on isoenzymes CYP1A2 and CYP2E1 (Gurley et al. 2005; Gurley et al. 2008a, 2008b). Goldenseal administered for 14 days (3210 mg daily) had no significant effect on P-glycoprotein function (Gurley et al. 2007).

Intravenous administration of the compound berberine (0.2 mg/kg/min) caused a significant decrease in blood pressure (Marin-Neto et al. 1988).

Animal Pharmacological Studies

Chronic administration of berberine to rats was shown to significantly decrease bilirubin protein binding at doses of 10 to 29 mg/kg (administered intraperitoneally), although at doses of 2 mg/kg the displacement was not significant (Chan 1993). Berberine is speculated to have possible interactions with drugs that displace bilirubin protein binding (Mills and Bone 2005).

Berberine was shown to promote blood coagulation in mice and rats (Ziablitskii et al. 1996).

In Vitro Pharmacological Studies

Two in vitro studies indicated that goldenseal tincture and the compound berberine significantly inhibit the drug-metabolizing isoenzyme CYP3A4 (Foster et al. 2003; Janbaz and Gilani 2000).

At non-relaxant doses, goldenseal extract was shown to potentiate the relaxant effects of isoprenaline in isolated guinea pig trachea (Abdel-Haq et al. 2000).

Berberine has been shown to increase the efflux of paclitaxel and rhodamine in human digestive tract and liver cancer cells by inducing P-glycoprotein (Chatterjee and Franklin 2003). Berberine may interfere with the action of tetracycline in the treatment of cholera (Khin et al. 1985).

IV. Pregnancy and Lactation

In rats administered daily doses of goldenseal at 65 times the human dose on either gestation days 1 through 8 or 8 through 15, no signs of maternal toxicity or effects on fertility, and no adverse effects in fetuses were observed

(Yao et al. 2005). In a related ex vivo study, dose-dependent adverse effects on development were observed in fetuses prematurely removed and subsequently treated with goldenseal extract. Fetuses treated with 2, 4, or 6 µg/ml had decreased length, number of somites, yolk sac size, brain size, and forelimb size (Yao et al. 2005). The authors of the study noted that the lack of adverse effects observed in vivo indicated that goldenseal may not be absorbed and available to fetuses (Yao et al. 2005).

No adverse effects were observed in pregnant mice or their fetuses administered doses of 2 g/kg goldenseal (5% berberine) daily on gestational days 6 to 17. A reduction in fetal weight was reported in offspring of mice administered 7.7 g/kg daily of goldenseal and an increase in maternal liver weight was reported in animals consuming more than 2 g/kg. The 7.7 g/kg dose rate is approximately 300 times the estimated average human dose (26 mg/kg) (NTP 2002).

No adverse effects were observed in pregnant rats administered goldenseal (5% berberine) at doses of 200 mg/kg on gestational days 6 to 20 or 0 to 20. At doses of 415 mg/kg or more, a dose-related increase was noted in maternal liver weight. At doses up to 1215 mg/kg daily, no effects were seen on prenatal mortality, average live litter size, average fetal body weight, or percent male fetuses per litter. No statistically significant dose-response patterns for malformations were seen, although a limited number of fetuses had multiple malformations; based on the absence of a dose-response relationship, however, these findings were not believed to be treatment-related (Price 2003).

In pregnant rats fed the compound berberine on gestational days 6 to 20, some reduction in maternal weight gain was observed, with a lowest-observed-adverse-effect level (LOAEL) of 530 mg/kg daily. Only a mild reduction in fetal weights was observed, and the LOAEL based on fetal weight reduction was 1000 mg/kg (Jahnke et al. 2006). Similarly, in mice administered berberine on gestational days 6 to 17, the maternal LOAEL was determined to be 531 mg/kg daily, and the developmental toxicity level was 1000 mg/kg daily (Jahnke et al. 2006).

A number of cases of kernicterus (brain damage caused by neonatal jaundice) were reported in south Asian countries in the 1970s and 1980s. Chinese goldthread (*Coptis chinensis*) was a common ingredient in traditional formulas used in pregnant women and newborns and has been shown to prevent bilirubin from binding to serum protein. Chinese goldthread contains berberine (also present in goldenseal), the compound believed to be responsible for the jaundice (Upton 2001), as berberine was shown to displace bilirubin in rats (*see* Animal pharmacological studies). A review of traditional Chinese medicine use in cases of neonatal jaundice indicated that no association could be made between maternal use of Chinese goldthread during pregnancy and neonatal jaundice (Fok 2001).

Berberine has been shown to stimulate uterine contractions in both pregnant and nonpregnant mice (Furuya 1957; Imaseki et al. 1961). A study of various berberine-containing herbal extracts on isolated uteruses, however, indicated that relaxation or stimulation of the uterus did not correlate with the concentration of berberine in the extract, suggesting that not all berberine-containing herbs will have the same effect on the uterus (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

V. Toxicity Studies

Acute Toxicity

In mice, the oral LD_{50} of goldenseal is 1.62 g/kg, whereas that of berberine is 329 mg/kg (Haginiwa and Harada 1962). The LD_{50} of orally administered berberine sulfate in rats could not be determined at doses up to 1000 mg/kg (Kowalewski et al. 1975).

Short-Term Toxicity

In a two week toxicity study, rats and mice were fed diets containing 0.156, 0.3121, 0.625, 1.25, 2.5, or 5% goldenseal. Liver weights of male rats administered 0.625% or higher and female rats administered 1.25% or higher were significantly greater than those of the controls. Minimal to moderate hepatocellular hypertrophy occurred in several males and all females administered 2.5% diets and in all males and females at the 5% dose (NTP 2010). Increases in liver weights occurred in male mice exposed at the 2.5 or 5% diets and in females on the 5% diet. Absolute and relative thymus weights of male mice in the two highest dose groups decreased. Minimal hypertrophy of centrilobular hepatocytes occurred in all males and females at the highest goldenseal concentration. The left epididymal weight in male mice was significantly decreased relative to controls. The incidences of hepatocyte hypertrophy were significantly increased in male and female mice exposed to 12,500 ppm or greater (NTP 2010).

Subchronic Toxicity

In a 90-day toxicity study, rats and mice were fed diets containing 0.156, 0.3121, 0.625, 1.25, 2.5, or 5% goldenseal. Liver weights were significantly increased in male rats fed diets containing 0.625% or greater and in all exposed groups of females. The incidences of hepatocyte hypertrophy were increased in the liver of male and female rats fed concentrations of 1.25% or more. In mice, liver weights were increased in males fed diets containing 1.25% or more goldenseal and in females fed diets containing 2.5 or 5% goldenseal (NTP 2010).

Chronic Toxicity

In a two-year toxicity study, rats and mice were fed diets containing 0.3, 0.9, or 2.5% goldenseal, equivalent to average

daily doses of approximately 135, 400, or 1175 mg/kg for male rats; 150, 470, or 1340 mg/kg for female rats; 375, 1120, or 3275 mg/kg for male mice; and 330, 1000, or 2875 mg/kg for female mice. These doses and the treatment duration are approximately equivalent to human exposure of 18, 54, and 150 g, given daily for 70 years (Hayes 2007). The standard oral dose for humans is 2 g daily (Upton 2001), and there are no uses recorded for goldenseal root that would recommend daily use over an entire lifetime. Survival was significantly greater than that of controls in female rats fed at the 0.9% level and significantly less in female mice at the same level, although the final report of the study states that survival "of all exposed groups of animals was similar to their controls." The rates of adenomas (benign tumors) of the liver was increased in male and female rats receiving 2.5% goldenseal, and male mice receiving goldenseal had increased rates of liver blastomas and multiple adenomas. The report concluded that, there was "no evidence of carcinogenic activity" of goldenseal in female mice at any of the feeding levels; "some evidence of carcinogenic activity" in male mice "based upon the increased incidence of hepatoblastoma in the 25,000 ppm [2.5%] group and the increased incidences of multiple hepatocellular adenoma in all exposed groups"; and "clear evidence of carcinogenic activity" in male and female rats as the study recorded, at the highest dosage level, that incidences of hepatocellular adenoma or hepatocellular carcinoma combined (note that the results "combined" a single carcinoma and several adenomas) in males and of hepatocellular adenoma in females "exceeded the current and historical control rates (NTP 2010)." A review of the report indicated, however, that these latter conclusions were "not appropriate" for a number of reasons, including that the one hepatocellular carcinoma at the high dose in a male rat "is within historic control incidence" (Beyer et al. 2009). Some potential protective roles of goldenseal root were recorded in this two-year feeding study. For example, incidences of cardiomyopathy were "significantly decreased in all exposed groups" of male rats and in the highest-dosed female rats, and the incidences of fibroadenoma of the mammary gland "occurred with a negative trend and were significantly decreased in all exposed groups" of female rats (NTP 2010).

Genotoxicity

No mutagenic activity of goldenseal was observed in *Salmonella typhimurium* strains TA100 or TA98 or *Escherichia coli* strain WP2 *uvrA* pKM101 with or without metabolic activation with S9. No increase in the frequency of micronucleated normochromatic (mature) erythrocytes was observed in peripheral blood samples from male or female B6C3F1 mice exposed to goldenseal root powder in feed (3121 to 50,000 ppm) for 3 months, and no significant exposure-related changes in the percentages of polychromatic (immature) erythrocytes were observed in peripheral blood of these mice, suggesting that no exposure-related bone marrow toxicity of goldenseal occurred (NTP 2010).

Hypericum perforatum L. — Clusiaceae

SCN: St. John's wort

Part: flowering top, herb

Quick Reference Summary

Safety Class: 2d
Interaction Class: C*

Contraindications

St. John's wort should not be used during phototherapy (laser or ultraviolet) (Beattie et al. 2005).

Other Precautions

Avoidance of excessive exposure to sunlight during St. John's wort use is warranted in fair-skinned persons (Martindale and Reynolds 1996; Weiss and Meuss 2001; Wichtl 2004).

* Low-hyperforin and hyperforin-free extracts are commercially available and are believed to be less likely to interact with drugs than extracts with standard amounts of hyperforin (Madabushi et al. 2006).

Drug and Supplement Interactions

St. John's wort has been shown to induce certain drug-metabolizing enzymes in the CYP450 enzyme system and the drug transporter protein P-glycoprotein (P-gp). Such induction may decrease the blood levels of certain orally administered drugs through increased metabolism or efflux, resulting in decreased therapeutic activity of these drugs. In human studies, significant induction of the enzyme CYP3A4 (Bauer et al. 2003; Dresser et al. 2003; Gurley et al. 2002, 2005; Wang et al. 2001) and some evidence of induction of the enzyme CYP2C19 have been shown (Wang et al. 2004a, 2004b), leading to reduced plasma levels of drugs metabolized by these enzymes or transported by P-gp. *See* CYP450 in Appendix 3 for more information.

The compound hyperforin is believed to be primarily responsible for the effects of St. John's wort on CYP450 enzymes and P-gp (Gerhard 2005; Mueller et al. 2004).

Human studies and case series have demonstrated that St. John's wort may decrease plasma levels of the following drugs (Borrelli and Izzo 2009):

Immunosuppressants: Cyclosporine (Bauer et al. 2003; Mai et al. 2004), tacrolimus (Hebert et al. 2004; Mai et al. 2003)
Anticoagulants: Warfarin (Jiang et al. 2004, 2006), phenprocoumon (Maurer et al. 1999)
Antiarrhythmics: Digoxin (Durr et al. 2000; Johne et al. 1999; Mueller et al. 2004), verapamil (Tannergren et al. 2004)
Calcium channel blockers: Nifedipine (Smith et al. 2001), verapamil (Tannergren et al. 2004)
Anti-anginals: Ivabradine (Portoles et al. 2006)
Hormonal contraceptives: Ethinylestradiol, norethindrone (Hall et al. 2003; Murphy et al. 2005; Pfrunder et al. 2003)
Anxiolytics: Quazepam (Kawaguchi et al. 2004), midazolam (Dresser et al. 2003; Gurley et al. 2002, 2005; Mueller et al. 2006; Xie et al. 2005), alprazolam (Markowitz et al. 2000, 2003)
Antidepressants (tricyclic): Amitriptyline (Johne et al. 2002)
Antivirals: Indinavir (Piscitelli et al. 2000), nevirapine (de Maat et al. 2001; L'homme et al. 2006)
Statins: Simvastatin (Sugimoto et al. 2001), atorvastatin (Andrén et al. 2007)
Anticancer drugs (chemotherapy and other) Irinotecan (Mathijssen et al. 2002), imatinib (Frye et al. 2004; Smith 2004)
Beta-adrenergic blockers: Talinolol (Schwarz et al. 2007)
Hypoglycemics: Gliclazide (Xu et al. 2008)
Antiulcer agents: Omeprazole (Wang et al. 2004a)
Antifungals: Voriconazole (Rengelshausen et al. 2005) (increase of plasma levels with single St. John's wort dose, decrease after continued use)
Anticonvulsants: Mephenytoin (Wang et al. 2004b)
Skeletal muscle relaxants: Chlorzoxazone (Gurley et al. 2002, 2005)
Antifungals: Voriconazole (Rengelshausen et al. 2005)
Antihistamines: Fexofenadine (studies have indicated mixed results, with some reporting that plasma levels are increased while others indicating that plasma levels are decreased) (Dresser et al. 2003; Hamman et al. 2001; Wang et al. 2002)

St. John's wort may decrease plasma levels of other drugs metabolized by the isoenzyme CYP3A4. *See* CYP450 in Appendix 3 for more information.

Human studies have shown a l ack of interaction between St. John's wort and some drugs including prednisone (Bell et al. 2007), mycophenolic acid (Mai et al. 2003), pravastatin (Sugimoto et al. 2001), tolbutamide (Wang et al. 2001), dextromethorphan (Markowitz et al. 2000, 2003; Wang et al. 2001; Wenk et al. 2004), carbamazepine (Burstein et al. 2000), and theophylline (Morimoto et al. 2004).

Due to the photosensitizing potential of St. John's wort, concomitant use with photosensitizing drugs is not advised (Fiume 2001).

Notice

Photosensitizing (Brockmoller et al. 1997; Cotterill 2001; Schempp et al. 2001, 2003); *see* Appendix 2.

Adverse Events and Side Effects

A systematic review of clinical trials indicated that St. John's wort has been well tolerated in trials, with no serious adverse effects reported. Patient dropout rates and adverse effects reports were similar to those of placebo (Knuppel and Linde 2004).

Evidence from clinical trials suggests that concerns regarding phototoxicity of St. John's wort are not a problem in the general population, but caution regarding excessive exposure to sunlight during St. John's wort use is warranted in fair-skinned persons. St. John's wort should not be used in persons undergoing phototherapy (laser or ultraviolet) or those taking photosensitizing drugs (Schempp et al. 2001; Schulz 2001; Woelk et al. 1994). Hypericin is the compound primarily responsible for phototoxic effects (Gulick et al. 1999; Jacobson et al. 2001). Cases of phototoxicity have been reported after oral and topical uses of St. John's wort products. Severe cases have been reported in persons undergoing laser or UV therapy and in persons taking the compound hypericin (Bove 1998; Cotterill 2001; Golsch et al. 1997; Gulick et al. 1999; Jacobson et al. 2001; Lane-Brown 2000).

Cases of adverse events that have been reported in two or more persons are hypomania and psychosis (Fahmi et al. 2002; Guzelcan et al. 2001; Khawaja et al. 1999; Laird and Webb 2001; Lal and Iskandar 2000; Moses and Mallinger 2000; Nierenberg et al. 1999; O'Breasail and Argouarch 1998; Shimizu et al. 2004; Shuster 1999) (note that in many

of these reports, patients had a history of psychiatric illness or concomitant diagnoses of psychiatric disorders), hypertension (Patel et al. 2002; Zullino and Borgeat 2003), and sexual dysfunction (Assalian 2000; Bhopal 2001). The relationship between these events and St. John's wort use is not known.

Pharmacological Considerations

St. John's wort has been shown to induce the drug-metabolizing isoenzyme CYP3A4 and the drug transporter P-glycoprotein (P-gp), leading to lower plasma levels of drugs metabolized by CYP3A4 or transported by P-gp (Borrelli and Izzo 2009). The effect on CYP3A4 lasts for approximately 7 days after St. John's wort use (Imai et al. 2008).

Pregnancy and Lactation

Studies on the effect of prenatal consumption of St. John's wort on pregnancy in mice and rats were generally associated with normal gestation and offspring development (Borges et al. 2005; Cada et al. 2001; Ferguson et al. 1999; Rayburn et al. 2000, 2001a, 2001b). A limited number of human case reports indicated healthy pregnancies and infants when St. John's wort was used prenatally (Gregoretti et al. 2004).

In studies of nursing mothers, the compound hyperforin was detected in low concentrations in mother's milk while the compound hypericin was not detected in milk (Klier et al. 2002, 2006).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Immunosuppressants

In kidney transplant patients orally administered 600 mg of St. John's wort daily for 2 weeks in addition to their standard dose of cyclosporine, an increase in the clearance of cyclosporine was observed. The maximum plasma concentration of cyclosporine was reduced by an average of 42% (Bauer et al. 2003). Similar effects were observed in healthy volunteers administered 2.5 mg/kg cyclosporine after daily administration of 900 mg St. John's wort for 14 days (Dresser et al. 2003).

In kidney transplant patients orally administered 900 mg daily of a low-hyperforin (0.6 mg hyperforin daily) or regular (42 mg hyperforin daily) St. John's wort preparation in addition to the standard dose of cyclosporine, no clinically relevant changes in cyclosporine levels were observed during the low-hyperforin treatment period. During treatment with the regular St. John's wort extract, a 45% reduction in plasma levels ($AUC_{0\text{-}12}$) of cyclosporine was observed (Mai et al. 2004). Cyclosporine is metabolized by CYP3A4 (Dresser et al. 2003).

In healthy volunteers orally administered 0.1 mg/kg of tacrolimus before or during 18 days of St. John's wort administration at a dose of 900 mg daily, a significant decrease in blood levels of tacrolimus was observed after St. John's wort dosing. Induction of CYP3A4 and P-gp were proposed as the mechanism for this interaction (Hebert et al. 2004).

In kidney transplant patients orally administered 600 mg St. John's wort daily for 2 weeks in addition to the regular regimen of tacrolimus and mycophenolic acid, a significant decrease in plasma levels of tacrolimus was observed. No changes in mycophenolic acid levels were observed (Mai et al. 2003).

No changes in plasma levels of prednisone were observed in healthy volunteers orally administered 900 mg St. John's wort daily for 4 weeks before or after single doses of prednisone (Bell et al. 2007).

Anticoagulants

A significant decrease in plasma levels of (*S*)-warfarin was observed in healthy volunteers orally administered 900 mg daily St. John's wort for 18 days. No change in the efficacy of (*S*)-warfarin was observed (Jiang et al. 2004, 2006). Both (*S*)-warfarin and (*R*)-warfarin were affected (Jiang et al. 2004).

In healthy volunteers orally administered 12 mg phenprocoumon before or after administration of 900 mg St. John's wort daily for 11 days, a significant reduction in plasma levels of phenprocoumon was observed after St. John's wort dosing (Maurer et al. 1999).

Antiarrhythmics

Clinical trials of standard St. John's wort and digoxin showed a significant decrease in plasma levels of digoxin both after a single dose (Durr et al. 2000) and after continued dosing of St. John's wort (Durr et al. 2000; Johne et al. 1999; Mueller et al. 2004). Digoxin is a P-gp substrate (Durr et al. 2000). In trials with low-hyperforin (3.5 mg hyperforin daily) St. John's wort products, the St. John's wort did not affect digoxin blood levels (Gerhard 2005; Mueller et al. 2004).

Calcium channel blockers

In healthy volunteers orally administered 10 mg nifedipine before or after 18 days of 900 mg St. John's wort daily, a significant decrease in the nifedipine plasma concentration was observed after St. John's wort dosing (Smith et al. 2001).

Concomitant use of 900 mg St. John's wort and 120 mg/l (*R*)- and (*S*)-verapamil (administered, via a tube, directly to the small intestine) caused a 77% decrease in the maximum plasma concentration of the (*R*)- and (*S*)-verapamil. Verapamil is primarily metabolized by CYP3A4 (Tannergren et al. 2004).

Anti-anginals

In healthy volunteers orally administered a single oral dose of ivabradine before or after 900 mg St. John's wort daily, a significant decrease in plasma levels of ivabradine was observed after St. John's wort dosing. Ivabradine is metabolized by CYP3A4 (Portoles et al. 2006).

Hormonal contraceptives

In healthy women using a hormonal contraceptive (ethinyl estradiol and norethindrone) and orally administered 900 mg St. John's wort daily for three menstrual cycles, a decrease in serum levels of ethinyl estradiol and norethindrone were observed. Testing with the CYP3A4 substrate midazolam on the last day of St. John's wort treatment confirmed activity of St. John's wort. Serum concentrations of follicle-stimulating hormone, luteinizing hormone, and progesterone were not significantly affected by St. John's wort dosing. Breakthrough bleeding occurred in 2 of 12 women in the control phase compared with 7 of 12 women in the St. John's wort phase. The oral clearance of midazolam after St. John's wort dosing was greater in women who had breakthrough bleeding than in those who did not (Hall et al. 2003). In another study with the same St. John's wort dosing regimen, a 15% decrease in exposure to ethinyl estradiol and norethindrone was observed along with an increase in intracyclic bleeding and evidence of follicle growth (Murphy et al. 2005). Participants in a third trial reported increased intracyclic bleeding as compared with contraceptive alone, but had no significant change in follicle maturation or serum estradiol and progesterone concentrations (Pfrunder et al. 2003).

In healthy volunteers who had taken a low-dose oral contraceptive (0.02 mg ethinylestradiol and 0.15 mg desogestrel) for at least 3 months, oral administration of 500 mg of a low-hyperforin (less than 1 mg hyperforin) St. John's wort extract daily for 14 days produced no significant effects on serum levels of the hormones or their metabolites (Will-Shahab et al. 2009).

Anxiolytics

In healthy volunteers orally administered a single dose of quazepam before or after oral administration of 900 mg St. John's wort daily for 14 days, a significant reduction in plasma levels of quazepam was observed after St. John's wort dosing. In subjective testing of volunteers, no significant effects of St. John's wort on quazepam activity were observed. Quazepam is metabolized by CYP3A4 (Kawaguchi et al. 2004).

A number of human studies have shown that St. John's wort decreases plasma levels of alprazolam (Markowitz et al. 2000, 2003) and midazolam (Dresser et al. 2003; Gurley et al. 2002, 2005; Wang et al. 2001; Xie et al. 2005) in healthy volunteers. These effects are not observed with low hyperforin-containing extracts (Arold et al. 2005) or after a short duration (3 days or less) of treatment (Markowitz et al. 2000).

Antidepressants (tricyclic)

Reduced serum levels of amitriptyline and its metabolite, nortriptyline, were observed in depressed patients taking amitriptyline along with 900 mg St. John's wort daily for 12 to 14 days (Johne et al. 2002).

Antivirals

A significant reduction in serum levels of indinavir was observed after oral administration of 800 mg indinavir to healthy volunteers who had been taking 900 mg St. John's wort daily for 2 weeks, as compared to indinavir administered prior to St. John's wort. Indinavir is metabolized by CYP3A4 (Piscitelli et al. 2000).

In HIV patients being treated with nevirapine, self-treatment with varying doses of St. John's wort led to a reduction in plasma levels of nevirapine. Nevirapine induces CYP3A4 (de Maat et al. 2002). In healthy volunteers orally administered 2 g of St. John's wort as an infusion daily for 14 days, before or after administration of single doses of nevirapine, a significant reduction in the half-life of nevirapine was observed after St. John's wort dosing (L'homme et al. 2006).

Statins

In healthy volunteers orally administered 900 mg St. John's wort daily for 14 days prior to oral administration of 10 mg simvastatin and 20 mg pravastatin, lowered plasma concentrations of simvastatin and its active metabolite were observed. Pravastatin concentrations were not significantly altered. Simvastatin is metabolized by CYP3A4 (Sugimoto et al. 2001).

In patients with hypercholesterolemia treated with a stable dose of atorvastatin (10–40 mg/day) for at least 3 months, administration of 600 mg of St. John's wort daily for 4 weeks resulted in an increased serum level of LDL cholesterol and total cholesterol. No significant changes were observed in HDL cholesterol or in triglycerides (Andrén et al. 2007). Atorvastatin is metabolized by CYP3A4 and is also a substrate for P-glycoprotein.

Anticancer drugs

In cancer patients undergoing treatment with irinotecan (350 mg/m^2, intravenously), oral administration of 900 mg daily of St. John's wort decreased plasma concentrations of the irinotecan active metabolite by 42%. Irinotecan is metabolized by CYP3A4 (Mathijssen et al. 2002).

In healthy volunteers orally administered 400 mg imatinib before and after oral administration of 900 mg St. John's wort daily for 14 days, a significant reduction in plasma levels of imatinib was observed after St. John's wort treatment. Imatinib is metabolized by CYP3A4 (Frye et al. 2004). Similar effects were observed in a second study with imatinib (Smith 2004).

Beta-adrenergic blockers

In healthy volunteers orally administered 900 mg St. John's wort daily for 12 days before or after single doses of

talinolol, a significant reduction in plasma levels of talinolol was observed (Schwarz et al. 2007).

Hypoglycemics

In healthy volunteers orally administered 80 mg glicazide with or without 900 mg St. John's wort daily for 15 days, a reduction in plasma levels of glicazide was observed in the St. John's wort group (Xu et al. 2008).

Antiulcer drugs

In healthy volunteers orally administered 900 mg St. John's wort daily for 14 days, before or after single doses of omeprazole, a significant reduction in plasma levels of omeprazole was observed (Wang et al. 2004a).

Skeletal muscle relaxants

In healthy volunteers orally administered 900 mg St. John's wort daily for 28 days before or after single doses of 500 mg chlorzoxazone, a reduction in plasma levels of chlorzoxazone was observed (Gurley et al. 2002, 2005).

Anticonvulsants

In healthy volunteers orally administered 900 mg St. John's wort daily for 14 days, before or after single doses of mephenytoin, a significant increase in excretion of a mephenytoin metabolite was observed after St. John's wort dosing. The effect was observed in volunteers with the CYP2C19 wild genotype, but not in those who are CYP2C19 poor metabolizers (Wang et al. 2004b).

In healthy volunteers orally administered carbamazepine before or after 900 mg St. John's wort daily for 11 days, no changes in plasma levels of carbamazepine were observed. Plasma levels of hypericin and pseudohypericin from St. John's wort were also monitored, and a slight decrease in pseudohypericin levels was observed (Johne et al. 2004).

No significant changes in plasma levels of carbamazepine were observed in healthy volunteers orally administered 900 mg St. John's wort with 400 mg carbamazepine daily for 14 days (Burstein et al. 2000).

Antifungals

In healthy volunteers orally administered 900 mg St. John's wort daily for 15 days, voriconazole was administered before and on days 1 and 15 of St. John's wort consumption. Administration of voriconazole on day 1 resulted in an elevation of voriconazole plasma levels, although the elevation was considered clinically irrelevant. Plasma levels of voriconazole were significantly decreased when administered on day 15 of St. John's wort consumption (Rengelshausen et al. 2005).

Antihistamines

Findings on the use of St. John's wort and fexofenadine, a P-gp substrate, are mixed. In healthy volunteers orally administered single doses of 60 mg fexofenadine before and after a single dose of 900 mg St. John's wort or the same dose repeated for 14 days, the single dose of St. John's wort was found to significantly increase plasma concentrations of fexofenadine. After repeated dosing with St. John's wort, no significant changes in fexofenadine disposition were observed as compared to the non-St. John's wort portion of the experiment (Wang et al. 2002). An increase in oral clearance, with no changes in elimination half-life, was observed in healthy volunteers orally administered a single dose of 60 mg fexofenadine after oral administration of 900 mg St. John's wort daily for 10 days (Xie et al. 2005). A significant increase in oral clearance of fexofenadine was observed in healthy volunteers orally administered 180 mg fexofenadine after oral administration of 900 mg of St. John's wort daily for 14 days (Dresser et al. 2003).

Bronchodilators

No significant changes in plasma levels of theophylline were observed in healthy volunteers orally administered 900 mg daily St. John's wort for 15 days before and after dosing with 400 mg theophylline (Morimoto et al. 2004).

Other

Administration of St. John's wort was associated with significantly reduced methadone plasma levels in patients being treated in a methadone clinic (Eich-Hochli et al. 2003).

Also see Human pharmacological studies for this entry.

Case Reports of Suspected Drug or Supplement Interactions

Immunosuppressants

Cyclosporine and tacrolimus are substrates of the drug-metabolizing isoenzyme CYP3A4. Multiple case reports have demonstrated that St. John's wort decreases blood levels of cyclosporine (Ahmed et al. 2001; Alscher and Klotz 2003; Barone et al. 2000; Beer and Ostermann 2001; Breidenbach et al. 2000a, 2000b; Karliova et al. 2000; Mai et al. 2000; Mandelbaum et al. 2000; Moschella and Jaber 2001; Ruschitzka et al. 2000; Turton-Weeks et al. 2001). St. John's wort consumption for as little as 3 days was correlated with decreased cyclosporine blood levels (Mandelbaum et al. 2000).

One case report noted a decrease in the blood level of tacrolimus in a patient taking St. John's wort (Bolley et al. 2002).

Anticoagulants

One publication reported seven cases of decreased INR (a standardized scale used to report the results of blood coagulation tests; decreased INR indicates accelerated blood clotting) in patients taking warfarin and St. John's wort. Several of the cases reported a return to normal INR levels

after cessation of St. John's wort; results of other cases were not reported (Yue et al. 2000).

Hormonal contraceptives

Several cases of intermenstrual bleeding and one case of unwanted pregnancy have been reported in women taking oral contraceptives and St. John's wort (Schwarz et al. 2003; Yue et al. 2000).

Antivirals

In patients taking St. John's wort and nevirapine, mild to moderate increases in oral clearance of nevirapine were recorded (de Maat et al. 2001, 2002).

Antidepressants (SSRI)

Several cases of suspected serotonin syndrome (Barbenel et al. 2000; Demott 1998; Gordon 1998; Lantz et al. 1999; Waksman et al. 2000) and one report of hypomania (Spinella and Eaton 2002) were reported in patients taking both St. John's wort and SSRIs (selective serotonin reuptake inhibitors).

Antipsychotics and anxiolytics

One case of possible serotonin syndrome was reported in a patient taking St. John's wort and buspirone (Dannawi 2002).

Bronchodilators

One case of lowered theophylline level was reported in a patient taking St. John's wort, theophylline, and numerous other drugs. Theophylline level returned to normal after St. John's wort was stopped (Nebel et al. 1999).

Animal Trials of Drug or Supplement Interactions

Animal trials of drug or supplement interactions were identified but omitted due to the availability of human data.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of adverse events reported in clinical trials of St. John's wort indicated that data from 35 double-blind randomized trials showed that dropout and adverse event rates in patients receiving St. John's wort extracts were similar to placebo, lower than with older antidepressants, and somewhat lower than with SSRI antidepressants. Dropout rates due to adverse events ranged from 0 to 5.7% in 17 observational studies that included 35,562 patients. No serious adverse events were reported in any of the studies (Knuppel and Linde 2004).

Case Reports of Adverse Events

A 35-year-old woman who had been taking 500 mg St. John's wort daily for 4 weeks developed subacute polyneuropathy after exposure to sunlight. Symptoms were restricted to areas of skin that were exposed to sunlight and abated after St. John's wort was discontinued (Bove 1998).

A 45-year-old woman developed a severe phototoxic reaction to laser treatment after taking St. John's wort (dose, duration, and product not specified). No adverse effects occurred during the same treatment prior to using or after discontinuation of St. John's wort (Cotterill 2001).

A 61-year-old woman developed recurring elevated itching erythematous lesions in light-exposed areas after taking six tablets daily of St. John's wort for 3 years. Routine patch testing did not reveal any relevant reactions and photo patch testing was negative. Using a systemic oral photoprovocation test with St. John's wort, a decrease of the MED-UVB (<0.039 J/cm^2) was observed and was reversible after discontinuation of St. John's wort (Golsch et al. 1997).

A 52-year-old woman with a history of cutaneous lupus developed a severe phototoxic reaction after using St. John's wort oil topically and orally three times daily for 2 weeks (Lane-Brown 2000).

A 63-year-old man with a history of psoriasis had a severe phototoxic reaction within 30 minutes of UVB phototherapy. The man had been taking six capsules of St. John's wort daily for an unspecified amount of time (Lane-Brown 2000).

A 45-year-old woman who had been using a topical St. John's wort cream for 3 weeks developed a phototoxic reaction after spending a day at the beach (Lane-Brown 2000).

Data from the 2002 U.S. National Health Interview Survey indicated a correlation between St. John's wort use and development of cataracts (Booth and McGwin 2009).

Cases of hypomania (Fahmi et al. 2002; Guzelcan et al. 2001; Nierenberg et al. 1999; O'Breasail and Argouarch 1998; Shuster 1999), mania (Moses and Mallinger 2000), psychosis (Laird and Webb 2001; Lal and Iskandar 2000; Shimizu et al. 2004), and delirium (Khawaja et al. 1999) have been associated with the use of St. John's wort. In many of these reports, patients were noted to have psychiatric histories or concomitant diagnoses of psychiatric disorders.

St. John's wort has been associated with hypertension in patients with no previous history of hypertension (Patel et al. 2002; Zullino and Borgeat 2003).

Sexual dysfunction was reported in a patient who had experienced similar dysfunction while on sertraline (Assalian 2000). Diminished libido was reported in a patient with a history of depression and anxiety (Bhopal 2001).

Other adverse events associated with the use of St. John's wort include the following: erythematous eruption (Holme and Roberts 2000), hair loss (Parker et al. 2001), cardiovascular collapse during anesthesia (Irefin and Sprung 2000), serotonin syndrome (Parker et al. 2001), bone marrow necrosis (Demiroglu et al. 2005), reduced TSH levels (Ferko and Levine 2001), and nausea and related physical or mental symptoms (Brown 2000; Dean et al. 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In trials of commercial St. John's wort extracts, humans ingesting up to 3600 mg of St. John's wort extract (11.25 mg of total hypericin) did not experience phototoxicity (Brockmoller et al. 1997). In patients taking the compound hypericin, doses as low as 0.05 mg/kg were associated with phototoxic reactions (Gulick et al. 1999; Jacobson et al. 2001).

St. John's wort ingestion has been associated with changes in P-gp expression. Studies have shown that single doses of St. John's wort inhibit P-gp expression (Hamman et al. 2001; Wang et al. 2002) but that doses taken over multiple days induce P-gp expression (Durr et al. 2000; Hennessy et al. 2002; Johne et al. 1999; Mueller et al. 2004; Schwarz et al. 2002; Wang et al. 2002; Xie et al. 2005). Conversely, one study showed that multiple doses had no effect on P-gp expression (Hamman et al. 2001). A hyperforin-free St. John's wort extract was shown to have a nonsignificant effect on P-gp expression as compared to an extract containing hyperforin (Mueller et al. 2004).

Multiple studies have demonstrated that St. John's wort significantly induces the drug-metabolizing enzyme CYP3A4 (Bauer et al. 2002; Dresser et al. 2003; Durr et al. 2000; Frye et al. 2004; Gurley et al. 2002; Kawaguchi et al. 2004; Markowitz et al. 2003; Roby et al. 2000; Wang et al. 2001; Xie et al. 2005). Clearance of probe drugs such as midazolam, cyclosporine, and imatinib increased by 40 to 90% (Dresser et al. 2003; Frye et al. 2004; Gurley et al. 2002; Wang et al. 2001). Most studies were conducted with a dose of 300 mg St. John's wort three times daily for 2 weeks.

In healthy men orally administered 5 mg of midazolam before or during 900 mg daily of St. John's wort, clearance of midazolam increased significantly during St. John's wort and returned to normal 7 days after cessation of St. John's wort (Imai et al. 2008).

The effects of St. John's wort ingestion on CYP2C19 were shown to vary from no significant effect (Burstein et al. 2000) to significant induction (Rengelshausen et al. 2005; Wang et al. 2004a, 2004b). Among the studies that showed induction, two indicated that all 2C19 genotypes (including wild and mutant) produced similar results (Wang et al. 2004a, 2004b), while a third study indicated that individuals with wild-type CYP2C19 were more affected than others (Rengelshausen et al. 2005).

In two studies, St. John's wort ingestion significantly induced the activity of CYP2E1 (Gurley et al. 2002, 2005).

Trials gave conflicting results on the effect of St. John's wort on CYP1A2 and CYP2D6 activity. Results indicated no effect (Gerhard 2005; Gurley et al. 2008; Markowitz et al. 2000; Wang et al. 2004b) and significant induction (Gurley et al. 2002).

In one study, St. John's wort demonstrated nonsignificant induction of CYP2C9 (Gerhard 2005).

In healthy volunteers orally administered St. John's wort capsules at the manufacturer's recommended dose (amount not specified) daily for two weeks, no effects on platelet function or other hematological parameters were observed, including prothrombin time, partial thromboplastin time, thrombin time, bleeding time, the collagen/epinephrine assay, or the collagen/adenosine diphosphate assay. Aspirin (325 mg daily) was used as a positive control and markedly inhibited platelet function (Beckert et al. 2007).

Animal Pharmacological Studies

Animal pharmacological studies were identified but omitted due to the availability of human data.

In Vitro Pharmacological Studies

In vitro pharmacological studies were identified but omitted due to the availability of human data.

IV. Pregnancy and Lactation

A number of studies on the effect of prenatal consumption of St. John's wort on pregnancy and offspring development in mice and rats were associated with normal gestation and offspring development (Borges et al. 2005; Cada et al. 2001; Ferguson et al. 1999; Rayburn et al. 2000, 2001a, 2001b). Morphological abnormalities were noted in rat embryos excised and exposed to high concentrations of hypericin (71.0 or 142.0 ng/ml) (Chan et al. 2001). One study noted hepatic and renal lesions in lactating rats that had ingested 100 or 1000 mg/kg/day St. John's wort (Gregoretti et al. 2004).

Two cases of healthy human pregnancy and baby were reported in mothers taking St. John's wort (Grush et al. 1998).

In nursing mothers taking 900 mg St. John's wort daily, levels of hypericin and hyperforin in mothers' milk and in mother and infant plasma were as follows: in mother's milk, hypericin was below quantification limits, hyperforin ranged from 0.58 to 18.20 ng/ml; in mother's plasma, hypericin was 10.71 ng/ml; hyperforin was 22.8–151 ng/ml; and in infant plasma, hypericin was below quantification limit and hyperforin was from below detection limits to 0.1 ng/ml (Klier et al. 2002, 2006). In a prospective study of breastfeeding mothers, no significant difference between the St. John's wort and control groups were reported (Lee et al. 2003).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered St. John's wort extract (up to 5% in olive oil) could not be determined at doses up to 20 ml/kg (Fiume 2001).

The LD_{50} of intraperitoneally administered extract fractions of St. John's wort administered to mice is 780 mg/kg for the polyphenol fraction, 4300 mg/kg for the lipophile fraction, and 2800 mg/kg for the water-soluble fraction (Fiume 2001; Yevstifeyeva and Sibiryak 1996).

Short-Term Toxicity

Sheep fed St. John's wort flowers at doses of 4 to 16 g/kg for 14 days exhibited some signs of toxicity including restlessness, photophobia, tachycardia, and erythema of the exposed parts of the tail and legs (Fiume 2001; Kako et al. 1993).

Chronic Toxicity

In rats fed St. John's wort as 5% of their daily diet, significant weight loss was reported as compared to control. No other toxicities were reported (Garrett et al. 1982).

Genotoxicity

St. John's wort (*Hypericum perforatum*) contains hypericin and hypericin-like substances as well as flavonoids, of which particularly quercetin has generated a widespread controversial discussion with respect to mutagenic action.

No mutagenic activity of a hydroethanolic extract of St. John's wort was observed in in vivo and in vitro studies, including the fur spot test in mice, the chromosome aberration test with bone marrow cells of the Chinese hamster, the hypoxanthine guanidine phosphoribosyltransferase test, the cell transformation test using Syrian hamster embryo cells, and the unscheduled DNA synthesis test (Okpanyi et al. 1990).

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA100 with or without metabolic activation from S9, a tincture of St. John's wort increased the number of revertants in TA98 with and without metabolic activation and in TA100 with metabolic activation (Goggelmann and Schimmer 1986).

Ethanol, chloroform, and ethyl acetate extracts of St. John's wort were assayed at concentrations of 10 or 40 µl in the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA100 with or without metabolic activation by S9. The ethanol and ethyl acetate extracts had mutagenic activity with and without metabolic activation. Testing of fractions of the extracts indicated that mutagenicity of the full extract was found exclusively in quercetin and that hypericin was not mutagenic (Poginsky et al. 1988). The compound quercetin is recognized to have mutagenic activity in vitro but is regarded as safe in humans (Harwood et al. 2007).

Hyssopus officinalis L. — Lamiaceae

SCN: hyssop

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Kuhn and Winston 2007; Madaus 1976; Riddle 1997).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Kuhn and Winston 2007); *see* Appendix 2.

Thujone (trace amounts) (Kerrola et al. 1994) ; *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Hyssop has traditionally been used as both an emmenagogue and an abortifacient (Kuhn and Winston 2007; Riddle 1997). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of hyssop during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Hyssop has traditionally been used as both an emmenagogue and an abortifacient (Kuhn and Winston 2007; Riddle 1997).

No information on the safety of hyssop during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered hyssop essential oil in rats could not be determined at doses up to 1.6 ml/kg, while that of pinocamphone and isopinocamphone is 0.05 ml/kg and that of thujone is 0.2 ml/kg (Steinmetz et al. 1980).

Genotoxicity

Some genotoxic activity of an alcohol extract of hyssop at concentrations of 0.05 and 0.1% was observed in human lymphocytes (Hadziselimovic and Sofradzija 1998).

Ilex paraguariensis A. St.-Hil. — Aquifoliaceae

SCN: mate
OCN: Paraguay tea; yerba mate

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: C*

Contraindications

None known.

Other Precautions

Mate (pronounced in two syllables) contains caffeine, a nervous system stimulant. If taken in large amounts, mate products containing caffeine can cause insomnia, nervousness, and the other well-known symptoms of excess caffeine intake (Donovan and DeVane 2001).

Due to the central nervous system (CNS) stimulant effects of caffeine, use of caffeine-containing products is cautioned in persons with heart disorders, as excessive caffeine consumption may increase heart rate or exacerbate arrhythmias; use is also cautioned in psychological disorders, as caffeine may aggravate depression or induce anxiety (Brinker 2001).

Drug and Supplement Interactions

Use of caffeine with other CNS stimulants, including bronchodilators or adrenergic drugs, may cause excessive central nervous system stimulation resulting in nervousness, irritability, insomnia, and possibly convulsions or cardiac arrhythmias (PDR 2006).

Notice

Caffeine (0.3–1.7%) (List and Hörhammer 1973; Wichtl 2004); *see* Appendix 1.

Diuretic (Brunton et al. 2006); *see* Appendix 2.

Tannins (4.0–16.0%) (List and Hörhammer 1973; Wichtl 2004); *see* Appendix 1.

Editors' Note

The American Herbal Products Association has established a trade requirement (AHPA 2011) that dietary supplement products that contain caffeine, whether as a direct ingredient or as a constituent of herbal ingredients, be labeled to disclose the presence of caffeine in the product and the quantity of added caffeine if greater than 25 mg; be formulated and labeled in a manner to recommend a maximum of 200 mg of caffeine per serving, not more often than every 3 to 4 hours; and bear the following or similar statement on the label of any dietary supplement that contains caffeine in sufficient quantity to warrant such labeling:

> Too much caffeine may cause nervousness, irritability, sleeplessness, and, occasionally, rapid heartbeat. Not recommended for use by children under 18 years of age.

See Appendix 1 for more specific details on this AHPA trade requirement.

Adverse Events and Side Effects

Epidemiological studies in regions where mate is frequently consumed have suggested an association between mate consumption and increased risk of developing certain cancers, such as esophageal, oral, lung, bladder, renal, and other cancers of the head and neck (Bates et al. 2007; De Stefani et al. 1996, 1998, 2007; Goldenberg et al. 2003; Pintos et al. 1994). The reason for the increased cancer rates is unknown, and several hypotheses have been suggested, including thermal injury from hot beverages, increased absorption of environmental carcinogens due to the temperature of mate at the time of consumption, or the presence of polycyclic aromatic hydrocarbons (compounds like those found in tobacco smoke and grilled meat) from smoke introduced during the traditional roasting process (new roasting processes used by some producers exclude smoke and thus the polycyclic aromatic hydrocarbons) (Heck and de Mejia 2007). Several of these studies also examined coffee, green tea, and other dietary factors such as red meat consumption, all of which had an increased risk of various cancers similar to or greater than that seen for mate (De Stefani et al. 1991, 1998; Heck and de Mejia 2007). In contrast to epidemiological data, a number of animal and in vitro studies have demonstrated anticancer effects of mate (Heck and de Mejia 2007).

Pharmacological Considerations

See Other Precautions and Drug and Supplement Interactions above.

* For caffeine-free preparations, no interactions are expected.

Pregnancy and Lactation

An epidemiological study on use of mate during pregnancy indicated no adverse effects of mate on pregnancy duration or birth weight (Santos et al. 2005).

Pregnant women are advised to limit use of mate to 300 mg caffeine daily (PDR 2006). Nursing women are advised to limit use of caffeinated mate products to 150 mg caffeine daily (AAP 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Epidemiological studies in countries in which mate is frequently consumed have suggested an association between mate consumption and increased risk of developing certain cancers, such as esophageal, oral, lung, bladder, renal, and other cancers of the head and neck (Bates et al. 2007; De Stefani et al. 1996, 1998, 2007; Goldenberg et al. 2003; Pintos et al. 1994). The reason for the increased cancer rates is unknown, and several hypotheses have been suggested (Heck and de Mejia 2007). Studies have suggested that drinking more than one liter of mate daily can increase the risk of head and neck cancers by three to five times, and that some association between mate consumption and lung cancer exists (De Stefani et al. 1996; Sewram et al. 2003; Vassallo et al. 1985).

Some research has suggested that the increased risk of oral cancers may be due to the temperature of the mate at the time of consumption, as thermal injury may be responsible for the increased risk of cancers (Rolon et al. 1995). The custom of drinking very hot mate through a metal straw (bombilla) can cause repeated scalding to the back of the throat and esophagus. Consumption of hot coffee or hot green tea is reported to increase the risk of oral cancers by two to four times (Heck and de Mejia 2007).

Studies of mate drinking by smokers showed that, among mate drinkers, bladder cancer was more prevalent in smokers than in nonsmokers. The study also indicated that black tea and coffee consumption were risk factors for bladder cancer (De Stefani et al. 1991). Another similar study indicated an increased risk of bladder cancer in mate drinkers who smoked but no risk in nonsmokers (Bates et al. 2007).

Another hypothesis regarding higher oral cancer rates among mate drinkers that smoke tobacco or drink alcohol is that, due to the high temperature at time of consumption, mate may increase the absorption of the carcinogens found in cigarette smoke and other environmental contaminants that are carcinogens or cancer promoters (Goldenberg et al. 2004).

Mate contains polycyclic aromatic hydrocarbons (PAHs) including benzo[*a*]pyrene, compounds like those found in tobacco smoke and grilled meat that have carcinogenic properties and have been associated with increased risk of esophageal cancer (Heck and de Mejia 2007). One human study showed a dose-related correlation between the amount of mate consumed and urinary levels of PAHs (Fagundes et al. 2006). A study in Brazil indicated that PAH levels in beverages were 10.12 μg/kg for coffee and 0.70 μg/kg for mate (Rojo de Camargo and Toledo 2002). The PAH content of roasted mate comes from the traditional processing method of drying the leaves over a smoky wood fire (Heck and de Mejia 2007). Dried, unsmoked mate is also sold commercially.

Examining incidences of renal cell carcinoma in Uruguay, researchers indicated that, after adjusting for major covariates, heavy mate consumption was associated with a 3-fold increase in risk of renal cell carcinoma, while consumption of red meat was associated with a 3.4-fold increase in risk (De Stefani et al. 1998).

In contrast to epidemiological data, a number of animal and in vitro studies have demonstrated anticancer effects of mate (Heck and de Mejia 2007).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Caffeine is a substrate of the drug-metabolizing isoenzyme CYP1A2 (Nordmark et al. 1999).

Animal Pharmacological Studies

Mate has been observed to significantly inhibit absorption of nonheme iron in rats (Gutnisky et al. 1992).

No significant increases in cancers of the aerodigestive tract were seen in rats administered mate aqueous extract as drinking water for 5 months (Pereira Jotz et al. 2006).

In Vitro Pharmacological Studies

Catalytic topoisomerase inhibition by an extract of mate was seen for topoisomerase II but not topoisomerase I in vitro in

an oral carcinoma cell line (Gonzalez de Mejia et al. 2005). Mate has been identified as a potent inhibitor of topoisomerase II, showing significant cancer cell growth inhibition, even at low concentrations (Heck and de Mejia 2007).

IV. Pregnancy and Lactation

In an epidemiological study of the effects of mate drinking in pregnancy on birth weight and the risk of preterm birth, no changes in duration of pregnancy and no harmful effects on intrauterine growth were detected. A total of 5189 single births were analyzed, and 68% of mothers reported drinking mate at least once a week during pregnancy (Santos et al. 2005).

A premature infant newborn of a mother who reported drinking one liter of mate tea (~930 mg caffeine) daily during pregnancy exhibited increased jitteriness and irritability, hypertonia in the limbs, and brisk tendon reflexes consistent with neonatal withdrawal syndrome. Symptoms progressively disappeared at 84 hours of age. High concentrations of caffeine and theobromine were detected in maternal and neonatal biological matrices, including the placenta, cord serum, neonatal urine, maternal and neonatal hair, meconium, and breast milk. The authors of the report indicated that while mate is frequently consumed by pregnant women in South America, neonatal withdrawal syndrome is rare, as infants are usually breast-fed within 4 hours after delivery, providing a dose of caffeine (Martin et al. 2007).

Caffeine is in the FDA pregnancy category C and has been shown to cross the placenta and achieve blood and tissue concentrations in the fetus. Excessive intake of caffeine by pregnant women has been associated with fetal arrhythmias. Pregnant women are advised to limit caffeine intake to less than 300 mg daily (PDR 2006).

Caffeine is listed as a "Maternal Medication Usually Compatible with Breastfeeding" by the American Academy of Pediatrics Committee on Drugs. The Committee noted that maternal consumption of caffeine may cause irritability and poor sleeping patterns in nursing infants, and that maternal consumption of caffeinated beverages should be limited to two to three cups daily (AAP 2001).

Epidemiological studies have indicated an association between high caffeine intake during pregnancy and an increased risk of spontaneous abortions. An analysis concluded that methodological flaws in many of the studies led to biased results and that a causal link between caffeine consumption and abortion cannot yet be confirmed (Signorello and McLaughlin 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered caffeine in rats is 335 mg/kg (Mills and Bone 2005).

Genotoxicity

No clastogenic or aneugenic activity of an aqueous extract of mate, without metabolic activation, was observed in a cytokinesis-blocked micronucleus assay (Alves et al. 2008).

No clastogenic activity of mate was observed in vivo in rat bone marrow cells, although an increased frequency of chromosomal aberrations was reported in vitro in human peripheral lymphocytes (da Fonseca et al. 1994). Genotoxic activity of an aqueous extract of mate was observed in *Escherichia coli* and *Salmonella typhimurium* without metabolic activation, but the addition of S9 microsomal fraction, catalase, thiourea, or dipyridyl counteracted the genotoxic activity of mate (da Fonseca et al. 1994; Leitão and Braga 1994).

Cytotoxicity

An extract of mate was cytotoxic against human liver cancer HepG2 cells in vitro with an IC_{50} value of the total polyphenol content of 12.01 µg/ml (Gonzalez de Mejia et al. 2005).

Illicium verum Hook. f.

Illiciaceae

SCN: star anise
AN: *takkola*

OCN: Chinese star anise
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Star anise (*Illicium verum*) is commonly confused with Japanese star anise, also known as shikimi, (*I. anisatum*), a species known to have neurological and gastrointestinal toxicity (Ize-Ludlow et al. 2004; Joshi et al. 2005; Small 1996). The fruit of the Japanese star anise is generally smaller than that of *I. verum* and consists of 6 to 8 follicles arranged in a star pattern and terminating in an upward curving tip. This curve is in contrast to the nearly straight beak of the standard species. Japanese star anise is reported to have a bitter flavor and smells of sassafras, whereas star anise is not bitter and smells of anise (Wichtl 2004; Youngken 1921).

Analytical methods to microscopically or chemically differentiate the species have been published (Howes et al. 2009; Joshi et al. 2005; Lederer et al. 2006; Techen et al. 2009; Upton 2006).

Seizures have been reported in infants administered teas labeled as star anise (Garzo Fernandez et al. 2002; Gil Campos et al. 2002; Ize-Ludlow et al. 2004; Minodier et al. 2003; Montoya-Cabrera 1990), but analysis of the tea products in several of the case reports indicated adulteration with Japanese star anise (*I. anisatum*). General malaise, nausea, and vomiting were reported in adults who consumed a tea product labeled as star anise that was later found to contain Japanese star anise (Johanns et al. 2002).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of star anise in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Seizures have been reported in infants administered teas labeled as star anise (Garzo Fernandez et al. 2002; Gil Campos et al. 2002; Ize-Ludlow et al. 2004; Minodier et al. 2003; Montoya-Cabrera 1990); however, analysis of the tea products in several of the case reports indicated adulteration with Japanese star anise (*I. anisatum*), a botanically similar species that has been documented to have neurological and gastrointestinal toxicity (Ize-Ludlow et al. 2004).

General malaise, nausea, and vomiting were reported in adults who consumed a tea product labeled as star anise that was later found to contain Japanese star anise (Johanns et al. 2002).

An anaphylactic reaction to the drug oseltamivir phosphate was reported in a patient with sensitization to star anise and celery-carrot-mugwort-spice syndrome (Hirschfeld et al. 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of star anise during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The compounds veranisatins A, B, and C, isolated from star anise, caused convulsions and were lethal at doses of 3 mg/kg after oral administration to mice. At lower doses, the compounds caused hypothermia (Nakamura et al. 1996; Okuyama et al. 1993).

Inula helenium L.

Asteraceae

SCN: elecampane
PN: *tu mu xiang* (root)

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as feverfew, chamomile, or *Echinacea*) should exercise caution with elecampane, as allergic cross-reactivity to Asteraceae plants is common (Paulsen 2002).

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Felter and Lloyd 1898); *see* Appendix 2.

Adverse Events and Side Effects

Allergic reactions, primarily contact dermatitis, to elecampane have been reported (Mateo et al. 1995; Paulsen 2002; Pazzaglia et al. 1995).

Large doses (standard dose listed as tea of 1 g taken 3 to 4 times daily) may cause vomiting, diarrhea, cramping, and symptoms of paralysis (Roth et al. 1984; Wichtl 2004).

Pharmacological Considerations

Sensitization studies in animals, and anecdotal reports from human use, have indicated that compounds in elecampane are relatively common skin sensitizers (Alanso Blasi et al. 1992; Paulsen 2002; Stampf et al. 1982).

Pregnancy and Lactation

A British herbal text indicates that elecampane should not be used during pregnancy or lactation but does not indicate the reason for these contraindications (Bradley 1992). A text on traditional Chinese medicine indicates that elecampane is sometimes used in cases of threatened miscarriage (PPRC 2005). Based on the available evidence, the editors of this text believe that elecampane is generally safe for use in pregnancy and lactation.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An erythema-multiforme-like eruption following allergic contact dermatitis was reported after contact with elecampane, with the effects attributed to sesquiterpene lactone compounds (Mateo et al. 1995).

Contact dermatitis due to a massage oil containing elecampane extract was reported (Pazzaglia et al. 1995).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Among plants of the Asteraceae family that cause allergic reactions and contact sensitization, elecampane has been recognized as one of the species that, relatively frequently, causes sensitization (Paulsen 2002).

Animal Pharmacological Studies

In sensitization tests in guinea pigs, the compounds alantolactone and isoalantolactone showed sensitizing activity after intradermal injection, with no sensitization shown for helenin (a crystalline portion of steam-distilled elecampane extract) (Stampf et al. 1982).

The compound alantolactone demonstrated sensitizing activity in an epicutaneous test in mice. No sensitizing activity of isoalantolactone was observed (Alanso Blasi et al. 1992).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A British herbal text indicates that elecampane should not be used during pregnancy or lactation, but does not indicate the reason for these contraindications (Bradley 1992). A text on traditional Chinese medicine indicates that elecampane is sometimes used in cases of threatened miscarriage (PPRC 2005). Based on the available evidence, the editors of this text believe that elecampane is generally safe for use in pregnancy and lactation.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered helenin (a crystalline portion of steam-distilled elecampane extract) in rabbits is 1.2 g/kg (Blaschek et al. 2002).

OCN: British inula

Inula japonica **Thunb.**
SCN: Japanese elecampane
Syn: *Inula britannica* L. var. *japonica* (Thunb.) Franch. & Sav.
PN: *xuan fu hua* (flower)
Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as feverfew, chamomile, or *Echinacea*) should exercise caution with British or Japanese elecampane, as allergic cross-reactivity to Asteraceae plants is common (Paulsen 2002).

Drug and Supplement Interactions

None known.

Editors' Note

Dried flowers of British or Japanese elecampane should be wrapped in cheesecloth or a similar filter prior to decocting to remove the small hairs from the flowers that may cause irritation of the throat or digestive tract (Chen and Chen 2004).

Adverse Events and Side Effects

Allergic reactions, primarily contact dermatitis, to Japanese and British elecampane have been reported (Bensky et al. 2004; Chen and Chen 2004).

Diarrhea has been associated with the use of Japanese elecampane (Chen and Chen 2004).

Pharmacological Considerations

A sensitization study in animals indicated that at least one compound in Japanese elecampane is a relatively common sensitizer (Stampf et al. 1982; Yong-Ming et al. 2006).

Pregnancy and Lactation

No information on the safety of Japanese and British elecampane during pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Repeated skin contact with British or Japanese elecampane flowers or stalks can cause allergic reactions such as contact dermatitis and pruritus (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In sensitization tests in guinea pigs, the compound isoalantolactone showed sensitizing activity after intradermal injection (Stampf et al. 1982).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of Japanese and British elecampane during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a 15% decoction of Japanese elecampane intraperitoneally administered to mice is 22.5 g/kg (Chen and Chen 2004).

Ipomoea purga (Wender.) Hayne — Convolvulaceae

SCN: jalap

Part: root

Quick Reference Summary

Safety Class: 3

Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Felter and Lloyd 1898; Wood and LaWall 1918).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations below.

Notice

Emetic (Felter and Lloyd 1898; Wood and LaWall 1918); *see* Appendix 2.

Stimulant laxative (BPC 1911; Felter and Lloyd 1898; Pereda-Miranda et al. 2006; Wood and LaWall 1918); *see* Appendix 2.

Adverse Events and Side Effects

Jalap is an irritant and cathartic that produces profuse and liquid stools, often accompanied by griping (BPC 1911; Felter and Lloyd 1898; Pereda-Miranda et al. 2006; Wood and LaWall 1918). Large doses may produce violent hypercatharsis (Felter and Lloyd 1898; Wood and LaWall 1918), which has led to fatalities in some cases (Felter and Lloyd 1898).

Pharmacological Considerations

The aqueous extract is reported to have a moderate purgative action, while the "portion not taken up by water" is reported to cause severe griping (Wood and LaWall 1918).

Concomitant use of stimulant laxatives such as jalap is cautioned with antiarrhythmic drugs and botanicals containing cardiac glycosides, as long-term use of jalap as a laxative can cause potassium loss, leading to increased toxicity of these drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Concomitant internal use of stimulant laxatives such as jalap is cautioned with thiazide diuretics, corticosteroids, or licorice, and long-term use of jalap as a laxative may increase the potassium loss induced by these drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Use of stimulant laxatives, such as jalap, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

While no information on the use of jalap during pregnancy or lactation was identified in the scientific or traditional literature, the use of purgatives during pregnancy is contraindicated (Bensky et al. 2004; Chen and Chen 2004; Maciocia 1998).

While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A reference text indicates that "large doses produce violent hypercatharsis, sometimes terminating fatally" (Felter and Lloyd 1898).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Fresh orris root may cause irritation of the gastrointestinal tract (Chadha 1988; Felter and Lloyd 1898). Large doses may cause nausea or vomiting (Wood and LaWall 1918).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of orris during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No sensitization was reported in healthy volunteers using 2% orris absolute in petrolatum in a repeated insult patch test with eleven 24-hour exposures (Opdyke 1979). No irritation of orris absolute was observed in healthy volunteers in a 48-hour closed patch test using 3% orris absolute in petrolatum (Opdyke 1979).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of orris during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orris absolute orally administered to rats is 9.4 g/kg (Opdyke 1979).

SCN: blue flag
OCN: larger blue flag

***Iris virginica* L.**
SCN: blue flag
Syn: *Iris caroliniana* S. Watson
OCN: southern blue flag
Part: rhizome, root

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (McGuffin et al. 1997).

Do not exceed recommended dose (Felter and Lloyd 1898; List and Hörhammer 1973; Wood and LaWall 1918).

Other Precautions

May cause nausea or vomiting (Felter and Lloyd 1898; List and Hörhammer 1973; Wood and LaWall 1918).

Drug and Supplement Interactions

See Pharmacological Considerations below.

Standard Dose

The standard dose is 10–20 drops tincture, 2 to 3 times daily (Smith 2008; Winston 2010).

Notice

Emetic (List and Hörhammer 1973; Wood and LaWall 1918); *see* Appendix 2.

Stimulant laxative (Felter and Lloyd 1898; Wood and LaWall 1918); *see* Appendix 2.

Adverse Events and Side Effects

Fresh blue flag may cause irritation of the gastrointestinal tract that can lead to vomiting, watery diarrhea, intestinal burning, and colic (Felter and Lloyd 1898).

Blue flag is reported to have caused neuralgia of the face, head, and extremities (Felter and Lloyd 1898).

Pharmacological Considerations

Concomitant use of stimulant laxatives such as blue flag is cautioned with antiarrhythmic drugs and botanicals containing cardiac glycosides, as long-term use of blue flag as a laxative can cause potassium loss, leading to increased toxicity of these drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Concomitant internal use of stimulant laxatives such as blue flag is cautioned with thiazide diuretics, corticosteroids, or licorice, and long-term use of blue flag as a laxative may increase the potassium loss induced by these drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Use of stimulant laxatives, such as blue flag, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

No information on the use of blue flag during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Isatis spp.

Brassicaceae

Isatis indigotica Fortune
SCN: isatis
PN: *ban lan gen* (root)
OCN: indigo woad

Isatis tinctoria L.
SCN: dyer's woad
OCN: woad
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with allergy to sulfonylurea (e.g., tolbutamide, glipizide, glyburide) or sulfonamide drugs (e.g., sulfadiazine, sulfisoxazole, sulfamethoxazole, trimethoprim-sulfamethoxazole) (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Editors' Note

Several plants are known by the common name *ban lan gen* in China, creating difficulty in understanding the identification and use of the different species. While one text on traditional Chinese medicine indicates that *Isatis indigotica* is the preferred species but *Baphicacanthus cusia* is a commonly traded acceptable alternate (Bensky et al. 2004), another text indicates that *Isatis tinctoria*, *Isatis indigotica, Baphicacanthus cusia, Polygonum tinctorium,* and *Clerodendron cyrtophyllum* are all acceptable species (Chen and Chen 2004).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of dyer's woad or isatis during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A case of bleeding in the upper gastrointestinal tract was reported in association with isatis use. Information on the product, dose, duration, concomitant medications, and relevant medical history was not provided (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Inhibition of platelet aggregation was observed in rabbits administered dyer's woad (dose, duration, and type of extract not specified in available English language translation) (Chen and Chen 2004).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of dyer's woad or isatis in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse reactions were observed in mice orally administered 5 g/kg of the compound indirubin (Chen and Chen 2004).

Literature Cited

Jasminum officinale L. — Oleaceae

SCN: jasmine
Syn: *Jasminum grandiflorum* L.
AN: *jati*
OCN: poet's jasmine
Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
An animal study indicated that large doses of jasmine had some anti-implantation activity but no adverse effects on developing fetuses (Iqbal et al. 1993).

No information on the safety of jasmine during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

J

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
In a maximization test in healthy volunteers, 3% jasmine absolute in petrolatum produced sensitization in 2 of 25 volunteers when tested with other sensitizing agents but produced no sensitization when tested alone in another 25 healthy volunteers (Opdyke 1979).

No irritation was observed after 3% jasmine absolute was tested in a 48-hour closed patch test in healthy volunteers (Opdyke 1979).

Animal Pharmacological Studies
No irritation was observed after undiluted jasmine absolute was applied to the backs of hairless mice and pigs or to intact or abraded rabbit skin (Opdyke 1979).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
In rats orally administered 250 or 500 mg/kg of an aqueous extract of jasmine daily, a dose-dependent anti-implantation effect was observed, although neither dose produced complete infertility. A decrease in serum progesterone levels was observed on day 5 of pregnancy. No abortifacient activity was observed in rats administered the extract on days 8 to 20 of pregnancy, and no abnormalities were observed in offspring (Iqbal et al. 1993).

No information on the safety of jasmine during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of jasmine absolute orally administered to rats and topically administered to rabbits could not be determined at doses up to 5 g/kg (Opdyke 1979).

Juglans nigra L. — Juglandaceae

SCN: black walnut

Part: hull, leaf

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for long-term use (Blumenthal et al. 1998).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (~10% in leaf) (Blumenthal et al. 2000); *see* Appendix 1.

Adverse Events and Side Effects

Although the German Commission E reported that daily use of juglone-containing preparations of walnut bark has been associated with an increased occurrence of cancer of the tongue and leukoplakia of the lips (Blumenthal et al. 1998), no epidemiological studies or case reports investigating the association of exposure to juglone and cancer risk in humans were identified (TRI 1999). Walnut bark, however, does contain tannins, and tannins have been associated with increased incidences of certain cancers (Chung et al. 1998).

Topical application of walnut hull preparations may result in a temporary yellow or brown discoloration of the skin at the site of application (Blumenthal et al. 1998).

Contact dermatitis in reaction to contact with English walnut (*Juglans regia*) hulls has been reported (Bonamonte et al. 2001; Neri et al. 2006). The compound juglone, present in the juice of fresh walnut hulls, is regarded as a strong skin irritant and may cause itching or burning sensations (Neri et al. 2006).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of black walnut during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Contact dermatitis of the finger webs was reported in a man who had been picking black walnuts. The reaction was believed to be due to exposure to the juice of the hull, and no reaction occurred on rechallenge (Siegel 1954). Contact dermatitis to English walnut (*Juglans regia*) hulls has been reported (Bonamonte et al. 2001; Neri et al. 2006).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A depressant effect of ether and petroleum ether extracts of black walnut hulls was observed in frogs, fish, mice, and

rabbits (Auyong et al. 1963; Westfall et al. 1961). In rabbits, an intravenously administered dose of 0.07 mg/kg juglone was reported to induce mild sedation; the toxicity is such that the dose reported to induce profound sleep was very close to the lethal dose (Westfall et al. 1961).

Horses exposed to black walnut sawdust or shavings develop laminitis, a hemodynamic dysfunction of the laminar vasculature of the hoof (Peroni et al. 2005).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of black walnut in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered juglone in mice is 2.5 mg/kg (Westfall et al. 1961).

In dogs intravenously administered the compound juglone at a dose of 5 mg/kg, histopathological changes in the lungs and liver were observed, indicating that juglone is toxic to the cell membrane and increases capillary permeability (Boelkins et al. 1968).

Genotoxicity

Mutagenic activity of the compounds juglone and plumbagin was observed in *Salmonella typhimurium* strain TA2637 with, but not without, metabolic activation (Matsushima et al. 1986; Tikkanen et al. 1983). No mutagenic activity of juglone was observed in *S. typhimurium* strains TA98 or TA100 with or without activation (Edenharder and Tang 1997; Matsushima et al. 1986; Tikkanen et al. 1983).

Carcinogenicity

Topical application of the compound juglone to mice promoted skin tumors induced with the carcinogen DMBA (7,12-dimethylbenz[*a*]anthracene) (Monks et al. 1990; Van Duuren et al. 1978), although no tumors were observed in mice treated with juglone alone (Van Duuren et al. 1978).

Cytotoxicity

HaCaT keratinocyte cells exposed to the compounds juglone or plumbagin at concentrations of 0 to 20 µ*M* exhibited dose-dependent decrease in cell viability. The cytotoxicity of these compounds is due to two different mechanisms, namely, redox cycling and reaction with glutathione (Inbaraj and Chignell 2004).

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Weiss and Meuss 2001; Wichtl 2004; Williamson 2003).

Not for use exceeding 6 weeks in succession (Weiss and Meuss 2001).

Other Precautions

Use with caution in persons with inflammatory kidney disease (Bone 1995; Yarnell 2002).

Drug and Supplement Interactions

None known.

Notice

Diuretic (Janků et al. 1957, 1960; Yarnell 2002); *see* Appendix 2.

Editors' Notes

Although some herbal references indicate that juniper has been associated with kidney toxicity (Blumenthal et al. 1998; Wichtl 2004), analyses of the literature and studies of juniper essential oil indicate that toxicity concerns are based on case reports likely involving misidentified or adulterated juniper essential oil (Bone 1995; ESCOP 2003; Schilcher et al. 1993; Schilcher and Heil 1994; Wichtl 2004; Yarnell 2002). Some of these analyses suggest that *Juniperus* species should be used with caution in cases of acute kidney inflammation (Bone 1995; Weiss and Fintelmann 2000; Yarnell 2002).

Adverse Events and Side Effects

No adverse events associated with oral use of *Juniperus* species were identified, although one infant suffered pulmonary edema and cardiovascular collapse after a rectal enema of cade juniper essential oil (Rahmani et al. 2004).

Pharmacological Considerations

An animal study demonstrated that juniper may modify glucose regulation (De Medina et al. 1994). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

An animal study indicated anti-implantation and abortifacient activity of juniper (Agrawal et al. 1980).

No information on the safety of *Juniperus* species in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 32-year-old man with a history of nephrolithiasis developed fever, severe hypotension, renal failure, hepatotoxicity, and severe cutaneous burns on the face after ingestion of homemade "*Juniper oxycedrus* tar." No information on dose or further details on the product consumed was reported (Koruk et al. 2005).

Pulmonary edema and cardiovascular collapse was reported in a 4-month-old after a rectal enema of cade juniper essential oil. No information on dose was provided (Rahmani et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In an irritation test, irritation reactions were observed in 2 of 20 volunteers patch tested with pure juniper essential oil for 24 h. No irritation reactions were observed in volunteers treated with 8% juniper oil in petrolatum in a 48-hour closed patch test (Johnson 2001).

Animal Pharmacological Studies

A reduction in glycemic levels in healthy rats was observed after administration of 250 mg/kg of a decoction of juniper. In diabetic rats, a reduction in blood glucose levels was observed after oral administration of a decoction of juniper equivalent to 125 mg/kg of berries daily for 24 days (De Medina et al. 1994).

In Vitro Pharmacological Studies

No adverse effects on normal renal mammalian fibroblasts or tubular epithelial cells were observed after treatment with methanol, water-methanol, or ethyl acetate extracts of juniper at concentrations of 1250 µg/ml (Wojcikowski et al. 2009).

IV. Pregnancy and Lactation
