A dose-dependent reduction in the number of implantation sites was observed on gestational day 10 in rats orally administered 300 or 500 mg/kg of an ethanol extract of juniper daily on days 1 to 7 of pregnancy. In animals administered the same doses on days 1 to 7 and 14 to 16 of pregnancy, a dose-dependent reduction in implantations was observed on gestational day 18, with animals at the 500 mg/kg dose having no implants on gestational day 18. In animals administered the same doses only on days 14 to 16 of pregnancy, fetuses were aborted and no pups were born. No implantations were reported when female rats from the first experiment that had no implantations on gestational day 10 were mated after a 2-month rest period. In pups that were born from these experiments, no teratogenic effects were observed (Agrawal et al. 1980).

A reduction of implantation sites was observed in rats orally administered 200 mg/kg of an acetone extract of juniper daily on days 1 to 7 of pregnancy (Prakash 1986).

No information on the safety of *Juniperus* species during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered lyophilized aqueous extract of juniper to mice is 3 g/kg (Lasheras et al. 1986). No adverse effects were observed in rats orally administered 2.5 g/kg of an 80% ethanolic extract of juniper (Mascolo et al. 1987).

The LD_{50} of juniper oil in rats is 6.28 g/kg after oral administration and could not be determined at doses up to 5 g/kg after topical administration (Opdyke 1979).

Toxicity testing of 10% juniper oil (species unspecified, but likely *J. communis*) in corn oil gave LD_{50} values of 750 mg/kg after intraperitoneal administration to mice, 1200 mg/kg after intra-abdominal administration to guinea pigs, 700 mg/kg after intramuscular administration to mice, and 1440 mg/kg after subcutaneous administration to guinea pigs (Mambetsadykov et al. 1990).

The LD_{50} of the compound terpinen-4-ol is 0.75 ml/kg after subcutaneous administration in mice, 0.78 ml/kg after intramuscular administration in mice, and 1.5 ml/kg after intramuscular administration in rats (Janků et al. 1960).

Short-Term Toxicity

In nephrotoxicity testing, rats were orally administered 100, 333, or 1000 mg/kg of an essential oil with an α-pinene + β-pinene to terpinen-4-ol ratio of 3:1, 100, 300, or 900 mg/kg of an essential oil with an α-pinene + β-pinene to terpinen-4-ol ratio of 5:1, or 400 mg/kg of the compound terpinen-4-ol daily for 28 days. Pathological and histological investigations indicated no toxic effects at any of the dose levels tested (Schilcher and Leuschnerb 1997).

Amelioration of tacrolimus-induced nephrotoxicity was observed in rats fed diets containing 5% juniper oil for 5 weeks, with tacrolimus administered the last 2 weeks. In rats administered juniper oil, a complete reversal of the decrease in inulin clearance seen with tacrolimus was observed, along with relatively high levels of urinary prostaglandin $F_{2\alpha}$ excretion (Butani et al. 2003).

Juniperus virginiana L. — Cupressaceae

SCN: eastern red cedar
OCN: pencil cedar; Virginia redcedar

Part: leaf, berry

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Moerman 1998; Wood and LaWall 1926).

Not for use exceeding six weeks in succession (Weiss and Meuss 2001).

Other Precautions

Use with caution in persons with inflammatory kidney disease (Bone 1995; Yarnell 2002).

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Moerman 1998; Wood and LaWall 1926); *see* Appendix 2.

Editors' Note

Information on eastern red cedar is limited. Based on chemical similarity, the data and classifications that apply to other species of juniper (*Juniperus* spp.) are believed to be applicable to eastern red cedar.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Eastern red cedar has been reported to have abortifacient activity (Moerman 1998; Wood and LaWall 1926).

No information on the safety of eastern red cedar during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose after ingestion of eastern red cedar essential oil has been associated with burning in the stomach, vomiting, convulsions, coma, and a slow pulse. Fatal cases have been reported, although details on the amount consumed are lacking (Wood and LaWall 1926).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Several sensitization studies with 5 to 10% eastern red cedar essential oil indicated sensitizing activity in zero to 2% of volunteers (Johnson 2001; Opdyke 1979).

Several skin irritation studies with 0.2 to 20% eastern red cedar essential oil indicated no irritant activity (Johnson 2001; Opdyke 1979).

Animal Pharmacological Studies

An increase in hexobarbital metabolism was observed in mice exposed to corncob bedding that had been sprayed with an ether extract of eastern red cedar (Wade et al. 1968).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Eastern red cedar has been reported to have abortifacient activity. No details were listed on the part used, dose, or whether the plant was used singly or in formula (Moerman 1998; Wood and LaWall 1926).

No information on the safety of eastern red cedar during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of eastern red cedar essential oil could not be determined at orally or topically administered doses up to 5 g/kg (Opdyke 1979).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In an irritation study, no signs of irritation were observed in rabbits topically treated with the hexane fraction of *Kaempferia galanga* (Kanjanapothi et al. 2004).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of *Kaempferia galanga* during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered ethanol extract of *Kaempferia galanga* in rats could not be determined at doses up to 5 g/kg (Kanjanapothi et al. 2004).

Short-Term Toxicity

No changes in organ weights or serum chemistry or histopathological changes were observed in rats orally administered 25, 50, or 100 mg/kg of an ethanol extract of *Kaempferia galanga* daily for 28 days. In the 50 and 100 mg/kg groups, a slight decrease in lymphocyte counts was observed (Kanjanapothi et al. 2004).

Lactuca spp.

Asteraceae

***Lactuca quercina* L.**
SCN: wild lettuce

***Lactuca serriola* L.**
SCN: wild lettuce
OCN: prickly lettuce

***Lactuca virosa* L.**
SCN: wild lettuce
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Lactucarium, the dried latex of wild lettuce (typically, *L. virosa*), is a brown substance that physically resembles opium and is sometimes referred to as "lettuce opium." While several historical texts have noted "narcotic" properties of lactucarium (Felter and Lloyd 1898; Scudder 1898), the U.S. Dispensatory notes, "we believe that the general experience is in accord with our own in finding it to be almost devoid of narcotic properties" (Wood and LaWall 1918). Although early investigation indicated the presence of small amounts of hyoscyamine-like alkaloids (Farr and Wright 1904), more recent studies have not identified any alkaloids (Frohne and Pfänder 2000; Stojakowska et al. 1999). Wild lettuce is acrid when fresh and becomes less acrid on drying.

Adverse Events and Side Effects

Intravenous administration of wild lettuce extract led to fevers, chills, abdominal and back pain, neck stiffness, headache, elevated white blood cell counts, and mild liver function abnormalities (Mullins and Horowitz 1998). Such effects are not expected after oral use of wild lettuce.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of wild lettuce during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

In a case series of nine patients, ages 12 to 38, reported to have eaten wild lettuce (*L. virosa*), adverse events were reported including mydriasis, dizziness, anxiety, urinary retention, decreased bowel sounds, and sympathetic overactivity. Amounts of the plant material ingested were not specified. A personal communication with the author indicated that the plant material was obtained and positively identified (Besharat et al. 2009).

Several young adult intravenous drug users had fevers, chills, abdominal and back pain, neck stiffness, headache, leukocytosis, and mild liver function abnormalities after intravenous administration of approximately 1 ml of an aqueous extract of wild lettuce powder. One also drank a

cup of the aqueous extract, and one also injected an evaporated ethanol extract of valerian. All three of the patients also took 2 to 6 pain relief tablets (325 mg acetaminophen, 30 mg caffeine, and 8 mg codeine), which one used chronically for headache relief. The authors of the report indicated that the plant material was labeled as *Lactuca virosa* but the identity was not confirmed (Mullins and Horowitz 1998).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of wild lettuce during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} values of the compound lactucin administered to mice are 900 mg/kg after oral administration, 50 mg/kg after subcutaneous administration, and 15 mg/kg after intravenous administration. For the compound lactucopicrin, the LD_{50} values are 12 to 20 g/kg after oral administration, 3 g/kg after subcutaneous administration, and 1.5 to 2 g/kg after intravenous administration. Sublethal doses of these compounds had no significant effect on respiration or blood pressure, and toxic doses had no effect on the motor nerves or intestinal motility (Forst 1940).

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with hyperthyroidism (Ishizuki et al. 1989; Shilo and Hirsch 1986; Teas et al. 2004).

Other Precautions

Take with at least 250 ml (8 oz) of liquid (CFR 2011a).

Drug and Supplement Interactions

None known, although use with thyroid medications should be under the supervision of a qualified healthcare

practitioner (Ishizuki et al. 1989; Shilo and Hirsch 1986; Shimizu et al. 2003; Teas et al. 2004).

Other drugs should be taken 1 hour prior to consumption of kelp, bull kelp, or kombu, or several hours after consumption, as mucilaginous plants such as kelp, bull kelp, or kombu may slow the absorption of orally administered drugs (Brinker 2001; De Smet 1993; Mills and Bone 2005).

Notice

Mucilages (Felter and Lloyd 1898); *see* Appendix 3.

Editors' Notes

Sections of kelp stems (known as laminaria tents) are used to dilate the cervix to induce labor or for surgical procedures including abortions (Boulvain et al. 2001). For use in this manner, the stem sections are inserted into the cervix. Safety of that use of kelp is not covered in this entry.

A number of seaweeds have been found to contain heavy metal residues (Almela et al. 2006; Rose et al. 2007). Total arsenic has been measured in kelp and kombu products at levels ranging from 40 to 105 mg/kg (Almela et al. 2006), though the inorganic form of arsenic is reported at much lower levels of 0.14–0.47 mg/kg (Almela et al. 2006) or as not detectable at a 0.3 mg/kg limit of detection (Rose et al. 2007). Evidence about the negative impact of inorganic arsenic on fetal health and infant development is emerging (EFSA 2009). Caution is therefore recommended in pregnancy and for young children.

U.S. regulations require that kelp directed for use as a dietary supplement must contain 225 µg or less of iodine per daily dose for supplements labeled without reference to age or physiological state. For supplements labeled for use by specific populations, iodine daily dose levels should not exceed 45 µg for infants, 105 µg for children under 4 years, 225 µg for adults and children over 4 years, and 300 µg for pregnant or nursing women (CFR 2011b).

Specific labeling is required in the United States for all over-the-counter drug products containing kelp and kombu (CFR 2011a); *see* Bulk-forming laxatives in Appendix 2.

Adverse Events and Side Effects

Cases of hyperthyroidism, hypothyroidism, and iodine-induced thyroid toxicity have been reported in association with excessive use of kelp and kombu (De Smet et al. 1990; Eliason 1998; Ishizuki et al. 1989; Mussig et al. 2006; Salas Coronas et al. 2002; Shilo and Hirsch 1986; Shimizu et al. 2003).

Kelp and kombu contain the element iodine (0.14–0.44% dry weight) (Dawczynski et al. 2007; Teas et al. 2004). Iodine idiosyncrasy, hyperthyroidism, and thyroid toxicity have been indicated as possible side effects after long-term, uncontrolled use of iodine-containing products, such as kelp, bull kelp, or kombu (Wichtl 2004). Excessive consumption of iodine can lead to goiter (swelling of the thyroid gland) (Baker 2004; Pennington 1990).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Infants are reported to be particularly sensitive to the effects of iodine (Baker 2004), and cases of infant goiter after maternal use of iodine during pregnancy or lactation have been reported (Pennington 1990). *Also see* Editors' Notes for this entry.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Cases of hyperthyroidism have been reported in association with use of kelp (De Smet et al. 1990; Eliason 1998; Salas Coronas et al. 2002; Shilo and Hirsch 1986). In one case, hyperthyroidism developed in a woman taking six 200 mg tablets of kelp daily (De Smet et al. 1990). In a second case, a 72-year-old woman ingested kelp tablets with an iodine dose of 2.8 to 4.2 mg daily for 6 months (Shilo and Hirsch 1986). The U.S. recommended dietary allowance for iodine is 150 µg/day (IOM 2001).

Hypothyroidism was reported in a 79-year-old woman who had been ingesting approximately 30 g of kombu weekly for approximately 1 year. Thyroid function tests indicated lowered levels of triiodothyronine (T_3) and thyroxine (T_4) and an increased level of thyroid-stimulating hormone (TSH), along with high blood levels of iodine. Symptoms resolved after cessation of kombu (Shimizu et al. 2003).

Iodine-induced thyroid toxicity was reported in a 39-year-old woman who was taking a combination of Chinese herbs that contained kombu and two other seaweeds in addition to other herbs. Based on the formula, the estimated iodine intake was 580 to 990 µg daily (Mussig et al. 2006). Two women, ages 42 and 59, developed iodine-induced thyroid toxicity 1 month and 1 year, respectively, after having eaten foods containing 28–140 mg/day of

iodine, calculated from their daily diet. Both patients had high concentrations of serum T_3, low ratios of serum T_3/T_4, and high blood levels of iodine. Kombu was part of the diet of these women, although their average intake was not reported in the available English language case synopses. Their thyrotoxic signs and symptoms disappeared and thyroid hormone levels normalized 1 month after the prohibition of kombu intake (Ishizuki et al. 1989).

Arsenic poisoning was reported in a 54-year-old woman taking two to four 41 mg capsules of kelp supplement daily for several months. Analysis of the supplement being taken indicated that the supplement contained an arsenic concentration of 8.5 mg/kg, although the amounts of organic and inorganic arsenic were not reported (Amster et al. 2007). Commenting on this case report, other authors noted that the patient was taking two to four times the recommended dose, and that iodine toxicity may have been the cause of the symptoms (McGuffin and Dentali 2007), although the reporting physicians replied that iodine toxicity was not believed to be the cause of the reported symptoms (Schenker et al. 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers with normal thyroid function orally administered two or four kelp capsules (containing 660 or 1320 µg of iodine) daily for 4 weeks, dose-related increases in TSH levels and urinary iodine levels were observed. In the high-dose group, a decrease in triiodothyronine and increase in poststimulation TSH response in the thyrotropin-releasing hormone stimulation test were observed. No changes in free thyroxine were reported. Two weeks after cessation of treatment, TSH levels in the high-dose kelp group were decreased, while all other thyroid values were normal for all groups (Clark et al. 2003).

In healthy volunteers ingesting 15 or 30 g of kombu (35 or 70 mg iodine) daily for 7 to 10 days, a significant increase in TSH concentrations was observed. In some cases, TSH levels exceeded normal limits. Serum levels of T_4 and T_3 were slightly decreased and within normal limits. During long-term administration (55–87 days), TSH levels were elevated and sustained while the T_4 and T_3 levels were essentially unchanged. Urinary excretion of iodine significantly increased during ingestion of kombu and returned to normal 7 to 40 days after cessation of kombu (Miyai et al. 2008).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An aqueous extract of kelp exhibited negative chronotropic effects on isolated right atria but no effect on atrial tension (Chiu and Fung 1997).

IV. Pregnancy and Lactation

Infants are reported to be particularly sensitive to the effects of iodine (Baker 2004), and cases of infant goiter after maternal use of iodine during pregnancy or lactation have been reported (Pennington 1990). *Also see* Editors' Notes for this entry.

V. Toxicity Studies

No toxicity studies were identified.

Lamium album L.

Lamiaceae

SCN: white nettle
OCN: dead nettle

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

A reference text on British herbal medicine notes that white nettle is generally considered harmless and that the tender young leaves can be eaten like spinach (Bradley 2006).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of white nettle during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of white nettle during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

L

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Heron and Yarnell 2001).

Not for use in persons with preexisting kidney disease or liver conditions, such as hepatitis or cirrhosis (De Smet 1993; McGuffin et al. 1997).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Reports of acute liver toxicity associated with consumption of chaparral surfaced from 1990 through 1997, leading to the issuance of a warning by the FDA to cease consumption of chaparral (FDA 1992). The American Herbal Products Association (AHPA) initiated a review of four cases (Watt et al. 1994) and found the reported toxicity to be due to idiosyncratic reactions in persons with preexisting liver conditions. The authors concluded, and AHPA recommended in 1995, that products containing chaparral should be labeled with the following cautionary statement: Seek advice from a health care practitioner before use if you have any history of liver disease. Discontinue use if nausea, fever, fatigue, or jaundice occur (e.g., dark urine or yellow discoloration of the eyes).

Adverse Events and Side Effects

Case reports have indicated a correlation between chaparral consumption and liver damage. Amounts of chaparral taken range from 0.3 to 6 g d aily, and the duration of use has been from 20 days to "many years," with chaparral being taken as capsules or tablets in most of the cases. The product taken was analyzed in only one case. Although one patient with toxic liver damage required a liver transplant, other cases resolved on cessation of chaparral (IOM 2001). A review of those case reports and associated toxicity studies noted that the severity of liver damage was not related to the dose or duration of chaparral use (IOM 2001).

A case of autoimmune hemolytic anemia was reported in association with chaparral use (Tregellas and South 1980).

Chaparral-induced dermatitis has been reported after contact with living plants or chaparral compresses (Leonforte 1986).

Pharmacological Considerations

Traditional use and animal studies have indicated that chaparral and the compound nordihydroguaiaretic acid (NDGA) may modify glucose regulation (Lambert et al. 2004; Luo et al. 1998; Reed et al. 1999). People with diabetes

are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

An animal study indicated that large doses (700 mg/kg) of chaparral extracts exhibited anti-implantation activity (Konno et al. 1987). In this work, the contraindication for use in pregnancy is based on concerns regarding the cases of hepatotoxicity reported in association with chaparral use, as the implications of these case reports and possible mechanisms of hepatotoxicity have yet to be fully understood (Heron and Yarnell 2001).

No information on the safety of chaparral in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Case reports have indicated a correlation between chaparral consumption and liver damage. Amounts of chaparral taken range from 0.3 to 6 g daily, and the duration of use has been from 20 days to "many years," with chaparral being taken as capsules or tablets in most of the cases. The product taken was analyzed in only one case. Although one patient with toxic liver damage required a liver transplant, other cases resolved on cessation of chaparral (IOM 2001). A voluntary rechallenge in one case led to a return of symptoms (Batchelor et al. 1995). A review of the case reports and associated toxicity studies noted that the severity of liver damage was not related to the dose or duration of chaparral use (IOM 2001).

Toxic liver damage with elevated aminotransferase levels and joint stiffness in the right hand were reported in a 38-year-old woman who had taken 400 mg chaparral daily for "many years." The patient had a history of drug abuse, alcohol use, and previous exposure to hepatitis C. The reporting authors indicated that chaparral might have potentiated or exacerbated underlying liver disease. The patient eventually required a liver transplant (Sheikh et al. 1997).

Toxic liver damage with jaundice and abdominal pain was reported in a 41-year-old woman who had taken tablets containing 259 mg/day of chaparral over an 11-week period. The patient retuned to normal after discontinuation of chaparral (Clark and Reed 1992; Sheikh et al. 1997).

Toxic liver damage with fatigue, jaundice, dark urine, nausea, abdominal pain, and diarrhea was reported in a 44-year-old woman who had taken capsules containing 2400 mg chaparral daily for 10 days and then 800 mg daily for another 10 days (Clark and Reed 1992; Sheikh et al. 1997).

Toxic liver damage with symptoms of cholecystitis and elevated aminotransferase levels were reported in a 60-year-old woman who had taken an unspecified amount of capsules containing chaparral (Sheikh et al. 1997).

Hepatic dysfunction with scleral icterus and diffuse jaundice was reported in a 42-year-old man who had consumed 1440 mg chaparral daily for 6 weeks. The patient returned to normal 1 month after discontinuing chaparral (Clark and Reed 1992; Sheikh et al. 1997).

Toxic liver damage with fatigue, jaundice, and dark urine was reported in a 25-year-old man who consumed 3830 mg chaparral capsules daily for 2 to 3 weeks, then 5760 mg daily for 10 weeks. After cessation of chaparral, the patient recovered within 2 weeks (Sheikh et al. 1997).

Toxic liver damage, confirmed by liver biopsy, with fatigue, jaundice, abdominal pain, light stools, and pruritus was reported in a 57-year-old woman who had consumed 480 mg of chaparral daily for 8 weeks. The woman had used conjugated estrogens in the past (a possible hepatotoxin with persistent effects, but noted as unlikely as the causative agent in the case) (IOM 2001; Sheikh et al. 1997).

Jaundice with possible toxic liver damage was reported in a 71-year-old man who had been taking an unspecified amount of chaparral capsules daily for an unspecified amount of time. Symptoms of flu-like illness, ascites, and jaundice abated 2 months after cessation of chaparral. The man had a history of alcohol use (14 oz wine daily). One month after restarting chaparral use, the man developed jaundice, ascites, scleral icterus, and nausea. Liver biopsy indicated diffuse necrosis with inflammation, portal tract expansion, mild cholestasis, and mild fibrous septation. A biopsy 3 months later indicated marked improvement (Batchelor et al. 1995).

Drug-induced hepatotoxicity was reported in a 33-year-old woman who had been taking 15 tablets (dose unspecified) of chaparral daily for 3 to 4 months. The patient had presented with jaundice, ascites, abdominal pain, fatigue,

scleral icterus, anorexia, and pedal edema due to subacute hepatic necrosis. The symptoms resolved after cessation of chaparral (Katz and Saibil 1990).

Subacute liver damage was reported in a 43-year-old woman who had taken approximately three tablets (dose unspecified) of chaparral daily for 6 weeks. The woman was also taking aspirin regularly (Batchelor et al. 1995).

Liver damage was reported in a 54-year-old woman who had taken 1600 mg of chaparral daily for 3 weeks. The patient recovered within 6 weeks of stopping chaparral intake (Sheikh et al. 1997).

Liver damage was reported in a 39-year-old woman who drank tea made from 4 tea bags of chaparral daily for approximately 1.5 years. The patient recovered within one week after stopping chaparral intake (Sheikh et al. 1997).

An additional two cases of subacute liver damage and one case of hepatotoxicity associated with consumption of chaparral have been reported, but without information on doses taken (Sheikh et al. 1997).

A 40-year-old man had a positive direct antiglobulin test (DAT) (due to the presence of IgG antibodies) leading to a diagnosis of autoimmune hemolytic anemia after consumption of four tablets (dose unspecified) of chaparral daily. Chaparral was discontinued and the DAT became weaker over the course of 19 weeks, eventually becoming negative. After 8 weeks of negative DAT, the patient began taking chaparral again and the DAT test became positive after 5 weeks. During the follow-up study, haptoglobin and hematocrit tests showed no evidence of decreased red blood cell survival (Tregellas and South 1980).

Acute dermatitis, with patch tests confirming reaction to chaparral, was reported in six men. The lesions were primarily on sun-exposed sites but were also on the legs and scrotum. Contact was with the living plant in two men, from moist compresses or baths in two men, and as a result of burning the bushes in two men (Leonforte 1986).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in plasma glucose concentrations with no changes in plasma insulin was observed in diabetic mice orally administered 300 mg/kg of the compound NDGA daily for 12 days (Luo et al. 1998).

A reduction in steady-state plasma glucose levels and glucose levels after an infusion of glucose was observed in diabetic rats orally administered 300 mg/kg of NDGA daily for 4 days (Reed et al. 1999).

Decreases in fasting plasma glucose levels and glucose response to an oral glucose load were observed in diabetic mice orally administered 300 mg/kg of the compound NDGA daily for 12 days (Luo et al. 1998).

In Vitro Pharmacological Studies

In vitro pharmacological studies were identified but omitted due to the availability of substantial human data.

IV. Pregnancy and Lactation

Anti-implantation activity was observed in rats orally administered 0.7 g/kg of a methanol extract, 0.58 g/kg of a chloroform extract, or 0.52 g/kg of a phenolic extract of chaparral daily on days 1 to 20 of pregnancy. The chloroform extract exhibited the strongest anti-implantation activity (Konno et al. 1987).

No information on the safety of chaparral during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of the compound nordihydroguaiaretic acid (NDGA) is 5.5 g/kg in rats, 4 g/kg in mice, and 0.8 g/kg in guinea pigs (Lehman et al. 1951). The LD_{50} of NDGA intraperitoneally administered to mice is 0.1 to 0.8 g/kg (Fujii et al. 1970; Kozubik et al. 1993; Madrigal-Bujaidar et al. 1998).

Short-Term Toxicity

Toxicity testing in mice examined the effects of chaparral phenolic resin as 0.5 to 5% of the diet, as well as oral gavage administered doses of 100 mg chaparral resin or 15 or 100 mg of the compound NDGA daily for 4 days. In animals administered chaparral as part of the diet, reductions in body mass and food intake were observed. Mice tolerated a maximum of 100 mg of phenolic resin in the diet, but oral gavage administered doses of 100 mg of resin or 15 mg of NDGA were lethal. No significant differences in detoxification, measured as glucuronic acid conjugates in urine, were detected among orally administered treatments (Rios et al. 2008).

In rats fed a diet containing 2% of the compound NDGA daily for 3 weeks and injected with endotoxin- or non-endotoxin-containing bacteria, a synergistic provocation of renal damage was observed in the animals injected with endotoxin-containing bacteria. Renal lesions were not characteristic of classic endotoxin treatment, and the results excluded bacterial colonization and intrarenal accumulation of NDGA as causes of nephropathy (Gardner et al. 1987).

Subchronic Toxicity

In hamsters fed a diet containing 4% of a hydroethanolic extract of chaparral for 70 days, marked growth retardation, pronounced irritability and aggressiveness, and a marked hypoplasia of testicles and accessory sex glands were observed (Granados and Cardenas 1994).

In rats fed a diet containing 2% of the compound NDGA daily for 1 to 24 weeks, the glomerular filtration rate was decreased as compared to control animals. Early during NDGA exposure, small polyps developed along the outer medullary segments of the collecting tubules in

the kidney. At 2 months of NDGA exposure, kidneys were infiltrated by polymorphonuclear leukocytes and macrophages. Basement membrane thickening, fibrosis, tubular atrophy, and eventually proximal tubular cell necrosis were characterized adjacent to these infiltrated areas. By 6 months of NDGA exposure, cysts were found throughout the kidneys (Evan and Gardner 1979).

In rats fed diets containing 2% of the compound NDGA for 99 days, lesions in the kidneys were observed, including hydropic changes in tubular epithelial cells, tubular necrosis, proliferation of lysosomes in number and size, and invasion by macrophages (Goodman et al. 1970).

Chronic Toxicity

In rats fed diets containing 0.5 or 1.0% of the compound NDGA for 74 weeks, cysts of the mesenteric lymph nodes at the ileocecal junction were observed. In one rat, the cystic nodes were invaded by a malignant reticulum cell sarcoma. Mean body weight was lower in the NDGA group as compared to the control group (Grice et al. 1968).

In rats fed diets containing 0.5% of the compound NDGA for 2 years, growth inhibition was observed after 6 months. After 2 years, inflammatory cecal lesions, massive cecal hemorrhages with single and multiple cysts in the mesentery near the cecum, and slight cystic enlargement of the paracecal lymph nodes were observed (Lehman et al. 1951).

Genotoxicity

In human lymphocytes, NDGA produced a dose-dependent increase in sister-chromatid exchanges, and, at the highest dose tested (27 µ*M*), a decrease in the cell cycle delay (Madrigal-Bujaidar et al. 1998). In bone marrow cells of mice orally administered 8.8, 17.6, 35.3, and 70.7 mg/kg of NDGA, an increase in sister-chromatid exchanges was observed at the two highest dose levels (Madrigal-Bujaidar et al. 1998).

Conversely, NDGA exhibited protective activity against genotoxic damage induced by the compound norgestrel. Study parameters included sister-chromatid exchanges, chromosomal aberrations, mitotic index, and replication index (Siddique et al. 2006).

Laurus nobilis L. — Lauraceae

SCN: bay
OCN: bay laurel; Grecian laurel; sweet bay; true bay

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic contact dermatitis, confirmed by patch testing, has been reported after contact with foods or topical products containing bay leaf or bay essential oil (Adisen and Onder 2007; Foussereau et al. 1975; Jirasek and Skach 1962; Opdyke 1979; Ozden et al. 2001).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of bay during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis, confirmed by patch testing, has been reported after contact with foods or topical products containing bay leaf or bay essential oil (Adisen and Onder 2007; Foussereau et al. 1975; Jirasek and Skach 1962; Opdyke 1979; Ozden et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound cinnamtannin B-1 reduced thrombin-induced aggregation in platelets from type 2 diabetic subjects (Bouaziz et al. 2007). The same compound reduced thrombin-evoked microtubular remodeling and activation of the tyrosine kinases Btk and pp60(src), which leads to inhibition of platelet aggregation (Ben Amor et al. 2007).

IV. Pregnancy and Lactation

No information on the safety of bay during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of bay essential oil is 3.95 g/kg after oral administration to rats, and could not be determined at doses up to 5 g/kg after topical administration to rabbits (Opdyke 1979).

See Eucalyptus globulus essential oil Toxicity Studies for information on the toxicity of the compound 1,8-cineol (eucalyptol), the primary component of bay leaf essential oil (36–46%) (Kovacevic et al. 2007).

Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

A series of case reports and an associated in vitro study suggested that lavender essential oil has estrogenic activity and that lavender as an ingredient in personal care products (i.e., shampoo, styling gel, and soap) was the cause of gynecomastia in several teenage boys (Henley et al. 2007). Those reports have been the subject of criticism (Dean 2007; Kalyan 2007; Kemper et al. 2007), with letters to the editor regarding the cases noting that estrogen levels reported were normal, and that traditional use of and research on lavender essential oil has not indicated estrogenic activity, although estrogenic activity has been shown for other essential oils (Kemper et al. 2007).

Adverse Events and Side Effects

Allergic contact dermatitis, confirmed by patch testing, has been reported in individuals exposed to lavender essential oil (Coulson and Ali Khan 1999; Rademaker 1994; Schaller and Korting 1995; Sugiura et al. 2000).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A 1935 study indicated that lavender stimulated uterine contractions in isolated pregnant guinea pig uteruses (Superbi and Crispolti 1935). No other information on the safety of lavender in pregnancy was identified.

No information on the safety of lavender during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis, confirmed by patch testing, has been reported in individuals exposed to lavender essential oil (Coulson and Ali Khan 1999; Rademaker 1994; Schaller and Korting 1995; Sugiura et al. 2000).

Confusion and deep drowsiness were reported in an 8-month-old boy who ingested a "small amount" of a "handmade extract" (no details provided) of lavandin, identified as a hybrid of *L. angustifolia* and *L. latifolia* (Landelle et al. 2008).

A case series of gynecomastia associated with the use of products scented with "lavender" includes cases of a 4-year-old who had been treated with a "healing balm containing lavender oil," a 10-year-old boy who used a styling gel daily and a shampoo regularly, both of which contained lavender essential oil, and a 7-year-old who had used "lavender-scented" soap and "lavender-scented" commercial skin lotions. Gynecomastia resolved after discontinuation of these products. In all cases, other ingredients, product name, amount used, and frequency and duration of application were not specified (Henley et al. 2007). Letters to the editor regarding the case report noted that estrogen levels reported in the cases were normal, and that traditional use of and research on lavender essential oil have not indicated estrogenic activity, although estrogenic activity has been shown for other essential oils (Kemper et al. 2007). Letters also indicated that other ingredients or packaging (notably phthalates) could have been responsible for the effects (Kemper et al. 2007), as could other environmental or dietary factors (Dean 2007; Kalyan 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In a mouse model of pulmonary thromboembolism induced by intravenous injection of a collagen–epinephrine mixture, administration of 100 mg/kg of lavandin essential oil daily significantly reduced thrombotic events without inducing prohemorrhagic complications at variance with acetylsalicylic acid used as a reference drug (Ballabeni et al. 2004).

In Vitro Pharmacological Studies

Inhibition of platelet aggregation induced by arachidonic acid, U46619, collagen, and ADP (with IC_{50} values of 51, 84, 191, and 640 µg/ml, respectively) was observed in guinea pig platelet-rich plasma treated with lavandin essential oil. Lavandin oil also destabilized clot retraction (IC_{50} of 149 µg/ml) induced by thrombin on rat platelet-rich plasma (Ballabeni et al. 2004).

In estrogen receptor-positive (MCF-7) and androgen receptor-positive (MDA-kb2) human breast cancer cells, lavender essential oil stimulated ERE-dependent luciferase activity in a dose-dependent manner, with the maximum activity observed at 0.025% (v/v), corresponding to ~50% of the activity elicited by 1 n*M* 17β-estradiol. The pure estrogen receptor antagonist fulvestrant inhibited transactivation of the reporter plasmid (Henley et al. 2007). A critique of the study indicated that the effects of lavender were "very weak" (Kalyan 2007).

IV. Pregnancy and Lactation

An older study indicated that a hot aqueous extract of lavender flower (dose not specified) stimulated uterine contractions in isolated pregnant guinea pig uteri (Superbi and Crispolti 1935).

No information on the safety of lavender during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of lavandin essential oil could not be determined at doses up to 5 g/kg after oral administration in rats or topical application in rabbits (Opdyke 1979).

The LD_{50} of lavender absolute is 4.25 g/kg after oral administration in rats, whereas the dermal LD_{50} could not be

determined at doses up to 5 g/kg in guinea pigs (Opdyke 1979).

The LD_{50} of spike lavender essential oil is 3.8 g/kg after oral administration in rats, whereas the dermal LD_{50} could not be determined at doses up to 2 g/kg in rabbits (Opdyke 1979).

Lawsonia inermis L.

Lythraceae

SCN: henna
Syn: *Lawsonia alba* Lam.

AN: *madayanti*
Part: leaf

Quick Reference Summary

Safety Class: 2a, 2d
Interaction Class: A

Contraindications

For external use only (McMillan et al. 2004; Zinkham and Oski 1996).

Not for use on infants or children with glucose-6-phosphate dehydrogenase (G6PD) deficiency (Devecioglu et al. 2001; Kandil et al. 1996; Kök et al. 2004; Raupp et al. 2001; Zinkham and Oski 1996).

Other Precautions

Use with caution on adults with G6PD deficiency (McMillan et al. 2004; Rund et al. 2007; Zinkham and Oski 1996).

Drug and Supplement Interactions

None known.

Editors' Notes

Some henna, particularly that marketed as "black henna," is mixed with the compound *para*-phenylenediamine (PPD), a black hair dye that frequently causes skin sensitization and has been responsible for numerous cases of allergic contact dermatitis, some of which have caused permanent scarring (Akhras and Ostlere 2005; Kang and Lee 2006). PPD is not a compound found in *Lawsonia inermis*.

Adverse Events and Side Effects

In children with glucose-6-phosphate dehydrogenase (G6PD) deficiency, a hereditary disease also known as favism, hemolytic anemia and hyperbilirubinemia have been reported after topical application of henna (Devecioglu et al. 2001; Kandil et al. 1996; Kök et al. 2004; Raupp et al. 2001; Zinkham and Oski 1996). In some cases, the patients also developed acute renal failure, sometimes fatal (Devecioglu et al. 2001; Kök et al. 2004). No case reports for such adverse effects in adults were identified after topical application. Relative thickness of skin and higher body mass to skin surface area ratio may account for a lack of case reports in adults.

Pharmacological Considerations

Animal and in vitro studies and human case reports indicated that the compound lawsone can produce hemolytic anemia in persons with G6PD deficiency (McMillan et al. 2004; Zinkham and Oski 1996).

In an in vitro study of skin absorption of henna, 0.3 to 1.3% of a henna hair coloring paste was absorbed into the

skin after 1 hour of treatment. Extended absorption studies indicated that most of the product remained on the skin and a relatively small amount was absorbed (Kraeling et al. 2007).

Pregnancy and Lactation

An animal study indicated no developmental toxicity of henna but some maternal toxicity at the highest dose (20 mg/kg) tested (Nawaf et al. 2003). Henna is reported to have been used internally as an abortifacient (List and Hörhammer 1973).

No information on the safety of henna in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a test of henna as a substance for creating temporary marks on patients undergoing external radiotherapy, no adverse reactions were reported in any of the 158 patients marked with henna (Wurstbauer et al. 2001).

Case Reports of Adverse Events

In children with glucose-6-phosphate dehydrogenase (G6PD) deficiency, a hereditary disease also known as favism, hemolytic anemia and hyperbilirubinemia were reported after topical application of henna (Devecioglu et al. 2001; Kandil et al. 1996; Kök et al. 2004; Raupp et al. 2001; Zinkham and Oski 1996). In some cases, the patients also developed acute renal failure, sometimes fatal (Devecioglu et al. 2001; Kök et al. 2004).

Some henna, particularly that marketed as "black henna," is mixed with the compound *para*-phenylenediamine (PPD), a black hair dye that frequently causes skin sensitization and has been responsible for numerous cases of allergic contact dermatitis (Akhras and Ostlere 2005; Kang and Lee 2006; Kazandjieva et al. 2007). Although the majority of allergic reactions to "henna" reported in the literature are reactions to PPD, allergic reactions to pure henna have been reported and confirmed by patch testing (Belhadjali et al. 2008; Garcia Ortiz et al. 1997; Gupta et al. 1986; Nigam and Saxena 1988; Oztas et al. 2001; Perez et al. 2003; Polat et al. 2009).

A young woman committed suicide by ingesting an unknown amount of henna. Autopsy findings were consistent with anaphylaxis, including laryngeal edema and pulmonary congestion (Kök et al. 2005).

Hemolysis, renal failure, and cardiac ischemia were reported in a 69-year-old man of northern Iraqi origin who mistakenly ingested two teaspoons of henna powder. The authors noted that, based on the man's origin, G6PD deficiency was likely but could not be tested for while the man was under care, due to inaccurate enzyme quantitation caused by the hemolysis (Rund et al. 2007).

Acute chemical colitis was reported in a 45-year-old woman with a history of ulcerative colitis who had reportedly ingested an unknown amount of henna mixed in 1 liter of water. The product was not verified and in the discussion section of the case report, the reporting physicians, citing a case of PPD-induced allergic contact dermatitis (Nawaf et al. 2003), indicated that henna was sometimes responsible for contact dermatitis (Uygur-Bayramicli et al. 2005), bringing into question authors' knowledge of the product ingested.

Newly applied henna is reported to block the passage of visible light to the skin. A case report indicated that a pulse oximeter was unable to provide readings on skin dyed with henna (Nirmalan and Baldwin 1997).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In a study on the role of oxidant stress in lawsone-induced hemolytic anemia, radiolabeled erythrocytes exposed in vitro to lawsone or its hydroquinone form, 1,2,4-trihydroxynaphthalene (THN), were intravenously administered in rats. Neither lawsone nor THN were directly hemolytic or methemoglobinemic, even at high concentrations (>3 m*M*). Lawsone had no effect on erythrocytic glutathione (GSH levels), whereas THN (3 m*M*) induced a modest depletion. In contrast, ortho-substituted 1,4-naphthoquinones without a 2-hydroxy group, such as 2-methyl- and 2-methoxy-1,4-naphthoquinone, were redox active, were able to deplete GSH, and were direct-acting hemolytic agents. The authors indicated that lawsone is a weak direct-acting hemolytic agent that does not require extraerythrocytic metabolism to cause hemotoxicity and that the

hemolytic response to henna may be restricted to individuals with compromised antioxidant defenses (McMillan et al. 2004).

In Vitro Pharmacological Studies

In blood from healthy and G6PD-deficient adults incubated with the compound lawsone (2.8×10^{-3} mol/l), methemoglobin (MHb) levels were 7.4% in the blood from healthy patients, and 40–44% in the blood from G6PD-deficient patients. The authors of the study noted that lawsone is capable of inducing oxidative injury in G6PD-normal red blood cells and produces more significant damage in G6PD-deficient red blood cells. The concentrations of lawsone producing oxidative damage are similar to those reported for the naphthalene metabolites α- and β-naphthol and α- and β-naphthoquinone, compounds documented to cause severe hemolysis in G6PD-deficient subjects (Zinkham and Oski 1996).

In a study of absorption of the compound lawsone, the principal color ingredient in henna, on human skin, two hair coloring products and two shampoo products, all containing henna, were tested on nonviable human skin. The shampoo was left on the skin for 5 min, while the coloring was left on for 1 h. For the henna hair paste products, 0.3 and 1.3% of the applied dose was absorbed into the receptor fluid in 24 hours while 2.2 and 4.0% remained in the skin. For both henna shampoo products, 0.3% of the applied dose was absorbed into the receptor fluid at 24 hours while 3.6 and 6.8% remained in the skin. For all products, most of the lawsone applied was washed from the surface of the skin (83–102%) at the end of the exposure period. Extended absorption studies were conducted for 72 hours to determine if skin levels of lawsone in the 24-hour studies might eventually be percutaneously absorbed. The studies determined that the majority of the lawsone remained in the skin with only a small increase in receptor fluid values (Kraeling et al. 2007).

IV. Pregnancy and Lactation

In rats orally administered 2, 7, or 20 mg/kg of the compound lawsone on days 6 to 15 of pregnancy, no adverse effects on pregnancy or embryo development were observed. In the 20 mg/kg group, one mouse aborted at day 15, but the authors indicated that this was not considered treatment related. Slight maternal toxicity, but no embryotoxicity, was observed in the 20 mg/kg dose group, and the no-observed-adverse-effect level (NOAEL) was established as 7 mg/kg daily for maternal toxicity (Nawaf et al. 2003).

No information on the safety of henna during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound lawsone orally administered in rats is 570 mg/kg for females and 500 to 2000 mg/kg for males (SCCNFP 2002).

Short-Term Toxicity

Chemopreventive activity against chemically induced skin cancer was observed in mice topically administered 150 or 300 mg/kg daily of an 80% ethanolic extract of henna for 21 days (Dasgupta et al. 2003).

Subchronic Toxicity

In rats orally administered 8, 20, or 50 mg/kg of the compound lawsone daily for 13 weeks, no mortalities occurred, although evidence of hemolytic anemia was observed in the 50 mg/kg dose group. All female dose groups exhibited a significant but not dose-related decrease in clotting time. Dose-related decreases in blood urea, creatinine and albumin/globulin ratio, and increased bilirubin, were seen in females at the 20 and 50 mg/kg doses, and similar changes were seen in males at the high dose (SCCNFP 2002).

In a similar study, rats were orally administered 2, 7, or 20 mg/kg of the compound lawsone daily for 13 weeks. A dose-related decrease in erythrocyte count was observed in females, which was significantly lower than control at the 7 and 20 mg/kg dose levels. A significant decrease was also seen in males at the top dose only. Dose-related decreases in blood urea (mid and high dose), creatinine (high dose only), and albumin/globulin ratio (all doses), and increased bilirubin, were seen in females. Macroscopic abnormalities were observed in the forestomach and kidneys of animals at the 20 mg/kg dose. Dose-related increases in kidney and spleen weights were apparent for both sexes, and for livers of females. The female relative kidney weights were significantly higher than control at 7 and 20 mg/kg. The authors concluded that treatment-related effects occurred at 20 mg/kg, affecting mainly the kidneys, forestomach, and spleen, and that the no-observed-adverse-effect level (NOAEL) was 7 mg/kg (SCCNFP 2002).

Genotoxicity

Moderate mutagenic activity of an ethanol extract of henna was observed in the Ames test for mutagenicity using *Salmonella typhimurium* strains TA98 and TA102 (Mahmoud et al. 1992).

No evidence of chromosomal or other damage leading to micronucleus formation was observed in the mouse bone marrow micronucleus assay in mice orally administered 300 mg/kg henna and sacrificed 24, 48, or 72 hours after administration (SCCNFP 2002).

In the Ames test for mutagenicity in *S. typhimurium* strain TA98, the compound lawsone was mutagenic at concentrations of 500 to 1000 µg/plate without metabolic activation, whereas an extract of henna demonstrated no mutagenic activity at concentrations up to 1000 µg/plate (Stamberg et al. 1979).

In 2002, the EU Scientific Committee on Cosmetics and Non-Food Products (SCCNFP) evaluated the safety of the compound lawsone as a coloring agent in hair dye

products of the European Union (EU). Based on in vitro and in vivo studies, the SCCNFP concluded that lawsone was mutagenic and not suitable for use as a hair coloring agent (SCCNFP 2002). More recent in vivo and in vitro studies have indicated a lack of mutagenic activity of lawsone (Kirkland and Marzin 2003; Marzin and Kirkland 2004).

Lentinula edodes (Berk.) Pegler

Tricholomataceae

SCN: shiitake
Syn: *Lentinus edodes* (Berk.) Singer
PN: *xiang xun* (fruiting body); *xiang gu* (fruiting body)
OCN: Japanese forest mushroom
Part: fruiting body, mycelium

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

A condition known as shiitake dermatitis or toxicoderma occurs in some individuals after the ingestion of raw or partially cooked shiitakes. The clinical features are linear dermatitis on the trunk, and sometimes on the extremities, neck, face, and head, typically occurring up to 48 hours after shiitake ingestion (Garg and Cockayne 2008; Lippert et al. 2002; Nakamura 1992). An analysis of case reports suggested that some cases involved photodermatitis (development of a rash after exposure to sunlight) (Hanada and Hashimoto 1998).

Occupational contact dermatitis from shiitake has been reported (Aalto-Korte et al. 2005; Curnow and Tam 2003; Tarvainen et al. 1990, 1991; Ueda et al. 1992).

Pharmacological Considerations

Studies have indicated immunomodulating effects of shiitake, suggesting that shiitake should be used with caution in persons taking immune-suppressant medications (Lee et al. 2009a, 2009b; Zheng et al. 2005).

Pregnancy and Lactation

No information on the safety of shiitake during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A condition known as shiitake dermatitis or toxicoderma occurs in some individuals after the ingestion of raw or partially cooked shiitakes. The clinical features are linear groups of pruritic erythematous papules or flagellate dermatitis on the trunk, and sometimes on the extremities, neck, face, and head, typically occurring up to 48 hours after shiitake ingestion. The pathogenicity of the dermatitis is not known; however, patients generally do not test positive to skin-prick or patch testing with shiitake extract (Garg and Cockayne 2008; Lippert et al. 2002; Nakamura 1992). A similar case was reported in a patient who had taken the compound lentinan (Shimizu 1990). In some cases, photosensitive skin lesions have been associated with shiitake dermatitis (Hanada and Hashimoto 1998).

Occupational exposure to shiitake has resulted in contact dermatitis, with shiitake-specific immunoglobulin E reported in at least one case (Aalto-Korte et al. 2005; Curnow and Tam 2003; Tarvainen et al. 1990, 1991; Ueda et al. 1992).

Respiratory and immunological reactions, thought to be due to airborne spores, have been reported among shiitake workers (Sastre et al. 1990).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a phase I clinical safety and tolerability trial with 26 healthy volunteers, subjects were orally administered 9 g of an active hexose correlated compound extracted from shiitake daily for 14 days. Adverse effects of nausea, diarrhea, bloating, headache, fatigue, and foot cramps occurred in a total of 6 subjects but were mild and transient, and 2 subjects left the study due to nausea and intolerance of the

shiitake extract. There were no laboratory abnormalities (Spierings et al. 2007).

Animal Pharmacological Studies

A study was conducted of the combined immune-potential effectiveness of intranasal application of the compound lentinan before and after administration in guinea pigs of BCG vaccination (Bacille Calmette-Guérin, a v accine for tuberculosis), with doses of 1 mg/kg of lentinan three times at 2-day intervals. The results indicated that intranasal application of BCG alone or in combination with lentinan induced a high level of alveolar macrophage activation. Pretreatment with the lentinan enhanced the local immunohistological response to BCG in lung and reduced the generalized side effects of BCG (Drandarska et al. 2005).

A decrease in expression of the CYP1A drug-metabolizing isoenzymes was observed in mice orally or intraperitoneally administered 10 mg/kg of the compound lentinan every other day for four doses (Okamoto et al. 2004). In mice intraperitoneally administered 10 mg/kg of the compound lentinan every other day for four doses, suppression of constitutive and 3-methylcholanthrene-induced CYP1A expression and ethoxyresorufin-O-deethylation activity in the liver was observed (Hashimoto et al. 2002).

A reduction in plasma glucose levels was observed in diabetic rats orally administered 50 mg/kg exopolymers from shiitake daily for 7 days (Kim et al. 2001).

In Vitro Pharmacological Studies

In mouse splenocytes and human peripheral blood mononuclear cells treated with an extract of shiitake, the expression levels of IL-2 and TNF-α genes were augmented in both sets of cells. The production of IL-2 was augmented in the mouse splenocytes, and the production of TNF-α was augmented in murine peritoneal exudate macrophages. The production of IL-2 and TNF-α was augmented in the human mononuclear cells (Liu et al. 1998).

In the lymphocyte transformation test, aqueous extracts of shiitake were able to enhance the proliferation of rat thymocytes directly and act as costimulators in the presence of the T-mitogen phytohaemagglutinin (PHA) (Israilides et al. 2008).

The compound lenthionine inhibited platelet aggregation induced by arachidonic acid and U-46619 (Shimada et al. 2004).

IV. Pregnancy and Lactation

No information on the safety of shiitake during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in rats orally administered 0.5 or 2 g /kg of an extract of shiitake mycelium (Koike et al. 2002a).

In mice orally administered 3, 6, or 9 g/kg of dried shiitake daily for 5 days, an increase in plasma creatine kinase activity was observed at the 9 g/kg dose. No other changes in blood chemistry were observed (Nieminen et al. 2009).

Short-Term Toxicity

No adverse effects, including changes in body or organ weights, hematological or histopathological changes, or changes in blood chemistry, were observed in rats orally administered 0.5 or 1 g/kg of a shiitake mycelium extract daily for 28 days (Koike et al. 2002b).

No adverse effects, including changes in body or organ weights, hematological or histopathological changes, or changes in blood chemistry, were observed in rats given the compound lentinan in water (concentration of 150 g/kg) as the sole source of drinking water for 18 hours a day for 28 days (Odagiri et al. 2006).

Genotoxicity

In the Ames test for mutagenicity in *Salmonella typhimurium*, mutagenic activity of shiitake was observed without metabolic activation in *Salmonella* tester strains sensitive to base-pair substitution mutagens. Mutagenicity of other commonly consumed edible mushrooms, including *Agaricus bisporus* and *Boletus edulis*, was observed (Von Wright et al. 1982).

In a chromosomal aberration test in cultured mammalian cells, no aberrations were observed after continuous (up to 48 h) or short (6 h) treatment with an extract of shiitake mycelium at concentrations up to 4000 µg/ml (Miwa et al. 2002).

Leonurus cardiaca L. — Lamiaceae

SCN: motherwort
OCN: common motherwort

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bradley 1992; Chadha 1988; List and Hörhammer 1973).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Chadha 1988; Felter and Lloyd 1898; List and Hörhammer 1973); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Information on the safety of motherwort in pregnancy is limited. Early studies of motherwort on uterine tissue provided conflicting results on uterine stimulant activity (Erspamer 1948; Pilcher 1916; Pilcher and Mauer 1918).

No information on the safety of motherwort in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An ethanol extract of motherwort stimulated growth of estrogen receptor-positive MCF-7 breast cancer cells half as much as estradiol (Zava 1998).

IV. Pregnancy and Lactation

In experiments on the effects of motherwort extract on isolated uteruses or uterine tissue, one study indicated a mild stimulating effect (Erspamer 1948), while two others showed no effect (Pilcher 1916; Pilcher and Mauer 1918).

The compound leonurine was observed to increase uterine tone and contractions in isolated uteruses (Kubota and Nakashima 1930).

No information on the safety of motherwort during lactation was identified.

V. Toxicity Studies

Acute Toxicity

Irritation, convulsions, and respiratory paralysis were observed in mice intraperitoneally administered the compound leonurine (dose unspecified in available translated material). The same compound administered to cats in "small" doses caused respiratory stimulation, while "excessive" doses produced respiratory distress (Kubota and Nakashima 1930).

Genotoxicity

No mutagenic activity was observed for motherwort in the Ames mutagenicity test (Schimmer et al. 1994).

Part: above-ground parts, herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Notice

Emmenagogue and uterine stimulant (Bensky et al. 2004; Chen and Chen 2004; Tang and Eisenbrand 1992); *see* Appendix 2.

Adverse Events and Side Effects

Overdose (standard dose is a decoction of 9–15 g; 30 g is listed as a large dose) of Chinese or Siberian motherwort has been associated with symptoms such as generalized weakness, stiffness and paralysis, generalized body pain, a sense of oppression in the chest, excessive sweating, low blood pressure, and cold extremities (Bensky et al. 2004).

Pharmacological Considerations

Animal and in vitro studies have indicated that Chinese motherwort and compounds in Chinese motherwort have antiplatelet activity (Chen and Chen 2004; Lee et al. 1991). Based on these studies, one text on traditional Chinese medicine notes that Chinese or Siberian motherwort should be used with caution in patients taking anticoagulant or antiplatelet drugs, noting that this caution is theoretical and interactions have not been observed clinically (Chen and Chen 2004).

Pregnancy and Lactation

A reference text on traditional Chinese medicine indicates that neither Chinese nor Siberian motherwort should be used during pregnancy (Bensky et al. 2004), while a second text indicates that these herbs may be used during pregnancy with extreme caution (Chen and Chen 2004). Human and animal studies and traditional use have indicated that Chinese and Siberian motherwort have a stimulating effect on the uterus (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of Chinese or Siberian motherwort during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose (standard dose is a decoction of 9–15 g; 30 g is listed as a large dose) of Chinese or Siberian motherwort is reported as slightly toxic, with adverse effects appearing 4 to 6 hours after ingestion. Associated symptoms included generalized weakness, stiffness and paralysis, generalized body pain, a sense of oppression in the chest, excessive sweating, low blood pressure, and cold extremities. Severe cases may also include shock, cyanosis, and respiratory paralysis (Bensky et al. 2004). Details on doses, durations, products used, and relevant patient medical history were not listed in the available English language translation.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

An alcohol extract of Chinese motherwort significantly inhibited platelet aggregation after intravenous administration (animal and dose not specified in available English language translation) (Chen and Chen 2004).

In Vitro Pharmacological Studies

The compound prehispanolone was found to be a platelet-activating factor receptor antagonist (Lee et al. 1991).

IV. Pregnancy and Lactation

A reference text on traditional Chinese medicine indicates that Chinese or Siberian motherwort should not be used during pregnancy (Bensky et al. 2004), while a second text indicates that these herbs may be used during pregnancy but that extreme caution must be used (Chen and Chen 2004).

Overdose of Chinese or Siberian motherwort (standard dose is decoction of 9–15 g; 30 g is listed as a large dose) has been associated with miscarriage (Bensky et al. 2004).

A uterine-stimulating effect was observed in rabbits, cats, dogs, and guinea pigs orally administered water or alcohol extracts of Chinese motherwort (doses not specified in available English language translation). The effect was observed in both pregnant and nonpregnant animals, and early and late in pregnancy (Chen and Chen 2004).

Contraction of the uterus was recorded in nonpregnant women after ingestion of 15 to 20 g of a decoction or other extract of Chinese motherwort. The strength of the contraction was not dependent on the dose of herb taken (Chen and Chen 2004).

No information on the safety of Chinese or Siberian motherwort during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered Siberian motherwort in rats could not be determined at doses up to 3 or 5 g/kg (Oga et al. 1986; Pin et al. 2009).

The LD_{50} of intravenously administered Chinese motherwort in mice is between 30 and 60 g/kg (Chen and Chen 2004).

Subchronic Toxicity

In rats fed diets containing 0.5, 5, or 25 g/kg body weight of Siberian motherwort daily for 90 days, effects on various systems were observed in the medium- and high-dose groups. In those groups, plasma creatinine and liver enzymes were elevated, hematological analysis indicated mild anemia, and histopathological changes in the liver and kidneys were observed. No adverse effects were reported in the 0.5 g/kg group (Pin et al. 2009).

Lepidium meyenii Walp.

Brassicaceae

SCN: maca

Part: hypocotyl, root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Human and animal studies have indicated that maca does not affect levels of hormones such as testosterone, estrogen, follicle-stimulating hormone, or prolactin (Brooks et al. 2008; Gonzales et al. 2001, 2003a, 2003b, 2005).

A study of maca in patients taking selective serotonin reuptake inhibitors (SSRI) indicated no changes in SSRI efficacy (Dording et al. 2008).

Pregnancy and Lactation

No adverse effects on pregnancy or fetal development have been observed in animal studies with daily doses up to 1 g/kg (D'Arrigo et al. 2004; Kuo et al. 2003; Oshima et al. 2003; Ruiz-Luna et al. 2005).

No information on the safety of maca during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a randomized, double-blind, placebo-controlled study, healthy postmenopausal women ingested 3.5 g of maca powder or placebo daily for 6 weeks. No differences were seen in serum concentrations of estradiol, follicle-stimulating hormone, luteinizing hormone, and sex hormone-binding globulin between baseline, maca treatment, and placebo (Brooks et al. 2008).

In a randomized, double-blind, placebo-controlled study, healthy men ingested 1.5 or 3 g of maca daily for 12 weeks. Testing at baseline and at weeks 2, 4, 8, and 12 of the study indicated that serum levels of luteinizing hormone, follicle-stimulating hormone, prolactin, 17α-hydroxyprogesterone, testosterone, and 17β-estradiol were unchanged (Gonzales et al. 2003a).

No changes in hormone levels, including luteinizing hormone, follicle-stimulating hormone, prolactin, testosterone, and estradiol, were observed in healthy men who ingested 1.5 or 3 g of maca daily for 4 months (Gonzales et al. 2001).

In a study on the effects of maca for sexual dysfunction induced by selective serotonin reuptake inhibitors (SSRI), patients who were stable on an SSRI (patients were taking escitalopram, citalopram, sertraline, venlafexine, fluoxetine, paroxetine, duloxetine, or fluvoxamine) were orally administered 1.5 or 3 g of maca daily for 12 weeks. No adverse effects of maca, including effects on SSRI efficacy, were reported, and patients in the high dose group had a modest improvement in depression (Dording et al. 2008).

Animal Pharmacological Studies

No changes in serum levels of testosterone or estradiol were observed in male rats orally administered 2 g/kg of red, yellow, or black ecotypes of maca daily for 7 days. Red maca, but neither yellow nor black maca, significantly reduced the ventral prostate size in treated animals (Gonzales et al. 2005).

In male rats orally administered 2 g/kg of red maca daily for 42 days with or without intramuscular injections of testosterone enanthate on days 1 and 7, maca prevented the prostate weight increase induced by testosterone treatment (Gonzales et al. 2005).

In male rats orally administered 48 or 96 mg/kg of maca daily for 7, 14, or 21 days, no changes in serum testosterone levels were observed. An increase in sperm count was observed after 7 days, while the sperm count was reduced at 14 and 21 days (Gonzales et al. 2003b).

In rats orally administered 0.01 to 5 g/kg of maca daily for 7 days, seminal vesicle weight was reduced at the 0.01 and 0.10 g/kg doses. Maca increased the length of stages VII–VIII of the seminiferous tubules in a dose-response fashion, with highest response at 1.0 g/kg. Cauda epididymal sperm count, sperm motility, and serum estradiol level were not affected at any of the doses studied (Chung et al. 2005).

Prevention of estrogen-deficient bone loss was observed in ovariectomized rats orally administered 240 mg/kg of an ethanol extract of maca daily for 28 weeks but not in animals administered 96 mg/kg (Zhang et al. 2006).

In hereditary hypertriglyceridemic rats, a strain used as a model for insulin resistance, improvement in glucose

tolerance was observed after administration of a diet containing 1% maca daily for 2 weeks (Vecera et al. 2007).

An increase in uterine weight was observed in ovariectomized mice orally administered 1 g/kg of a freeze-dried aqueous extract of maca daily for 42 days (Ruiz-Luna et al. 2005).

In Vitro Pharmacological Studies

No estrogenic or androgenic activity of aqueous or methanolic extracts of maca was observed at concentrations up to 4 mg/ml in yeast β-galactosidase reporter assays (Brooks et al. 2008). Conversely, estrogenic activity of maca was reported in an assay with estrogen receptor-positive human breast cancer cells (MCF-7) with an IC_{50} of 100 to 200 µg/ml (Valentova et al. 2006).

In a set of assays (luciferase and β-galactosidase) selected to assess whether maca was able to bind to the human androgen receptor, no regulation of the glucocorticoid response element activation was observed in tests with methanol, ethanol, hexane, and chloroform extracts of maca (Bogani et al. 2006).

IV. Pregnancy and Lactation

In female mice provided with a maca extract (5 g maca in 100 ml water) as the sole source of drinking water for 30 days (estimated intake not listed), increases in progesterone and testosterone levels were observed, but with no changes in levels of 17β-estradiol. After mating, no differences in the rate of embryo implantation were observed (Oshima et al. 2003).

No adverse effects on implantation or on fetal development were observed in mice orally administered 1 g/kg of a freeze-dried aqueous extract of maca on days 1 to 4 of pregnancy (D'Arrigo et al. 2004).

No adverse effects on fetal development or offspring growth were observed in mice fed diets containing 30% maca daily throughout pregnancy and lactation. The litter size was larger in treated animals than in controls (Kuo et al. 2003).

An increase in litter size was observed in mice orally administered 1 g/kg of a freeze-dried aqueous extract of maca daily 15 days prior to mating, throughout gestation, and for 21 days after birth. No adverse effects on fetal or pup development were observed (Ruiz-Luna et al. 2005).

No information on the safety of maca during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in rats orally administered 5 g/kg maca daily for 7 days (Chung et al. 2005).

In the brine shrimp lethality assay, the LC_{50} of micropulverized maca is 822.68 g/ml (Valerio and Gonzales 2005).

Subchronic Toxicity

In rats orally administered 1 g/kg of maca daily for 84 days, no histological effects on the liver or spleen or changes in DNA levels in the testis were observed (Gasco et al. 2007).

Ligusticum porteri J.M. Coult. & Rose — Apiaceae

SCN: osha
OCN: Porter's lovage

Part: rhizome

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Conway and Slocumb 1979; Moore 1979).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Osha has been used as an emmenagogue (Conway and Slocumb 1979). While a 1979 text on medicinal plants of the western United States indicated that large amounts (decoction of ~55 g) of osha have reportedly been used as an abortifacient (Moore 1979), a more recent edition of the same text notes that the dried root is thought to be safe "in any but the most difficult pregnancies" (Moore 2003).

No information on the safety of osha during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Osha has been used as an emmenagogue, and large amounts (decoction of ~55 g) have reportedly been used as an abortifacient (Conway and Slocumb 1979; Moore 1979).

No information on the safety of osha during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered dichloromethane and methanol extract of osha in mice is 1085 mg/kg. In the brine shrimp lethality assay, the LC_{50} of the same extract is 778 µg/ml (Deciga-Campos et al. 2007).

Ligusticum spp. Apiaceae

Ligusticum sinense Oliv. 'Chuanxiong'
SCN: Sichuan lovage
Syn: *Ligusticum chuanxiong* Hortorum ex Qiu, et al.
PN: *chuan xiong* (rhizome)

Ligusticum wallichii (Benth. & Hook. f.) Franch.
SCN: *Ligusticum wallichii*
PN: *chuan xiong* (rhizome)
Part: rhizome

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004).

Other Precautions

Use with caution in excessive menstruation (Bensky et al. 2004; Chen 1987).

Drug and Supplement Interactions

See Pharmacological Considerations.

Adverse Events and Side Effects

Allergic skin reactions to Sichuan lovage or *Ligusticum wallichii* have been reported after oral ingestion (Bensky et al. 2004).

Pharmacological Considerations

Based on animal studies demonstrating anticoagulant and antiplatelet activity (Chen and Chen 2004; Zhu 1998), a text on traditional Chinese medicine suggests that Sichuan lovage or *Ligusticum wallichii* should be used with caution in patients taking anticoagulant or antiplatelet drugs, noting that this caution is theoretical, and interactions have not been observed clinically (Chen and Chen 2004).

Pregnancy and Lactation

A reference text on traditional Chinese medicine indicated that Sichuan lovage and *Ligusticum wallichii* should be used with caution during pregnancy (Bensky et al. 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

An animal study on the compounds tetramethylpyrazine and ferulic acid indicated that the compounds inhibited uterine contractions (Ozaki and Ma 1990).

No information on the safety of Sichuan lovage and *Ligusticum wallichii* during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Ingestion of Sichuan lovage or *Ligusticum wallichii* has been associated with tingling pain in the abdomen, urinary frequency, pain on urinating, intense headache, and vomiting. Information on doses and products used was not listed in the available English language translation (Bensky et al. 2004).

Allergic skin reactions to Sichuan lovage or *Ligusticum wallichii* have been reported after oral ingestion (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

The compound tetramethylpyrazine inhibited ADP- or collagen-induced platelet aggregation in healthy volunteers and in patients with coronary heart disease. Information on dose was not provided in the available English language translation (Zhu 1998).

Animal Pharmacological Studies

A dose-dependent reduction in plasma glucose levels was observed in diabetic mice intraperitoneally administered 10, 25, or 50 mg/kg of the compound tetramethylpyrazine (Lee et al. 2002).

In male rats orally administered 1 g (average animal weight 250 g) of an ethanol extract of Chinese lovage, a 2.3-fold increase in progestogenic activity was observed. After subcutaneous administration of 2 g of the same extract, a 4.5-fold increase was observed (Lim et al. 2006).

In rats orally administered water or alcohol extracts of Chinese lovage at doses equivalent to 3 g /kg of the dried herb daily, mild inhibition of the drug-metabolizing isoenzymes CYP1A2, CYP2C9, CYP2D6, CYP2E1, and CYP3A were observed (Tang et al. 2006).

A text on traditional Chinese medicine indicates that animal studies have demonstrated marked antiplatelet and anticoagulant effects. Details on doses and preparations used were not listed in the available English language translation (Chen and Chen 2004). The compound tetramethylpyrazine inhibited ADP- or collagen-induced platelet aggregation in rabbits. Information on dose was not provided in the available English language translation (Zhu 1998).

In Vitro Pharmacological Studies

The compound tetramethylpyrazine, at concentrations of 50 to 200 µ*M*, stimulated nitric oxide production in human platelets (Sheu et al. 2000).

Proestrogenic activity of Sichuan lovage was observed in HeLa cells with progesterone receptors (PR) and a PR-driven promoter (Lim et al. 2006).

IV. Pregnancy and Lactation

Inhibition of uterine contractions was observed in rats orally administered 100 or 300 mg/kg or intravenously administered 10 or 30 mg/kg of the compounds tetramethylpyrazine or ferulic acid. Synergistic activity was observed when the compounds were administered intravenously together, at doses individually insufficient to inhibit contractions (1 mg/kg tetramethylpyrazine, 3 m g/kg ferulic acid) (Ozaki and Ma 1990).

No information on the safety of Sichuan lovage or *Ligusticum wallichii* during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of Sichuan lovage in mice is 65.86 g/kg after intraperitoneal administration and 66.42 g/kg after intravenous administration (Chen and Chen 2004).

The LD_{50} of the compound tetramethylpyrazine intravenously administered in mice is 239 mg/kg (Zhu 1998).

Short-Term Toxicity

No adverse effects on liver or kidney function or changes in serum chemistry were observed in mice orally administered 5 or 10 mg/kg of the compound chuanxiongzine daily for 4 weeks (Chen and Chen 2004).

Ligustrum lucidum W.T. Aiton — Oleaceae

SCN: ligustrum
PN: *nu zhen zi* (fruit)

OCN: glossy privet; white wax tree
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
Traditional use and animal studies have indicated that ligustrum may modify glucose regulation (Chen and Chen 2004; Gao et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation
No information on the safety of ligustrum in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
In diabetic rats orally administered 100 or 200 mg/kg of the compound oleanolic acid daily for 40 days, changes in blood glucose levels and in oral glucose tolerance tests showed that hypoglycemia was more pronounced in treated groups than in the control group. Rats treated with oleanolic acid also had increased serum insulin levels, while no changes in thyroid hormone or thyroid-stimulating hormone were observed (Gao et al. 2007).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of ligustrum during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
No adverse effects were reported in rabbits that ingested 75 g of ligustrum (animal weight not specified in available English language translation) (Chen and Chen 2004).

Subchronic Toxicity

A protective effect against diabetes-induced adverse effects on spermatogenesis was observed in diabetic rats orally administered an extract of ligustrum equivalent to 30 g/kg of the herb daily for 110 days (Feng et al. 2001).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to the *Lilium* species included in this entry have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Brown's lily, tiger lily, or coral lily in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Oral administration of lily bulb was reported to prolong sleeping time induced by barbiturates. Study details were not listed in the available English language translation (Chen and Chen 2004).

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to the *Lilium* species included in this entry have been reported in the literature on traditional Chinese medicine (Bensky et al. 2004).

Although the above-ground parts (bulbs are the part used medicinally) of tiger lily are toxic to cats, causing acute kidney damage and sometimes kidney failure (Berg et al. 2007; Gulledge et al. 1997; Langston 2002; Rumbeiha et al. 2004), no toxic effects have been identified in rats or rabbits,

and dogs develop a mild, self-limiting gastroenteritis after ingesting large quantities of plant material (Hall 2001). No cases of ingestion of lily bulbs by cats or other animals were identified in the literature.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of monoamine oxidase B (MAO-B) was observed in rat brain homogenates treated with an extract of Brown's lily (*L. brownii* var. *colchesteri*) with an IC_{50} value of 0.40 mg/ml (Lin et al. 2003).

IV. Pregnancy and Lactation

No information on the safety of Brown's lily, tiger lily, or coral lily during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Linum usitatissimum L. — Linaceae

SCN: flax
AN: *atasi*
PN: *ya ma zi* (seed)
OCN: linseed (seed)
Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

When taken as a bulk-forming laxative, flax should not be used in persons with bowel obstruction or with abnormal esophageal or intestinal narrowing (Wichtl 2004).

Flaxseed should be taken with at least 200 ml (6 oz) of water (Wichtl 2004).

Drug and Supplement Interactions

Other drugs should be taken 1 hour prior to consumption of flax or several hours after consumption, as flax may reduce the absorption of certain drugs due to the mucilage content and the increased speed of passage through the intestines. *See* Mucilages (Appendix 3).

Notice

Bulk-forming laxative (Wichtl 2004); *see* Appendix 2.

Mucilages (5–9%) (Bhatty 1993; Fedeniuk and Biliaderis 1994; Mazza and Biliaderis 1989); *see* Appendix 3.

Cyanogenic glycosides (0.1–1.5%) (Oomah et al. 1992; Wichtl 2004); *see* Appendix 1.

Editors' Note

Flaxseed contains the compound secoisolariciresinol diglycoside (SDG), which is converted by bacteria in the colon to the mammalian lignans enterodiol and enterolactone, compounds that have phytoestrogenic activity (Power and Thompson 2007).

Adverse Events and Side Effects

Allergic reactions, including anaphylactic reactions, to flaxseed have been reported (Alonso et al. 1996; Leon et al. 2003; Lezaun et al. 1998).

Pharmacological Considerations

In cases of bowel inflammation, flaxseed should be preswollen with fluids prior to consumption (Wichtl 2004). Overweight persons using flaxseed should consume the whole, unground seed to avoid caloric absorption (Wichtl 2004).

Studies in healthy women with normal menstrual cycles have generally shown no significant hormonal effects from ingestion of 5 to 10 g of flaxseed daily (Frische et al. 2003; Phipps et al. 1993). One study indicated changes in urinary ratios of some estrogen metabolites after ingestion of 5 or 10 g of flaxseed daily (Haggans et al. 1999). A longer luteal phase, with an increased progesterone/estradiol ratio, was observed in one study (Phipps et al. 1993). An animal study showed that a diet of 2.5 to 10% flaxseed increased in the length of estrus cycle, while animals fed flax with tamoxifen (an estrogen receptor agonist) showed an increase in irregular cycles (Orcheson et al. 1998).

Studies show a decrease in estrogen receptor-positive breast cancer tumor size in animals administered diets of 2.5 to 10% flaxseed (Bergman Jungestrom et al. 2007; Chen et al. 2007b; Dabrosin et al. 2002; Saarinen et al. 2006; Serraino and Thompson 1992; Thompson et al. 1996).

Pregnancy and Lactation

A human study of flaxseed oil in pregnancy indicated no difference in delivery time as compared to a control group (Knudsen et al. 2006).

Animal studies have indicated no adverse effects on fetal development in offspring of animals fed diets of 10% flaxseed during pregnancy (Collins et al. 2003; Flynn et al. 2003; Sankaran et al. 2006; Sprando et al. 2000). One study indicated conflicting effects of different dietary levels of flaxseed in pregnancy and lactation on hormone levels in offspring (Tou et al. 1998). Several animal studies indicated that exposure to flaxseed during gestation and lactation provided a protective effect against breast cancer later in life (Thompson et al. 2003; Tou and Thompson 1999), although one study showed the opposite effect (Khan et al. 2007).

A reduction in pregnancy losses was observed in cows administered a diet containing 10% flaxseed as compared to those fed a diet containing sunflower seed (Ambrose et al. 2006).

Animal studies have indicated no adverse effects on fetal development in offspring of animals fed diets of 10% flaxseed during pregnancy and lactation (Collins et al. 2003; Ward et al. 2001a, 2001b).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Hematuria (blood in the urine) was reported in a man on chronic aspirin approximately 1 month after starting to take 1 tablespoon of flaxseed daily (Gruver 2003). Nosebleeds were reported after a man taking baby aspirin daily began to take flaxseed oil daily (dose unspecified) (Gruver 2003).

Animal Trials of Drug or Supplement Interactions

Coadministration of diets containing 5 or 10% flaxseed with tamoxifen (an estrogen receptor agonist) for 6 or 16 weeks to athymic rats with estrogen receptor-positive human breast cancer cells (MCF-7) caused a regression in tumor size. In rats fed flax but not tamoxifen, no effects on tumor growth were observed (Chen et al. 2004, 2007a, 2007b).

II. Adverse Events

Case Reports of Adverse Events

Anaphylactic reactions to flaxseed, confirmed by skin prick testing, have been reported (Alonso et al. 1996; Leon et al. 2003; Lezaun et al. 1998).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy women that ingested 10 g flaxseed in baked goods daily for 2 menstrual cycles, urinary lignan excretion significantly increased, but no changes in serum hormone concentrations or sex hormone-binding globulin were observed (Frische et al. 2003).

In healthy postmenopausal women, addition of 5 or 10 g daily of flaxseed dose-dependently increased urinary 2-hydroxyestrogen excretion and the ratio of urinary 2-hydroxyestrogen to 16α-hydroxyestrone. There were no significant differences in urinary 16α-hydroxyestrogen excretion (Haggans et al. 1999).

In a study of healthy, normally cycling women administered a diet containing 10 g flaxseed daily for 3 menstrual cycles, flax consumption was associated with longer luteal phase (LP) lengths. There were no significant differences between flax and control cycles for concentrations of either estradiol or estrone during the early follicular phase, midfollicular phase, or luteal phase. Although flaxseed ingestion had no significant effect on LP progesterone concentrations, the LP progesterone/estradiol ratios were significantly higher during the flax cycles. Midfollicular phase testosterone concentrations were slightly higher during flax cycles (Phipps et al. 1993).

Animal Pharmacological Studies

No stimulation of tumor growth was observed in athymic rats with estrogen receptor-positive MCF-7 human breast cancer cells. Administration of diets containing 5 or 10% flaxseed for 16 weeks did not stimulate tumor growth (Chen et al. 2007b). A reduction in tumor growth was observed in mice with established estrogen receptor-negative human breast cancer tumors (MDA-MB-435 cell line) administered a diet containing 10% flaxseed for 6 weeks (Dabrosin et al. 2002). In ovariectomized athymic mice with estrogen receptor-positive human breast cancer tumors, a diet of 10% flaxseed caused a regression in tumor size and reduced the tumor growth-stimulating effect that was induced by a diet containing 20% soy protein (Saarinen et al. 2006). In rats with induced mammary tumors, a diet of 5% flaxseed reduced tumor size by an average of 66.7%. Flaxseed feeding at the tumor initiation stage also tended to reduce the number of tumors per tumor-bearing animal (Serraino and Thompson 1992).

In rats with established mammary tumors, administration of diets containing 1.82% flaxseed oil (equivalent to 5% flaxseed) or 2.5% or 5% flaxseed for 7 weeks led to 50% smaller tumor volume as compared to control animals. There was no relationship between new or total tumor development and urinary lignan levels (Thompson et al. 1996).

In ovariectomized mice treated continuously with estradiol, a diet containing 10% flaxseed counteracted the estradiol-induced growth and angiogenesis in solid estrogen receptor-positive MCF-7 tumors. Extracellular vascular endothelial growth factor was significantly decreased compared with tumors in the basal diet group (Bergman Jungestrom et al. 2007).

An increase in expression of *Brca1* and *Brca2* genes was observed in ovariectomized rats administered a diet containing 10% flaxseed (~2% lignans) for 90 days (Vissac-Sabatier et al. 2003).

In immature rats fed a diet of 5% defatted flaxseed for 7 days, cadmium exposure through the diet, reportedly from flaxseed, was sixfold higher than allowed for humans by the World Health Organization, and cadmium significantly accumulated in the liver and kidneys of the rats (Khan et al. 2007).

A dose-related cessation or lengthening of estrous cycles was observed in approximately 66% of rats administered a diet containing 2.5, 5, or 10% flaxseed. When animals on the same diet were administered tamoxifen, 83% of the animals had irregular menstrual cycles or were in persistent diestrus (Orcheson et al. 1998).

No adverse effects on the hemopoietic system, including red or white blood cells, granulocytes, lymphocytes, monocytes, and platelets, were observed in normal or hypercholesterolemic rabbits orally administered 40 mg/kg daily of a flax-derived lignan complex for 2 months (Prasad 2005).

In obese rats administered diets containing 20% flax, no change in plasma glucose levels was observed, although plasma insulin levels were lower as compared to groups administered equal amounts of casein or soy protein concentrate (Velasquez et al. 2003).

An oil-in-water nanoemulsion made with flaxseed oil and saquinavir resulted in a significant increase in bioavailability of saquinavir in mice after oral or intravenous administration (Vyas et al. 2008).

In Vitro Pharmacological Studies

A dose-dependent decrease in trophoblast tumor cell proliferation was observed in estrogen receptor-positive Jeg3 cells treated with flaxseed extract or certain flaxseed extract fractions, with two fractions producing a 58 to 86% decrease in the production of progesterone. Some extract fractions showed a stimulating effect on hormone production and cell proliferation (Waldschlager et al. 2005).

IV. Pregnancy and Lactation

No differences in timing of spontaneous delivery were observed in pregnant women administered capsules containing 4 g flax oil (2.2 g α-linolenic acid) daily on weeks 17–27 of gestation until delivery, as compared to control. No adverse events were reported (Knudsen et al. 2006).

In rat pups whose mothers were fed a diet containing 10% flaxseed on postnatal days 0 to 21, exposure to flaxseed during suckling enhanced mammary gland morphogenesis through modulation of epidermal growth factor receptor and estrogen receptors (ER-α and ER-β), which resulted in more differentiated mammary glands at postnatal days 49 to 51. This suppressed chemically induced mammary tumorigenesis without causing adverse reproductive effects in dams or their offspring (Thompson et al. 2003).

A reduction in pregnancy losses was observed in pregnant cows administered a diet containing 9.8% flaxseed as compared with those fed a diet with 27% sunflower seed (Ambrose et al. 2006).

In a study examining the effects of exposure to flax during gestation only or during gestation and maturation in a lifetime study, no adverse effects on development were observed in 20-day-old fetuses of rats administered diets of 20 or 40% flaxseed or 13 or 26% defatted flaxseed meal during pregnancy. In the lifetime study group, the flaxseed but not defatted flax meal caused an increase in the anogenital index of females. Defatted flaxseed meal, but not flaxseed, caused delayed puberty in male offspring. Both diets caused a dose-dependent increase in the number of females with irregular estrous cycles, and a decrease in the thymus/body weight and thymus/brain ratios (Collins et al. 2002, 2003).

No significant embryotoxic effects were observed in rat embryos cultured for 45 hours in serum of pregnant rats that had been administered a diet of 20 or 40% flaxseed or 13 or 26% defatted flaxseed meal (Flynn et al. 1999, 2003).

In offspring of rats administered a diet of 5 or 10% flax during pregnancy or lactation, a shortened mammary tumor latency was observed in animals with chemically induced tumors, and 10% flaxseed exposure increased tumor multiplicity, as compared to the controls. When assessed in 8-week-old rats, offspring of mothers fed a 10% diet in pregnancy had increased lobular ER-α protein levels, and both in utero and postnatal flaxseed exposures dose-dependently reduced ER-β protein levels in the terminal end bud lobules and ducts (Khan et al. 2007).

In a study of the effects of flax on development of rat mammary gland structures, rats were administered diets of 5 or 10% flaxseed or secoisolariciresinol diglycoside (SDG) during the whole lifetime, during gestation and lactation, or after weaning. The results of the study indicated that lifetime or gestation and lactation exposure to 5 or 10% flaxseed induced structural changes in the mammary gland that may potentially reduce mammary cancer risk (Tou and Thompson 1999).

In rats exposed to diets of 5 or 10% flaxseed during pregnancy and lactation, or after weaning, perinatal exposure to 10% flaxseed increased serum estradiol and produced premature irregular cycles in female offspring, and elevated testosterone levels and increased the prostate weight in male offspring. Conversely, perinatal exposure to 5% flaxseed delayed puberty and produced persistent diestrus in female offspring (although sex hormone levels were unaffected), and elevated the estradiol/testosterone ratio and decreased the prostate weight in male offspring (Tou et al. 1998).

In rats administered 5 or 10% flaxseed diet starting at weaning on postnatal day (PND) 21 or continuously from gestation to PND 132 for lifetime exposure, compared to the control, exposure to flaxseed after weaning produced no marked reproductive effects, whereas lifetime flaxseed exposure produced some dose-dependent changes in the reproductive organs of offspring. In female rats, lifetime exposure to 5% flaxseed caused delayed puberty onset. In contrast, lifetime exposure to 10% flaxseed caused earlier puberty onset, higher relative ovarian weight, higher serum estradiol levels, and lengthened estrous cycles. In male rats, lifetime 10% flaxseed exposure raised serum testosterone and estradiol levels and produced higher relative sex organ weights and prostate cell proliferation. In contrast, lifetime exposure to 5% flaxseed reduced adult relative prostate weight and cell proliferation (Tou et al. 1999).

Flax seed contains the compound SDG, which is converted by bacteria in the colon to the mammalian lignans enterodiol and enterolactone. No significant effects on any reproductive indices were observed in male and female rats exposed, via maternal ingestion of a diet containing 10% flax or the equivalent isolated SDG, during suckling only or during suckling through the postsuckling period (Ward et al. 2001a).

No adverse effects on bone strength were observed after female mice were exposed to SDG purified from flaxseed during suckling via mother's milk or continuously to adolescence (Ward et al. 2001b).

No significant effects on reproduction were observed in male and female suckling rats whose mothers were fed a diet containing 10% flaxseed during lactation and then themselves were administered the same diet until postnatal day 132. The reproductive indices observed were anogenital distance, age and body weight at puberty onset, estrous cycle length, reproductive organ weights, and histological analysis of reproductive organs (Ward et al. 2001a).

In offspring of rats with inherited cystic kidney disease administered a diet of 7% flaxseed oil during pregnancy and lactation, with offspring then administered the same diet until 10 weeks of age, decreases in creatinine clearance and proteinuria were observed. The authors concluded that exposure to flax oil during pregnancy and lactation produced beneficial changes in adult renal disease (Sankaran et al. 2006).

No significant adverse effects on testis structure or spermatogenesis were observed in mice whose mothers were administered a diet containing up to 40% flaxseed during pregnancy and who were administered the same diet for 70 days after weaning (Sprando et al. 2000).

V. Toxicity Studies

Acute Toxicity

No toxic effects of flaxseed were observed in the brine shrimp lethality assay (Mahmoud et al. 1992).

Short-Term Toxicity

No adverse effects on growth, development, or behavior were observed in rats administered diets of 10% flaxseed from age 18 days to 86 days. There were no signs of toxicity, and plasma levels of alanine aminotransferase and γ-glutamyltranspeptidase (GGT) were the same as those of animals on a standard diet. The activity of GGT was increased in the livers of flax chow-fed rats after puberty, with the effect being more pronounced in males than females (Hemmings and Barker 2004).

Chronic Toxicity

A number of studies on the effects of lifetime exposure to flaxseed have indicated no signs of toxicity in rats administered diets of 10% flax daily for over 130 days (Tou et al. 1999; Tou and Thompson 1999; Ward et al. 2001a). *Also see* Pregnancy and Lactation for this entry.

Genotoxicity

Some genotoxic activity of flaxseed oil was observed in a *Drosophila* somatic mutation and recombination test after animals were administered media containing 6 or 12% flaxseed oil (Rojas-Molina et al. 2005).

No mutagenic effects of flaxseed were observed in the Ames test with *Salmonella typhimurium* strains TA98 and TA102 (Mahmoud et al. 1992).

Cytotoxicity

Flaxseed enhanced proliferation in Chinese hamster ovary cells at doses in the micromolar range (Sujjavanich and Gibson 2006).

Lobelia inflata L.

Campanulaceae

SCN: lobelia
OCN: Indian tobacco; puke weed

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Ellingwood 1919; Felter and Lloyd 1898).

Other Precautions

May cause nausea or vomiting (Bradley 1992; Felter and Lloyd 1898; Kaufmann and Bensimon 1960; Leung and Foster 1996; List and Hörhammer 1973; Rapp and Olen 1955; Scott et al. 1962; Williamson 2003).

Standard Dose

As an expectorant: 100 mg of the leaf; 0.6 to 2.0 ml of the tincture (Leung and Foster 1996; Martindale and Reynolds 1996; Osol and Farrar 1955).

Notice

Emetic (Bradley 1992; Felter and Lloyd 1898; Leung and Foster 1996; List and Hörhammer 1973; Williamson 2003); *see* Appendix 2.

Drug and Supplement Interactions

None known.

Editors' Notes

Controversy over the safety of lobelia dates to the early 19th century (Bergner 1998b). Ellingwood reported that "death has occurred in a very few cases from excessive doses of the remedy, but toxic effects are not apparent where the medicinal dose is prescribed" (Ellingwood 1919), and Felter and Lloyd state that "the emetic action is so prompt and decided, that the contained alkaloid could not, under ordinary circumstances, produce fatal results" (Felter and Lloyd 1898). Reviews note that information was insufficient to establish lobelia as being the likely cause of death in the alleged fatalities (Bergner 1998a, 1998b).

Adverse Events and Side Effects

In clinical trials of the compound lobeline, side effects of treatment included nausea and a burning sensation in the mouth and throat when taken at doses of 0.5 mg (London 1963). Higher doses were associated with nausea, vomiting, vertigo, and increased heart rate (tachycardia) (Kaufmann and Bensimon 1960; Rapp and Olen 1955; Scott et al. 1962).

Pharmacological Considerations

An increase in blood pressure and variable effects of the compound lobeline on heart rate were reported in one human study (Butler et al. 2001). Animal studies have shown transient and minor effects on the cardiovascular system (Dwoskin and Crooks 2002; Korczyn et al. 1969; Sloan et al. 1988).

Pregnancy and Lactation

Historical herbal texts note that lobelia promotes normal uterine contraction after the os is dilated, and relaxes the perineal tissues (Ellingwood 1919; Felter and Lloyd 1898). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No adverse effects were reported after pregnant women were injected with a single dose of 0.03 mg/kg of the compound lobeline (Klauer 1959).

No information on the safety of lobelia in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Nausea (14% lobeline group, 28% control group) and a burning sensation in the mouth or throat (50% lobeline group, 6% control group) were reported as side effects of treatment in a trial of the compound lobeline sulfate in chronic smokers. Lobeline sulfate was orally administered in pastilles containing 0.5 mg of the compound at a rate of one every 1 to 2 hours for the first week, one every 3 hours the second week, one every 4 hours the third week, and one every 4 to 6 hours the fourth week. The side effects occurred during the first week of treatment, decreased in frequency the second week, and were absent during the third and fourth weeks of treatment (London 1963).

A review of early clinical trials of the compound lobeline for smoking cessation indicated that doses of 2 mg or more were poorly tolerated, with a significant portion of trial participants refusing to complete the studies (London 1963). Side effects at the 2 mg dose were reported as nausea, vomiting, vertigo, and tachycardia (Kaufmann and Bensimon 1960; Rapp and Olen 1955; Scott et al. 1962). In a trial of lobeline sulfate with tablets containing 8 mg of the compound, few patients were willing to take more than 3 doses daily for more than 3 days (Von Wright et al. 1982). A more recent systematic review indicated that a large percentage of trials of lobeline for smoking cessation were not controlled and that in studies that were placebo controlled, descriptions of appropriate methods of randomization were frequently missing (Stead and Hughes 2000).

Case Reports of Adverse Events

Use of more than 0.5 ml of tincture three times daily may cause nausea in some people. Up to 1 ml of tincture three times daily may be needed in a larger adult and may not cause adverse effects. Mild nausea is not an indication for total discontinuation (Yarnell 1999). Severe overdose is reported to cause prostration, convulsions, coma, respiratory depression, and death from respiratory failure (Ellingwood 1919).

One controversial death sometimes cited as being a result of lobelia toxicity is that of Ezra Lovett, who allegedly died by lobelia poisoning at the hands of Samuel Thomson in Massachusetts in 1807. The death was the basis

of murder charges 2 years later, but the judge and jury hearing the case found that no basis had been established for charges of murder or manslaughter. An analysis of the case and of the pharmacokinetics of lobeline indicated that death from lobelia was unlikely and may instead have been due to conventional medical treatment or another cause (Bergner 1998b). A second death attributed to lobelia, that of T.G. French in New York City in 1837, was reported, although no details of the case, including the dose of lobelia administered or the nature of the illness being treated, are available (Bergner 1998a).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In human lung transplant patients intravenously administered 18 to 60 µg/kg of the compound lobeline, varying effects on heart rate were observed, with a rate increase in some patients and a decrease in others. A dose-dependent decrease in mean arterial pressure was also observed (Butler et al. 2001). At doses above 18 µg/kg, intravenously administered lobeline induced cough in healthy patients (Gandevia et al. 1998).

Lobeline-induced cough has been observed in humans intravenously administered the compound at doses of 35 µg/kg or more (Jaju et al. 1998; Raj et al. 2005). The cough is believed to be due to stimulation of the J receptors (Paintal 1995; Raj et al. 2005).

Animal Pharmacological Studies

The compound lobeline is reported to be a cardiovascular stimulant, producing effects through the carotid chemoreceptors (Cambar et al. 1969; Korczyn et al. 1969). Cardiovascular effects of the compound lobeline have been described as transient and minor, resulting from primary stimulant and secondary depressant effects on sympathetic and parasympathetic ganglia and the adrenal medulla (Dwoskin and Crooks 2002; Sloan et al. 1988). After administration of lobeline to dogs, an initial slowing of heart rate was observed, with a subsequent increase in blood pressure. Long-term administration, however, resulted in a decrease in blood pressure (Dwoskin and Crooks 2002; Korczyn et al. 1969).

In cats and dogs intramuscularly administered the compound lobeline sulfate at doses of 0.25 to 0.6 mg/kg, a dose of 0.5 mg/kg caused all cats and dogs to vomit (Laffan and Borison 1957).

In monkeys injected with 142 µg/kg of the compound lobeline, either apnea or excitation of breathing was reported, but no change in heart rate (Deep et al. 2001). Transitory hyperpnea with an increase in tidal volume and respiratory rate was induced in horses administered the compound lobeline. The increase in ventilation lasted for about 90 seconds and was accompanied by a sharp rise in the respiratory peak airflows, especially the expiratory flows (Art et al. 1991). Similar activity was reported in pigs and rabbits (Bredeck et al. 1961; Utashiro 1941).

In mice, administration of the nicotinic antagonist chlorisondamine stopped the physiological effects of nicotine but not lobeline (Decker et al. 1994).

In Vitro Pharmacological Studies

The compound lobeline has been shown to have a high affinity for nicotinic acetylcholine receptors and inhibits the function of vesicular monoamine and dopamine transporters (Felpin and Lebreton 2004; Flammia et al. 1999; Reavill et al. 1990; Teng et al. 1998). In guinea pig brain homogenates, lobeline functioned as a mu opioid receptor antagonist (Miller et al. 2007).

The compound lobeline reversed multidrug resistance in human colorectal adenocarcinoma cells in vitro by inhibiting P-glycoprotein (P-gp) activity. Lobeline, however, did not block breast cancer resistance protein-dependent mitoxantrone efflux (Ma and Wink 2008).

IV. Pregnancy and Lactation

Historical herbal texts note that lobelia promotes normal uterine contraction after the os is dilated, and relaxes the perineal tissues (Ellingwood 1919; Felter and Lloyd 1898).

No adverse events were reported after pregnant women were injected with a single dose of 0.03 mg/kg of the compound lobeline (Klauer 1959).

No information on the safety of lobelia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered lobeline in mice is 107 mg/kg (Ganellin et al. 1997).

A lethal dose of 10 mg per animal was reported for the compound lobeline in rabbits (animal weight not specified in English language abstract) (Utashiro 1941).

Lobelia siphilitica L.

Campanulaceae

SCN: blue lobelia
OCN: great blue lobelia

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner.

Other Precautions

May cause nausea or vomiting (Felter and Lloyd 1898).

Drug and Supplement Interactions

None known.

Notice

Emetic (Felter and Lloyd 1898); *see* Appendix 2.

Editors' Notes

Blue lobelia is reported to contain similar alkaloids to lobelia (*L. inflata*). The compound lobeline has been identified in blue lobelia, although the quantity is not known (Kesting et al. 2009). *See* Editors' Notes for *L. inflata*.

Adverse Events and Side Effects

Blue lobelia may cause nausea or vomiting (Felter and Lloyd 1898).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although no information on the safety of blue lobelia during pregnancy was identified, based on the similarity of this species to other species of *Lobelia*, use during pregnancy is not recommended unless under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

Lomatium dissectum (Nutt.) Mathias & Constance — Apiaceae

SCN: lomatium
Syn: *Leptotaenia multifida* Nutt.; *Ferula multifida* (Nutt.) A. Gray

OCN: biscuit root; desert parsley; fern-leaf lomatium; Indian balsam
Part: root

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (McGuffin et al. 1997).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Skin rashes have been associated with internal use of lomatium. Rashes have been associated more with use of the fresh root than the dried root (Moore 1993). Mild fevers have been reported in some individuals after long-term consumption.

Pharmacological Considerations

None known.

Pregnancy and Lactation

The professional experience of the editors of the first edition of this text indicates that lomatium should not be used in pregnancy except under the supervision of a qualified healthcare practitioner (McGuffin et al. 1997).

No information on the safety of lomatium during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Rashes have been reported as an occasional side effect of lomatium use. Rashes were associated more with use of the fresh root than the dried root. Some individuals that reacted to fresh root preparations did not react to dried root (Moore 1993).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

Lycium spp. — Solanaceae

Lycium barbarum L.
SCN: lycium
PN: *gou qi zi* (fruit)
OCN: Barbary wolfberry; matrimony vine; goji

Lycium chinense **Mill.**
SCN: lycium
PN: *gou qi zi* (fruit)
OCN: Chinese boxthorn; Chinese wolfberry; goji
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Interactions.

Editors' Notes

Although lycium fruit has been reported to contain the alkaloid atropine up to 0.95% (Harsh 1989), the presence of tropane alkaloids has been disputed (Frohne and Pfänder 1997; Merz and Stolte 1960), and a more recent analysis indicates that the atropine content of dried lycium fruit is very low, generally less than 10 parts per billion (ppb), with the highest level of analyzed fruit containing 19 ppb. Severe atropine intoxication with the examined lycium fruit samples would require the unrealistic consumption of several tons of berries (Adams et al. 2006).

Adverse Events and Side Effects

Allergic reaction to lycium fruit has been reported (Bensky et al. 2004).

Pharmacological Considerations

One case report indicated increased INR (a standardized scale used to report the results of blood coagulation tests; increased INR indicates slowed blood clotting) in a woman previously stable on warfarin who drank lycium fruit tea for several days. After cessation of the tea, INR levels returned to normal (Lam et al. 2001). The woman was also taking other drugs, at least one of which has been associated with increased INR levels in persons on warfarin (Trilli et al. 1996).

Pregnancy and Lactation

Information on the safety of lycium fruit in pregnancy is limited. While one Chinese medicine reference text advises caution for use in pregnancy, based on a study in rabbits showing that lycium fruit had a stimulating effect on the uterus (Chen and Chen 2004), another text lists no concerns for use in pregnancy (Bensky et al. 2004).

No information on the safety of lycium fruit during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

An elevated (4.1) INR (a standardized scale used to report the results of blood coagulation tests; increased INR indicates slowed blood clotting) level was reported in a woman previously stable on warfarin. Her other medical conditions were hypertension, hypercholesterolemia, and tricuspid regurgitation, and other medications were benazepril, atenolol, digoxin, and fluvastatin. The woman had consumed 3 to 4 cups daily of a lycium fruit tea prior to her clinic visit. After cessation of the tea, INR levels returned to normal within 7 days. An in vitro study completed in conjunction with this case report indicated that only weak effects of lycium fruit

extract were observed on activity of the drug-metabolizing isoenzyme CYP2C9, the isoenzyme that metabolizes warfarin (Lam et al. 2001). Fluvastatin has been associated with increased INR in patients taking warfarin (Trilli et al. 1996).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A Chinese herbal text indicates that lycium fruit is generally regarded as safe, with no adverse effects expected at the normal dose. Allergic reactions, including urticaria-like or papular rashes, have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A marked decrease in fasting plasma insulin levels was observed in streptozotocin-induced diabetic rats administered 10 mg/kg daily polysaccharides isolated from lycium fruit for 3 weeks. In an oral glucose tolerance test, administration of 2 g/kg significantly reduced postprandial glucose levels at 30 minutes and increased insulin-sensitive index values (Zhao et al. 2005).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A decoction of lycium fruit had a stimulating effect on the uterus in rabbits (dose and route of administration not specified in available translation) (Chen and Chen 2004). Based on that study, one reference text on Chinese herbal medicine indicates that lycium fruit should be used with caution in pregnancy (Chen and Chen 2004), while another text does not list any cautions in pregnancy (Bensky et al. 2004).

No information on the safety of lycium fruit during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally or intraperitoneally administered aqueous lycium fruit extract in mice is 83.2 g/kg (Chen and Chen 2004).

OCN: Chinese boxthorn; Chinese wolfberry
Part: root bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Several animal studies have shown that lycium root bark causes a decrease in fasting blood glucose levels and an increase in serum insulin levels in diabetic animals (Gao et al. 2007a, 2007b; Kim et al. 1994). Diabetic persons are advised to discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of lycium root bark in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A traditional Chinese medicine text indicates that no adverse effects are expected at standard therapeutic doses, although ingestion of a high dose (50 g) was reported to cause vertigo, palpitations, nausea, vomiting, and premature contractions (tissue or organ not specified, presumably premature uterine contractions) (Bensky et al. 2004). Case details were not available.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Dose-dependent decreases in fasting blood glucose levels and increases in serum insulin levels were observed in streptozotocin-induced diabetic mice administered 100 or 200 mg/kg of a dried aqueous extract of lycium root bark extract daily for 28 days (Gao et al. 2007a, 2007b; Kim et al. 1994).

In Vitro Pharmacological Studies

No effects on the drug-metabolizing isoenzymes CYP1A2 or CYP3A4 were observed after treatment with an ethanolic extract of lycium root bark (Brandin et al. 2007).

IV. Pregnancy and Lactation

No information on the safety of lycium root bark in pregnancy or lactation was identified. Reference texts on Chinese medicine do not indicate any precautions regarding use in pregnancy (Bensky et al. 2004; Chen and Chen 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered extract of lycium root bark in mice is 12.8 g/kg (Chen and Chen 2004). The LD_{50} of an orally administered dried aqueous extract of lycium root bark in mice could not be determined at doses up to 2 g/kg. No toxic effects were seen at this dose (Gao et al. 2007a).

OCN: Virginia bugleweed
Part: herb

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: B

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Beer et al. 2008; De Smet 1993; Mills and Bone 2005; Winterhoff et al. 1994).

Not for use in persons with hypothyroidism or thyroid enlargement (Beer et al. 2008; Vonhoff et al. 2006).

Other Precautions

None known.

Drug and Supplement Interactions

Bugleweeds should not be used with thyroid medications except under the supervision of a qualified healthcare practitioner (Beer et al. 2008; Winterhoff et al. 1994).

Adverse Events and Side Effects

Long-term use of "high" doses (standard dose listed as 1–2 g as a tea) of bugleweed or European bugleweed has been associated with enlargement of the thyroid, while sudden discontinuation of bugleweeds has been reported to cause increased symptoms of hyperthyroidism (Blumenthal et al. 1998).

Pharmacological Considerations

Bugleweeds have traditionally been used for hyperthyroidism. Several animal studies and one human study have indicated the effects of bugleweeds on thyroid hormones (Beer et al. 2008; Vonhoff et al. 2006; Winterhoff et al. 1994).

Pregnancy and Lactation

A recent reference on herbal safety suggests that bugleweeds should not be used during pregnancy or lactation due to effects on thyroid hormones in pregnancy and the possible transmission of antithyroid compounds during lactation (Mills and Bone 2005). An older study indicated that European bugleweed reduced the number of offspring in mice and rats (De Smet 1993). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

L

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Long-term use of "high" doses (standard dose listed as 1–2 g as a tea) of bugleweed or European bugleweed has been associated with enlargement of the thyroid, while sudden discontinuation of bugleweeds has been reported to cause increased symptoms of hyperthyroidism (Blumenthal et al. 1998).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In an open label study, patients with a basal *thyroid-stimulating hormone* (TSH) value less than 1.0 mU/l and hyperthyroidism-associated symptoms were administered one tablet containing 20 mg of European bugleweed daily for approximately 15 weeks. In treated patients, an increase in urinary thyroxine (T_4) excretion was observed, along with a reduction in symptoms related to hyperthyroidism, notably, a reduction in heart rate in the morning. In this study, European bugleweed was generally well tolerated, with only minor adverse events reported in the study. Of these, only one adverse event, subjective "disturbances of the cardiac rhythm," was reported after 7 weeks of treatment (Beer et al. 2008).

Animal Pharmacological Studies

In hyperthyroid rats treated with an ethanol extract equivalent to 400 mg/kg of European bugleweed alone or 10 or 400 mg/kg of European bugleweed with 0.7 mg/kg T_4 daily for 56 days, no significant changes of thyroid hormone concentrations or TSH levels were observed. Treatment reduced the increase in heart rate and blood pressure induced by T_4 administration, alleviated cardiac hypertrophy, and reduced the density of β-adrenoceptors in heart tissue (Vonhoff et al. 2006).

In rats orally administered 1 g/kg of an aqueous extract of European bugleweed, a decrease in triiodothyronine (T_3) levels (lasting over 24 h), not related to TSH levels, and due to peripheral T_4 deiodination, was observed. The decrease in T_3 levels was accompanied by a decrease in luteinizing hormone (Winterhoff et al. 1994).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Changes in the estrous cycle in mice and rats and a reduction in the number of offspring in the animals were reported after administration of European bugleweed. Extracts, doses, and duration of administration were not listed in the available English language translation (De Smet 1993).

Although one reference text indicates that bugleweeds should be avoided in pregnancy and lactation, due to "pronounced antiprolactin effects" (De Smet 1993), a more recent animal study indicated no effects of European bugleweed on prolactin levels (Beer et al. 2008). Another reference contraindicates bugleweeds during lactation due to the theoretical passage of antithyroid compounds through breast milk (Mills and Bone 2005).

V. Toxicity Studies

Acute Toxicity

In mice, intravenous administration of a dose of 3 ml of pressed juice of Virginia bugleweed was lethal, while a dose of 1 ml orally administered did not cause any toxic symptoms (De Smet 1993).

Magnolia officinalis Rehder & E.H. Wilson — Magnoliaceae

SCN: magnolia
PN: *hou po* (bark, root bark)

Part: bark, root bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Magnolia bark contains trace amounts of the alkaloids magnocurarine and tubocurarine (Huang 1993). Tubocurarine has also been isolated from curare, the arrow poison used by indigenous hunters of South America that can produce death by asphyxiation when administered intravenously (Blubaugh and Linegar 1948). Intravenous use of magnolia bark is noted as exhibiting some curare-like effects, though the herb is considered generally safe for oral use (Bensky and Gamble 1993), and curare itself has long been recognized as innocuous when taken orally (Blubaugh and Linegar 1948).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Although compounds from magnolia bark have demonstrated anticoagulant activity in vitro (Teng et al. 1988), animal studies indicated no effects of magnolia bark extract on coagulation (Liu et al. 2007).

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that magnolia bark and root bark should be used with caution in pregnancy (Bensky et al. 2004; Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of magnolia bark or root bark in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

M

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

An increase in anxiolytic activity was observed in mice administered 0.2 mg/kg of the compound honokiol with diazepam as compared to diazepam alone (Maruyama and Kuribara 2000).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No effects on coagulation were observed in rats fed diets containing up to 480 mg/kg of magnolia bark extract daily for 21 days or up to 240 mg/kg for 90 days (Liu et al. 2007).

In Vitro Pharmacological Studies

No estrogenic activity of an ethanol extract of magnolia bark was observed in a yeast assay system with human estrogen receptors (Shin et al. 2001).

The compounds magnolol and honokiol inhibited aggregation and ATP release of rabbit platelet-rich plasma induced by collagen and arachidonic acid without affecting that induced by ADP, platelet-activating factor (PAF), or thrombin. Aggregation of washed platelets was more markedly inhibited than that of platelet-rich plasma, while the aggregation of whole blood was least affected by both inhibitors (Teng et al. 1988).

IV. Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that magnolia bark and root bark should be used with caution in pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of magnolia bark and root bark in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} values of a magnolia bark decoction are 6.12 g/kg after intraperitoneal administration in mice, 4.25 g/kg after intravenous administration in cats, and could not be determined at doses up to 60 g/kg after oral administration in mice (Chen and Chen 2004).

Short-Term Toxicity

In rats fed diets containing 0, 60, 120, 240, or 480 mg/kg of magnolia bark extract daily for 21 days, no treatment-related effects in clinical observations, macroscopic or microscopic findings, or hematology, clinical chemistry, urinalysis, or organ weight measurements were observed, and there were no deaths or significant differences in body weight and weight gain (Liu et al. 2007).

Subchronic Toxicity

In rats fed diets containing 0, 60, 120, or 240 mg/kg of magnolia bark extract daily for 90 days, no mortality, ophthalmic abnormalities, or treatment-related changes in clinical observations, hematology, coagulation, organ weight measurements, or macroscopic or microscopic evaluations were found (Liu et al. 2007).

Genotoxicity

In a bacterial reverse mutation assay and an in vivo micronucleus test, no genotoxic activity of magnolia bark extract was observed (Li et al. 2007).

No genotoxic activity of magnolia bark extract was observed in chromosomal aberration assays with Chinese hamster ovary cells and Chinese hamster lung tissue (Zhang et al. 2008).

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to magnolia flower bud have been reported (Bensky et al. 2004).

Pharmacological Considerations

Overdose of magnolia flower bud may cause dizziness, thirst, and dry nose (Bensky et al. 2004).

Pregnancy and Lactation

Magnolia flower bud should be used with caution in pregnancy (Bensky et al. 2004). Uterine stimulant activity of magnolia flower bud has been observed in an animal study (Chen and Chen 2004). Use during pregnancy is therefore not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of magnolia flower bud during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to magnolia flower bud have been reported (Bensky et al. 2004).

Overdose of magnolia flower bud is reported to cause dizziness, thirst, and dry nose (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of the drug-metabolizing isoenzyme CYP2D6 was observed in rat liver microsomes treated with an extract of magnolia flower (Yu et al. 2007).

IV. Pregnancy and Lactation

Uterine stimulant activity of magnolia flower bud has been observed in dogs and rabbits. Details on product, dose, and route of administration were not listed in the available English language translation (Chen and Chen 2004).

Reference texts on traditional Chinese medicine suggest that magnolia flower bud be used with caution in pregnancy (Bensky et al. 2004) and cite a study in which uterine stimulant activity was observed in rabbits and dogs after ingestion of magnolia flower (Chen and Chen 2004).

No information on the safety of magnolia flower bud during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intravenously administered magnolia flower bud could not be determined at doses up to 1 g/kg in dogs and 4.75 g/kg in rabbits (Chen and Chen 2004).

Short-Term Toxicity

No adverse effects were observed in rats orally administered 18 g/kg of an alcohol extract or 30 g/kg of a water extract of magnolia flower bud daily for 30 days (Chen and Chen 2004).

Magnolia virginiana L.

Magnoliaceae

SCN: sweetbay magnolia
Syn: *Magnolia glauca* (L.) L.

OCN: laurel magnolia; swamp laurel; sweetbay
Part: bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Sweetbay magnolia bark is not contraindicated in pregnancy in prominent 19th and early 20th century therapeutic texts in which it is listed (Ellingwood 1919; Felter and Lloyd 1898; Shoemaker 1893). Due to its close botanical relationship to other species of *Magnolia* which are recognized as not for use in pregnancy, however, it is recommended that sweetbay magnolia bark be avoided in pregnancy except under the supervision of a qualified healthcare practitioner.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

No cautions for use of sweetbay magnolia are reported in historical American medical texts (Felter and Lloyd 1898; Remington and Wood 1918).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although no information on the safety of sweetbay magnolia during pregnancy was identified, based on the similarity of this species to other species of *Magnolia,* use during pregnancy is not recommended.

No information on the safety of sweetbay magnolia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Berberine (Leung and Foster 1996; List and Hörhammer 1973); *see* Appendix 1. The total isoquinoline alkaloid content is reported as 7 to 16% in the root bark, and 2.4 to 4.5% in the stem bark (Fleming 2000), although the typically traded portion is the whole root, which contains a s ignificantly smaller percentage of berberine than the root bark.

Editors' Note

Most safety concerns reported for Oregon grape are based on studies of the compound berberine and other similar alkaloids. Data regarding isolated compounds may not apply directly to products or extracts made from Oregon grape.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

The use of berberine-containing herbs is contraindicated or cautioned against in pregnancy in several contemporary texts on herbal safety (Brinker 2001; Mills and Bone 2005; Mills et al. 2006). These contraindications are based primarily on the uterine stimulant activity of the isolated compound berberine in excised mouse uteruses (Furuya 1957; Imaseki et al. 1961), and the potential ability of berberine to displace bilirubin and cause neonatal jaundice (Chan 1993). Although definitive data confirming the safety of Oregon grape during pregnancy is lacking, several reproductive toxicity studies on the isolated compound berberine in mice and rats have shown no adverse effects at doses of 530 mg/

kg in rats and mice (Jahnke et al. 2006; Marr et al. 2005; Price and George 2003).

Some concerns exist for use of berberine-containing plants during pregnancy, including uterine stimulation (Furuya 1957; Imaseki et al. 1961), although no uterine stimulation was noted in rats administered high doses of berberine during pregnancy (Jahnke et al. 2006), and a study of berberine-containing herbal extracts on isolated uteri showed no correlation between uterine stimulation and berberine concentration (Haginiwa and Harada 1962).

Although other berberine-containing plants in this text are classified as contraindicated in pregnancy except under supervision of a qualified healthcare practitioner, the lower percentage of berberine in Oregon grape root as compared to other berberine-containing botanicals led to the less restrictive classification (De Smet 1992; Fleming 2000; Leung and Foster 1996; List and Hörhammer 1973; Upton 2001).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

M

II. Adverse Events

Adverse Events Reported in Clinical Trials

No drug-related adverse events were reported in a 12-week trial of a topically applied Oregon grape ointment containing 0.1% berberine (Gulliver 2004). Itching and burning were reported as adverse events in 4% of patients topically administered a preparation of Oregon grape. In that study, patients were simultaneously treated with placebo on one arm and Oregon grape on the other (Wiesenauer 1996). Other similar studies of topically applied Oregon grape preparations note adverse events of itching and burning in up to 1.2% of trial participants (Bernstein et al. 2006; Gieler et al. 1995).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Intraperitoneal administration of 0.02 mg/kg of the compound berberine daily for 1 week to adult rats resulted in a significant decrease in mean bilirubin serum protein binding due to a displacement effect (Chan 1993).

In Vitro Pharmacological Studies

The compound berberine was found to be 10 times more potent in vitro than phenylbutazone, a known displacer of bilirubin, and approximately 100 times more potent than papaverine (Chan 1993).

IV. Pregnancy and Lactation

In pregnant rats fed the compound berberine on gestational days (GD) 6 to 20, some reduction in maternal weight gain was observed, with a lowest-observed-adverse-effect level (LOAEL) of 530 mg/kg daily. Only a mild reduction in fetal weights was observed, and the LOAEL based on fetal weight reduction was 1000 mg/kg (Jahnke et al. 2006). Similarly, in mice administered berberine on GD 6 to 17 at doses up to 1155 mg/kg daily, the maternal LOAEL was determined to be 531 mg/kg daily, and the developmental toxicity level was 1000 mg/kg daily. In mice, 33% of the treated females died. Surviving animals had increased relative water intake, and average fetal body weight per litter decreased 5–6% with no change in live litter size (Jahnke et al. 2006).

Berberine has been shown to stimulate uterine contractions in both pregnant and nonpregnant mice (Furuya 1957; Imaseki et al. 1961). A study of various berberine-containing herbal extracts on isolated uteruses, however, indicated that relaxation or stimulation of the uterus did not correlate with the concentration of berberine in the extract, suggesting that not all berberine-containing herbs will have the same effect on the uterus (Haginiwa and Harada 1962).

Berberine has been shown to be present in the breast milk of lactating women who have taken berberine-containing plants (Chan 1993).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered berberine in mice is 329 mg/kg (Haginiwa and Harada 1962). The LD_{50} of orally administered berberine sulfate in rats is greater than 1000 mg/kg (Kowalewski et al. 1975).

Genotoxicity

Fractions of Oregon grape extracts showed antimutagenic activity using *Euglena gracilis* as an eukaryotic test model. Both bisbenzylisoquinoline and protoberberine alkaloid fractions were active in this respect, but only the protoberberine derivatives jatrorrhizine and berberine showed significant concentration-dependent antimutagenic activity (Cernakova et al. 2002).

No mutagenic activity of berberine was observed in *Salmonella typhimurium* TA100 and TA98 with or without metabolic activation by S9 mix. Berberine hydrochloride was weakly mutagenic to strain TA98 without S9 mix, but showed no mutagenic activity in TA100 without S9 mix (Nozaka et al. 1990).

No genotoxic, mutagenic, or recombinogenic activity of berberine with or without metabolic activation was observed in the SOS chromotest. Berberine did not induce significant cytotoxic, mutagenic, or recombinogenic effects during treatments performed under nongrowth conditions; in dividing cells, however, the alkaloid induced cytotoxic and cytostatic effects in proficient and repair-deficient strains of *Saccharomyces cerevisiae*. In dividing cells, the induction of frameshift and mitochondrial mutations, as well as crossing over, indicated that berberine is not a potent mutagenic agent (Pasqual et al. 1993).

Malva sylvestris L. — Malvaceae

SCN: high mallow
OCN: common mallow; malva

Part: flower, leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Should be taken with at least 250 ml (8 oz) of liquid.

Drug and Supplement Interactions

Other drugs should be taken 1 hour prior to consumption of high mallow or several hours after consumption, as the mucilage content of high mallow may slow the absorption of orally administered drugs (Classen and Blaschek 1998; Franz 1966; Gonda et al. 1990; Tomoda et al. 1989).

Notice

Mucilages (5 to 12%) (Classen and Blaschek 1998; Franz 1966; Gonda et al. 1990; Tomoda et al. 1989); *see* Appendix 3.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of high mallow in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No studies on the use of high mallow during pregnancy or lactation were identified.

V. Toxicity Studies

Cytotoxicity

No cytotoxic activity of a dichloromethane and methanol extract of the aerial parts of high mallow was observed in mouse fibrosarcoma cells (L929sA) (Kaileh et al. 2007).

Maranta arundinacea L.

Marantaceae

SCN: arrowroot
OCN: St. Vincent arrowroot; West Indian arrowroot

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

A flour made from arrowroot is commonly used in cooking, notably in biscuits made for infants (Felter and Lloyd 1898; Kay and Gooding 1987).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of arrowroot in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

Marrubium vulgare L. — Lamiaceae

SCN: horehound
OCN: white horehound

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Kchouck and Chadli 1963; List and Hörhammer 1973).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (List and Hörhammer 1973); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Studies in rabbits and rats have indicated that horehound may help to regulate blood sugar levels (Novaes et al. 2001; Roman Ramos et al. 1992).

"Large doses" may have laxative effects (Chadha 1988; Osol and Farrar 1955).

Pregnancy and Lactation

Horehound has traditionally been used as an emmenagogue (List and Hörhammer 1973). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of horehound in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Extracts of horehound helped decrease experimentally induced hyperglycemia in rabbits and in alloxan-induced diabetic rats (Novaes et al. 2001; Roman Ramos et al. 1992).

One reference indicates that a standard dose of horehound has a normalizing effect on extrasystolic arrythmias, whereas larger doses may disturb the heart rhythm in a manner that can be counteracted by atropine (List and Hörhammer 1973).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Horehound has traditionally been used as an emmenagogue (List and Hörhammer 1973).

In pregnant rats, mice, and guinea pigs subcutaneously, intraperitoneally, or orally administered approximately 2 ml/kg of a horehound decoction either once or twice during pregnancy, some abortifacient activity in rats was observed, with a lesser effect on mice and guinea pigs (Kchouck and Chadli 1963). This study did not include control groups, making results difficult to interpret.

No information on the safety of horehound in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound marrubiin orally administered to rats is 370 mg/kg (Krejci and Zadina 1959).

Matricaria chamomilla L. — Asteraceae

SCN: chamomile
Syn: *Chamomilla recutita* (L.) Rauschert; *Matricaria recutita* L.

OCN: German chamomile; Hungarian chamomile; mayweed; sweet false chamomile; true chamomile
Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as feverfew or *Echinacea*) should exercise caution with chamomile, as allergic cross-reactivity is common to Asteraceae plants (Upton 2007).

Drug and Supplement Interactions

None known.

Editors' Note

The German Standard License, as presented by Wichtl (2004), requires the following label warning: The infusion should not be used near the eyes.

Adverse Events

Allergic reactions to chamomile, including anaphylactic reactions, have been reported (Benner and Lee 1973; Foti et al. 2000; Giordano-Labadie et al. 2000; Jensen-Jarolim et al. 1998; Lundh et al. 2006; McGeorge and Steele 1991; Pereira et al. 1997; Rodriguez-Serna et al. 1998; Rudzki et al. 2003; Subiza et al. 1989; Thien 2001). No other types of adverse events or interactions have been reported in association with chamomile.

Highly concentrated hot tea is noted as emetic (Chadha 1988).

Pharmacological Considerations

Chamomile has been indicated as an herb with the theoretical potential for interacting with warfarin due to the coumarin content of the herb (Heck et al. 2000). The coumarin content, however, consists of the coumarin derivatives herniarin and umbelliferone. Herniarin has been shown to have hemostatic activity (Ahmad and Misra 1997) and umbelliferone has shown no evidence of anticoagulant activity (Egan et al. 1990; Feuer 1974; Pelkonen et al. 1997). The flavonoid apigenin has been shown to inhibit platelet aggregation in vitro (Landolfi et al. 1984; Teng et al. 1985).

Coadministration of chamomile tea and iron-fortified bread reduced absorption of the iron (Hurrell et al. 1999).

Pregnancy and Lactation

Limited information on the safety of chamomile in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

One woman taking warfarin had an increased INR, from 3.6 to 7.9 (a standardized scale used to report the results

of blood coagulation tests; increased INR indicates slowed blood clotting), and pelvic and abdominal ecchymoses after consuming 4 or 5 cups of chamomile tea daily and applying a chamomile-containing skin lotion. The woman denied any dietary changes (Segal and Pilote 2006).

Animal Trials of Drug or Supplement Interactions

No relevant animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to chamomile including anaphylaxis (Benner and Lee 1973; Jensen-Jarolim et al. 1998; Subiza et al. 1989; Thien 2001) and contact dermatitis have been reported (Foti et al. 2000; Giordano-Labadie et al. 2000; Lundh et al. 2006; McGeorge and Steele 1991; Pereira et al. 1997; Rodriguez-Serna et al. 1998; Rudzki et al. 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Coadministration of iron-fortified bread and chamomile tea reduced absorption of the iron by 47%, an effect that was less pronounced than that of black tea, cocoa, or tea made with peppermint, European pennyroyal, European vervain, or linden flower (Hurrell et al. 1999).

Animal Pharmacological Studies

Administration of a 2% chamomile tea to rats for 4 weeks resulted in significant inhibition of the drug-metabolizing isoenzyme CYP1A2 (Maliakal and Wanwimolruk 2001).

In Vitro Pharmacological Studies

An extract of chamomile demonstrated inhibitory activity on the drug-metabolizing isoenzyme CYP3A4 in vitro (Budzinski et al. 2000).

IV. Pregnancy and Lactation

No adverse effects on prenatal development or signs of teratogenicity were observed after long-term oral administration of a commercial chamomile extract in rats (Homburg Pharma 1986).

No information on the safety of chamomile in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered chamomile essential oil in rats could not be determined at doses up to 5 g/kg (Opdyke 1974).

Chronic Toxicity

Long-term oral administration of chamomile extract in rats and dogs produced no signs of toxicity. Rat behavior was affected only at 500 mg/kg, the highest dose tested (Fundaro and Cassone 1980).

None known.

Pharmacological Considerations

Alfalfa is sometimes cited as a potential anticoagulant due to the presence of coumarin compounds and confusion between coumarins and the anticoagulant drug coumadin (sometimes referred to as coumarin). Different naturally occurring coumarins have been shown to have varying activities on coagulation, with some having anticoagulant activity, some having procoagulant activity, and others having no effects on coagulation (Booth et al. 2004). An in vitro study of alfalfa demonstrated some anticoagulant activity (Pierre et al. 2005), although the relevance of those in vitro data to human use is not known.

Animal studies of alfalfa seed and seed sprouts have indicated some association between those products and the autoimmune disease lupus. The amount of alfalfa used in the studies, however, was highly excessive, with animals being fed diets containing 40% alfalfa sprouts or 45% alfalfa seed (Malinow et al. 1982; Montanaro and Bardana 1991). Related studies implicated the compound L-canavanine as being responsible for the effects of alfalfa. Although the compound is present in alfalfa seed and sprouts, it is not present in the mature herb that is the subject of this entry (Brown 2000; Farnsworth 1995; Malinow et al. 1982; Whittam et al. 1995).

Pregnancy and Lactation

No information on the safety of alfalfa in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

In two patients with well-controlled systemic lupus erythematosus (SLE), consumption of alfalfa tablets was associated with exacerbation of SLE symptoms. In one case, involving a 40-year-old woman with a 26-year history of SLE, exacerbation was observed after the woman had been taking 15 tablets of alfalfa daily for 9 months. In the second case, a 50-year-old woman with a 25-year history of SLE experienced an increase in symptoms over the course of 18 months. She had been taking 8 tablets of alfalfa daily for 2.5 years (Roberts and Hayashi 1983).

The compound L-canavanine has been suggested as the causative agent in SLE exacerbation. L-canavanine is found in minor amounts in the seed and sprouts of alfalfa but not in the mature plant. Alfalfa tablets from two manufacturers tested negative for L-canavanine (Brown 2000; Farnsworth 1995; Malinow et al. 1982; Whittam et al. 1995).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In cynomolgus macaques fed diets containing 45% ground alfalfa seed, three of five monkeys developed autoimmune hemolytic anemia associated with systemic findings. All three of those animals developed significant antinuclear antibodies along with elevated antibodies to double-stranded DNA. During a 20-month observational period, one of the animals developed clinical signs consistent with the appearance of systemic lupus erythematosus temporally related to the ingestion of alfalfa seed. Withdrawal of alfalfa seed from the diet was associated with the normalization of immunologic parameters and serum complements. Antinuclear antibodies and antidouble-stranded DNA antibodies persisted for 2 years (Montanaro and Bardana 1991).

Hematological and serological abnormalities similar to those observed in human systemic lupus erythematosus (SLE) developed in cynomolgus macaques fed a diet containing 40% alfalfa sprouts. In animals that developed hematological and serological abnormalities, placement on a diet containing 1% of the compound L-canavanine sulfate for 4 weeks reactivated previously observed abnormalities associated with ingestion of alfalfa sprouts (Malinow et al. 1982).

In Vitro Pharmacological Studies

In an estrogen-dependent MCF-7 breast cancer cell proliferation assay, a methanol extract of alfalfa sprouts exhibited binding activity to estrogen receptor (ER) β with an IC_{50} value of 198 μg/ml. The pure estrogen antagonist, ICI 182,780, suppressed cell proliferation induced by the extracts. The ER-β binding activity was significantly less than that of kudzu root, red clover blossom, soy beans, and red clover sprouts. No activity of the alfalfa sprout extract was observed on ER-α (Boue et al. 2003).

The average content of the compound coumestrol in alfalfa tablets sold as supplements was 20 to 190 ppm (average of 99 ppm) (Elakovich and Hampton 1984). Other reports indicate that alfalfa meal contains 25 to 65 ppm or 80 to 100 ppm of the compound coumestrol (Livingston et al. 1961; Saloniemi et al. 1995). The amount of "estrogenic substances" in alfalfa meal was reported as 1.1 to 1.8 μg/g, which was greater than that of soybean meal (Kato et al. 2004).

An aqueous extract of alfalfa inhibited ADP- and collagen-induced human platelet aggregation but had no effect on arachadonic acid- or thrombin-induced platelet aggregation. Alfalfa inhibited thromboxane B_2 synthesis induced by ADP or collagen, and whole blood aggregation induced by collagen (Pierre et al. 2005).

The compound L-canavanine demonstrated dose-related effects on human immunoregulatory cells, including abrogation of concanavalin A–induced suppressor cell function and diminution of the mitogenic response to both phytohemagglutinin and concanavalin A but not to pokeweed mitogen (Alcocer-Varela et al. 1985).

IV. Pregnancy and Lactation

No information on the safety of alfalfa during pregnancy or lactation was identified.

V. Toxicity Studies

Subchronic Toxicity

No adverse effects in any of the observed parameters, including changes in liver, spleen, stomach, and kidney, were seen in rats fed diets containing 1 or 2% alfalfa saponins for 6 months (Malinow et al. 1981).

Genotoxicity

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA100, no mutagenic activity of an acetone extract of alfalfa was observed with or without metabolic activation (White et al. 1983).

M

Melia azedarach L.

Meliaceae

SCN: melia
Syn: *Melia toosendan* Siebold & Zucc.
AN: *mahanimba*

PN: *chuan lian zi*
OCN: Chinaberry; Chinatree; pagoda tree
Part: fruit

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

The entire melia plant is reported to be toxic, with the fruit listed as the most toxic part (Chen and Chen 2004). Eating six to eight fresh melia fruits may cause dizziness, vomiting, diarrhea, difficulty breathing, palpitations, and muscle spasms (Chen and Chen 2004). Onset of symptoms generally occurs 4 to 6 hours after ingestion, although they may appear as soon as 30 minutes (Chen and Chen 2004; Phau 2007). More severe toxicity may include symptoms of numbness, muscle cramps, tremors, arrhythmia, respiratory distress, convulsions, and unconsciousness or altered consciousness (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of melia fruit in pregnancy or lactation was identified. While this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Editors' Notes

The cautions and concerns stated here are for raw, unprocessed melia fruit. Heat treated melia fruit is the primary article in trade, however, and processing by dry-frying is

reported to minimize the toxicity of the fruit (Chen and Chen 2004).

Although *M. toosendan* is considered to be a taxonomic synonym for *M. azerdarach* (McGuffin et al. 2000), contemporary references list *M. azedarach* fruit as an adulterant of or potentially inappropriate substitute for *M. toosendan* fruit and regard the former as more toxic (Bensky et al. 2004; Chen and Chen 2004).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Eating six to eight fresh melia fruits may cause dizziness, vomiting, diarrhea, difficulty breathing, palpitations, and muscle spasms (Chen and Chen 2004). Adverse reactions are reported to begin 4 to 6 hours after ingestion, although they may appear as soon as 30 minutes after ingestion (Chen and Chen 2004). More severe toxicity may include symptoms of numbness, muscle cramps, tremors, arrhythmia, respiratory distress, convulsions, and unconsciousness or altered consciousness (Bensky et al. 2004; Chen and Chen 2004).

In addition to the above-listed symptoms, overdose of melia fruit may result in jaundice, toxic hepatitis, arrhythmia, damage to the heart muscle, nosebleeds, bloody stools or urine, low blood pressure, and shock (Bensky et al. 2004).

Melia fruit poisoning has been reported in a number of animal species, including pigs, dogs, goats, cattle, poultry, rats, and guinea pigs. Symptoms of poisoning in animals are reported to appear 2 to 4 hours after ingestion and include nausea, vomiting, diarrhea, constipation, colic, convulsions, ataxia, depression, respiratory distress, muscle impairment, and coma (Hare 1998; Hare et al. 1997; Hothi et al. 1976). Muscle tremors, kicking, and respiratory distress were reported in ostriches that consumed melia fruit. Postmortem examination of a 7-month-old ostrich revealed a hemorrhage in the gut and enlargement of the liver (Cooper 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of melia fruit in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of melia fruit extract in rats is 1.03 g/kg after intraperitoneal administration but could not be determined at doses up to 16 g/kg after oral administration (Carpinella et al. 1999).

The LD_{50} of a hydroalcoholic extract of melia fruit is 700 mg/kg in mice and 925 mg/kg in rats after intravenous administration. After oral administration of the same extract, no toxic effects were reported at doses up to 1.5 g/kg (Zakir Ur et al. 1991).

In calves orally administered melia fruit at doses of 5 to 30 g/kg, half of the animals that received 15 g/kg and all animals that received 25 or 30 g/kg died. Clinical signs, which appeared 4 to 24 hours after administration, included depression, ruminal stasis, anorexia, diarrhea, incoordination, muscle tremors, difficulty standing, sternal recumbence, hypothermia, and dyspnea. Serum levels of aspartate aminotransferase (AST) and creatine phosphokinase (CPK) were elevated (Mendez et al. 2002). Feeding studies in pigs and sheep indicated that the toxic dose of melia fruit was approximately 5 g/kg (Hare 1998; Kingsbury 1964).

The LD_{50} of orally administered toosendanin is 244 mg/kg in mice, 120 mg/kg in rats, and 3.5 mg/kg in cats (Chen and Chen 2004).

AN: *mahanimba*
PN: *ku lian pi* (stem and root bark)
OCN: Chinaberry; Chinatree; pagoda tree
Part: bark, root bark

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004; Chen and Chen 2004; Felter and Lloyd 1898).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emetic (Felter and Lloyd 1898); *see* Appendix 2.

Adverse Events and Side Effects

Melia bark or root bark may cause side effects within the normal dosage range including dizziness, headache, nausea, vomiting, drowsiness, and abdominal pain. These symptoms disappear spontaneously when use of the herb is discontinued (Bensky et al. 2004; Chen and Chen 2004).

Allergic skin reactions to melia bark or root bark have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A reference text on traditional Chinese medicine indicates that melia bark or root bark should not be used during pregnancy (Bensky et al. 2004). Animal studies have indicated that melia root significantly reduces implantation and causes an increase in fetal resorptions (Keshri et al. 2003, 2004).

No information on the safety of melia bark or root bark in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Melia bark or root bark may cause side effects within the normal dosage range including dizziness, headache, nausea, vomiting, drowsiness, and abdominal pain. These symptoms will disappear spontaneously when use of the herb is discontinued (Bensky et al. 2004; Chen and Chen 2004; Felter and Lloyd 1898).

Overdose of melia bark or root bark may cause severe vomiting, diarrhea, abdominal distention, respiratory paralysis, palpitations, tachycardia, and blue coloration of the lips (Bensky et al. 2004; Chen and Chen 2004; Felter and Lloyd 1898).

In cases of severe overdose, melia bark or root bark may cause gastrointestinal bleeding, jaundice, hepatomegaly, elevated liver enzymes, toxic hepatitis, visual impairment, and respiratory or circulatory failure (Bensky et al. 2004; Chen and Chen 2004).

Melia bark poisoning was reported in a couple (77-year-old man and 66-year-old woman) who had been drinking an unspecified amount of melia root bark boiled in water daily for 3 weeks. Both the man and woman noted drooling after ingestion of larger amounts (~500 or 1000 ml of extract), later experiencing muscle weakness, ptosis, and elevated liver enzymes. The couple recovered after several days of supportive management (Phua et al. 2008).

An 18-year-old woman became comatose after ingesting an aqueous extract of an unspecified amount of melia bark. After remaining in a comatose state for 3 days, with doctors unsuccessfully attempting treatment, the woman died (Toh 1969).

Allergic skin reactions to melia bark or root bark have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No estrogenic activity of an ethanol extract of melia bark was observed in a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation

A 60 to 75% reduction in implantation was observed in rats orally administered 250 or 500 mg/kg of an ethanol extract of melia root bark daily on days 1 to 10 after mating. In animals that became pregnant, there was also a significant reduction in the number of implantations, and all implantations exhibited signs of resorption (Keshri et al. 2003).

An 83% reduction in implantation was observed in rats orally administered 250 mg/kg of a chloroform extract of melia root bark daily on days 1 to 7 after mating (Keshri et al. 2004).

A reference text on traditional Chinese medicine indicates that melia bark or root bark should not be used during pregnancy (Bensky et al. 2004).

No information on the safety of melia bark or root bark in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered toosendanin is 244 mg/kg in mice, 120 mg/kg in rats, and 3.5 mg/kg in cats (Chen and Chen 2004).

Melissa officinalis L. — Lamiaceae

SCN: lemon balm
OCN: balm; bee balm; melissa; melissa balm

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Clinical trials of orally and topically administered lemon balm preparations have demonstrated that they have been generally well tolerated with few adverse events (Akhondzadeh et al. 2003; Buchner et al. 1974; Kennedy et al. 2002, 2004; Koytchev et al. 1999; Wolbling and Leonhardt 1994).

Pharmacological Considerations

Initial animal and in vitro studies indicate that lemon balm may affect thyroid hormone levels and inhibit binding of thyroid-stimulating hormone (TSH) to TSH receptors (Auf'mkolk et al. 1985; Santini et al. 2003; Sourgens et al. 1982), although no human cases of thyroid effects have been reported.

Pregnancy and Lactation

No information on the safety of lemon balm in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Animal studies indicated that extracts of lemon balm may increase the sedative activity of pentobarbital and hexobarbital (Soulimani et al. 1991; Wagner and Sprinkmeyer 1973).

II. Adverse Events

Adverse Events Reported in Clinical Trials

Reviews (Brendler et al. 2006; ESCOP 2003) of clinical trials of lemon balm indicated that both internal (Akhondzadeh et al. 2003; Buchner et al. 1974; Kennedy et al. 2002, 2004) and topical administration (Koytchev et al. 1999; Wolbling and Leonhardt 1994) are generally very well tolerated. Headache and heart palpitations were reported in one early clinical trial of lemon balm (Buchner et al. 1974). Local reddening, burning sensation, paresthesia, residual pigmentation, and dermal irritation have been reported in clinical studies of topically applied lemon balm products (Wolbling and Leonhardt 1994; Wolbling and Milbradt 1984).

Case Reports of Adverse Events

Contact dermatitis was reported after topical use of a cosmetic containing lemon balm. Patch testing confirmed sensitivity to lemon balm and to other ingredients in the cosmetic (West and Maibach 1995).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers administered single doses of up to 900 mg of a standardized lemon balm extract, self-rated "calmness" was elevated while "alertness" was significantly reduced (Kennedy et al. 2002).

Animal Pharmacological Studies

A very weak sensitizing effect was observed in guinea pigs topically treated with lemon balm (Hausen and Schulze 1986).

Intravenous administration of 25 mg/kg of a freeze-dried extract of lemon balm to normal rats resulted in reduced serum and pituitary gland levels of TSH. In rats with goiter, no change in TSH levels was observed after administration of lemon balm. No changes in serum prolactin were observed in either the normal or goitrous rats (Sourgens et al. 1982).

In Vitro Pharmacological Studies

Incubation of thyroid-stimulating immunoglobulin G (IgG) found in the blood of patients with Graves' disease

(IgG resembles TSH in the ability of IgG to bind to the thyroid plasma membrane, probably at the TSH receptor) with a freeze-dried lemon balm extract decreased the TSH-binding activity of IgG in a dose-dependent manner (Auf'mkolk et al. 1985).

In Chinese hamster ovary cells transfected with the recombinant human TSH receptor, lemon balm produced a dose-dependent inhibition of TSH-stimulated adenylate cyclase activity, inhibited the cAMP production stimulated by TSH receptor antibody, and produced a significant inhibition of TSH binding to its receptor and of antibody binding to TSH (Santini et al. 2003).

IV. Pregnancy and Lactation

No information on the safety of lemon balm during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed after intravenous injection of 25 mg/kg of lemon balm extract to rats (Sourgens et al. 1982).

Genotoxicity

No mutagenic effects of alcoholic extracts of lemon balm were observed in the Ames mutagenicity test with *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation, or in *Aspergillus nidulans* using a plate incorporation assay (Ramos Ruiz et al. 1996; Schimmer et al. 1994). The aqueous extract also showed no genotoxic activity in *Aspergillus nidulans* using a plate incorporation assay (Schimmer et al. 1994).

Mentha piperita L. — Lamiaceae

SCN: peppermint

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with gastroesophageal reflux or with a hiatal hernia, as peppermint may decrease esophageal sphincter pressure (Brinker 2001; Hiki et al. 2003; Hills and Aaronson 1991; Mills and Bone 2005).

Use with caution in persons with gastrointestinal ulcers or significant gastrointestinal inflammation (Mills and Bone 2005).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

A review of botanicals used in the treatment of dyspepsia indicated that peppermint leaf had an "encouraging safety profile" (Thompson Coon and Ernst 2002).

Pharmacological Concerns

Peppermint essential oil has been shown to relax the smooth muscles of the gastrointestinal tract (McKay and Blumberg 2006), which may exacerbate gastroesophageal reflux or hiatal hernias.

Coadministration of peppermint tea and iron-fortified bread reduced absorption of the iron (Hurrell et al. 1999).

Pregnancy and Lactation

Limited information on the safety of peppermint leaf in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

M

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No human trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events with peppermint leaf were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Coadministration of iron-fortified bread and peppermint tea reduced absorption of the iron by 84%. This observed inhibition compared to a similar effect associated with black tea at a rate of 79–94% (Hurrell et al. 1999).

Animal Pharmacological Studies

Administration of peppermint leaf tea (ad libitum) to male rats for 30 days caused an increase in follicle-stimulating hormone and luteinizing hormone and a decrease in testosterone, and a decrease in iron absorption was observed in rats administered the tea (Akdogan et al. 2004).

A reduction in activity of the drug-metabolizing isoenzymes CYP1A2 and CYP2E was observed in rats administered a 2% tea of peppermint leaf for 4 weeks (Maliakal and Wanwimolruk 2001).

In Vitro Pharmacological Studies

Aqueous extracts of peppermint leaf showed a dose-dependent relaxation effect on isolated rabbit duodenum (Mahmood et al. 2003).

IV. Pregnancy and Lactation

See *Mentha piperita* essential oil entry for information on the safety of peppermint during pregnancy and lactation.

V. Toxicity Studies

See *Mentha piperita* essential oil entry for additional toxicity studies on peppermint.

Short-Term Toxicity

In rats administered peppermint leaf tea for 30 days as the sole source of drinking water, no significant histopathological changes were observed in the kidneys (Akdogan et al. 2003).

Mentha piperita L. — Lamiaceae

SCN: peppermint

Part: leaf essential oil

Quick Reference Summary

Safety Class: 2b

Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Tiran and Mack 2000).

Other Precautions

Peppermint leaf essential oil may cause heartburn in sensitive individuals (Nash et al. 1986; Somerville et al. 1984). Use is cautioned in persons with gastroesophageal reflux or with a hiatal hernia, as peppermint may decrease esophageal sphincter pressure (Brinker 2001; Hiki et al. 2003; Hills and Aaronson 1991; Mills and Bone 2005).

Use is cautioned in persons with gastrointestinal ulcers or significant gastrointestinal inflammation (Mills and Bone 2005).

Enteric-coated peppermint leaf essential oil capsules may cause anal burning, especially in patients with diarrhea (Grigoleit and Grigoleit 2005; Mills and Bone 2005).

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 180–350 mg in enteric-coated capsules, three times daily (Grigoleit and Grigoleit 2005; Pittler and Ernst 1998).

Adverse Events and Side Effects

A review of botanicals used in the treatment of dyspepsia indicated that peppermint leaf oil had an "encouraging safety profile" (Thompson Coon and Ernst 2002).

Side effects reported in clinical trials of peppermint leaf essential oil include heartburn, and anal or perianal burning or discomfort (Grigoleit and Grigoleit 2005; Nash et al. 1986; Pittler and Ernst 1998; Somerville et al. 1984).

Allergic reactions, including contact dermatitis, to peppermint leaf essential oil have been reported (Foti et al. 2003; Morton et al. 1995; Sainio and Kanerva 1995; Wilkinson and Beck 1994).

Cases of mucosal ulcers have been associated with the oral ingestion of products containing peppermint, including mouthwashes and candies (Moghadam et al. 1999; Rogers and Pahor 1995).

Pharmacological Considerations

Peppermint leaf essential oil has been shown to slow intestinal transit, which may slow the absorption rate or increase the total absorption of coadministered drugs (Goerg and Spilker 2003).

Peppermint leaf essential oil has been shown to relax the smooth muscles of the gastrointestinal tract (McKay and Blumberg 2006), which may exacerbate gastroesophageal reflux or hiatal hernias.

Preliminary human and animal data suggest that large doses of peppermint leaf essential oil may inhibit the drug-metabolizing isoenzyme CYP3A4, leading to increased plasma levels of drugs metabolized by that isoenzyme (Dresser et al. 2002; Wacher et al. 2002).

Pregnancy and Lactation

Due to the highly concentrated nature of peppermint leaf essential oil, until further safety data is available, internal use during pregnancy should only be under the supervision of a qualified healthcare practitioner (Tiran and Mack 2000).

A study on the use of topical peppermint gel applied to nipples of nursing mothers indicated that no change occurred in infant breast-feeding behavior (Sayyah Melli et al. 2007).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Coadministration of cyclosporine (25 mg/kg) and peppermint leaf oil (100 mg/kg) in rats significantly increased serum levels of cyclosporine (Wacher et al. 2002).

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a systematic review of botanical products for non-ulcer dyspepsia, peppermint leaf essential oil was noted as having an "encouraging safety profile" (Thompson Coon and Ernst 2002).

Enteric-coated peppermint leaf essential oil capsules may produce anal burning in patients with diarrhea, due to excretion of peppermint oil. Use of enteric-coated capsules has been associated with adverse effects such as rashes, headache, bradycardia, muscle tremors, and ataxia (Mills and Bone 2005). Non-enteric-coated preparations of peppermint leaf essential oil have been reported to cause heartburn in sensitive individuals (Nash et al. 1986; Somerville et al. 1984).

A meta-analysis of trials on peppermint leaf essential oil for irritable bowel syndrome indicated that five of eight trials reported adverse effects including heartburn, perianal burning, blurred vision, nausea, and vomiting while taking the peppermint oil. The effects were observed in 11 to 36% (mean 20%) of the patients studied. The occurrence of adverse events in placebo groups was not reported (Pittler and Ernst 1998).

A review of 16 clinical trials on 180–200 mg enteric-coated peppermint leaf essential oil capsules in the treatment of irritable bowel syndrome indicated that adverse events reported in trials were generally mild and transient, but very specific, with peppermint leaf essential oil causing heartburn and anal or perianal burning or discomfort sensations (Grigoleit and Grigoleit 2005).

Case Reports of Adverse Events

Ingestion of a large dose (40 drops) of peppermint leaf essential oil resulted in a chemical burn of the oral cavity and pharynx with tachycardia, tachypnea, and edema of the lips, tongue, and uvula (Tamir et al. 2005). Several cases of mucosal ulcers have been associated with the oral ingestion of products containing peppermint, including mouthwashes and candies (Moghadam et al. 1999; Rogers and Pahor 1995).

Allergic reactions, including contact dermatitis, to peppermint leaf essential oil have been reported (Foti et al. 2003; Morton et al. 1995; Sainio and Kanerva 1995; Wilkinson and Beck 1994).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Coadministration of peppermint leaf essential oil (600 mg) and felodipine moderately increased the plasma concentration of felodipine, possibly through inhibition of the drug-metabolizing isoenzyme CYP3A4 (Dresser et al. 2002).

Peppermint leaf essential oil has been shown to slow intestinal transit, which may slow the absorption rate or increase the total absorption of coadministered drugs (Goerg and Spilker 2003; Mills and Bone 2005).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No teratogenic effects of the compound menthol were observed in mice fed 190 mg/kg, rats fed 220 mg/kg, hamsters fed 400 mg/kg, or rabbits fed 430 mg/kg (FAO/WHO 1999). The compound menthol has been reported to cause jaundice in newborn babies. This jaundice has been correlated with the hereditary disease glucose-6-phosphate dehydrogenase deficiency (Owa 1989).

No changes in breast-feeding frequency or duration were observed in infants of mothers using a topical application of peppermint gel daily for 14 days to prevent nipple cracking (Sayyah Melli et al. 2007).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered peppermint leaf oil in mice is 2.4 g/kg, and in rats is 4.4 g/kg (Della Loggia et al. 1990). No toxic effects were observed after mice were administered 4 g/kg of a peppermint extract (Della Loggia et al. 1990).

The estimated lethal dose for the compound menthol has been reported to be 2 g, although individuals have survived doses up to 9 g (De Smet 1993).

Short-Term Toxicity

No adverse effects were observed in mice fed 20 to 500 mg/kg daily (containing 1 to 2% pulegone) of peppermint leaf oil for 5 weeks (Mengs and Stotzem 1989).

Subchronic Toxicity

Some histopathological changes were noted in the cerebellum of mice fed 100 mg/kg peppermint leaf essential oil for 90 days. In male rats, some nephrotoxicity was noted. No adverse effects were observed in mice fed 10 or 40 mg/kg doses, and a no-observed-adverse-effect level (NOAEL) of 40 mg/kg per day was suggested (Spindler and Madsen 1992). In a similar study, peppermint leaf essential oil was associated with lesions in the cerebellum at doses of 40 and 100 mg/kg. No lesions or other adverse effects were observed at a dose of 20 mg/kg (Thorup et al. 1983).

Genotoxicity

Genotoxicity assays indicated that peppermint leaf essential oil induced sister-chromatid exchanges in a dose-independent manner. In the SMART test, peppermint leaf essential oil induced mutations in a dose-independent manner (Lazutka et al. 2001).

Mentha pulegium L.

Lamiaceae

SCN: European pennyroyal

Part: herb

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use during pregnancy or lactation (Anderson et al. 1996; Chadha 1988; Ciganda and Laborde 2003; Gordon et al. 1987; List and Hörhammer 1973).

Not for use by women with a heavy menstrual flow (Kuhn and Winston 2007).

Other Precautions

Not recommended for use in persons with liver or kidney disease (Brinker 2001; Gordon et al. 1987; Mizutani et al. 1987; Speijers 2001; Sztajnkrycer et al. 2003).

Not recommended for use in children or infants (Bakerink et al. 1996; Brinker 2001).

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Chadha 1988); *see* Appendix 2.

Editors' Note

European pennyroyal leaf contains 1.0–2.0% essential oil consisting of 80.0–94.0% pulegone (List and Hörhammer 1973), a compound that causes severe liver toxicity when administered to rats in high doses (Gordon et al. 1987; Mizutani et al. 1987; Speijers 2001; Sztajnkrycer et al. 2003).

European pennyroyal and American pennyroyal (*Hedeoma pulegioides*) are historically interchangeable as the source for pennyroyal oil (De Smet 1992).

Adverse Events and Side Effects

Transient and generally mild adverse effects, including nausea, dizziness, and abdominal cramping, have been reported in association with the use of pennyroyal herb tea, even at doses as low as 1–3 cups. Much more serious side effects, including fatalities, are recorded with consumption of pennyroyal essential oil (*see* next entry) (Anderson et al. 1996).

Case reports also appear in the literature of significant adverse events with the use of incompletely described pennyroyal preparations to induce abortion. These include an epileptic event after use of 9–12 "pennyroyal tablets" daily for 4 days (Early 1961), and two deaths. One of the recorded deaths occurred after use of "a bottle of pennyroyal mixture" on two subsequent days (Vallance 1955). The other death was associated with ingestion of European pennyroyal herb extract in 48–56% alcohol by a 24-year-old diagnosed with a possibly ruptured ectopic pregnancy (Anderson et al. 1996). Two cases of coma associated with consumption of "essence of pennyroyal" are also reported (Anderson et al. 1996); the latter of these speculated that the material used was dilute pennyroyal oil (Braithwaite 1906).

Pharmacological Considerations

Coadministration of European pennyroyal tea and iron-fortified bread reduced absorption of the iron (Hurrell et al. 1999).

Pregnancy and Lactation

Pennyroyal essential oil (*see* next entry), has historically been used by women attempting to induce abortion (De Smet 1992; Williamson 2003). Although animal or other

studies on the use of European pennyroyal herb during pregnancy and lactation are lacking, the content of the potentially toxic compound pulegone and traditional use of the oil suggest that European pennyroyal herb should not be used during pregnancy or when nursing.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A review of pennyroyal toxicity identified 22 adverse events from 1883 to 1996, generally without differentiation between American pennyroyal (*Hedeoma pulegioides*) and European pennyroyal. Two of the identified events were associated with pennyroyal herb tea alone; two with use of pennyroyal herb tea and one or more additional preparations of pennyroyal herb; one with an alcohol extract of the herb; and the balance with pennyroyal essential oil (*see* next entry for further information on the case reports for essential oil). In women who drank pennyroyal tea, one or two cups of tea were associated with dizziness, weakness, and abdominal cramping. Consumption of the tea along with other preparations, including the essential oil, was associated with more severe symptoms including vomiting, stupor, and coma (Anderson et al. 1996). The case involving the extract, identified as "pennyroyal herb, 48% to 56% in an alcohol base" (probably an extract of the herb in 48–56% alcohol), was associated with the death of a 24-year-old woman with an undiagnosed ectopic pregnancy (Anderson et al. 1996; Young 1995).

Acute hepatic and neurological injury was observed in two Hispanic infants administered tea made from homegrown plants believed to be mint. An 8-week-old male developed fulminant liver failure with cerebral edema and necrosis, resulting in death, following a single dose of 120 ml of tea brewed from the plant's leaves. A 6-month-old male experienced hepatic dysfunction and severe epileptic encephalopathy after thrice weekly ingestion of 90 ml of leaf tea. Upon examination of samples of the plants involved, it was suggested that the subspecies used contained pennyroyal oil, and serum analyses identified pulegone in one infant and its metabolite menthofuran in both. (Bakerink et al. 1996).

A case of contact dermatitis was reported in a woman who had recently picked European pennyroyal leaves (Roe et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Coadministration of iron-fortified bread and European pennyroyal tea reduced absorption of the iron by 73%, an effect that was less pronounced than that of black tea or peppermint tea, but more inhibitory than cocoa or tea made with European vervain, linden flower, or chamomile (Hurrell et al. 1999).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Menthofuran, a metabolite of the compound pulegone, has been shown to be a significant inhibitor of the drug-metabolizing isoenzyme CYP2A6 (Khojasteh-Bakht et al. 1998).

IV. Pregnancy and Lactation

Pennyroyal oil has been traditionally used as an abortifacient (De Smet 1992; Gordon et al. 1987; Williamson 2003). Although animal or other studies on the use of pennyroyal herb during pregnancy and lactation are lacking, the content of the potentially toxic compound pulegone (*see* Toxicity Studies) and traditional use of the oil suggest that pennyroyal herb should not be taken during pregnancy or while nursing.

V. Toxicity Studies

Toxicity testing of pulegone in rats indicated that the no-observed-adverse-effect level (NOAEL) for the compound ranges between 20 mg/kg (administered by gavage) and 250 mg/kg (administered in food) daily (Imaizumi et al. 1985; Thorup et al. 1983).

The compound pulegone is metabolized to form menthofuran, a r ecognized hepatotoxin (Gordon et al. 1987; Mizutani et al. 1987; Speijers 2001; Sztajnkrycer et al. 2003).

Acute Toxicity

The LD_{50} of orally administered pennyroyal essential oil in rats is 220 to 580 mg/kg (Opdyke 1972).

Short-Term Toxicity

Rats administered pulegone at doses of 80 or 160 mg/kg daily had induced atonia, decreased blood creatinine content, lowered terminal body weight, and histopathological changes in the liver and in the white matter of the

cerebellum. Rats administered 20 mg/kg daily did not exhibit these signs of toxicity (Thorup et al. 1983).

Genotoxicity

The compound pulegone tested negative for genotoxicity in a *Salmonella typhimurium* test and was weakly positive in the *Drosophila melanogaster* wing spot test (Franzios et al. 1997).

Immunotoxicity

In a screening study for immunotoxicity, mice treated orally with the compound isopulegol at doses up to 500 mg/kg daily for 5 days exhibited no signs of toxicity (Vollmuth et al. 1989).

Mentha pulegium L. — Lamiaceae

SCN: European pennyroyal

Part: herb essential oil

Quick Reference Summary

Safety Class: 2a, 2b, 2c
Interaction Class: A

Contraindications

Not to be used during pregnancy (Anderson et al. 1996; Chadha 1988; Ciganda and Laborde 2003; Gordon et al. 1987; List and Hörhammer 1973).

For external use only (Anderson et al. 1996; Sullivan et al. 1979; Vallance 1955).

Other Precautions

If applying pennyroyal essential oil topically in humans or animals, the oil must be diluted in a carrier oil to minimize risk of adverse reactions. To avoid ingestion by companion animals, topical application of diluted essential oil should only be on a collar and not directly on fur or skin.

Not recommended for use in persons with liver or kidney disease (Gordon et al. 1987; Mizutani et al. 1987; Speijers 2001; Sztajnkrycer et al. 2003).

Not recommended for use in children or infants (Bakerink et al. 1996).

Not recommended for nursing women due to the theoretical potential for transfer of the compound pulegone through breast milk (Brinker 2001).

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Chadha 1988); *see* Appendix 2.

Abortifacient (De Smet 1992; Gordon et al. 1987; Williamson 2003); *see* Appendix 2.

Editors' Notes

Pennyroyal essential oil consists of 80.0 to 94.0% pulegone (List and Hörhammer 1973), a compound that causes severe liver toxicity when administered to rats in high doses (Gordon et al. 1987; Mizutani et al. 1987; Speijers 2001; Sztajnkrycer et al. 2003).

European pennyroyal and American pennyroyal (*Hedeoma pulegioides*) have been historically interchangeable as the source for pennyroyal oil (Furia and Bellanca 1971). The cautions presented here are relevant to the essential oil derived from either plant.

Adverse Events and Side Effects

Cases of toxicity have been reported in persons consuming pennyroyal essential oil (Anderson et al. 1996; Anonymous 1978; Macht 1913; Vallance 1955). Death was reported after consumption of as little as 15.0 ml (1/2 oz) of the oil and, in one instance, following consumption of an alcohol extract of pennyroyal over a 2-week period. Symptoms of toxicity ranged from nausea, dizziness, and dilation of pupils to respiratory depression, generalized seizures, and coma (Anderson et al. 1996).

Pharmacological Considerations

See Adverse Events and Side Effects.

Pregnancy and Lactation

Pennyroyal essential oil has been traditionally used as an abortifacient (Conway and Slocumb 1979; De Smet 1992; Williamson 2003). Although animal or other studies on the use of pennyroyal essential oil during pregnancy and lactation are lacking, the content of the potentially toxic compound pulegone and traditional use indicate that it should not be taken orally or used externally during pregnancy or while nursing.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A review of pennyroyal toxicity identified 22 adverse events from 1883 to 1996, most of which involved oral consumption of the essential oil at doses greater than 10 ml. Four cases had fatal outcomes; the remaining cases had mild to severe outcomes ranging from nausea, dizziness, and dilation of pupils to respiratory depression, generalized seizures, and coma (Anderson et al. 1996). *See* above entry on European pennyroyal herb for a detailed discussion of this reference.

Toxicosis followed by death was reported in a dog treated topically with pennyroyal oil (Sudekum et al. 1992).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Menthofuran, a metabolite of the compound pulegone, has been shown to be a significant inhibitor of the drug-metabolizing isoenzyme CYP2A6 (Khojasteh-Bakht et al. 1998).

IV. Pregnancy and Lactation

Pennyroyal essential oil has been traditionally used as an abortifacient (Conway and Slocumb 1979; De Smet 1992; Williamson 2003). Although animal or other studies on the use of pennyroyal essential oil during pregnancy and lactation are lacking, the content of the potentially toxic

compound pulegone and traditional use indicate that it should not be taken orally or used externally during pregnancy or while nursing.

V. Toxicity Studies

Toxicity testing of the compound pulegone in rats indicated that the no-observed-adverse-effect level (NOAEL) for the compound ranges between 20 mg/kg (administered by gavage) and 250 mg/kg (administered in food) daily (Imaizumi et al. 1985; Thorup et al. 1983).

The compound pulegone is metabolized to form menthofuran, a recognized hepatotoxin (Gordon et al. 1987; Mizutani et al. 1987; Speijers 2001; Sztajnkrycer et al. 2003).

Acute Toxicity

The LD_{50} of orally administered pennyroyal essential oil in rats is 220 to 580 mg/kg (Opdyke 1972).

Short-Term Toxicity

Rats administered pulegone at doses of 80 or 160 mg/kg daily had induced atonia, decreased blood creatinine content, lowered terminal body weight, and histopathological changes in the liver and in the white matter of the cerebellum. Rats administered 20 mg/kg daily did not exhibit those signs of toxicity (Thorup et al. 1983).

Genotoxicity

The compound pulegone tested negative for genotoxicity in a *Salmonella typhimurium* test and was weakly positive in the *Drosophila melanogaster* wing spot test (Franzios et al. 1997).

Immunotoxicity

In a screening study for immunotoxicity, mice treated orally with the compound isopulegol at doses up to 500 mg/kg daily for 5 days exhibited no signs of toxicity (Vollmuth et al. 1989).

Mentha spicata L. — Lamiaceae

SCN: spearmint
Syn: *Mentha viridis* L.

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Although spearmint leaf is the subject of this entry, spearmint essential oil is also available and is a highly concentrated extract. Safety considerations for spearmint essential oil are different than those for spearmint leaf.

Adverse Events and Side Effects

Cases of contact allergy to spearmint essential oil have been reported (Andersen 1978; Clayton and Orton 2004; Skrebova et al. 1998).

Spearmint essential oil may cause sensitivity reactions in certain individuals and especially in children (Mills and Bone 2005).

Pharmacological Considerations

Some changes in reproductive hormone levels have been reported in one human and two animal studies (Akdogan et al. 2004b, 2004c, 2007).

Pregnancy and Lactation

No information on the safety of spearmint in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

M

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a clinical trial of spearmint essential oil, some of the trial participants ingesting 500 mg of oil daily experienced chest pain, heartburn, or regurgitation (Bulat et al. 1999).

Case Reports of Adverse Events

Cases of contact allergy to spearmint essential oil have been reported (Andersen 1978; Clayton and Orton 2004; Skrebova et al. 1998). A case of allergic contact dermatitis to spearmint essential oil was reported (Bonamonte et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No effects on lower esophageal sphincter tone were observed in healthy volunteers administered up to 500 mg spearmint essential oil, indicating that spearmint has no adverse effects on acid reflux (Bulat et al. 1999).

In women with hirsutism, drinking one cup of spearmint tea daily for 5 days was associated with a decrease in free testosterone and an increase in luteinizing hormone, follicle-stimulating hormone, and estradiol (Akdogan et al. 2007).

Animal Pharmacological Studies

A decrease in testosterone and an increase in luteinizing hormone and follicle-stimulating hormone were observed in male rats that consumed spearmint tea ad libitum for 30 days. Some adverse effects on testicular cells were observed (Akdogan et al. 2004c). A decrease in iron absorption was observed in rats administered spearmint tea (Akdogan et al. 2004a).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No studies on the safety of spearmint during pregnancy or lactation were identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered spearmint essential oil in rats is 5000 mg/kg (Spectrum 2003).

Short-Term Toxicity

In rats administered spearmint tea for 30 days as the sole source of drinking water, some histopathological changes were observed in the kidneys (Akdogan et al. 2003). Similarly, in female rats administered spearmint tea for 30 days as the sole source of drinking water, some histopathological changes were observed in uterine tissues (Guney et al. 2006).

In rats given spearmint tea ad libitum for 30 days, liver enzyme changes were observed. Decreases in superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), and catalase (CAT) and an increase in thiobarbituric acid-reactive substance (TBARS) were noted (Akdogan et al. 2004b).

Genotoxicity

Spearmint essential oil showed some mutagenic activity in *Drosophila melanogaster* (Franzios et al. 1997).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with diarrhea, dysentery, or colitis (Bradley 1993).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Bog bean may cause gastrointestinal irritation, especially in high doses (standard dose listed as a tea made from 0.5 or 1 g of herb in a cup of water) (Weiss and Meuss 2001; Wichtl 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of bog bean in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Felter and Lloyd 1898; List and Hörhammer 1973).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Felter and Lloyd 1898; List and Hörhammer 1973; Williamson 2003); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Species of *Monarda* have traditionally been used as an emmenagogue (Felter and Lloyd 1898; List and Hörhammer 1973; Williamson 2003). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of *Monarda* during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Some inhibition of arachidonic acid-induced platelet aggregation in guinea pig and rat plasma was observed after treatment with Oswego tea essential oil (Tognolini et al. 2006).

IV. Pregnancy and Lactation

Species of *Monarda* have traditionally been used as an emmenagogue (Felter and Lloyd 1898; List and Hörhammer 1973; Williamson 2003).

No information on the safety of *Monarda* in lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Excessive doses of bayberry may cause vomiting (Felter and Lloyd 1898; Remington and Wood 1918).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of bayberry in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Morinda citrifolia L. — Rubiaceae

SCN: noni
OCN: Indian mulberry

Part: fruit

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Several cases of hepatotoxicity have been reported in persons taking noni juice (Lopez-Cepero Andrada et al. 2007; Millonig et al. 2005; Stadlbauer et al. 2005, 2008; Yuce et al. 2006). In some of the cases, the patients were taking other drugs or supplements. In one case, noni was being taken with a drug that commonly causes liver dysfunction (Francis et al. 2003; Yuce et al. 2006). Animal and human studies of noni juice have not shown any elevated levels of liver enzymes (Davies and Mugglestone 2003; Glerup 2000; Kalandakanond et al. 2004; Mancebo et al. 2002; Product Safety Labs 2000), and a 2006 review of case reports and toxicological data by the European Food Safety Authority indicated that no convincing evidence exists for a causal relationship between noni consumption and the reported cases of hepatotoxicity (EFSA 2006).

Hyperkalemia was reported in a man with chronic kidney insufficiency who was taking noni. Analysis of a noni juice indicated potassium levels similar to those of other common fruit juices, all of which are typically restricted in persons with kidney insufficiency (Mueller et al. 2000).

Pharmacological Considerations

A dose escalation study of capsules containing noni fruit indicated that it was well tolerated at doses up to 10 g daily for 28 days (Issell et al. 2005).

Pregnancy and Lactation

Animal studies on the use of noni provide conflicting information, with one study showing no adverse effects on development at very large (6 g/kg) doses, while another study indicated that use of noni juice in pregnancy caused a delay in fetal bone formation (Marques et al. 2010; West et al. 2008).

One ethnobotanical text indicated that ingestion of "a large amount" of noni fruit was reported to cause an abortion (Cambie and Brewis 1997), although this activity has not been confirmed experimentally (Pawlus and Kinghorn 2007). No other information on the safety of noni in pregnancy or lactation was identified.

In this text, the contraindication for use in pregnancy is based on concerns regarding the recent cases of hepatotoxicity reported in association with noni use, as the implications of these case reports and possible mechanisms of hepatotoxicity have yet to be fully understood.

No information on the safety of noni fruit lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Acquired coumadin resistance and decreased INR (a standardized scale used to report the results of blood coagulation tests; decreased INR indicates faster blood clotting) were reported in a 41-year-old woman who had been consuming "two small glasses" daily of noni juice for an unspecified length of time. The reporting physicians indicated that the product used might have been fortified with vitamin K, which causes acquired coumadin resistance (Carr et al. 2004).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Hepatotoxicity was reported in a 45-year-old man who had been consuming "a glass" of noni juice daily for approximately 3 weeks. Highly elevated transaminase and gamma-glutamyltransferase (GGT), elevated lactate

dehydrogenase, and slightly elevated direct bilirubin levels were reported, and liver damage was confirmed by biopsy. Following cessation of noni juice, transaminase levels returned to normal after 1 month (Millonig et al. 2005). Anthraquinones were suggested as the possible cause of the hepatotoxicity (Millonig et al. 2005), although subsequent independent analysis of noni juice purchased from the manufacturer of the product implicated in this case report indicated that no anthraquinones were present in the juice (Jensen et al. 2006) and that absence of anthraquinones was a prerequisite for approval as a novel food by the European Commission (EC 2003; Jensen et al. 2006).

A 29-year-old man with a history of toxic hepatitis associated with small doses of paracetamol developed subacute hepatic failure following consumption of 1.5 liters of noni juice over a 3-week period. He was also taking approximately 7 g daily of a Chinese herbal remedy containing *Bupleurum*, *Pinellia*, *Scutellaria*, *Codonopsis*, *Glycyrrhiza*, *Schizonepeta*, and *Paeonia*. Liver function tests indicated elevated levels of bilirubin, aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyltransferase (GGT), and alkaline phosphatase (ALP) (Stadlbauer et al. 2005).

A 62-year-old woman with no history of liver disease developed an episode of self-limited acute hepatitis following consumption of 2 liters of noni juice over a 3-month period. A percutaneous liver biopsy revealed acute hepatitis consistent with an idiosyncratic drug reaction. Elevated levels of AST, ALT, and bilirubin were observed and returned to normal after cessation of noni. The woman had been treated the previous year with fludarabine for chronic B-cell leukemia (Stadlbauer et al. 2005).

Acute hepatitis was reported in a 24-year-old woman with multiple sclerosis who had been consuming noni juice (dose and frequency not specified) for 4 weeks. The woman had been treated with interferon b1a (IFN) for 6 weeks, a drug that commonly causes hepatic dysfunction of varying severity in multiple sclerosis patients (Francis et al. 2003). IFN was initially suspected as the cause of hepatotoxicity in this case. IFN administration was ceased, and approximately 1 week later noni was ceased. Liver enzyme levels (ALT and bilirubin) increased dramatically for 2 weeks after cessation of IFN and then returned to normal levels (Yuce et al. 2006).

Hepatotoxicity was reported in a 43-year-old man who had been recently diagnosed with a malignant brain tumor (glioblastoma). The man had consumed 20 ml daily of noni juice for 2 weeks and was also taking levetiracetam twice daily (Stadlbauer et al. 2008). Hepatotoxicity was reported in a 33-year-old woman who had consumed several doses of noni (amount unspecified) over a period of several weeks (Lopez-Cepero Andrada et al. 2007).

A case of hyperkalemia was reported in a man with chronic renal insufficiency. The man had consumed approximately 4.5 oz of noni juice daily for an unspecified length of time. The reporting physicians ordered and submitted for analysis a separate noni juice product that also contained grape juice, natural flavors, and benzoic acid. This juice was found to contain approximately 56 mEq/l of potassium, similar to that of orange, tomato, and grapefruit juices, all of which are usually restricted in the diets of patients with end-stage renal disease (Mueller et al. 2000).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A dose escalation study of capsules containing 500 mg of an extract of ripe noni fruit in patients with advanced cancers showed that noni was well tolerated at doses up to 10 g daily for 28 days. That dose corresponds to approximately 200 ml of noni fruit juice. No adverse events were observed in the study (Issell et al. 2005).

In a clinical study, healthy volunteers were administered noni juice at three dose levels of up to 750 ml daily for 28 days. No significant changes in hematological, biochemical, or urological measurements were observed on examination at weeks 0, 2, 4, and 6. Biochemical analyses included alkaline phosphatase, ALT, AST, total bilirubin, lipids, creatine kinase, creatinine, gamma-glutamyltransferase, glucose, total protein, and uric acid (Davies and Mugglestone 2003).

Animal Pharmacological Studies

No allergic reactions were observed in guinea pigs subjected to sensitization and challenge tests with noni juice (Kaaber 2000; Product Safety Labs 2000).

In Vitro Pharmacological Studies

In human liver cells (HepG2), freeze-dried noni fruit puree did not decrease viability or induce neutral lipid accumulation or phospholipidosis (West et al. 2009).

IV. Pregnancy and Lactation

In rats orally administered 1.72, 3.43, or 6.86 g/kg freeze-dried noni puree daily on days 1 to 21 of pregnancy, no adverse effects on fetal development were observed, including decreased number of live fetuses, resorptions, decreased fetal weight and length, skeletal abnormalities, or gross malformations (West et al. 2008).

In rats orally administered 0.4, 2, or 20 ml/kg of noni aqueous extract or 0.4, 2, or 20 ml/kg of noni juice on days 7 to 15 of pregnancy, ossification in fetuses was delayed. No signs of maternal toxicity were observed (Marques et al. 2010).

In rats orally administered 7.5, 75, or 750 mg/kg of an aqueous extract of noni daily, no adverse effects on pregnancy duration, number of implants, litter size, or live birth index were observed. At the 7.5 mg/kg dose, a reduction in the parturition index was observed (Müller et al. 2009).

One ethnobotanical text indicates that ingestion of "a large amount" of noni fruit has been reported to cause an abortion (details on dose, duration, and preparation not available) (Cambie and Brewis 1997), although this activity has not been confirmed experimentally (Pawlus and Kinghorn 2007).

No information on the safety of noni during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered methanol extract of noni fruit in mice is 3.5 g/kg (Chearskul et al. 2004; Nakanishi et al. 1965), whereas that of an aqueous extract is 7.5 g/kg (Chearskul et al. 2004).

Short-Term Toxicity

No changes in clinical chemistry measurements, including serum glutamic pyruvic transaminase (SGPT) and serum glutamic oxaloacetic transaminase (SGOT), alkaline phosphatase, blood urea nitrogen, creatinine, Na^+, K^+, and Cl^-, were observed in rats administered noni juice daily (dose not specified in English language translation) for 30 days (Kalandakanond et al. 2004).

No signs of toxicity or behavioral changes were observed in rats orally administered 15 g/kg of pureed noni fruit (Product Safety Labs 2000). No changes in biochemical parameters and no histopathological findings were observed in rats administered 1 g /kg of noni fruit extract daily for 28 days (Mancebo et al. 2002).

Subchronic Toxicity

No changes in histology, clinical chemistry (including liver enzymes), hematology, weight gain, or behavior were observed in rats administered 80 ml/kg noni juice daily for 13 weeks (Wang et al. 2002). Based on this study, a no-observable-adverse-effect level (NOAEL) was determined to be greater than 80 ml/kg body weight (Glerup 2000).

In rats orally administered 1.72, 3.43, or 6.86 g/kg of a freeze-dried noni fruit puree daily for 90 days, no histopathological changes or evidence of dose-related responses in hematological and clinical chemistry measurements, including liver function tests, were observed. Based on the results the NOAEL for freeze-dried noni fruit puree was determined as greater than 6.86 g/kg body weight, equivalent to approximately 90 ml/kg of noni fruit juice (West et al. 2009).

Genotoxicity

A slight mutagenic effect of noni juice extract was observed in the *Salmonella* microsome assay in strain TA1537 but not in strains TA98 or TA100. The activity was attributed to the presence of flavonoids (Westendorf et al. 2007). No mutagenicity of noni juice was observed in the mammalian mutagenicity test with V79 Chinese hamster fibroblasts (Westendorf et al. 2007). Rats treated with a noni juice concentrate did not show DNA repair synthesis in primary rat hepatocytes, nor could DNA adducts or DNA strand breaks be observed (Westendorf et al. 2007).

No clastogenic activity of noni was observed in mice orally administered a single dose of 10 g/kg of the dehydrated juice. Observation of bone marrow showed no increase in micronuclei related to ingestion of noni juice (Edwards 2002).

No activity of noni juice at concentrations of 625, 1250, 2500, and 5000 μg/ml (dry weight) was observed in the chromosomal aberration test with human lymphocytes with or without metabolic activation from S9 mix (Edwards 2003).

Morus alba L. — Moraceae

SCN: white mulberry
PN: *sang shen zi* (fruit)

Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to white mulberry fruit, including an anaphylactic reaction, have been reported (Bensky et al. 2004; Navarro et al. 1997).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of white mulberry fruit in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A reference text on traditional Chinese medicine indicates that "high doses" of white mulberry fruit (standard dose is listed as a decoction of 9–15 g of dried fruit) can cause hemorrhagic colitis in children, and that two such cases have been reported in the literature. In one of the cases, a 3-year-old boy ate three handfuls of fruit (no indication of whether the fruit was fresh or dried). No details on this case or the second case were noted (Bensky et al. 2004). Conversely, another text on traditional Chinese medicine indicates no such concerns and notes that white mulberry fruit has a gentle and subtle effect and is appropriate as a long-term tonic (Chen and Chen 2004).

Allergic skin reactions to mulberry have been reported (Bensky et al. 2004). An anaphylactic reaction after eating a mulberry was reported in a woman with hypersensitivity to a number of tree pollens. The allergy to white mulberry was confirmed by skin prick testing (Navarro et al. 1997).

A small study in patients with multiple sensitizations to food allergens (mostly fruit) indicated that hypersensitivity to figs and mulberries might be associated as the result of allergen cross-reactivity (Caiaffa et al. 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No estrogenic activity of an ethanol extract of white mulberry fruit was observed in a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of white mulberry fruit during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Human and animal studies have demonstrated that white mulberry leaf may modify glucose regulation (Abou-Seif and Kamel 2008; Butt et al. 2008; Kimura et al. 2007; Mudra et al. 2007; Musabayane et al. 2006; Naowaboot et al. 2009). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

An animal study indicated that antidopaminergic activity of white mulberry leaf extract was observed in mice injected with relatively large doses (up to 200 mg/kg) (Yadav et al. 2008). The relevance of that finding to oral use at standard therapeutic doses is not known.

Pregnancy and Lactation

A study in pregnant sheep indicated no adverse effects of white mulberry leaf on the birth weight of offspring (Prasad et al. 1995).

No information on the safety of white mulberry leaf during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered single doses of 0.4, 0.8, or 1.2 g of a white mulberry leaf powder enriched with the compound 1-deoxynojirimycin to a concentration of 1.5%, doses of 0.8 or 1.2 g of powder significantly suppressed the elevation of postprandial blood glucose and secretion of insulin (Kimura et al. 2007).

A reduction in blood glucose increases and a decrease in peak to trough fluctuations in blood glucose were observed in type 2 diabetes patients (without complications and with use of oral hypoglycemic agents) orally administered single doses of 1 g white mulberry leaf extract. Patients were allowed to continue taking any medication except acarbose (Mudra et al. 2007).

A survey indicated that white mulberry leaf is commonly used in the management of type 1 diabetes in Turkey (Arykan et al. 2009). White mulberry leaf has also been used in the management of diabetes in Chile, Thailand, and other countries (Lemus et al. 1999; Naowaboot et al. 2009).

Animal Pharmacological Studies

Amelioration of hyperglycemia was observed in diabetic rats orally administered 200 mg/kg of an aqueous extract of white mulberry leaf daily for 2 weeks (Abou-Seif and Kamel 2008). A reduction in blood glucose levels was observed in diabetic rats orally administered 200 mg/kg of a white mulberry leaf extract daily for 5 weeks. No effects on glucose levels in healthy rats were observed (Musabayane et al. 2006). A 22% reduction in blood glucose levels was observed in diabetic rats orally administered 1 g/kg white mulberry leaf aqueous extract daily for 6 weeks (Naowaboot et al. 2009). Several other animal studies have indicated similar findings (Chen et al. 1995; Devi and Urooj 2008; Hosseinzadeh and Sadeghi 1999; Miyahara et al. 2004).

In mice intraperitoneally administered doses of 50, 100, or 200 mg/kg of a methanol extract of white mulberry leaf, a reduction in the number of fights and an increased latency to fights in foot shock induced-aggression was observed, along with a dose-dependent decrease in amphetamine-induced stereotyped behavior and a prolongation of sleeping time induced by phenobarbitone. The authors of the study indicated that the results suggest antidopaminergic activity of white mulberry leaf methanol extract (Yadav et al. 2008).

In Vitro Pharmacological Studies

No estrogenic activity of an ethanol extract of white mulberry leaf was observed in a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation

No effects on birth weight were observed in lambs from pregnant sheep (6 to 8 weeks pregnant) fed a hay containing 30 or 50% white mulberry leaf in addition to a base diet for 3 months (Prasad et al. 1995).

No information on the safety of white mulberry leaf during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered aqueous extract of white mulberry is 4 g/kg in mice and 5 g/kg in rats. The LD_{50} of the same extract orally administered to mice and rats could not be determined at doses up to 5 g/kg (Trabsung 2004).

Short-Term Toxicity

No adverse effects were observed in rats orally administered up to 3 g/kg daily of an aqueous extract of white mulberry leaf for 60 days. Observed parameters included blood chemistry, hematological values, and microscopic evaluation of major organs (Trabsung 2004).

No adverse effects were observed in rats fed diets containing 1 or 5% powdered white mulberry leaf daily for 4 weeks. Observed parameters included organ weights, hematologic and biochemical values, and pathological examination (Mitsuya et al. 2001).

No adverse effects, including signs of toxicity or changes in organ weights, were observed in rats fed diets containing 25% white mulberry leaf powder for 28 days (Srivastava et al. 2003).

No adverse effects in milking cows or changes in the yield or butterfat content of their milk were observed after animals were fed up to 6 kg of white mulberry leaf daily for 100 days (Srivastava et al. 2003).

Subchronic Toxicity

No adverse effects were observed in rats fed diets containing up to 1% white mulberry leaf extract (approximate daily mulberry dose of 884.5 mg/kg for males and 995.7 mg/kg for females) daily for 90 days. Observed parameters included body weight gain, hematology and blood chemistry, and microscopic examination of major organs (Miyazawa et al. 2003).

Morus alba L. — Moraceae

SCN: white mulberry
PN: *sang bai pi* (root bark)

Part: root bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
An animal study demonstrated that white mulberry root bark may modify glucose regulation (Singab et al. 2005). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation
No information on the safety of white mulberry root bark in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
Reduction in glucose levels and increase in insulin levels were observed in diabetic rats orally administered 200 or 400 mg/kg of a hydroalcoholic extract of white mulberry root bark daily for 10 days (Singab et al. 2005).

In Vitro Pharmacological Studies
In assays to assess the immunomodulatory activity of a polysaccharide isolated from white mulberry root bark, the compound was found to enhance proliferation of splenic lymphocytes in a synergistic manner in the presence of mitogens. However, the compound suppressed primary IgM antibody production from B cells, which was activated with lipopolysaccharide, a polyclonal activator, or immunized with a T-cell-dependent antigen, sheep red blood cells (Kim et al. 2000).

No estrogenic activity of an ethanol extract of white mulberry root was observed in a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation
No information on the use of white mulberry root bark during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
The LD_{50} values of water or alcohol extracts of white mulberry root bark in mice are 10 g/kg after oral administration and 5 g /kg after intravenous administration (Chen and Chen 2004).

Mucuna pruriens (L.) DC. — Fabaceae

SCN: velvet bean
AN: *atmagupta; kapikacchu*
OCN: buffalo bean; cowage; cowitch
Part: root, seed

Quick Reference Summary

Safety Class; 2b

Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Nath et al. 1992).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Velvet bean contains trace amounts of certain hallucinogenic compounds. While the compound DMT (*N,N*-dimethyltryptamine) has been reported in velvet bean (Ghosal et al. 1971), a recent analysis did not find any DMT, but indicated the presence of the related compounds bufotenin (5-hydroxydimethyltryptamine) at a concentration of 1.2 to 1.5 ppm and 5-MeODMT (5-methoxydimethyltryptamine) at a concentration of 0.34 to 0.63 ppm (Szabo 2003).

Velvet bean contains 3.6 to 7% of the compound L-dopa (3,4-dihydroxyphenylalanine), an amino acid used in the treatment of Parkinson's disease (Pugalenthi et al. 2005).

Adverse Events and Side Effects

Contact with the hairs on the velvet bean seed pod can cause severe itching (pruritis) (Davidson et al. 2007; Kosteletzky et al. 2009; MMWR 1985).

Pharmacological Considerations

Animal studies have indicated that velvet bean may modify glucose regulation (Akhtar et al. 1990; Bhaskar et al. 2008; Rathi et al. 2002). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

An increase in fetal malformations was observed in an animal study with velvet bean (Nath et al. 1992). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of velvet bean during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An outbreak of cases of acute toxic psychosis was reported in a village in Mozambique during a period of famine and disruption of agriculture, when village residents were forced to subsist on wild plants, including velvet bean. Symptoms included severe headache and heart palpitations, confusion, agitation, hallucinations, and paranoid delusions. The average amount of velvet bean consumed by each person was not reported. Although the bean was traditionally boiled in repeated changes of water prior to consumption, a water shortage during the outbreak may

have contributed to insufficient processing of the beans (Infante et al. 1990).

Contact with the hairs on the outside of velvet bean seed pods can cause severe itching (pruritis). An outbreak of pruritis was reported after someone maliciously placed velvet bean pods in a couple's bed. The couple, and people who came in physical contact with the couple for the few hours after contact, all developed moderate to severe pruritis (MMWR 1985).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a trial of velvet bean in patients with Parkinson's disease, patients were administered single doses of 200 mg L-dopa with 50 mg decarboxylase inhibitor (carbidopa) (LD/CD), 15 g velvet bean powder (containing 500 mg of L-dopa), or 30 g of velvet bean powder (containing 1000 mg of L-dopa). After treatment, one patient experienced vomiting after 30 g velvet bean; mild nausea was reported in two patients after LD/CD and in two after 15 g velvet bean. Dizziness occurred in one patient each after each LD/CD and 15 g velvet bean. No clinically relevant changes in hematology or biochemistry parameters were observed (Katzenschlager et al. 2004).

Animal Pharmacological Studies

In healthy and diabetic rabbits orally administered 0.5, 1, or 2 g/kg of velvet bean, a reduction in blood glucose levels was observed in healthy animals at all doses and in diabetic animals at doses of 1 g/kg or more (Akhtar et al. 1990). Reductions in blood glucose levels were reported in diabetic rats orally administered 100, 200, or 400 mg/kg of an alcohol extract of velvet bean daily for 21 days. No significant changes in blood sugar levels were observed in diabetic mice administered the same extract at the same doses for 60 days (Rathi et al. 2002). In diabetic rats orally administered 100 or 200 mg/kg of an aqueous extract of velvet bean daily for 21 days, a reduction in blood glucose levels was observed (Bhaskar et al. 2008).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

An increase in fetal malformations was observed in the fetuses of rats orally administered 175 mg/kg of an aqueous extract of velvet bean on days 0 to 10 of pregnancy (Nath et al. 1992).

No information on the safety of velvet bean during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Short-Term Toxicity

No adverse effects were observed in rats orally administered 600 mg/kg of an alcohol extract of velvet bean daily for 30 days (Tripathi and Upadhyay 2002).

A reduction in growth rate was observed in chicks fed diets containing 10, 20, or 30% velvet bean for 28 days. At the 30% rate, feed intake declined significantly and animals weighed 39% of those in a control group (Del Carmen et al. 1999). After being processed by cracking, soaking, and cooking prior to being used as a feed, velvet beans could be used as up to 25% of chicken feed without adversely affecting growth or animal health (Emenalom et al. 2005).

In sheep fed diets containing 330, 670, or 1000 g/kg velvet bean (24 g/kg L-dopa) for 42 days, no changes in concentrations of blood ceruloplasmin or L-dopa, or concentrations of L-dopa metabolites, were observed (Chikagwa-Malunga et al. 2009).

Genotoxicity

No mutagenic activity of raw or lightly roasted velvet bean seed was observed in the Ames test for mutagenicity with *Salmonella typhimurium* strains TA97a, TA98, TA100, TA102, and TA1535 with or without metabolic activation (Burgess et al. 2003).

Myristicaceae

SCN: mace (aril); nutmeg (seed)
Syn: *Myristica moschata* Thunb.; *Myristica officinalis* L. f.
AN: *jatiphala*

PN: *rou dou kou* (seed)
Part: aril, seed

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Weil 1965; Zaki et al. 1987).

Do not exceed recommended dose (Barceloux 2008; Bensky et al. 2004; Forrest and Heacock 1972; Stein et al. 2001; Weil 1965).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 0.5 to 1 g unroasted seed (Kapoor 1989); 3 to 10 g of properly roasted seed as a decoction (Bensky et al. 2004; Chen and Chen 2004); or 1.5 to 3 g of powdered, properly roasted seed (Chen and Chen 2004).

Amounts of 5 g or more of unroasted nutmeg have been associated with nutmeg poisoning, including symptoms listed below (Barceloux 2008).

Editors' Notes

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

In traditional Chinese medicine, nutmeg is almost always roasted before using. The roasting process reduces the toxicity of nutmeg (Bensky et al. 2004; Chen and Chen 2004; PPRC 2005). An Eclectic medical text includes a nutmeg-based preparation that required roasting of the seed prior to use (Felter and Lloyd 1898). Nutmeg sold for use as a spice is not roasted.

In Finland, cases of nutmeg poisoning and abuse led authorities to discourage the sale of whole nutmeg and recommend that nutmeg be sold only as a powder with the packages labeled "Only for spice use. Harmful for health if consumed as such" (Evira 2009).

Adverse Events and Side Effects

The majority of cases of nutmeg intoxication have been reported in persons attempting to use nutmeg as a recreational hallucinogen (Abernethy and Becker 1992; Forrester 2005; Sangalli and Chiang 2000). A review of the literature on nutmeg indicates that use of nutmeg as a hallucinogen has been relatively limited due to the need for a large unpalatable dose, a high risk (unpleasantness)-to-benefit ratio, a lack of effectiveness as compared to other hallucinogens, and an unpredictable response (Sangalli and Chiang 2000).

Clinical features of nutmeg poisoning are similar to those of belladonna (anticholinergic), with facial flushing, tachycardia, hypertension, dry mouth, and blurred vision. Initial symptoms include nausea, vomiting, abdominal

pain, chest pain, restlessness, agitation, tremor, ataxia, involuntary eye movement, vertigo, hallucinations, and a feeling of doom or giddiness. These symptoms occur with alternating periods of lethargy and delirium (Barceloux 2009). Although a lack of pupil dilation in nutmeg intoxication is sometimes noted as a way to differentiate between nutmeg and anticholinergic poisoning (Barceloux 2009), pupil dilation does occur in some cases of nutmeg poisoning (Ahmad and Thompson 1975; McKenna et al. 2004; Stein et al. 2001).

A review on nutmeg poisoning indicated that the last fatality reported in the medical literature related solely to nutmeg was in 1908 (Barceloux 2009; Cushny 1908).

Pharmacological Considerations

Although 6 g of nutmeg did not produce any significant effects in healthy young people (Beattie 1968), 5 g is typically listed as a toxic dose (Barceloux 2008). Ingestion of 25 to 28 g has been associated with more severe poisoning symptoms including tachycardia, palpitations, and anticholinergic symptoms (Barceloux 2008; Stein et al. 2001).

Pregnancy and Lactation

Nutmeg has been used by many women to bring on menstruation or to attempt to induce abortion, although the literature suggests that nutmeg is not efficacious as an abortifacient (Weil 1965). An increase in maternal and fetal heart rate was observed in a pregnant woman who consumed cookies containing an excessive amount of nutmeg. The baby was delivered healthy at term (Lavy 1987).

Animal studies have provided conflicting results, with no adverse effects of the essential oil at doses up to 400 mg/kg in rabbits (FDRL 1974) but some abnormalities in rats administered 300 mg/kg of nutmeg (Zaki et al. 1987). An animal study indicated that after administration of mace to lactating mice, physiological effects were observed on both mothers and nursing offspring (Chhabra and Rao 1994).

Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Clinical features of nutmeg poisoning are similar to those of belladonna (anticholinergic), with facial flushing, tachycardia, hypertension, dry mouth, and blurred vision. However, dilation of the pupils is uncommon in nutmeg intoxication. Symptoms usually begin about 3 to 6 hours after ingestion and resolve within 24 to 36 hours. Initial symptoms include nausea, vomiting, abdominal pain, chest pain, restlessness, agitation, tremor, ataxia, involuntary eye movement, vertigo, and a feeling of doom. These symptoms occur with alternating periods of lethargy and delirium. Other effects of nutmeg intoxication documented in case reports include the sensation of warmth and coldness of the extremities, distortion of space and colors, auditory and tactile hallucinations, headache, and generalized weakness (Barceloux 2009).

A review of nutmeg poisoning cases reported to a poison control center indicated that doses of 14 to 80 g elicited symptoms ranging from weakness or restlessness to nausea, vomiting, and tachycardia. None of the cases was fatal (Stein et al. 2001).

Chronic delusions, hallucinations, and disturbed behavior have been reported in persons who routinely ingested nutmeg. In one case, a 23-year-old man had been taking 5 g of nutmeg daily for several months and had increased intake several months prior to psychiatric referral (Kelly et al. 2003). In a similar case, a 25-year-old man had been taking 120 to 650 mg of nutmeg daily for an unspecified period of time (Brenner et al. 1993).

The only reported fatality attributed solely to nutmeg was of an 8-year-old boy who ate two whole nutmegs, became comatose, and died within 24 hours (Cushny 1908).

Numerous other cases of nutmeg poisoning have been reported in the literature (Abernethy and Becker 1992; Dinakar 1977; Faguet and Rowland 1978; Forrester 2005; Green 1959; INCHEM 1991; McCord and Jervey 1962; McKenna et al. 2004; Payne 1963; Perez Valdivieso 2007; Sjoholm et al. 1998; Wallace 1903).

An autopsy of a 55-year-old woman indicated toxic levels of flunitrazepam, a finding that alone could not account for the woman's death. Further examination indicated a nutmeg-like smell of the stomach contents, with a blood analysis indicating 4.0 µg/ml of the compound myristicin (Stein et al. 2001).

Occupational asthma has been reported in individuals working with mace in the food industry. Skin prick tests elicited positive reactions to mace (Sastre et al. 1996; van Toorenenbergen and Dieges 1985).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered a single dose of 400 mg of the compound myristicin, alertness, "a feeling of irresponsibility," a sense of euphoria in two subjects, and an unpleasant reaction (anxiety, fear, tremors, tachycardia, and nausea) in two subjects were reported. The dose of myristicin used was equivalent to approximately 40 g of nutmeg, although the author noted that myristicin does not reproduce the entire activities of whole nutmeg (Truitt et al. 1960).

Administration of 6 g of nutmeg to healthy students did not significantly alter performance on neuropsychiatric tests (Beattie 1968).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of platelet aggregation induced by arachidonic acid was observed in rabbit platelets treated with nutmeg essential oil (Rasheed et al. 1984).

IV. Pregnancy and Lactation

An increase in maternal and fetal heart rate was observed in a pregnant woman who consumed cookies containing an excessive amount of nutmeg. Adverse effects subsided within 24 hours, and the baby was delivered healthy at term (Lavy 1987).

In rabbits orally administered 4 to 400 mg/kg of nutmeg essential oil daily on days 6 to 18 of pregnancy, no adverse effects on fetal survival or soft or skeletal tissue abnormalities were observed (FDRL 1974).

Administration of 300 mg/kg nutmeg to rats on day 8 of pregnancy resulted in deformed fetuses accompanied by a decrease in body weight (Zaki et al. 1987).

Nutmeg has been used by many women to bring on menstruation or attempt to induce abortion, although the literature suggests that nutmeg is not efficacious as an abortifacient (Weil 1965).

In mice orally administered an aqueous suspension of mace at doses of 0.025 or 0.1 g per animal daily on lactation days 1 to 14 or 21, mice receiving mace and their offspring had significantly elevated hepatic sulfhydryl content, glutathione S-transferase, and glutathione reductase activity and cytochrome b_5 content (Chhabra and Rao 1994).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered nutmeg essential oil in rats is 2.63 g/kg (Jenner et al. 1964).

The LD_{50} of the compound myristicin could not be determined at doses up to 1 mg/kg after intraperitoneal administration to rats (Truitt et al. 1960).

Short-Term Toxicity

No adverse effects were observed in rats fed diets containing myristicin at amounts equivalent to 10 mg/kg daily for 26 days. Observed parameters included body weight and histological examination of the livers and kidneys (Hallstrom and Thuvander 1997).

In mice intraperitoneally administered 20, 40, or 80 mg/kg of an aqueous extract of nutmeg daily for 6 weeks, alterations in indicators of liver function were observed, including reduction of total protein and serum albumin and elevation of serum glutamic pyruvic transaminase (SGPT) and serum glutamic oxaloacetic transaminase (SGOT), and elevation of blood urea. Examination of the liver revealed hydropic and fatty degeneration. Myocardial indices including SGOT and lactate dehydrogenase (LDH) were elevated. No adverse effects on kidneys were observed (Al-Hazmi et al. 2004).

Genotoxicity

No genotoxic activity was observed in the mouse micronucleus assay in mice fed diets containing 0.5 or 2% mace daily (Kumari 1992).

Some mutagenic activity of nutmeg and other common spices was observed in assays with *Salmonella typhimurium* strains TA98 and TA102 (Mahmoud et al. 1992).

In pregnant mice orally administered the compound myristicin as a single dose on day 16 of pregnancy, or one dose each on days 16 and 17 of pregnancy, liver adducts were reported in the mothers, and significantly smaller amounts of liver adducts were observed in the fetuses. The number of adducts observed in pregnant mice was higher than that observed in nonpregnant treated mice (Randerath et al. 1993).

***Myroxylon balsamum* (L.) Harms var. *pereirae* (Royle) Harms**
SCN: balsam-of-Peru tree
OCN: Peruvian balsam
Part: oleoresin

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with fevers (Felter and Lloyd 1898).

Other Precautions

May cause kidney irritation (Felter and Lloyd 1898).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions and sensitization to tolu balsam tree and balsam-of-Peru tree are relatively common and have been reported after topical and internal use (Pfutzner et al. 2003; Salam and Fowler 2001; Wichtl 2004; Zug et al. 2009).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of tolu balsam tree and balsam-of-Peru in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Exacerbation of chronic eczema was reported in a 51-year-old brewery worker who showed delayed-type patch test reactions to balsam-of-Peru tree and fragrance-mix. Repeated oral challenges with balsam-of-Peru tree led to exacerbation of the eczema (Pfutzner et al. 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a retrospective analysis of North American patients with suspected allergic contact dermatitis, balsam-of-Peru tree was the second most common allergen, with 11.6% of people tested producing positive reactions (Zug et al. 2009). Similarly, a r etrospective study of patch test data from Denmark between 1985 and 2007 indicated that of the 16,173 patients tested, approximately 4% tested positively to balsam-of-Peru tree (Thyssen et al. 2008).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of tolu balsam tree and balsam-of-Peru tree during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Nardostachys jatamansi (D. Don) DC. — Valerianaceae

SCN: jatamansi
Syn: *Nardostachys grandiflora* DC.
AN: *jatamansi*
PN: *gan song* (root and rhizome)
OCN: Indian spikenard; nard; spoon-leaf nardostachys
Part: rhizome, root

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Pole 2006).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Chadha 1988); *see* Appendix 2.
Diuretic (Chadha 1988); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

An animal study on the antidepressant activity of jatamansi indicated that activity was due to MAO inhibition and/or interaction with GABA-B receptors (Dhingra and Goyal 2008).

Pregnancy and Lactation

Based on traditional use as an emmenagogue, use of jatamansi in pregnancy is not recommended (Chadha 1988; Pole 2006).

No information on the safety of jatamansi during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

N

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Antidepressant-like activity of jatamansi was observed in rats orally administered 100, 200, or 400 mg/kg of an ethanol extract daily for 14 days. The antidepressant activity was attributed to a reduction in whole brain MAO-A and MAO-B activities and an increase in the level of monoamines. Pretreatment of animals with a GABA-B agonist resulted in a partial inhibition of the antidepressant effect, indicating a potential effect on GABA-B receptors (Dhingra and Goyal 2008).

In Vitro Pharmacological Studies

Methanol and water extracts of jatamansi exhibited acetylcholinesterase inhibitory activity at concentrations of 47.21 µg/ml, with the methanol extract demonstrating more activity than the water extract. Similar activity was observed at a lower concentration for ashwagandha and other botanicals (Vinutha et al. 2007).

IV. Pregnancy and Lactation

Based on traditional use as an emmenagogue, use of jatamansi in pregnancy is not recommended (Chadha 1988; Pole 2006).

No information on the safety of jatamansi during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered aqueous extract of jatamansi in mice could not be determined at doses up to 2 g/kg (Debelmas and Hache 1976).

The LD_{50} of an ethanol extract of jatamansi in rats is 569 mg/kg after intraperitoneal administration but could not be determined at doses up to 1000 mg/kg after oral administration (Rao et al. 2005).

Part: seed

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with constipation, dry stools, or abdominal distention (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Sacred lotus seed as used in traditional Chinese medicine is prepared by removing the seed embryo (PPRC 2005).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Reference texts on traditional Chinese medicine do not indicate any cautions for the use of sacred lotus in pregnancy (Bensky et al. 2004; Chen and Chen 2004).

Oral and intraperitoneally administered extracts of sacred lotus seed exhibited effects on the estrus cycle in rats and mice (Mazumder et al. 1992; Mutreju et al. 2008).

An unreferenced statement in one published article asserts that sacred lotus seed is used as an antifertility agent by tribal women near Udaipur, India (Mutreju et al. 2008), but none of the classic texts on Indian materia medica indicate such usage (Chopra 1933; Dutt 1922; Kirtikar and Basu 1935; Nadkarni 1954). One contemporary ethnobotanical review reports that the seed is given in pregnancy (Singh et al. 2010).

No information on the safety of sacred lotus in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered 800 mg/kg of an ethanol extract of sacred lotus daily for 41 days, a decrease in the weights of the uterus, ovaries, and vagina was observed, along with a prolongation of the estrus cycle (Mutreju et al. 2008).

In mice intraperitoneally administered 3 mg/kg of a petroleum ether extract of sacred lotus every other day for 15 days, arrest of the estrus cycle was observed along with a decrease in uterine weight (Mazumder et al. 1992).

In diabetic rats orally administered 5 g/kg of the compound neferine daily for 3 weeks, a decrease in fasting blood glucose, insulin, triglycerides, and TNF-alpha and an enhancement of insulin sensitivity in insulin-resistant rats were observed (Pan et al. 2009).

In Vitro Pharmacological Studies

The compound neferine inhibited rabbit platelet aggregation induced by ADP, collagen, arachidonic acid, and platelet-activating factor (Yu and Hu 1997).

IV. Pregnancy and Lactation

References on traditional Chinese medicine (Bensky et al. 2004; Chen and Chen 2004) and classic texts on Indian materia medica (Chopra 1933; Dutt 1922; Dymock 1890; Kirtikar and Basu 1935; Nadkarni 1954) do not indicate any cautions for the use of sacred lotus in pregnancy.

Although one recent article reports that sacred lotus seed has traditionally been used as an antifertility agent by women in one tribal area in northern India (Mutreju et al. 2008), a contemporary ethnobotanical study records that the seed is given in pregnancy (Singh et al. 2010).

No information on the safety of sacred lotus in lactation was identified.

Also see Animal pharmacological studies for this entry.

V. Toxicity Studies

Acute Toxicity

The LD_{50} value of compounds from sacred lotus intravenously administered to mice is 34.9 mg/kg for liensinine, 26.0 mg/kg for neferine, and 20.0 mg/kg for the total alkaloids (Zhu 1998).

Nepeta cataria L. — Lamiaceae

SCN: catnip
PN: *jia jing jie* (whole plant)
OCN: catmint
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Notice
Emmenagogue (Felter and Lloyd 1898); *see* Appendix 2.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
An animal study indicated that a diet of 10% catnip during pregnancy resulted in weight loss in mothers and fetuses but had no other effects on fetal health or survival (Bernardi et al. 1998). Catnip has been used as an emmenagogue (Felter and Lloyd 1898).

No information on the safety of catnip in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
A 19-month-old boy became lethargic after eating an unknown amount of raisins that had been soaked in a catnip tea that had been brewing in the refrigerator for 3 weeks (Osterhoudt et al. 1997).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
In mice fed a diet containing 10% catnip on days 6 to 18 of pregnancy, a decrease in maternal body weight at 18 days of pregnancy and a reduction of fetal and placental weights was observed. No differences were observed between the number of living and dead fetuses, in the number of resorptions, or in the ratio of maternal body weight to fetus weight plus placental weight of both groups. Catnip prenatal exposure reduced the body weight of male and female pups at birth while only females showed a decrease in this parameter at 7 days of lactation. The female eye, ear, and vaginal openings and male testis descent were delayed in the treatment group as compared to control (Bernardi et al. 1998).

Older herbal texts list catnip as an emmenagogue (Cook 1869; Felter and Lloyd 1898), although one text notes that the emmenagogue activity is weak (Cook 1869).

No information on the safety of catnip in lactation was identified.

V. Toxicity Studies

Acute Toxicity
The LD_{50} of catnip essential oil in mice is 1.3 g/kg (route of administration not listed) (De Vincenzi et al. 1996).

A decrease in CNS activity was observed in rats intraperitoneally administered up to 750 mg/kg catnip essential oil (Harney et al. 1978).

Notopterygium incisum K.C. Ting ex H.T. Chang — Apiaceae

SCN: notopterygium
PN: *qiang huo* (root and rhizome)

Part: root and rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Overdose (standard dose listed as a decoction of 3–10 g) of notopterygium may injure the stomach and cause nausea or vomiting (Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of notopterygium in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

N

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose (standard dose listed as a decoction of 3–10 g) of notopterygium may injure the stomach and cause nausea or vomiting (Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed in human liver microsomes treated with a decoction or an ethanolic extract of notopterygium (Guo et al. 2001).

IV. Pregnancy and Lactation

No information on the safety of notopterygium during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered notopterygium essential oil in mice is 2.83 g/kg (Chen and Chen 2004). The LD_{50} of an aqueous extract of notopterygium orally administered in mice could not be determined at doses up to 12 g/kg (Chen and Chen 2004).

Genotoxicity

No mutagenic activity of an aqueous extract of notopterygium was observed in the Ames mutagenicity assay with *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation by S9 (Yin et al. 1991).

In mouse micronucleus and chromosomal aberration assays, mice were intraperitoneally administered an aqueous extract of notopterygium at doses of 0.1, 0.5, 1, or 2 g/kg. An increase in the incidence of chromosomal aberrations was observed at the 2 g/kg dose level. An increase of polychromatic erythrocytes was observed in the micronucleus assay at the 1 and 2 g/kg dose levels (Yin et al. 1991).

Ocimum basilicum L. — Lamiaceae

SCN: basil
OCN: sweet basil

PN: *jiu ceng ta*
Part: leaf

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Alkenylbenzenes (estragole as 70–85% of essential oil; safrole as a minor constituent) (De Vincenzi et al. 2000; Leung and Foster 1996; Siano et al. 2003); *see* Appendix 1.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

An allergic reaction to basil has been reported (Vartholomaios et al. 2007).

Pharmacological Considerations

An animal study demonstrated that basil may modify glucose regulation (Zeggwagh et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

A text on traditional Chinese medicine indicates that basil should not be used during pregnancy (Chen and Chen 2004).

No information on the safety of basil during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

O

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An allergic reaction to basil has been reported (Vartholomaios et al. 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in blood glucose levels was observed in healthy and diabetic rats orally administered an aqueous extract of basil in a single dose of 20 mg/kg or a dose of 20 mg/kg daily for 15 days. Plasma insulin levels were unchanged. The hypoglycemic effect was greater in diabetic than in healthy animals (Zeggwagh et al. 2007).

In Vitro Pharmacological Studies

An extract of basil inhibited the drug-metabolizing isoenzyme CYP1A2 in a screening of several plant extracts (Jeurissen et al. 2007).

IV. Pregnancy and Lactation

A text on traditional Chinese medicine indicates that basil should not be used during pregnancy (Chen and Chen 2004).

No information on the safety of basil during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an alcohol extract of basil orally administered in mice is 956 mg/kg (Lagarto Parra et al. 2001).

In the brine shrimp lethality assay, the LC_{50} of an alcohol extract of basil is 9.92 µg/ml (Lagarto Parra et al. 2001).

Short-Term Toxicity

In rats orally administered basil essential oil at doses of 0.005, 0.05, 0.5, 1, 1.5, 2, 3, or 3.5 mg/kg daily for 14 days, no adverse effects were observed at doses below 1.5 g/kg. At doses of 2 g/kg or more, erosion zones in the stomach mucosa were observed with disappearance of the surface epithelium and hemorrhagic exudation of the muscularis mucosae. Swelling of cells in the liver was observed at doses over 1.5 g/kg. The no observed adverse effect level (NOAEL) was reported as 1 g/kg (Fandohan et al. 2008).

Genotoxicity

No mutagenic activity of basil essential oil was observed in the Ames test for mutagenicity in *Salmonella typhimurium* strains TA98, TA100, or TA102, with or without metabolic activation, or in the *Escherichia coli* WP2 reversion assay (Beric et al. 2008; Stajkovic et al. 2007).

Ocimum gratissimum L. — Lamiaceae

SCN: African basil
Syn: *Ocimum viride* Willd.
AN: *vana tulsi*

OCN: East Indian Basil; forest tulsi; gratlastmum; Russian basil; tree basil
Part: above-ground parts

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Kamatenesi-Mugisha and Oryem-Origa 2007; Noumi and Tchakonang 2001).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Alkenylbenzenes (eugenol as 12–92% of essential oil) (Cimanga et al. 2002); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that African basil may modify glucose regulation (Aguiyi et al. 2000; Egesie et al. 2006; Mohammed et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Ethnobotanical surveys indicate that the juice of African basil is used to induce or facilitate labor (Kamatenesi-Mugisha and Oryem-Origa 2007; Noumi and Tchakonang 2001). Although occasional doses of aqueous extracts of African basil may not cause any safety concern, large doses should be avoided, especially during the third trimester.

No information on the safety of African basil during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In healthy and diabetic rats intraperitoneally administered 400 mg/kg of a methanol extract of African basil, a reduction in plasma glucose levels was observed. The hypoglycemic effect was more pronounced in diabetic than in healthy animals (Aguiyi et al. 2000). A reduction in plasma glucose levels was observed in diabetic rats orally administered 500 to 1500 mg/kg of an aqueous extract of African basil daily for 28 days (Egesie et al. 2006).

A reduction in blood glucose levels was observed in diabetic rats intraperitoneally administered 500 mg/kg but not in animals administered 250 or 1000 mg/kg of an aqueous extract of African basil (Mohammed et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

An ethnobotanical survey indicated that the juice of fresh African basil was listed as one of 75 species used in western Uganda to induce labor (Kamatenesi-Mugisha and Oryem-Origa 2007). A similar survey in southern Cameroon indicated that African basil had oxytocic effects and was sometimes added to abortifacient formulas. African basil alone was not used as an abortifacient (Noumi and Tchakonang 2001).

No information on the safety of African basil during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of African basil essential oil is 1.41 g/kg in mice and in rats has been reported as 1.75 and 2.29 g/kg (Fandohan et al. 2008; Orafidiya et al. 2004).

The LD_{50} of a dried aqueous extract of African basil intraperitoneally administered in rats is 1.26 mg/kg (Mohammed et al. 2007). The intraperitoneal LD_{50} of African basil essential oil is 0.27 g/kg in mice and 0.43 g/kg in rats (Orafidiya et al. 2004).

Short-Term Toxicity

No changes in liver enzyme levels (AST, ALT, ALP, TPT, ALB, and bilirubin) were observed in diabetic rats orally administered 500 to 1500 mg/kg of an aqueous extract of African basil daily for 28 days (Egesie et al. 2006).

In rats orally administered 5, 50, 500, 1000, 1500, 2000, 3000, or 3500 mg/kg of African basil essential oil daily for 14 days, no adverse effects were observed at the 5 to 500 mg/kg dose levels. Animals administered more than 1500 mg/kg died by the fourth day of the experiment. Histological examination revealed changes in stomach tissues at doses over 1000 mg/kg. No liver changes were noted at any dose level (Fandohan et al. 2008).

In rabbits orally administered 400, 800, or 1600 mg/kg of an aqueous extract of African basil twice a week for 4 weeks, adverse histopathological changes (hypertrophy, cytoplasmic contraction in hepatocytes, and sinusoidal

congestion) were observed in the liver at the 400 mg/kg dose, while livers showed no such changes at the 1600 mg/kg dose (Effraim et al. 2003).

In rats orally administered 133 mg/kg of African basil essential oil daily for 30 days, enlargement of the liver was observed (Orafidiya et al. 2004).

In rats intraperitoneally administered 80, 133, or 213 mg/kg of African basil essential oil daily for 14 days, enlargement of the liver and brain were observed. Histopathological changes were consistent with those observed in chronic inflammation. No significant changes in relative weights of testes, hearts, kidneys, intestines, or lungs were observed (Orafidiya et al. 2004).

Ocimum tenuiflorum L.

Lamiaceae

SCN: holy basil
Syn: *Ocimum sanctum* L.
AN: *tulasi*

OCN: sacred basil; tulsi
Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Alkenylbenzenes (eugenol as 8–43% of essential oil, essential oil is 0.17–0.5% dry weight of plant); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Human and animal studies have demonstrated that holy basil may modify glucose regulation (Chattopadhyay 1993; Gholap and Kar 2004; Kar et al. 2003; Narendhirakannan et al. 2006; Rai et al. 1997). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Animal studies have indicated that holy basil may temporarily reduce sperm count and sperm motility (Ahmed et al. 2002, 2009; Khanna et al. 1986; Seth et al. 1981).

A reduction in serum levels of thyroxine (T_4) was observed in an animal study with relatively high doses (500 mg/kg) of holy basil (Panda and Kar 1998).

Pregnancy and Lactation

In animal studies with relatively large doses of holy basil (0.2 to 4 g/kg), reductions in embryo implantation and in litter size were observed (Khanna et al. 1986; Vohora et al. 1969).

No information on the safety of holy basil during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a randomized, placebo-controlled, crossover single-blind trial with type 2 diabetes volunteers, patients were administered 2.5 g of holy basil daily for 60 days. After treatment with holy basil, decreases in fasting and postprandial blood glucose levels were observed (Agrawal et al. 1996).

Animal Pharmacological Studies

In male rats orally administered 250 mg/kg of a benzene extract of holy basil daily for 48 days, a decrease in total sperm count, sperm motility, and forward velocity were observed along with an increase in abnormal sperm in caudal epididymal fluid. All parameters returned to normal within 2 weeks after cessation of treatment (Ahmed et al. 2002). In a related study with the same treatment regimen, changes in cells of the cauda epididymis were observed. After a fertility performance test, no implantations were observed in female rats mated with treated males (Ahmed et al. 2009).

In male rats orally administered 100, 150, or 200 mg/kg of a benzene extract of holy basil, a reduction in sperm count, sperm motility, and testis weight was observed. No changes in weights of the epididymis, seminal vesicle, prostate, or vas deferens were observed (Seth et al. 1981).

In male rats orally administered 100, 150, 200, or 400 mg/kg of holy basil extract daily for 15 days, a decrease in the sexual behavioral score was observed at the 200 and 400 mg/kg dose levels (Kantak and Gogate 1992).

In male rats orally administered 0.2, 2, or 4 g/kg of holy basil, a reduction of sperm motility, number of successful matings, and resulting pregnancies were observed in male rats at the 2 and 4 g/kg doses (Khanna et al. 1986).

A prolongation of the diestrus phase of the estrus cycle was observed in female rats orally administered 80 mg of fresh holy basil (average animal weight 200 g) daily for 2 weeks. In this study, effects were measured by observing reproductive behavior, and no hormone levels were measured (Sardessai et al. 1999).

In diabetic rats orally administered 200 mg/kg of a dried ethanolic extract of holy basil daily for 30 days, a decrease in blood glucose levels was observed along with an increase in insulin levels and glucose tolerance (Narendhirakannan et al. 2006). A reduction in blood glucose levels was observed in diabetic rats orally administered 750 mg/kg of a dried ethanol extract of holy basil daily for 14 days (Kar et al. 2003). A reduction in blood glucose levels was observed in mice given 500 mg/kg of an aqueous extract of holy basil daily for 15 days (Gholap and Kar 2004). Other studies on holy basil in diabetic rats reported similar findings (Chattopadhyay 1993; Rai et al. 1997).

In mice orally administered 500 mg/kg of a holy basil aqueous extract daily for 15 days, a reduction in serum thyroxine (T_4) concentrations and glucose-6-phosphatase activity was observed. Serum levels of triiodothyronine (T_3) and the T_3/T_4 ratio were unaffected (Panda and Kar 1998).

In Vitro Pharmacological Studies

No in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A reduction in implantation was observed in female rats orally administered 200 mg/kg of an aqueous extract of holy basil daily on days 1 to 7 of pregnancy (Vohora et al. 1969).

In female rats orally administered 0.2, 2, or 4 g/kg of holy basil, a reduction in the number of full-term pregnancies and the litter size were observed at the 2 and 4 g/kg dose levels (Khanna et al. 1986).

No information on the safety of holy basil during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an alcohol extract of holy basil orally administered in mice is 1.54 mg/kg (Lagarto Parra et al. 2001).

In the brine shrimp lethality assay, the LC_{50} of an alcohol extract of holy basil is 18.75 µg/ml (Lagarto Parra et al. 2001).

Oenothera biennis L.

Onagraceae

SCN: evening primrose

Part: seed, seed oil

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Evening primrose oil has been characterized as generally well tolerated in clinical trials and postmarketing surveillance studies (Gateley et al. 2001; Horrobin 1992). Headaches, abdominal pain, nausea, and loose stools have been reported as adverse events in clinical trials of evening primrose oil (Bamford et al. 1985; Barber 1988).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No adverse effects on mothers or on pregnancy outcomes have been observed in three clinical trials of evening

primrose oil use during pregnancy (Laivuori et al. 1993; Moodley and Norman 1989; O'Brien and Broughton Pipkin 1983). In one retrospective study, evening primrose oil use was associated with an increased need for obstetric intervention during labor and delivery (Dove and Johnson 1999).

Gamma-linolenic acid (GLA), one of the primary constituents of evening primrose oil, is a compound naturally formed in the human body and is a component of human breast milk (Carter 1988).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A 1992 review of evening primrose oil use indicated that no significant adverse effects were reported in approximately 500,000 users in the United Kingdom (Horrobin 1992). Adverse events reported in clinical trials of evening primrose oil include headache, abdominal pain, nausea, and loose stools (Bamford et al. 1985; Barber 1988). Evening primrose oil was reported as well tolerated at doses up to 3 g daily for 1 year (Gateley et al. 2001).

In a clinical trial of evening primrose oil (4 g daily for 4 months) and vitamins in chronic schizophrenics, 3 of 23 people enrolled in the study experienced grand mal seizures, 2 of which were in the evening primrose oil group. Both subjects taking evening primrose oil were also taking phenothiazine (Holman and Bell 1983), an antipsychotic medication that can lower seizure thresholds (Tobias et al. 2006). Other clinical trials of evening primrose oil in psychiatric patients, including schizophrenic patients, were not associated with any increase in adverse effects at daily doses up to 540 mg of the compound gamma-linolenic acid (GLA) (Vaddadi et al. 1989; Wolkin et al. 1986). A more recent review of the safety of evening primrose oil in persons with epilepsy indicated that there is no evidence that intake of the omega-6 fatty acids linoleic acid and gamma-linolenic acid may cause seizures and concluded, "It is therefore suggested that formularies should now remove seizures or epilepsy as a side-effect of evening primrose oil, and should remove a history of seizures or epilepsy as a contraindication to taking evening primrose oil supplementation or evening primrose oil-containing products" (Puri 2007).

Case Reports of Adverse Events

Three hospitalized schizophrenics who had failed to respond adequately to standard drug therapy were administered evening primrose oil (8 g daily in one patient, no dose stated for the other two patients). The condition of the patients worsened and electroencephalogram (EEG) features of temporal lobe epilepsy became apparent. The patients had taken or were taking phenothiazine (Vaddadi 1981), an antipsychotic medication that can lower seizure thresholds and may induce a discharge pattern in EEG (Tobias et al. 2006).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Studies on the effects of evening primrose oil on blood pressure have yielded opposing results, with one study demonstrating a decrease in blood pressure in overweight subjects (Garcia et al. 1986) and a second study indicating no change in blood pressure of hyperlipidemic subjects (Viikari and Lehtonen 1986).

One study of evening primrose oil use in persons with Raynaud's phenomenon indicated some antiplatelet effect of evening primrose oil (Belch et al. 1985). Two other studies, however, one in multiple sclerosis patients and a second in patients with hypertriglyceridemia, indicated no effects on platelet function (Boberg et al. 1986; McGregor et al. 1989).

Animal Pharmacological Studies

Animal pharmacological studies were identified but omitted due to presence of human data.

In Vitro Pharmacological Studies

In vitro pharmacological studies were identified but omitted due to presence of human data.

IV. Pregnancy and Lactation

In women with preeclampsia treated with 4 g daily evening primrose oil, no adverse effects on perinatal outcome were observed (Moodley and Norman 1989). No adverse effects were reported in two small studies of evening primrose oil supplementation in pregnant women for 1 or 5 weeks (Laivuori et al. 1993; O'Brien and Broughton Pipkin 1983).

In a survey of American nurse midwives, 30% of respondents indicated that they used evening primrose oil to stimulate labor (McFarlin et al. 1999). A retrospective study on evening primrose use during pregnancy indicated that oral administration of evening primrose oil

from the 37th gestational week until birth did not shorten gestation. The use of evening primrose oil was associated with an increase in the incidence of prolonged rupture of membranes, oxytocin augmentation, arrest of descent, and vacuum extraction (Dove and Johnson 1999).

Supplementation with evening primrose oil in rats prior to mating had no effect on parturition or postnatal growth (Leaver et al. 1986). Diabetic pregnant rats fed evening primrose oil showed a significantly greater live fetal mass as compared with a control group (Garland et al. 1997).

In a study of male and female blue foxes fed a diet supplemented with 4.5 g daily of evening primrose oil, an increased rate of abortions in the evening primrose oil group was observed along with a nonsignificant decrease in the frequency of barren females, resulting in a similar level of females without litters in both groups. A tendency for increased litter size in the evening primrose oil group was found, mainly as an effect of male treatment (Tauson and Forsberg 1991).

Gamma-linolenic acid (GLA), one of the primary constituents of evening primrose oil, is naturally formed in the human body. Adult women produce an average of 20 mg/kg daily, and 23 to 65 mg/kg daily is ingested by the average breast-fed infant (Carter 1988).

Essential fatty acid levels and total fat content of breast milk was increased in women who took evening primrose oil during months 2 to 6 of lactation (Cant et al. 1991).

In minks fed evening primrose oil as part of the diet, less weight loss was observed during the lactation period as compared to control, and no changes in nursing behavior were observed (Tauson et al. 1991).

V. Toxicity Studies

Chronic Toxicity

No adverse effects were observed in mice fed up to 2.5 ml/kg daily of evening primrose oil for 52 weeks, or rats fed the same dose for 104 weeks (Everett et al. 1988a; Everett et al. 1988b). No adverse effects were observed in dogs fed up to 5 ml/kg daily of evening primrose oil for 52 weeks (Everett et al. 1988a).

Ophiopogon japonicus (L. f.) Ker Gawl.

Liliaceae

SCN: ophiopogon
PN: *mai men dong* (root tuber)

OCN: dwarf lilyturf
Part: root tuber

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Systemic allergic reactions to ophiopogon have been reported (Bensky et al. 2004).

Pharmacological Considerations

Animal studies have demonstrated that ophiopogon may modify glucose regulation (Kako et al. 1995; Zhu 1998). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of ophiopogon in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Severe allergic reactions to ophiopogon, including symptoms of nausea, vomiting, nervousness, agitation, generalized erythema, tingling, abdominal pain, pruritus, and occasionally delirium and loss of consciousness, have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in blood glucose levels was observed in rabbits orally administered 0.2 g/kg of an aqueous or alcoholic extract of ophiopogon. At doses of 0.5 g/kg of ophiopogon daily for 4 days, a hypoglycemic effect was observed in diabetic rabbits (Zhu 1998). A single oral dose of 100 mg/kg of polysaccharides from ophiopogon produced a 54% reduction in blood sugar in 11 hours in diabetic mice (Zhu 1998).

A reduction in blood glucose levels was observed in normal and diabetic mice intraperitoneally administered 100 mg/kg of an *n*-butanol extract of ophiopogon (Kako et al. 1995).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of ophiopogon during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered ophiopogon extract in mice was 20.6 g/kg. Intravenous administration of 1 ml of the same ophiopogon extract (equivalent to 2 g of the herb and over 100 times the human dose) produced no toxic reactions (Zhu 1998).

Oplopanax horridus (Sm.) Miq.

Araliaceae

SCN: devil's club
Syn: *Echinopanax horridus* (Sm.) Decne. & Planch, nom. inval.

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Use by indigenous people of devil's club in diabetes has been recorded, though several human case studies and animal studies have provided equivocal results in evaluating effects on blood sugar levels, and no contemporary substantiation of efficacy in diabetes was found (Lantz et al. 2004; Smith 1983; Stuhr and Henry 1944; Thommassen et al. 1990).

Pregnancy and Lactation

No information on the safety of devil's club in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a hospital-based study, one insulin-dependent diabetes patient and one newly diagnosed non-insulin-dependent diabetes patient were orally administered 80 ml of a devil's claw decoction three to four times daily for several days. No significant effects on glucose levels were observed in the insulin-dependent patient, while a gradual reduction in glucose levels was observed in the non-insulin-dependent patient. No changes were observed in glucose levels in healthy volunteers (Thommassen et al. 1990).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of devil's club during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Origanum vulgare L. ssp. *hirtum* (Link) Ietswaart — Lamiaceae

SCN: oregano
Syn: *Origanum heracleoticum* auct. non L.

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic sensitivity to oregano has been reported (Benito et al. 1996; Futrell and Rietschel 1993).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A limited number of animal studies have provided mixed results on the safety of oregano use during pregnancy. Studies of oregano leaf and essential oil in pigs resulted in improvement in a number of pregnancy and lactation parameters (Allan and Bilkei 2005; Amrik and Bilkei 2004).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

One case of allergy to oregano was reported (Benito et al. 1996). In patch testing of 55 allergy patients, four tested positive to oregano (Futrell and Rietschel 1993).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Addition of 1000 ppm oregano dried leaf and flower enriched with 500 g/kg oregano essential oil to prefarrowing and lactation diets of pigs resulted in improvement in a number of pregnancy and lactation parameters, including a lower mortality rate among sows, increased farrowing weight, and increased number of liveborn piglets. No adverse effects on mothers or offspring were observed (Allan and Bilkei 2005; Amrik and Bilkei 2004).

V. Toxicity Studies

No toxicity studies on oregano were identified.

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Adverse Events and Side Effects

Allergic reactions to Chinese peony have been reported (Bensky et al. 2004).

Pharmacological Considerations

Animal and in vitro studies have indicated that Chinese peony may inhibit thrombosis and platelet aggregation (Chen and Chen 2004; Ji et al. 1981; Wang and Ma 1990; Zhu 1998). Although no cases of interactions have been reported, Chinese peony should be used with caution in persons taking anticoagulant drugs (Chen and Chen 2004).

An animal study demonstrated that compounds from Chinese peony may modify glucose regulation (Hsu et al. 1997). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

A human study indicated that Chinese peony increased the rate of absorption of the drug valproic acid but did not change serum levels or the elimination rate of the drug (Chen et al. 2000).

Animal studies indicated that Chinese peony increased the rate of absorption of the drug carbamazepine and decreased the rate of absorption of the drug phenytoin but did not change serum levels or the elimination rates of either drug (Chen et al. 2001, 2002).

Pregnancy and Lactation

No information on the safety of Chinese peony in pregnancy or lactation was identified in the scientific or traditional literature, although two references on traditional Chinese medicine do not contraindicate use of this herb in either condition (Bensky et al. 2004; Chen and Chen 2004).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In an open label, two-way crossover study, healthy volunteers were orally administered 1.2 g of a powdered extract of Chinese peony daily for 7 days prior to oral administration of 200 mg valproic acid. An increase in the absorption rate of valproic acid in the treatment group was observed as compared to control, but no significant effects on distribution, metabolism, or elimination were observed (Chen et al. 2000).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

In rats orally administered 100 mg/kg carbamazepine with or without 300 mg/kg of a concentrated aqueous extract of Chinese peony, an increase in the absorption rate of carbamazepine was observed. Absorption extent, distribution, metabolism, and elimination of carbamazepine remained unchanged, although a decrease in protein binding rate was observed when carbamazepine and Chinese peony were coadministered (Chen et al. 2002).

In rats orally administered 300 mg/kg of a powdered aqueous extract of Chinese peony with 100 mg/kg of the drug phenytoin, or phenytoin alone, a delay in the absorption of phenytoin was observed in animals coadministered Chinese peony and phenytoin. Coadministration of Chinese peony and phenytoin did not significantly affect the extent

of absorption, metabolism, or elimination of phenytoin (Chen et al. 2001).

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to Chinese peony have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No significant effects on the drug-metabolizing isoenzyme CYP2C9 were observed in healthy volunteers orally administered 25 mg of losartan (a CYP2C9 substrate) before or after oral administration (average volunteer weight was 71 kg) of an aqueous extract 30 g of Chinese peony daily for 5 days (Xie et al. 2002).

Animal Pharmacological Studies

A reduction in blood sugar was observed in diabetic and healthy rats administered the compounds paeoniflorin and 8-debenzoylpaeoniflorin. The effect was stronger in diabetic than in healthy rats. Plasma insulin was not changed in paeoniflorin-treated healthy rats, indicating an insulin-independent action (Hsu et al. 1997).

Animal and in vitro studies indicated that Chinese peony and compounds in Chinese peony inhibit thrombosis and platelet aggregation, increase fibrinolytic activity, and promote thrombolysis. Details on doses and routes of administration were not listed in English language translations of the studies (Chen and Chen 2004; Ji et al. 1981; Wang and Ma 1990; Zhu 1998).

In Vitro Pharmacological Studies

Extracts of Chinese peony inhibited the drug-metabolizing isoenzymes CYP1A1/2, CYP2B1/2, and CYP2E1 (Jeong et al. 2002).

IV. Pregnancy and Lactation

No information on the safety of Chinese peony in pregnancy or lactation was identified in the scientific or traditional literature, although two references on traditional Chinese medicine do not contraindicate use of this herb in either condition (Bensky et al. 2004; Chen and Chen 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of Chinese white peony (*bai shao*) orally administered in rats is 81 g/kg (Zhu 1998). The LD_{50} values of Chinese red peony (*chi shao*) extracts intraperitoneally administered in mice are 10.8 g/kg for the aqueous extract, 2.9 g/kg for the ethanol extract, and 4.6 g/kg for the butanol extract (Zhu 1998).

The LD_{50} values of the compound paeoniflorin in mice are 3.52 g/kg after intravenous administration and 9.53 g/kg after intraperitoneal administration (Zhu 1998).

The maximum safe dose of Chinese red peony (*chi shao*) intravenously administered in mice is 50 g/kg (Chen and Chen 2004).

Genotoxicity

No mutagenic activity of an aqueous extract of Chinese peony was observed in the Ames test for mutagenicity in *Salmonella typhimurium* or in the micronucleus test in cultured Chinese hamster ovary cells (Yu et al. 2004).

Paeonia officinalis L. — Paeoniaceae

SCN: European peony
OCN: piney

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Contact dermatitis from European peony has been reported in persons occupationally exposed to peony plants (Bruynzeel 1989; Timmermans et al. 2009).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Limited information on the safety of European peony in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Contact dermatitis was reported in a man who had worked in a peony nursery for over 40 years. Sensitivity to peony was reported during the last year of work, and patch testing with extracts of root, flower, and leaf of European peony confirmed the plant as the causative agent (Timmermans et al. 2009).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

European peony was listed as an ingredient in a traditional abortifacient formula. Among formulas listed, some commonly consumed nontoxic plants are listed (i.e., kidney bean and pomegranate) along with other plants recognized to be toxic or inappropriate for use in pregnancy (i.e., pennyroyal). Parts and doses of botanicals used in these formulas were not listed (Madari and Jacobs 2004).

No information on the safety of European peony during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Paeonia suffruticosa Andrews

Paeoniaceae

SCN: tree peony
Syn: *Paeonia moutan* Sims
PN: *mu dan pi* (root bark)

OCN: mountain peony
Part: root bark

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Not for use in excessive menstruation (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Dizziness and nausea have been reported as occasional side effects of tree peony (Bensky et al. 2004).

Pharmacological Considerations

Human and in vitro studies have indicated that tree peony and compounds from tree peony may inhibit platelet aggregation (Hirai et al. 1983).

Traditional use and animal studies have demonstrated that tree peony and compounds in tree peony may modify glucose regulation (Jung et al. 2006; Lau et al. 2007; Suzuki et al. 1983). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that tree peony should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of tree peony during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Dizziness and nausea have been reported as occasional side effects of tree peony (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In platelets taken from healthy volunteers who orally ingested an aqueous extract of tree peony at a dose of 3 g of the herb daily for 1 week, a significant reduction in platelet aggregation and thromboxane B_2 formation induced by collagen, epinephrine, and ADP was observed (Hirai et al. 1983).

Animal Pharmacological Studies

Decreases in blood glucose levels were observed in rabbits, rats, and cats intravenously administered 50 to 100 mg/kg of an aqueous extract of tree peony (Suzuki et al. 1983).

A reduction in blood glucose levels was observed in healthy rats orally administered 100 mg/kg of an ethanol extract of tree peony, while a slight elevation of glucose levels was observed in diabetic rats administered the same extract (Jung et al. 2006).

The compound paeonol, orally administered at doses of 200 or 400 mg/kg, improved oral glucose tolerance in diabetic rats (Lau et al. 2007).

In Vitro Pharmacological Studies

Extracts of tree peony inhibited the drug-metabolizing isoenzymes CYP1A1/2, CYP2B1/2, and CYP2E1 (Jeong et al. 2002).

No estrogenic activity of tree peony was observed in a recombinant yeast system featuring a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

A synergistic growth-inhibitory effect on an esophageal cancer cell line was observed with a combination of the compound paeonol and the drug cisplatin as compared to the activity of either substance alone (Wan et al. 2008).

The compound paeonol was found to cause dose-dependent inhibition of ADP- and collagen-induced platelet aggregation in human blood platelets (Hirai et al. 1983).

IV. Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that tree peony should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of tree peony during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an aqueous extract of tree peony in mice is 4.07 g/kg after intraperitoneal administration, 8 g/kg after subcutaneous administration, and could not be determined at doses up to 12.5 g/kg after oral administration (Suzuki et al. 1983).

The LD_{50} of the compound paeonol in mice is 3430 mg/kg after oral administration, 782 mg/kg after intraperitoneal administration, and 196 mg/kg after intravenous administration (Chen and Chen 2004).

Genotoxicity

In the mouse micronucleus assay, some chromosomal aberrations were observed in mice orally administered 3.0 g/kg of an aqueous extract of tree peony, but not in mice that were administered 0.15 to 1.5 g/kg of the same extract. An increase in the number of micronucleated polychromatic erythrocytes was observed in mice administered 0.75, 1.5, or 3.0, but not 0.15 g/kg of the same extract (Yin et al. 1991).

No mutagenic activity of the essential oil of tree peony was observed in *Salmonella typhimurium* strain TA100 with or without metabolic activation (Park 2002). Similarly, no mutagenic activity of an aqueous extract of tree peony was observed in *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation (Yin et al. 1991).

An extract of tree peony and compounds from tree peony inhibited oxidative DNA damage and cleavage caused by phenylhydroquinone and *tert*-butylhydroquinone (Okubo et al. 2000).

OCN: dillisk
Part: thallus

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with hyperthyroidism (Lee et al. 2007; Teas et al. 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

A number of seaweeds have been found to contain heavy metal residues (Almela et al. 2002; Rose et al. 2007). Total arsenic has been measured in dulse products at levels ranging from 5 to 12 ppm (Almela et al. 2002; McSheehy and Szpunar 2000; Phaneuf et al. 1999).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of dulse in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Panax ginseng C.A. Mey. — Araliaceae

SCN: Asian ginseng
Syn: *Panax schinseng* T. Nees
PN: *ren shen* (root)

OCN: Chinese ginseng; Korean ginseng
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Concurrent use with stimulants is not advised, as overstimulation may occur in susceptible persons (Mills and Bone 2005).

Drug and Supplement Interactions

Case reports of decreased blood clotting in patients taking warfarin and Asian ginseng have been reported (Janetzky and Morreale 1997; Rosado 2003), although trials of warfarin and Asian ginseng in humans and in rats have not shown any interaction (Jiang et al. 2004, 2006; Lee et al. 2008; Zhu et al. 1999).

Editors' Note

The use of red ginseng (processed by steaming) may potentiate the effects of caffeine and other stimulants (Bradley 1992).

Adverse Events and Side Effects

A systematic review of case reports of adverse events and adverse events in clinical trials indicated the relative safety of Asian ginseng. Adverse events in clinical trials were reported as similar for both Asian ginseng and placebo groups (Coon and Ernst 2002).

Cases of mastalgia, irregular menstrual bleeding, postmenopausal bleeding, hypertension, stroke, arteritis, and a coagulation disorder have been reported in people taking Asian ginseng (Coon and Ernst 2002). None of these cases has been causally attributed to Asian ginseng.

Allergic reactions to Asian ginseng have been reported (Dega et al. 1996; Wiwanitkit and Taungjaruwinai 2004).

Wichtl (2004) reports "relatively rare" side effects, "only with high doses and/or use over very long periods of time." These include sleeplessness, nervousness, diarrhea (particularly in the morning), menopausal bleeding, and hypertony. Martindale and Reynolds (1996) present a litany of side effects attributed to Siegel, whose work has been refuted due to methodological flaws (Blumenthal 1991; Buettner et al. 2006; De Smet 1992; Siegel 1979).

Pharmacological Considerations

A systematic review of human studies on the effects of Asian ginseng on blood pressure indicated mixed results, with most studies showing either no substantial change or slight decreases in blood pressure (Buettner et al. 2006).

Human studies have demonstrated that Asian ginseng may modify glucose regulation (Reay et al. 2006; Sotaniemi et al. 1995; Vuksan et al. 2008; Xie et al. 2005). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

No significant effects of Asian ginseng on the drug metabolizing isoenzymes CYP3A4 or CYP2D6 were observed in human studies (Anderson et al. 2003; Gurley et al. 2002, 2005).

No changes in platelet function or blood clotting parameters were observed in healthy volunteers taking Asian ginseng (Beckert et al. 2007).

Pregnancy and Lactation

Two retrospective studies of Asian ginseng use by pregnant women have not indicated any adverse effects of Asian ginseng on mother or fetus (Chin 1991; Chuang et al. 2006).

Although a British herbal text contraindicates Asian ginseng during pregnancy (Bradley 1992), no concerns for use in pregnancy are listed in texts on traditional Chinese medicine (Bensky et al. 2004; Chin 1991).

No information on the safety of Asian ginseng during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

A study of *rac*-warfarin (25 mg) and Asian ginseng indicated that 1 week of supplementation with Asian ginseng (0.5 g) did not affect single doses of warfarin (25 mg) (Jiang et al. 2004, 2006). Asian ginseng (46 mg/kg) taken in conjunction with alcohol showed a significant reduction in blood alcohol levels as compared with alcohol alone (Lee et al. 1987).

In patients with a history of stroke taking warfarin alone (2 mg daily for 7 days, then 5 mg daily for 7 days) or warfarin with an aqueous extract of 0.5 g Asian ginseng daily for 14 days, changes in blood clotting parameters (international normalized ratio and prothrombin time) were equivalent in both groups. No significant changes in plasma levels of warfarin or changes in the rate of warfarin clearance were observed in the group being treated with Asian ginseng, as compared to the control group (Lee et al. 2008).

Case Reports of Suspected Drug or Supplement Interactions

Decreased international normalized ratio (INR) (a standardized scale used to report the results of blood coagulation tests) was reported in a patient taking warfarin and other prescription drugs for cardiovascular conditions (Janetzky and Morreale 1997). Thrombosis of a prosthetic aortic valve and a decrease in INR were reported in a patient taking warfarin and ginseng (species and dose unspecified). The patient had a history of erratic INR levels (Rosado 2003).

Edema and hypertension were reported in a patient taking furosemide and a germanium-containing ginseng supplement (Becker et al. 1996). Symptoms of mania were reported in a woman with a history of depression taking phenelzine and ginseng (species and dose unspecified) (Jones and Runikis 1987). Two incidents of insomnia, tremulousness, and headache were reported in a woman taking phenelzine and ginseng (Shader and Greenblatt 1985, 1988). The woman was reported to have taken at least two different ginseng products, one of which has been suspected to be a product containing eleuthero (formerly called Siberian ginseng) and not Asian ginseng (Treasure 2006).

Animal Trials of Drug or Supplement Interactions

In rats administered warfarin (2 mg/kg) and Asian ginseng (2 g/kg), both single and multiple dose regimens of warfarin were unaffected by Asian ginseng (Zhu et al. 1999).

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a systematic review of over 3500 trial participants in clinical trials of Asian ginseng monopreparations, adverse events in trials were characterized as "relatively few." Events reported included diarrhea and other gastrointestinal disorders, anxiety, sleep-related problems, epigastralgia, flu/cold, headache, contact urticaria, itching, eye burning, improved motor efficiency, feelings of well-being and stimulation, increased appetite, skin eruptions, lighter hand, and skin feeling "too tight." The types and frequency of adverse events were generally similar to those recorded in placebo groups (Coon and Ernst 2002).

Case Reports of Adverse Events

In a systematic review of case reports of adverse events and drug interactions of Asian ginseng, the supplement was noted as being rarely associated with adverse events or drug interactions. Events and interactions that were identified were characterized as mild and transient (Coon and Ernst 2002).

Asian ginseng was associated with a case of menometrorrhagia and tachyarrhythmia in a 39-year-old woman taking Asian ginseng (1000–1500 mg daily) for 7 months. The woman also consumed four to six cups of coffee and smoked 20 cigarettes daily (Kabalak et al. 2004).

Episodes of mania have been reported in individuals taking Asian ginseng. One episode was reported in a woman with major depression taking Asian ginseng (300 mg daily) along with clomipramine and haloperidol (Vazquez and Aguera-Ortiz 2002). Another episode was in an otherwise healthy man, and a third episode was in a woman with depression taking Asian ginseng while interrupting her antidepressant (lithium and amitriptyline) treatment (Engelberg et al. 2001; Gonzalez-Seijo et al. 1995).

Cases of mastalgia have been reported in six women taking ginseng (species and doses unspecified); one woman took ginseng for 6 weeks, and the duration of ginseng ingestion for the other women was unspecified (Koriech 1978; Palmer et al. 1978).

Irregular menstruation and postmenopausal bleeding have been reported in association with ginseng use. Postmenopausal bleeding was reported in a 72-year-old woman taking an Asian ginseng and multivitamin supplement (Greenspan 1983). Irregular menstrual bleeding (metrorrhagia) was reported in a 48-year-old woman who had taken an Asian ginseng and multivitamin supplement daily for 2 months (Palop-Larrea et al. 2000).

Cerebral arteritis was reported in a woman taking an alcoholic extract of ginseng (Ryu and Chien 1995). A transient stroke secondary to a hypertensive crisis was reported in a woman taking Asian ginseng (Martinez-Mir et al. 2004). Hypertension was reported in a man with a family history of hypertension taking "a variety of ginseng products" (species unspecified) (Hammond and Whitworth 1981).

An allergic reaction to an Asian ginseng-based syrup was reported in one man (Wiwanitkit and Taungjaruwinai 2004). One case of Stevens Johnson syndrome (a type of allergic reaction in response to medication or infection) was reported in a woman taking ginseng (Dega et al. 1996).

In a study of ginseng users, a "ginseng abuse syndrome" was reported in people who had taken ginseng (multiple species) for long periods of time (Siegel 1979). Symptoms observed and noted to characterize the syndrome were reported as nervousness, irritability, insomnia, and morning diarrhea. The study, however, has been criticized due to methodological flaws, and a number of persons experiencing the ginseng abuse syndrome were noted to be consuming large amounts of caffeine with their ginseng (Blumenthal 1991; Buettner et al. 2006).

The toxicity of the herb has been noted as mild, although intake of large doses has been reported to cause toxic effects with symptoms reported as maculopapular rashes, pruritus, headache, dizziness, sudden rise in temperature, fever, and bleeding (Bensky et al. 2004; Chen and Chen 2004). One case of lethal poisoning was reported in a man who took two doses of an Asian ginseng decoction, each containing 40 g of red ginseng (Bensky et al. 2004). Gross overdose has been reported to cause reactions such as nausea, vomiting, irritability, restlessness, urinary and bowel incontinence, fever, increased blood pressure, increased respiration, decreased sensitivity to light, decreased heart rate, cyanotic facial complexion, red face, seizures, convulsions, delirium, and bleeding (Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No significant effects of Asian ginseng on CYP3A4 or CYP2D6 were observed in human volunteers taking Asian ginseng (1500 mg/day) for 28 days (Anderson et al. 2003; Gurley et al. 2002, 2005).

In healthy volunteers orally administered Asian ginseng capsules at the manufacturer's recommended dose (amount not specified) daily for two weeks, no effects on platelet function or other hematological parameters were observed, including prothrombin time, partial thromboplastin time, thrombin time, bleeding time, the collagen/epinephrine assay, or the collagen/adenosine diphosphate assay. Aspirin (325 mg daily) was used as a positive control and markedly inhibited platelet function (Beckert et al. 2007).

A systematic review of human studies on the effects of Asian ginseng on blood pressure indicated that results were mixed, with most studies showing either no substantial change or slight decreases in either systolic and/or diastolic blood pressure. Slight increases in blood pressure, seen in a minority of studies, were noted as not being clinically significant (Buettner et al. 2006). In healthy volunteers, a mild decrease in diastolic blood pressure was observed in persons administered Asian ginseng at doses of 200 mg (Caron et al. 2002). In administration of Asian red ginseng in adults with essential hypertension, a significant decrease in systolic blood pressure and a tendency of decline in diastolic blood pressure was observed (Han et al. 1998). No effect was observed in patients with white coat hypertension (Han et al. 1998). No effects of long-term Asian ginseng on blood pressure were observed in hypertensive adults administered infusions of vasoactive substances (Sung et al. 2000).

In healthy volunteers, single doses (200 or 400 mg) of Asian ginseng were observed to have opposing effects under fasting and raised blood glucose conditions, suggesting that Asian ginseng improves glucose regulation (Reay et al. 2006).

In newly diagnosed non-insulin-dependent diabetes mellitus (NIDDM) patients, administration of Asian ginseng (100 or 200 mg daily) reduced fasting blood glucose. At the 200 mg dose, Asian ginseng administration resulted in improved glycated hemoglobin (Sotaniemi et al. 1995).

In patients with type 2 diabetes, administration of 6 g daily of Korean red ginseng for 12 weeks maintained good glycemic control and improved plasma glucose and plasma insulin regulation safely beyond usual therapy in people with well-controlled type 2 diabetes (Vuksan et al. 2008).

Animal Pharmacological Studies

Information on animal studies was available but omitted due to availability of human data.

In Vitro Pharmacological Studies

In vitro studies suggest that Asian ginseng may interfere with certain types of serum digoxin immunoassays (Dasgupta and Reyes 2005; Dasgupta et al. 2003).

Other information on in vitro studies was available but omitted due to availability of human data.

IV. Pregnancy and Lactation

In a cross-sectional analysis of over 14,500 pregnant women in Taiwan, approximately 1100 took ginseng (species unspecified) during the first trimester of pregnancy. No malformations of infants were associated with ginseng use (Chuang et al. 2006).

In a retrospective study of 88 women in Hong Kong who had taken ginseng (species unspecified) during

pregnancy, a slightly higher number of gestational diabetes cases were reported and a significantly lower number of pre-eclampsia cases were reported as compared to the control population (Chin 1991).

No information on the safety of Asian ginseng during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No toxicological effects were noted in mice that were administered an Asian ginseng extract of 6 g/kg intraperitoneally or up to 30 g/kg orally (Singh et al. 1983). In mice, the LD_{50} of orally administered Asian ginseng is 5 g/kg, and the LD_{50} of subcutaneously administered Asian ginseng is 16.5 ml/kg (Chen and Chen 2004).

Subchronic Toxicity

No toxicological effects were observed in beagle dogs fed up to 15 mg/kg daily for 90 days (Hess et al. 1983).

Reproductive Toxicity

In a study of standardized Asian ginseng on reproduction in rats, no adverse effects of Asian ginseng were identified in either the F_1 or F_2 generations (Hess et al. 1982).

In a study in male rabbits and rats fed 100 mg/kg daily Asian ginseng for 60 days, animals were reported to have decreased testicular germ cell counts, size, and other marks of reduced fertility (Sharma et al. 1999).

Panax notoginseng (Burkill) F.H. Chen ex C.Y. Wu & K.M. Feng — Araliaceae

SCN: tienchi ginseng
Syn: *Panax pseudoginseng* Wall. var. *notoginseng* (Burkill) G. Hoo & C.J. Tseng

PN: *san qi* (root); *tian qi* (root)
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Reference texts on traditional Chinese medicine indicate that tienchi ginseng should be used with caution during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Rare cases of esophagitis and several types of allergic reactions have been reported in persons using tienchi ginseng (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that tienchi ginseng should be used with caution during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

In rare cases, tienchi ginseng has been associated with bleeding such as nosebleeds, bleeding gums, and increased menstrual bleeding (Bensky et al. 2004; Chen and Chen 2004). Other reported rare cases of adverse events associated with low doses of tienchi ginseng include nausea and vomiting. These symptoms were noted to have disappeared without termination of herbal treatment, although in severe cases administration of the herb was discontinued. Cases of esophagitis have been reported. A high dose (5 g single dose) of tienchi ginseng was associated with second degree atrioventricular block (Bensky et al. 2004), although no other information suggests adverse cardiac effects of tienchi ginseng. Other side effects that have been reported include loss of appetite, dizziness, headache, toothache, fatigue, and restlessness (Chen and Chen 2004).

A number of types of allergic reactions have been reported in association with tienchi ginseng, including two cases of esophagitis, seven cases of allergic exanthema, two cases of allergic shock, two cases of allergic purpura, two cases of epidermolysis (one in an infant whose mother had taken tienchi ginseng), and single cases of pruritus and punctuate erythema (Dharmananda 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Reference texts on traditional Chinese medicine indicate that tienchi ginseng should be used with caution during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

One case of an allergic reaction was reported in a breast-feeding infant whose mother had taken tienchi ginseng (Dharmananda 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} for tienchi ginseng administered intravenously is 0.075 g/kg in mice, 0.5 g/kg in rats, and 2.5 g/kg in rabbits (Chen and Chen 2004).

Oral administration of tienchi ginseng powder at 15 g/kg did not cause any significant adverse reactions (Chen and Chen 2004).

Panax quinquefolius L. — Araliaceae

SCN: American ginseng
PN: *xi yang shen* (root)

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: B

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

Concomitant use of warfarin and American ginseng may reduce the efficacy of warfarin and should be under the supervision of a healthcare professional (Yuan et al. 2004).

Adverse Events and Side Effects

Allergic reactions to American ginseng have been reported (Bensky et al. 2004).

Pharmacological Considerations

Human studies have demonstrated that American ginseng may modify glucose regulation (Sotaniemi et al. 1995; Vuksan et al. 2000a, 2000b). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Human studies have shown a lack of interaction between American ginseng and indinavir or zidovudine (Andrade et al. 2008; Lee et al. 2008).

Pregnancy and Lactation

No information on the safety of American ginseng in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Coadministration of warfarin (5 mg/day) and American ginseng (2 g/day) led to a decrease in INR and a decrease in plasma levels of warfarin after 3 weeks of ginseng supplementation, suggesting that American ginseng may reduce the efficacy of warfarin (Yuan et al. 2004).

No changes in plasma levels or clearance rate of indinavir, as compared to baseline, were observed in healthy volunteers orally administered indinavir (800 mg 3 times daily for 3 days, then 1 g 3 times daily for 2 weeks) after two weeks of coadministration of 3g American ginseng capsules daily (Andrade et al. 2008).

No changes in plasma levels or clearance rate of zidovudine, as compared to baseline, were observed in healthy volunteers orally administered zidovudine after two weeks coadministration of 300 mg zidovudine and 200 mg American ginseng daily (Lee et al. 2008).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Adverse events in six clinical trials of American ginseng monopreparations were similar in the American ginseng and placebo groups (Hsu et al. 2005; McElhaney et al. 2004; Predy et al. 2005; Sievenpiper et al. 2004; Stavro et al. 2005, 2006).

Case Reports of Adverse Events

Improper use of American ginseng is reported to cause side effects such as headache, weakness, apathy, aversion to cold, distended abdomen, vomiting, and delayed menstruation. Allergic reactions including asthma and drug rashes have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A reduction in area under the glycemic curve was observed in healthy and type 2 diabetes patients administered 3 g daily of American ginseng for 2 days (Vuksan et al. 2000a). Administration of 3, 6, or 9 g of American ginseng prior to an oral glucose challenge test reduced postprandial glycemia at all doses in patients with type 2 diabetes (Vuksan et al. 2000b). A reduction in fasting blood glucose was observed in newly diagnosed non-insulin-dependent diabetes mellitus (NIDDM) patients administered 100 or 200 mg daily American ginseng for 8 weeks (Sotaniemi et al. 1995).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

One study showed that an American ginseng extract significantly induced the growth of an estrogen receptor-positive breast cancer cell line (MCF-7) in vitro. The extract, however, did not show any estrogenic activity in the α- or β-estrogen receptors, and no increase in uterine weight was observed after 4 days of administration of the extract to mice (Amato et al. 2002).

IV. Pregnancy and Lactation

No information on the safety of American ginseng in pregnancy or lactation was identified.

V. Toxicity Studies

Subacute Toxicity

No significant toxic effects were observed after intraperitoneal administration of 450 mg/kg daily for 7 days in laboratory animals (Chen and Chen 2004).

Parietaria spp. Urticaceae

Parietaria judaica L.
SCN: pellitory-of-the-wall
Syn: *Parietaria diffusa* Mert. & W.D.J. Koch
OCN: spreading pellitory

Parietaria officinalis **L.**
SCN: pellitory-of-the-wall
OCN: upright pellitory
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Giachetti et al. 1986; Wood and LaWall 1918); *see* Appendix 2.

Adverse Events and Side Effects

The pollen of pellitory-of-the-wall is a major airborne pollen allergen in Europe and the Mediterranean (Ferrer et al. 2005; Pajno et al. 2004; Passalacqua et al. 1999).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of pellitory-of-the-wall in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

The pollen of pellitory-of-the-wall is one of the major airborne pollen allergens in Europe and the Mediterranean (Ferrer et al. 2005; Pajno et al. 2004; Passalacqua et al. 1999).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of pellitory-of-the-wall during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Passiflora incarnata L. — Passifloraceae

SCN: passionflower
OCN: apricot vine; maypop; wild passionflower

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Passionflower contains trace amounts of β-carboline alkaloids (e.g., harmane, harmine, and harmol). Analyses of commercial passionflower samples indicated that harmane content ranged from 0 to 0.1 µg/g and harmine ranged from 0 to 0.27 µg/g (Abourashed et al. 2003; Grice et al. 2001; Tsuchiya et al. 1999); another study indicated that these alkaloids were undetectable in all but 1 of 17 commercial samples (Rehwald et al. 1995).

Adverse Events and Side Effects

A meta-analysis of clinical trials of passionflower in the treatment of anxiety indicated that no serious adverse events were reported and that passionflower was generally well tolerated (Miyasaka et al. 2007).

Allergic reactions to passionflower have been reported (Echechipia et al. 1996; Giavina-Bianchi et al. 1997; Smith et al. 1993).

One case of gastrointestinal and cardiovascular disturbances was reported in a woman who had taken passionflower for several days (Fisher et al. 2000).

Pharmacological Considerations

None known.

Pregnancy and Lactation

One animal study showed no adverse effects of passionflower on fetal development (Hirakawa et al. 1981). No other information on the safety of passionflower in pregnancy or lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal studies of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A meta-analysis of clinical trials of passionflower for the treatment of anxiety indicated that no serious adverse events were reported in either of the trials; allergic reaction and dizziness were reported as adverse events, although the incidence of those was similar between those taking passionflower and those taking benzodiazepines (Miyasaka et al. 2007).

Case Reports of Adverse Events

An IgE-mediated case of anaphylactic reaction to an herbal product containing passionflower was reported in an 8-year-old boy with a history of latex allergy. Patch testing confirmed the allergy to passionflower (Echechipia et al. 1996). Vasculitis and urticaria caused by a hypersensitivity reaction were reported in association with passionflower use (Smith et al. 1993).

Occupational allergic asthma and rhinitis to passionflower, confirmed by patch testing, were reported in a pharmacy worker who prepared herbal products (Giavina-Bianchi et al. 1997).

Severe nausea, vomiting, drowsiness, prolonged QT_c, and episodes of nonsustained ventricular tachycardia were reported in a 34-year-old woman who had taken three or four 500 mg capsules of passionflower daily for several days. A sample of the product taken by the patient was analyzed and compared to other capsules produced by the same manufacturer and to other commercial samples of passionflower, and also tested for the presence of two

pharmaceutical drugs. Results indicated that the product taken was passionflower, and no adulteration with the tested drugs was found (Fisher et al. 2000).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Ethanol and aqueous extracts of passionflower inhibited GABA transaminase and glutamic acid decarboxylase in vitro. The half-maximal inhibitory concentration (IC_{50}) values were between 1.2 and 2.5 mg/ml (Awad et al. 2007).

IV. Pregnancy and Lactation

No adverse effects on development were observed in offspring of rats administered 400 mg/kg of a passionflower extract on days 7 to 17 of pregnancy (route of administration not stated in English language translations) (Hirakawa et al. 1981).

No information on the safety of passionflower during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No toxic effects were observed in mice intraperitoneally administered passionflower extracts at doses of 500 or 900 mg/kg (Aoyagi et al. 1974; Speroni and Minghetti 1988).

Short-Term Toxicity

No adverse effects were observed in rats orally administered 5 g/kg daily of an aqueous-ethanolic extract of passionflower for 21 days (Sopranzi et al. 1990).

Genotoxicity

No mutagenic activity of a fluid extract of passionflower was observed in the somatic segregation assay (Ramos Ruiz et al. 1996).

Paullinia cupana Kunth

Sapindaceae

SCN: guaraná

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: C*

Contraindications

None known.

Other Precautions

Guaraná extracts typically contain caffeine, a nervous system stimulant. If taken in large amounts, guaraná products containing caffeine can cause insomnia, nervousness, and the other well-known symptoms of excess caffeine intake (PDR 2006).

Due to the central nervous system (CNS) stimulant effects of caffeine, use of caffeine-containing products is cautioned in persons with heart disorders, as excessive caffeine consumption may increase heart rate or exacerbate arrhythmias; caution is also indicated in psychological disorders, as caffeine may aggravate depression or induce anxiety (Brinker 2001).

Drug and Supplement Interactions

Use of caffeine with other CNS stimulants, including bronchodilators or adrenergic drugs, may cause excessive central nervous system stimulation resulting in nervousness, irritability, insomnia, and possibly convulsions or cardiac arrhythmias (PDR 2006).

Caffeine is metabolized by the isoenzyme CYP1A2. Drugs that inhibit this isoenzyme (including fluvoxamine, ciprofloxacin, cimetidine, amiodarone, fluoroquinolones, furafylline, interferon, methoxsalen, and mibefradil) may slow the metabolism of caffeine, resulting in high blood levels of caffeine in persons drinking multiple cups of guaraná daily (Carrillo and Benitez 2000).

Notice

Caffeine (2.6–7.0%) (Leung and Foster 1996; List and Hörhammer 1973); *see* Appendix 1. A typical cup of guaraná contains approximately 200 to 400 mg caffeine, as compared to coffee, which contains 100 to 200 mg per cup.

Diuretic (Brunton et al. 2006); *see* Appendix 2.

Tannins (12%) (Leung and Foster 1996); *see* Appendix 1.

Editors' Note

The American Herbal Products Association has established a trade requirement (AHPA 2011) that dietary supplement products that contain caffeine, whether as a direct ingredient or as a constituent of herbal ingredients, be labeled to disclose the presence of caffeine in the product and the quantity of added caffeine if greater than 25 mg; be formulated and labeled in a manner to recommend a maximum of 200 mg of caffeine per serving, not more often than every 3 to 4 hours; and bear the following or similar statement on the label of any dietary supplement that contains caffeine in sufficient quantity to warrant such labeling:

> Too much caffeine may cause nervousness, irritability, sleeplessness, and, occasionally, rapid heartbeat. Not recommended for use by children under 18 years of age.

See Appendix 1 for more specific details on this AHPA trade requirement.

Adverse Events and Side Effects

Adverse events, primarily cardiovascular in nature, have been reported in persons consuming "energy drinks" and weight-loss supplements that contain guaraná and multiple other botanical extracts, added caffeine, and other stimulant compounds (Pittler et al. 2005).

Pharmacological Considerations

Caffeine is a central nervous system (CNS) stimulant, and excessive use may result in insomnia and nervousness (PDR 2006).

Guaraná has been reported to inhibit platelet aggregation in mice and in vitro (Bydlowski et al. 1988, 1991).

Pregnancy and Lactation

No studies on the safety of guaraná during pregnancy or lactation were identified. Caffeine is in FDA pregnancy category C and has been shown to cross the placenta and achieve blood and tissue concentrations in the fetus. Pregnant women are advised to limit caffeine intake to 300 mg or less daily (PDR 2006).

Caffeine is listed as a "Maternal Medication Usually Compatible with Breastfeeding" by the American Academy of Pediatrics Committee on Drugs. The Committee noted that maternal consumption of caffeine may cause irritability and poor sleeping patterns in nursing infants, and that maternal consumption of caffeinated beverages should be limited to 150 mg caffeine daily (AAP 2001).

* For caffeine-free preparations, no interactions are expected.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a trial of 500 mg daily guaraná (2.1% caffeine) in healthy volunteers over age 60 for 5 months, one case of tachycardia and three cases of gastrointestinal upset were reported in the guaraná group, and one case each of gastrointestinal upset and insomnia were reported in the placebo group (Galduroz and Carlini 1996).

No adverse events were reported in a human study of single doses of 37.5, 75, 150, or 300 mg of standardized guaraná extract (11 –12% caffeine) administered to healthy adults (Haskell et al. 2007).

Case Reports of Adverse Events

Cardiovascular and other adverse events have been reported in persons consuming "energy drinks" and weight-loss supplements that contain guaraná and multiple other botanical extracts, added caffeine, and other stimulant compounds (Pittler et al. 2005). These adverse events are consistent with the known actions of stimulant compounds taken in excessive doses.

One case of acute tubular necrosis was reported in a woman who had taken guaraná and occasionally used injectable nonsteroidal painkillers (Vagasi et al. 2007). The use of nonsteroidal anti-inflammatory drugs is associated with kidney disease (Abuelo 1995).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A decrease in platelet aggregation in response to ADP or arachidonate was observed in rabbits administered 1 ml of guaraná intravenously or 20 ml of guaraná through a nasogastric tube (Bydlowski et al. 1988).

Administration of 500 mg/kg of an aqueous extract of guaraná administered to glycogenolytic mice suppressed exercise-induced hypoglycemia, increased blood glucose and decreased liver glycogen after oral administration of maltose (Miura et al. 1998).

In Vitro Pharmacological Studies

A dose-dependent decrease in platelet aggregation was observed in vitro after the application of aqueous guaraná extracts to human or rabbit platelet-rich plasma (Bydlowski et al. 1988, 1991).

IV. Pregnancy and Lactation

No studies on the safety of guaraná during pregnancy or lactation were identified.

Caffeine is in the FDA pregnancy category C and has been shown to cross the placenta and achieve blood and tissue concentrations in the fetus. Excessive intake of caffeine by pregnant women has been associated with fetal arrhythmias. Pregnant women are advised to limit caffeine intake to less than 300 mg daily (PDR 2006).

Caffeine is listed as a "Maternal Medication Usually Compatible with Breastfeeding" by the American Academy of Pediatrics Committee on Drugs. The committee noted that maternal consumption of caffeine may cause irritability and poor sleeping patterns in nursing infants, and that maternal consumption of caffeinated beverages should be limited to two to three cups daily (AAP 2001).

Epidemiological studies have indicated an association between high caffeine intake during pregnancy and an increased risk of spontaneous abortions. An analysis concluded that methodological flaws in many of the studies led to biased results, and that a causal link between caffeine consumption and abortion cannot yet be confirmed (Signorello and McLaughlin 2004).

V. Toxicity Studies

Acute Toxicity

No toxic effects were observed in mice treated with guaraná at oral doses of 2 g/kg and at intraperitoneal doses of 1 or 2 g/kg when compared to control groups. Histopathological examination did not detect any differences between the guaraná and control groups in a number of organs, including liver, kidneys, and stomach (Mattei et al. 1998).

Chronic Toxicity

No adverse effects were observed in mice administered a 3 mg/ml aqueous-ethanolic extract of guaraná as the sole source of drinking water for 12 months (Mattei et al. 1998).

Cytotoxicity

No cytotoxicity was observed in three in vitro assays at concentrations of guaraná up to 40 mg/ml (Santa Maria et al. 1998).

Genotoxicity

In mice orally administered 133, 265, and 530 mg/kg daily of an aqueous extract of guaraná for 7 days, changes in the frequency of micronuclei in the femoral cells and inductions of testicular chromosomal aberrations were observed. An increase of malondialdehyde and depletion of nonprotein sulfhydryl, RNA, and DNA in both hepatic and testicular cells were observed (Al-Majed 2006).

No genotoxic effects of guaraná were observed in bacterial cells in the presence of S9 microsomal fraction, catalase, superoxide dismutase, or thiourea, although genotoxic effects were observed in the absence of these compounds (da Fonseca et al. 1994).

Pausinystalia johimbe (K. Schum.) Pierre ex Beille — Rubiaceae

SCN: yohimbe
Syn: *Corynanthe yohimbe* K. Schum.

OCN: johimbe
Part: bark

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: B

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (De Smet 1997). Use in lactation is also not recommended.

Not for use in persons with liver or kidney diseases or in chronic inflammation of the sexual organs or prostate gland (Martindale and Reynolds 1996; Roth et al. 1984).

Not for excessive or long-term use (De Smet and Smeets 1994).

Other Precautions

Use is cautioned in persons with high blood pressure (Tam et al. 2001).

Drug and Supplement Interactions

See Pharmacological Considerations below.

Standard Dose

The standard dose is 5.0 to 6.0 mg of the contained alkaloid (yohimbine), three to four times daily (Martindale and Reynolds 1996; Osol and Farrar 1955).

Editors' Notes

Yohimbe contains the compound yohimbine (~0.6–1.1%), from which the standardized drug yohimbine hydrochloride is derived (Betz et al. 1995; Chen et al. 2008). Yohimbine hydrochloride is a prescription drug used primarily in the treatment of male impotence, female hyposexual disorder, and sexual dysfunction caused by SSRI antidepressants, and to raise blood pressure (Tam et al. 2001).

Adverse Events and Side Effects

In especially high dosages, yohimbe can raise blood pressure and produce unpleasant digestive and central nervous system symptoms (Bruneton 1995; Osol and Farrar 1955; Roth et al. 1984).

A review of studies on the compound yohimbine indicated that doses up to 10 mg three times daily were generally well tolerated. Doses of 20 to 40 mg occasionally caused a small increase in blood pressure, and doses of 45.5 mg or more sometimes caused an increase in heart rate in normotensive subjects (Tam et al. 2001). The most commonly reported side effects of yohimbine are anxiety and increased urinary frequency (Tam et al. 2001).

Pharmacological Considerations

The compound yohimbine and prescription drug yohimbine hydrochloride are selective α_2-adrenergic receptor antagonists and produce dose-dependent increases in blood pressure with no effects on heart rate (Tam et al. 2001).

Several drug interactions are listed for the drug yohimbine hydrochloride. These include adrenergic or antiadrenergic drugs, antihypertensive agents, MAO inhibitors, any drugs that may increase blood pressure, and drugs metabolized by the isoenzyme CYP3A4 (Tam et al. 2001; Ulbricht and Basch 2005). Although the yohimbine content of yohimbe is relatively low, and the relevance of these suggested interactions to yohimbe use is not known, concomitant use of yohimbe with these drugs is cautioned.

Pregnancy and Lactation

While no information on the use of yohimbe in pregnancy was identified, animal studies suggest that the compound yohimbine has depressant effects on the uterus, while another reported that a single intravenous dose of yohimbine in rats did not alter the course of pregnancy. Until further research is undertaken, use in pregnancy should be under the supervision of a qualified healthcare practitioner (De Smet 1997).

No information on the safety of yohimbe during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established and use is not advised.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of suspected drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 63-year-old man experienced a hypertensive crisis (blood pressure 240/140 mm Hg; normal is 120/80 mm Hg) after taking one tablet of "yohimbine-containing herbal product" (no details on product or dose provided) daily for approximately 1 month (Ruck et al. 1999).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A review of human clinical studies on the prescription drug yohimbine hydrochloride indicated that the majority of studies show that the drug induces a dose-dependent, transient, moderate increase in blood pressure but has no effect on heart rate, as would be expected for a selective α_2-adrenergic receptor antagonist. The elevation of blood

pressure depends on dose and the hemodynamic baseline. Doses of 4 to 16.2 mg generally have no effect on blood pressure in normotensive adults, while doses of 20 to 40 mg cause a moderate increase in blood pressure and doses over 45 mg may increase mean arterial pressure and heart rate. Studies in hypotensive patients do not show any exaggerated effects (Tam et al. 2001). A dose of 15 to 20 mg of yohimbine may induce anxiety (De Smet and Smeets 1994).

A brief review of adverse effects of the compound yohimbine (De Smet and Smeets 1994) noted that doses of 5 to 15 mg have been associated with elicitation of manic symptoms in patients with bipolar disorder, lupus-like syndrome, and bronchospasm (Landis and Shore 1989; Price et al. 1984; Sandler and Aronson 1993).

Animal Pharmacological Studies

Administration of an aqueous extract of yohimbe at doses of 1 to 1000 ng/kg elicited a dose-dependent increase in mean blood pressure and an increase in medullary blood flow. Both the pressor action and renal medullary vasodilation were blocked by endothelin A and B receptor antagonists in combination. N^{ω}-nitro-L-arginine methyl ester also inhibited the increase in medullary blood flow induced by yohimbe. The authors of the study concluded that preliminary observations indicate that, in addition to the α-adrenergic antagonist actions that characterize yohimbine, yohimbe possesses endothelin-like actions and affects nitric oxide production in the renal circulation (Ajayi et al. 2003).

In male mice orally administered an aqueous extract of yohimbe at a dose of 188 to 750 mg/kg daily for 90 days, an increase in the weight of seminal vesicles and motility and count of spermatozoa was observed, although fertility was decreased. The data on biochemical parameters showed an increase of malondialdehyde and depletion of nonprotein thiols, proteins, RNA, and DNA in the testicular cells. When treated male mice were bred with untreated females, a decrease in pregnancies was observed in the females bred with treated males as compared to untreated control males (Al-Majed et al. 2006). In male mice orally administered an aqueous extract of yohimbe at doses of 750, 1500, or 3000 mg/kg daily for 7 days, significant changes in the frequency of micronuclei in femoral cells and induced spermatozoal abnormalities and testicular chromosomal aberrations were noted (Al-Yahya 2006).

In Vitro Pharmacological Studies

In isolated perfused kidney and in pressurized renal microvessels, treatment with an aqueous yohimbe extract demonstrated dose-dependent vasoconstrictor activity. Endothelin A (ETA) and B (ETB) receptor antagonists separately and significantly attenuated the renal vasoconstrictor actions of the extract (Ajayi et al. 2003).

IV. Pregnancy and Lactation

While no information on the use of yohimbe in pregnancy was identified, animal studies suggest that the compound yohimbine has depressant effects on the uterus. On the other hand, a single intravenous dose of yohimbine in rats did not alter the course of pregnancy. Until further research is undertaken, use in pregnancy should be under the supervision of a qualified healthcare practitioner (De Smet 1997).

No information on the safety of yohimbe in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound yohimbine in mice is 43 mg/kg after oral administration and 20 mg/kg after subcutaneous administration (RTECS 1987).

Pelargonium sidoides DC.

Geraniaceae

SCN: *Pelargonium sidoides*

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions, including anaphylactic reactions, to *Pelargonium sidoides* have been reported (de Boer et al. 2007; Timmer et al. 2008).

Pharmacological Considerations

An animal test indicated no interaction between *Pelargonium sidoides* and warfarin (Koch and Biber 2007). A human study indicated no interaction between *Pelargonium sidoides* and penicillin V (Roots et al. 2004).

A systematic review of clinical trials with *Pelargonium sidoides* in adults and children indicated that adverse events were rarely reported but were slightly more common with *Pelargonium sidoides* than control groups. Adverse events were generally gastrointestinal in nature, and none were severe (Timmer et al. 2008).

Pregnancy and Lactation

No information on the safety of *Pelargonium sidoides* in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No significant changes in serum levels of penicillin V were observed in healthy volunteers orally administered 30 drops of a *Pelargonium sidoides* extract three times daily and penicillin V at a dosage of 1,200,000 IU three times over 8 days (Roots et al. 2004).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No changes in the anticoagulant activity (thromboplastin time or partial thromboplastin time) of warfarin was observed in rats orally coadministered single doses of 500 mg/kg of *Pelargonium sidoides* and 0.05 mg/kg of warfarin or in rats orally administered 500 mg/kg daily for 2 weeks prior to administration of a single dose of warfarin. The authors noted that coumarin-type anticoagulants inhibit the synthesis of vitamin K-dependent coagulation factors via identical mechanisms in rats and humans, and have a similar pattern of metabolism in both species (Koch and Biber 2007).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of eight clinical trials with *Pelargonium sidoides* in adults and children with a total of 1565 patients indicated that adverse events were rarely reported but were slightly more common with *Pelargonium sidoides* than control groups. Adverse events were generally gastrointestinal in nature, including nausea, vomiting, diarrhea and heartburn, and there were also allergic skin reactions with pruritus and urticaria. None of the adverse events were severe (Timmer et al. 2008).

Case Reports of Adverse Events

Between 2002 and 2006, 34 cases of hypersensitivity reactions to *Pelargonium sidoides* were reported to the WHO Uppsala Monitoring Centre. The case reports are anonymous and heterogeneous and vary with regard to their source, documentation, and likely relationship to the drug administered. All original reports were requested and reviewed individually. In 10 reports, concomitant use of other drugs was noted, but none of the other medications were reported as being cosuspect. In 15 of the 34 reports, the description and timing of the event, notably the combination of a skin rash with itching, urticaria, angioedema, and/or systemic involvement were suggestive of a Coombs and Gell Type I acute hypersensitivity reaction. Two of the patients needed treatment for circulatory failure or anaphylactic shock. A skin prick test confirmed allergy to *Pelargonium sidoides* in a patient who experienced life-threatening acute urticaria and circulatory failure (de Boer et al. 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No effects on thromboplastin time, partial thromboplastin time, or thrombin time were observed in rats orally administered 10, 75, or 500 mg/kg of *Pelargonium sidoides* daily for 2 weeks. The authors noted that the coumarins identified in *Pelargonium sidoides* do not posses the structural characteristics needed for anticoagulant activity, and that it is unlikely that *Pelargonium sidoides* would increase the tendency for hemorrhage in persons taking this herb (Koch and Biber 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of *Pelargonium sidoides* during pregnancy or lactation was identified.

V. Toxicity Studies

A review of *Pelargonium sidoides* indicated that a full set of toxicity studies had been completed, including acute short-term toxicity studies in rats, 2-week dose finding and 13-week toxicity studies in dogs, the Ames test for mutagenicity, the chromosomal aberration test, the mouse micronucleus test, tumor promotion studies, immunotoxicity studies, and reproductive toxicology studies. The review reported that all studies yielded unremarkable results. Information on products and doses used were not reported in the review (Conrad et al. 2007).

Toxicity studies in rats and dogs indicated that the no-observed-adverse-effect level (NOAEL) is greater than 750 mg/kg (Loew et al. 2009).

Petroselinum crispum (Mill.) Nyman ex A.W. Hill — Apiaceae

SCN: parsley
Syn: *Petroselinum sativum* Hoffm.

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Chadha 1988; Watt and Breyer-Brandwijk 1962); *see* Appendix 2.

Editors' Note

Concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Parsley leaf contains furanocoumarins, compounds recognized to cause photodermatitis after topical exposure followed by exposure to sun or other sources of ultraviolet radiation (Beier and Ivie 1985; Zaynoun et al. 1985). Cases of dermatitis (phytophotodermatitis) have been reported in farm workers harvesting parsley (Lagey et al. 1995; Smith 1985). No cases of photosensitivity after ingestion of parsley were identified (Zaynoun et al. 1985).

Pharmacological Considerations

Animal studies and traditional use have indicated that parsley may modify glucose regulation (Ozsoy-Sacan et al. 2006; Tahraoui et al. 2007; Yanardağ et al. 2003). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Several references indicate that parsley has historically been used as an emmenagogue and abortifacient. None of the references, however, indicates whether the leaf, seed, or root were the parts typically used (Ciganda and Laborde 2003; Laborde and Ciganda 1998; Mele 1968; Riddle 1997). Apiol, a compound found primarily in the seed but also in lesser concentrations in the leaf and root of parsley, is reported as abortifacient in high doses (Wichtl 2004). Parsley essential oil and parsley seed should not be used during pregnancy, although moderate use of parsley leaf is thought to be safe.

No information on the safety of parsley leaf during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Phytophotodermatitis has been reported in persons commercially harvesting parsley (Lagey et al. 1995; Smith 1985).

Phytophotodermatitis was reported in pigs allowed to graze in a field of parsley. Vesicles with erythema and skin fissures were reported on the snouts, ears, and mammary gland teats (Griffiths and Douglas 2000). Acute photosensitivity was reported in a flock of ostriches exposed to parsley. Avian photosensitivity was confirmed by experimental reproduction of the typical lesions in ducks (Perelman and Kuttin 1988).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic rats orally administered 2 g/kg aqueous extract of parsley leaf daily for 28 days, a reduction in blood glucose, serum alkaline phosphatase activity, sialic acid, uric acid, potassium, and sodium levels, and liver lipid peroxidation and non-enzymatic glycosylation levels was observed, along with an increase in GSH levels (Ozsoy-Sacan et al. 2006). A reduction in blood glucose levels was observed in diabetic rats orally administered 2 g/kg of an aqueous extract of parsley leaf daily for 28 days (Yanardağ et al. 2003).

In Vitro Pharmacological Studies

Dose-dependent inhibition of thrombin- and ADP-induced platelet aggregation was observed in rat platelets treated with an aqueous extract of parsley leaf. The IC_{50} was approximately 6.5 mg/ml (Mekhfi et al. 2004).

A methanol extract of aerial parts of parsley exhibited estrogenic activity in human estrogen receptor-positive breast cancer cells (MCF-7), with activity reported as similar to that of soy isoflavones (Shimoda et al. 2000; Yoshikawa et al. 2000).

IV. Pregnancy and Lactation

Several references indicate that parsley has historically been used as an emmenagogue and abortifacient. None of the references, however, indicate whether the leaf, seed, or root were the parts typically used (Ciganda and Laborde 2003; Laborde and Ciganda 1998; Mele 1968; Riddle 1997). Apiol, a compound found in the seed but also in lesser amounts in parsley leaf and root, has been reported as an abortifacient in high doses (Wichtl 2004).

No information on the safety of parsley leaf during lactation was identified.

V. Toxicity Studies

Genotoxicity

No mutagenic activity of an ethanolic extract of parsley leaf was observed in the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA102 (Mahmoud et al. 1992).

Peumus boldus Molina — Monimiaceae

SCN: boldo

Part: leaf

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with obstructions of the bile duct (ESCOP 2003; Wichtl 2004) or serious liver conditions (Wichtl 2004).

In persons with gallstones, boldo should only be used under the supervision of a qualified practitioner (Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

An anaphylactic reaction to boldo has been reported (Monzon et al. 2004).

Hepatotoxicity was reported in an elderly man who had been taking an herbal stimulant laxative for many years. The hepatotoxicity appeared shortly after the laxative was reformulated to contain boldo (Piscaglia et al. 2005). An animal study reported a protective effect of boldo against chemical-induced liver injury (Lanhers et al. 1991).

Pharmacological Considerations

None known.

Pregnancy and Lactation

An animal study indicated no adverse effects of boldo on fetal development at doses up to 500 mg/kg. At higher doses (800 mg/kg), equivalent to a human dose of approximately 58 g, some incidences of malformations of fetuses were observed (Almeida et al. 2000).

No information on the safety of boldo during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An anaphylactic reaction to boldo has been reported (Monzon et al. 2004).

An 82-year-old man with fatty liver who regularly used laxatives (herbal and nonherbal) over the course of the prior 20 years developed hepatotoxicity with elevated levels of liver enzymes after the commercial herbal laxative that he had been taking changed formulas to include an extract of boldo as one of the ingredients in a multi-ingredient product. Liver enzymes returned to normal after cessation of the herbal laxative (Piscaglia et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound boldine prevented ferric ATP-induced inactivation of the drug-metabolizing isoenzyme CYP2E1 but not inactivation induced by carbon tetrachloride (Kringstein and Cederbaum 1995).

IV. Pregnancy and Lactation

In rats orally administered 500 or 800 mg/kg daily of either an ethanolic extract of boldo or the same doses of the compound boldine on days 1 to 5 or days 7 to 12 of pregnancy, an increase in the number of fetal resorptions was observed at the 800 mg/kg level for both products in both treatment periods, with no adverse effects observed at the 500 mg/kg dose in either treatment period with either product. A timing-dependent increase in fetal malformations was observed in 3% of animals administered 800 mg/kg boldine on days 7 to 12, while malformations were observed in 1.5% of animals administered the same dose of boldine on days 1 to 5 of pregnancy (Almeida et al. 2000).

No information on the safety of boldo during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No signs of toxicity were observed in rats orally administered 3 g/kg of a hydroalcoholic extract of boldo (Magistretti 1980). The oral LD_{50} of the compound boldine is 500 mg/kg in mice and 1000 mg/kg in guinea pigs (Kreitmair 1952).

Subchronic Toxicity

In rats orally administered 500 or 800 mg/kg of an ethanol extract of boldo or of the compound boldine daily for 90 days, increases in the levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and cholesterol were observed in the 800 mg/kg groups for both products after 30 or 60 days, but levels returned to normal after 90 days. A decrease in bilirubin was observed in the 800 mg/kg groups for both products. No changes in liver enzymes or cholesterol levels were observed in the 500 mg/kg group (Almeida et al. 2000).

Genotoxicity

No significant effects on sister-chromatid exchanges were observed in the mouse bone marrow micronucleus assay in animals orally administered 225, 450, or 900 mg/kg of the compound boldine (Tavares and Takahashi 1994). Similarly, no significant effects on sister-chromatid exchanges were observed in vitro on human peripheral blood lymphocytes treated with the compound boldine at concentrations of 10, 20, and 40 µg/ml (Tavares and Takahashi 1994).

No genotoxic activity of the compound boldine was observed in the SOS chromotest and Ames test for mutagenicity with *Salmonella typhimurium* strains TA100, TA98, and TA102 with or without metabolic activation. Boldine weakly induced mitotic recombinational events such as crossing-over and gene conversion in diploid yeast cells. Weak induction of cytoplasmic *petite* mutation in haploid yeast cells was also observed after treatment with boldine (Moreno et al. 1991).

Pfaffia paniculata (Mart.) Kuntze

Amaranthaceae

SCN: suma
OCN: pfaffia

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of suma in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Occupational asthma was reported in a worker routinely exposed to suma dust. Sensitivity to the dust was confirmed by immediate skin test reactivity, a positive bronchial challenge (immediate response), and the presence of specific IgE detected by ELISA (enzyme-linked immunosorbent assay) (Subiza et al. 1991).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats provided with suma extract (5 g suma/100 ml water, estimated dose per animal not reported) as the sole source of drinking water for 30 days, increases in plasma concentrations of estradiol-17β and progesterone in female mice, and of testosterone in male mice, were observed (Oshima and Gu 2003).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of suma during pregnancy or lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

No adverse effects were observed in mice orally administered 400 mg/kg of suma daily for 10 days. Observed parameters included alanine aminotransferase levels and histology of the liver, spleen, and kidneys (Matsuzaki et al. 2003).

In mice orally administered 250, 500, or 1000 mg/kg of a methanol extract of suma daily for 10 days, no histological changes were observed in liver, lung, brain, cerebellum, eye, or kidney tissues. An increase in body weight was observed at the 250 mg/kg dose, and a decrease in body weight was observed at the 1000 mg/kg dose as compared to control animals (Carneiro et al. 2007).

Genotoxicity

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA97a, TA98, TA100, and TA104, with or without metabolic activation, an aqueous extract (1:5) of suma exhibited some mutagenic activity in TA100 with and without metabolic activation but showed no mutagenic activity in other strains (Rivera et al. 1994).

Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Berberine (0.6–2.5% in *P. amurense*; 4.0–8.0% in *P. chinense*) (Bensky et al. 2004; De Smet 1992; Leung and Foster 1996); *see* Appendix 1.

Adverse Events and Side Effects

One case of rash associated with ingestion of phellodendron has been recorded (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of phellodendron in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

See Berberis vulgaris for information on the safety of the compound berberine in pregnancy and lactation.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

One case of rash associated with ingestion of phellodendron has been recorded (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Purified polysaccharide fractions of phellodendron extract demonstrated immunopotentiating activity in mice administered doses up to 100 mg/kg (Park et al. 2004). Immunesuppressant effects of the compounds magnoflorine and phellodendrine were observed after mice were intraperitoneally administered the compounds at doses of 5 to 20 mg/kg (Mori et al. 1994).

An ethanol extract of phellodendron did not show estrogenic activity in a recombinant yeast system (Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of phellodendron in pregnancy or lactation was identified, although texts on traditional Chinese medicine do not contraindicate phellodendron during pregnancy or lactation.

See Berberis vulgaris for information on the safety of the compound berberine in pregnancy and lactation.

V. Toxicity Studies

See Berberis vulgaris for toxicity studies on the compound berberine.

Acute Toxicity

The LD_{50} of intraperitoneally administered phellodendron extract in mice is 2.7 g/kg (Chen and Chen 2004).

SCN: American mistletoe
Syn: *Phoradendron flavescens* Nutt. ex Engelm.; *Phoradendron serotinum* (Raf.) M.C. Johnst.

OCN: oak mistletoe
Part: herb

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Hall et al. 1986; Krenzelok et al. 1997; Moore 1963; Spiller et al. 1996).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Ingestion of several leaves or berries generally caused gastrointestinal upset or did not produce symptoms. Intentional cases of self-poisoning, including one attempted abortion, have been fatal. Details on doses, preparations, and part used are lacking (Hall et al. 1986; Moore 1963; Spiller et al. 1996).

American mistletoe has been used as an emetic for ritual purposes. No information on doses used is available (Moerman 1998).

Pharmacological Considerations

None known.

Pregnancy and Lactation

A reference ethnobotanical text indicates that American mistletoe has been used as an abortifacient and as a "medicine for pregnant women" (Moerman 1998). In the early 1900s, American mistletoe was reportedly used to stimulate uterine contractions (Wood and LaWall 1926).

No information on the safety of American mistletoe during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Information on case reports of intentional or accidental exposure to mistletoe is primarily from reviews of information reported to poison control centers and generally lacks details on amount and part ingested and specific symptoms. A review of 92 cases of American mistletoe exposure indicated that 14 of these were symptomatic with 6 cases of gastrointestinal upset, 2 cases of mild drowsiness, and 1 case each of ataxia and seizure (in an infant). None of the cases included any arrhythmias or cardiovascular changes. Amount ingested ranged from one berry or leaf to more than five leaves or 20 berries. In cases of leaf ingestion (1–5 leaves), three of five patients reported gastrointestinal upset, while a patient who ate five leaves was asymptomatic. The case of seizure was reported in an infant with an unwitnessed exposure, found with both berries and leaves in the crib. A case of ingestion of 20 berries in a 2-year-old resulted in one episode of vomiting prior to administration of activated charcoal, with no subsequent symptoms (Spiller et al. 1996).

Of the approximately 1860 exposures to American mistletoe listed in reviews of information reported to poison control centers, none were fatal (Hall et al. 1986; Krenzelok et al. 1997; Spiller et al. 1996). Other literature reports two fatal cases. One patient drank an unspecified amount of American mistletoe (part not specified), although symptoms and events leading to the fatality were not available. A woman who ingested an unspecified amount of berries in an attempted abortion developed abdominal pain, hypoventilation, and died from cardiovascular collapse (Hall et al. 1986; Moore 1963).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Studies completed in the early 1900s indicated that injections of American mistletoe produced a hypertensive effect (Crawford 1911; Wood and LaWall 1926). An ethnobotanical text reports use of American mistletoe as a hypotensive (Moerman 1998).

The compounds viscotoxin A3 and phoratoxin produced reflex bradycardia, negative inotropic effect on the heart, and, in high doses, vasoconstriction of vessels in skin and skeletal muscle in cats (Rosell and Samuelsson 1966).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A reference ethnobotanical text indicates that American mistletoe has been used as an abortifacient and as a "medicine for pregnant women" (Moerman 1998). In the early

1900s, American mistletoe was reportedly used to stimulate uterine contractions (Wood and LaWall 1926).

No information on the safety of American mistletoe during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Martins et al. 1994; Rao and Alice 2001; Taylor 2005).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Srividya and Periwal 1995; Taylor 2005); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that phyllanthus may modify glucose regulation (Adeneye et al. 2006; Garg et al. 2008; Kumar et al. 1989; Okoli et al. 2010). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

An animal study indicated that *Phyllanthus amarus* inhibited the drug-metabolizing isoenzymes CYP1A1, CYP1A2, and CYP2B1/2 (Hari Kumar and Kuttan 2006).

Pregnancy and Lactation

An animal study demonstrated temporary antifertility effects of *Phyllanthus amarus* in female mice (Rao and Alice 2001). Some sources indicate that "large" doses of phyllanthus or *Phyllanthus amarus* have been used to produce abortion (Martins et al. 1994; Taylor 2005). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of *Phyllanthus amarus* during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of human clinical trials with *Phyllanthus amarus* indicated a lack of reported adverse events or side effects (Calixto et al. 1998).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A study in 40- to 60-year-old subjects indicated that, after 10 days of administration of *Phyllanthus amarus,* an increase in urinary volume and urinary sodium levels was observed, along with reductions in blood pressure (Srividya and Periwal 1995). A review of the study noted that the control group was not well matched to the study group, making the results difficult to interpret (Wright et al. 2007).

Animal Pharmacological Studies

In diabetic rats orally administered 200 or 400 mg/kg of a methanol extract of phyllanthus, a dose-dependent reduction in fasting blood glucose levels and postprandial glucose levels was observed (Okoli et al. 2010). Hypoglycemic activity was observed in diabetic rabbits orally administered 250 mg/kg of an alcohol extract of phyllanthus (Kumar et al. 1989).

Dose-dependent decreases in fasting blood glucose levels were observed in healthy mice orally administered 150, 300, or 600 mg/kg of aqueous leaf and seed extracts of *Phyllanthus amarus* (Adeneye et al. 2006).

In diabetic rats orally administered 500 mg/kg of water, ethanol, or petroleum ether extracts of phyllanthus daily for 21 days, a reduction in blood sugar levels was observed. The ethanol extract was the most active, followed by the aqueous extract and then the petroleum ether extract (Garg et al. 2008).

Inhibition of the drug-metabolizing isoenzymes CYP1A1, CYP1A2, and CYP2B1/2 was observed in rats orally administered 250 mg/kg of a methanol extract of *Phyllanthus amarus* (Hari Kumar and Kuttan 2006).

In Vitro Pharmacological Studies

The compound methyl brevifolincarboxylate, isolated from phyllanthus, inhibited platelet aggregation induced by ADP and collagen (Iizuka et al. 2007).

An ethanol extract of *Phyllanthus amarus* was found to induce the drug-metabolizing isoenzymes CYP3A5 and CYP3A7 (Agbonon et al. 2010).

IV. Pregnancy and Lactation

After being orally administered 100 mg/kg of an alcohol extract of *Phyllanthus amarus* daily for 30 days, female mice were unable to become pregnant. On withdrawal of *Phyllanthus amarus* for 45 days, mice were successfully mated. Reductions in 3β- and 17β-hydroxysteroid dehydrogenase (HSD) levels were noted as probably affecting hormonal conversions in the ovaries (Rao and Alice 2001).

No information on the safety of *Phyllanthus amarus* during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a methanol extract of phyllanthus orally administered to mice is 471 mg/kg (Okoli et al. 2010).

The LC_{50} of phyllanthus for brine shrimp is 581 µg/ml (Nascimenlo et al. 2008).

Short-Term Toxicity

In mice orally administered different fractions of *Phyllanthus amara* at doses of 400, 800, or 1600 mg/kg daily for 14 days, changes in serum biochemistry were observed. Changes included elevations in aspartate aminotransferase (AST) and alkaline phosphatase (ALP), with differing effects on protein, total bilirubin, creatinine, and other liver enzyme levels. The changes were generally not dose-dependent (Adedapo et al. 2005).

Phytolacca americana L.

Phytolaccaceae

P

SCN: poke
Syn: *Phytolacca decandra* L.
OCN: pokeweed

PN: *shang lu*
Part: root

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Brooke et al. 2001; De Smet 1993; French 1900; Frohne and Pfänder 2000; Lawrence 1990; Lewis and Smith 1979; Roberge et al. 1986).

Other Precautions

Topically applied poke root preparations are sometimes used to treat mastitis. To avoid exposure of nursing infants to poke, such preparations should not be applied on or near the nipple (Mills and Bone 2005).

Drug and Supplement Interactions

None known.

Editors' Notes

In the southern United States, the young shoots of poke are traditionally consumed as a green vegetable, after cooking in two to three changes of water. Poke berry is used medicinally. Even with proper preparation, both poke shoots and berries may cause diarrhea or nausea. Improperly prepared shoots and berries can cause gastroenteritis and other symptoms characteristic of poke poisoning.

Caution is advised for persons handling poke on a commercial scale. To avoid nausea, headaches, and diarrhea associated with dermal and respiratory exposure in commercial facilities, the use of gloves, a r espirator, and other appropriate protective gear is recommended.

Adverse Events and Side Effects

In overdose, poisoning with characteristic symptoms of gastroenteritis, severe abdominal cramping, nausea,

repeated vomiting, salivation, sweating, generalized weakness, and frothy diarrhea has been reported after ingestion of fresh or dried poke root (Brooke et al. 2001; French 1900; Lawrence 1990; Lewis and Smith 1979; Roberge et al. 1986).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Poke is contraindicated in pregnancy (Bensky et al. 2004). *Also see* Other Precautions for this entry.

No information on the safety of poke root during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and poke root is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Saponins isolated from poke root enhanced the absorption of heparin in mice by increasing the activated partial thromboplastin time (APTT) and thrombin time, modulating the transport of heparin via the intestinal route (Cho et al. 2003).

II. Adverse Events

Case Reports of Adverse Events

Poisonings with characteristic symptoms of gastroenteritis, severe abdominal cramping, nausea, repeated vomiting, salivation, sweating, generalized weakness, and frothy diarrhea have been reported after ingestion of fresh, dried, or cooked poke root, leaf, or stem (Callahan et al. 1981; Guthrie 1887; Hamilton et al. 1995; Jaeckle and Freemon 1981; Stein 1979). Poisoning from the berry was also reported (Edwards and Rodgers 1982; Mack 1982).

An 18-year-old man died after eating 4 to 5 inches of freshly dug poke root that he had mistaken for parsnip. He developed epigastric pain and vomiting 45 minutes after ingesting the root, collapsed, and was found to be in ventricular fibrillation 2 hours after ingestion. Treatment attempts were unsuccessful (Brooke et al. 2001). A 65-year-old woman experienced severe abdominal cramps, protracted vomiting, and profuse watery diarrhea after chewing on raw poke root (Roberge et al. 1986). After ingesting approximately 1 teaspoon of poke root that had been mistaken for horseradish root, a man experienced a warm sensation of the stomach followed by severe stomach cramps and vomiting, accompanied by a weak pulse and labored breathing, that continued for approximately 10 hours (French 1900). Grated fresh poke root, mistaken for horseradish, was served in a salad and as a side dish to 32 adults. All of the patients experienced symptoms ranging from dry throat to severe nausea, vomiting, and diarrhea, and most experienced extreme thirst. Symptoms began within 30 minutes to 6 hours after ingestion (Lawrence 1990).

A 43-year-old woman developed nausea, vomiting, cramping, generalized weakness, hematemesis, bloody diarrhea, and hypotension after ingesting one cup of poke root tea (~1 g of root) (Lewis and Smith 1979).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Pokeweed contains compounds known as pokeweed antiviral proteins, ribosome-inactivating proteins that are currently under investigation in human and animal studies for use in the treatment of HIV and in several cancers, notably leukemia, lymphoma, and Hodgkin's disease (Ek et al. 1998; Hertler and Frankel 1989; Irvin and Uckun 1992; Messinger et al. 1999; Uckun et al. 1999; Waurzyniak et al. 1997).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Mitogenic activity of lectin compounds from poke root has been observed (Barker et al. 1965; Farnes et al. 1964; Kino et al. 1995).

IV. Pregnancy and Lactation

Poke root is contraindicated in pregnancy (Bensky et al. 2004).

No adverse effects on reproductive ability, neonatal survival, or pup development were observed in mice that had been treated prior to pregnancy with an intravaginally administered gel formulation of pokeweed antiviral protein (PAP) at doses of 0, 0.025, 0.05, or 0.1% PAP, 5 days per week for 13 weeks (D'Cruz et al. 2004). No other information on the safety of poke during pregnancy was identified.

One reference text indicates, with no details, that preparations of poke root have been used as abortifacients (Watt and Breyer-Brandwijk 1962).

No information on the safety of poke root during lactation was identified.

V. Toxicity Studies

Acute Toxicity

Cats intraperitoneally administered 1 g/kg of a hydroalcoholic extract of poke root experienced discomfort, retching, emesis, weakness of the legs, stupor, profound narcosis, and death from respiratory failure (Golstein et al. 1973).

No acute toxic effects were observed in rats intraperitoneally administered 3.6 ml/kg of ether, chloroform, water, or Prollius fluid extract of poke root. The extracts were prepared such that 1 ml was equivalent to 1 g of dried poke root. In rats administered an alcohol extract at the same dose, catharsis and uresis occurred, followed by drowsiness, labored breathing, paralysis of the lower limbs, failure of respiration, and death (Ahmed et al. 1949).

The LD_{50} of intraperitoneally administered saponins from poke root is 181 mg/kg in mice and 208 mg/kg in rats (Woo et al. 1976).

Intraperitoneal administration of 0.25 ml of a saline suspension of poke root was lethal to mice (animal weight not specified) (Macht 1937). The lethal dose of the same extract in rats and guinea pigs was 5 ml/kg (Macht 1937).

Subchronic Toxicity

No adverse effects on blood chemistry, histology, or reproductive performance were observed in a subchronic and reproductive toxicity screening of an intravaginally administered gel formulation of pokeweed antiviral protein (PAP) in mice. Animals were administered gel containing 0, 0.025, 0.05, or 0.1% PAP, 5 days a week for 13 weeks (D'Cruz et al. 2004).

Picrasma excelsa (Sw.) Planch. — Simaroubaceae

SCN: Jamaica quassia
Syn: *Quassia excelsa* Sw.

OCN: bitterwood
Part: bark, root, wood

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bradley 1992; List and Hörhammer 1973).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

As infusion (tea) of 0.5 g (~0.25 tsp) of the bark 30 minutes prior to meals (Wichtl 2004), or decoction of 1–2 g d aily (Merck 1930).

Editors' Note

Jamaica quassia should not be confused with quassia (*Quassia amara*) or senna (*Senna* spp., formerly classified as *Cassia* spp.).

Adverse Events and Side Effects

Consumption of large amounts of Jamaica quassia can irritate the mucous membrane of the stomach and lead to vomiting (Bradley 1992; List and Hörhammer 1973; Wichtl 2004; Wood and LaWall 1918).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Several herbal reference texts indicate that Jamaica quassia should not be used during pregnancy (Bradley 1992; List and Hörhammer 1973).

No information on the safety of Jamaica quassia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An Eclectic medical text reports that a s trong infusion, administered as an enema to a 4-year-old, caused collapse and related symptoms. No further details on the dose or the relevant medical history were provided (Felter and Lloyd 1898). The relevance of this information to oral use at standard therapeutic levels is not known.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats treated with a tumor-initiating agent (diethylnitrosamine) 2 weeks prior to being fed diets containing 500, 5000, or 30,000 ppm Jamaica quassia for 6 weeks, an increase in tumor promotion was observed in animals fed the 30,000 ppm dose. In this group, the numbers and areas of glutathione S-transferase placental form-positive liver cell foci were increased. Sodium phenobarbital, a representative tumor promoter, was used as a positive control (Woo et al. 2007).

In Vitro Pharmacological Studies

Moderate inhibition of the drug-metabolizing isoenzyme CYP1A1 was observed after treatment with a Jamaica quassia extract or the compounds quassin and neoquassin. IC_{50} values were 9.2 µ*M* for quassin and 11.9 µ*M* for neoquassin. No significant activity was observed on CYP2D6, CYP3A4, CYP1A2, CYP2C9, or CYP2C19 (Shields et al. 2009).

IV. Pregnancy and Lactation

Several herbal reference texts indicate that Jamaica quassia should not be used during pregnancy (Bradley 1992; List and Hörhammer 1973).

No information on the safety of Jamaica quassia during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

SCN: jaborandi
OCN: Maranhao jaborandi

Pilocarpus pennatifolius **Lem.**
SCN: jaborandi
OCN: Paraguay jaborandi
Part: leaf

Quick Reference Summary

Safety Class: 3
Interaction Class: B

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Felter and Lloyd 1898; Wiseman and Faulds 1995).

Other Precautions

None known.

Drug and Supplement Interactions

Interaction considerations are the same as those for the drug pilocarpine.

Editors' Notes

Jaborandi is the source of the drug pilocarpine and typically contains 0.002 to 0.25% pilocarpine (Avancini et al. 2003; Sandhu et al. 2006). The drug pilocarpine is used orally and topically. For oral use, pilocarpine is typically prescribed in doses of 5 or 10 mg (Wiseman and Faulds 1995).

Adverse Events and Side Effects

Ingestion of jaborandi typically causes abundant perspiration and salivation. Jaborandi may also cause nausea, vomiting, vertigo, hiccup, diarrhea, heaviness of the head, and contraction of the pupils. Large doses of jaborandi may cause temporary impairment of vision (Felter and Lloyd 1898; Wood and LaWall 1918).

Pharmacological Considerations

None known.

Pregnancy and Lactation

An early study reported that the compound pilocarpine was associated with adverse effects on fetal development (Laundauer 1956). Pilocarpine is listed in FDA pregnancy category C, which states, "Animal reproduction studies have shown an adverse effect on the fetus, and there are no adequate and well-controlled studies in humans, but potential benefits may warrant use of the drug in pregnant women despite potential risks."

No information on the safety of jaborandi during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and jaborandi is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Pimenta dioica (L.) Merr. — Myrtaceae

SCN: allspice
Syn: *Eugenia pimenta* DC.; *Pimenta officinalis* Lindl.

OCN: Jamaica pepper; myrtle pepper; pimenta
Part: unripe fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Occupational allergic contact dermatitis from allspice, confirmed by patch testing, was reported in a food service worker (Kanerva et al. 1996).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of allspice in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Among 1000 food service workers that visited a dermatological clinic between 1991 and 1995, five had occupational allergic contact dermatitis from spices. Allspice was confirmed as one of the causative spices (Kanerva et al. 1996).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In an estrogen receptor expression assay and in reporter and endogenous gene assays, an extract of allspice exhibited estrogenic activity which was inhibited by the addition of an estrogen antagonist (Doyle et al. 2009).

A hydromethanolic extract of allspice enhanced CYP3A4 promoter activity but had no effect on the pregnane-X receptor (Kluth et al. 2007).

IV. Pregnancy and Lactation

No information on the safety of allspice during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in mice orally administered up to 7.5 g/kg of an aqueous suspension of allspice (Al-Rehaily et al. 2002).

Genotoxicity

Allspice oleoresin gave a positive result in the DNA-repair test but not in the Ames *Salmonella* reversion assay or the *Bacillus subtilis rec* assay (Sekizawa and Shibamoto 1982). Antimutagenicity via antioxidant activity of allspice was observed in the DPPH radical reduction assay and lipid peroxidation inhibition testing (Ramos et al. 2003).

Pimpinella anisum L. — Apiaceae

SCN: anise
Syn: *Anisum vulgare* Gaertn.

Part: fruit (commonly known as "seed")

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Alkenylbenzenes (estragole as 1–3% of essential oil) (De Vincenzi et al. 2000; Wichtl 2004); *see* Appendix 1.

Adverse Events and Side Effects

Allergic reactions to anise have been reported (Fraj et al. 1996; Garcia-Gonzalez et al. 2002; Gazquez Garcia et al. 2007; Wichtl 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

The European Scientific Cooperative on Phytotherapy indicates that infusions of anise may be used in pregnancy but that alcohol extracts or the essential oil should not be used (ESCOP 2003).

An animal study suggested some anti-implantation activity of anise, but no adverse effects on fetal development (Dhar 1995).

No information on the safety of anise during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

P

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to anise have been reported (Wichtl 2004). A case of occupational allergy to anise associated with rhinoconjunctivitis and gastrointestinal symptoms was reported and confirmed by skin prick testing. Skin

prick tests showed a positive immediate response to anise, asparagus, caraway, coriander, cumin, dill, and fennel extracts, and an intense late response to anise. Skin prick tests to celery, carrot, birch pollen, and mugwort pollen extracts were negative (Garcia-Gonzalez et al. 2002).

Occupational asthma induced by anise was observed in a butcher. Skin prick testing confirmed anise as the causative agent (Fraj et al. 1996). A case of anise-induced tongue angioedema was reported and confirmed by skin prick testing (Gazquez Garcia et al. 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In a study in mice intraperitoneally administered 0.125 to 0.5 ml/kg of anise essential oil, assays with GABA receptor agonists indicated that anise essential oil activated the GABAergic mechanism that depends on the GABA-A receptor subtype (Sahraei et al. 2002).

In Vitro Pharmacological Studies

In estrogen receptor-positive human breast cancer cells (MCF-7), antiestrogenic activity of an aqueous extract of anise was observed (Kassi et al. 2004). Some estrogenic activity of anise essential oil was observed in a yeast estrogen screening assay (Tabanca et al. 2004).

IV. Pregnancy and Lactation

Anise is used in herbal formulas for women in the first trimester of pregnancy (Noe et al. 2002).

Anise is one of 39 species listed as ingredients in 6 traditional abortifacient formulas. These species include commonly consumed nontoxic plants (e.g., kidney bean and pomegranate) as well as with other plants recognized to be toxic or inappropriate for use in pregnancy (e.g., pennyroyal). Parts and doses of botanicals used in these formulas were not listed (Madari and Jacobs 2004).

In rats orally administered 50, 70, or 80 mg/kg of the compound *trans*-anethole on days 1 to 10 of pregnancy, inhibition of implantation was 33, 66, and 100%, respectively (Dhar 1995).

In rats administered 80 mg/kg *trans*-anethole on days 1 to 2 of pregnancy, normal implantation and delivery occurred. After administration of *trans*-anethole on days 3 to 5, implantation was completely inhibited; and on days 6 to 10, three of five rats failed to deliver at term. No gross malformations were observed in any of the groups (Dhar 1995).

No information on the safety of anise during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered anise essential oil in rats is reported as 2.25 g/kg and 2.7 g/kg (Opdyke 1979; von Skramlik 1959).

The LD_{50} of orally administered *trans*-anethole is 3.41 g/kg in mice, 2.65 g/kg in rats, and 2.16 g/kg in guinea pigs (Lin 1991).

Genotoxicity

No mutagenic activity of an aqueous extract of anise was observed in the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98, TA100, and TA102 (Al-Bataina et al. 2003).

A dried ethanolic extract of anise exhibited mutagenic activity at high concentrations (5 mg/plate) in a streptomycin-dependent strain of *Salmonella typhimurium* TA98 (Shashkanth and Hosono 1986).

No mutagenic activity of an anise ethanol extract was observed at concentrations up to 0.1 mg/ml in chromosomal aberration tests using a Chinese hamster fibroblast cell line (Ishidate et al. 1984).

Pinellia ternata (Thunb.) Makino ex Breit. — Araceae

SCN: pinellia
PN: *ban xia* (rhizome); *jiang ban xia* (ginger-cured rhizome); *fa ban xia* (licorice-cured rhizome)

Part: prepared rhizome

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 3 to 10 g as a decoction (up to 60 g under professional supervision) (Bensky et al. 2004; Chen and Chen 2004).

Editors' Notes

Unprocessed pinellia is generally considered toxic and inappropriate for internal use. Proper processing reduces toxicity (Bensky et al. 2004; PPRC 2005; Wu et al. 1999, 2007). A review of research on pinellia processing and toxicity indicated that if unprocessed pinellia is cooked for an extended period of time, or if unprocessed pinellia is in a formula with fresh ginger, the toxicity is minimized (Chen and Chen 2004). The prepared rhizome, that has been processed to reduce toxicity, is the subject of this entry.

The unprocessed tuber of *Pinellia ternata* has been reported to contain ephedrine at a concentration of 0.002 to 0.003% (Oshio et al. 1978; Wu et al. 1996). This low concentration of ephedrine is further reduced by several traditional processing steps (Bensky et al. 2004; PPRC 2005; Wu et al. 1996, 1999, 2007). The U.S. Food and Drug Administration declared in 2004 that dietary supplements containing ephedrine alkaloids are adulterated, and identified *Pinellia ternata* as containing ephedrine alkaloids (FDA 2004). In establishing this ban for ephedrine in dietary supplements, however, the FDA stated that it does not apply to "traditional Asian medicine" that contains ephedrine alkaloids (FDA 2004).

Pinellia is sometimes adulterated with *Typhonium* spp. including *T. flagelliforme*, *T. divaricatum*, and *T. trilobatum* (Bensky et al. 2004).

Adverse Events and Side Effects

Ingestion of fresh pinellia or overdosage of processed pinellia can cause severe irritation of the mucosa of the mouth, pharynx, and gastrointestinal tract (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

A text on traditional Chinese herbs indicates that pinellia may act synergistically with barbiturates. No further details were reported (Bensky et al. 2004).

Pregnancy and Lactation

A text on traditional Chinese medicine reports that while a classic text on Chinese medicine indicates that pinellia may cause miscarriage, modern practitioners commonly use

pinellia to treat nausea and vomiting during pregnancy (Chen and Chen 2004).

Some effects on development were observed in the fetuses of rats administered high doses (2 g/kg) of pinellia during pregnancy (Shin et al. 2007). The compound pinellin has demonstrated anti-implantation activity in rabbits (dose unspecified in available translation) (Chen et al. 1984).

The compound pinellin has been shown to have abortifacient activity (Lu et al. 1986).

No information on the safety of pinellia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Occupational asthma and rhinitis have been reported and confirmed by skin prick testing. In one case, the patient also tested positively to *Dioscorea batatas*, and in a second case, the patient tested positive to unspecified species of *Dioscorea* and *Cnidium* (Lee et al. 2001; Park et al. 1994).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No estrogenic activity of an ethanol extract of pinellia was observed in a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation

In pregnant rats orally administered 20, 200, or 2000 mg/kg of pinellia extract on days 6 to 15 of pregnancy, some adverse effects on development were observed in the 2000 mg/kg dose group. In that group, the rates of ureteric dilatation and renal malposition in fetuses were increased. Rates of skeletal malformations and variations of fetuses were also increased in the high-dose group, including asymmetric alignment of ribs, dumbbell ossification of thoracic centrum, and 14th supernumerary ribs. No adverse effects on the mothers were observed at any dose. Observed parameters in mothers included clinical signs, body weight gain, feed and water consumption, fertility parameters, and placental and organ weights (Shin et al. 2007).

The compound pinellin has demonstrated anti-implantation activity in rabbits. Doses and route of administration used were not listed in available English language translations (Chen et al. 1984).

A reference text on traditional Chinese medicine reports that while a classic text on Chinese medicine indicates that pinellia may cause miscarriage, modern practitioners commonly use pinellia to treat nausea and vomiting during pregnancy (Chen and Chen 2004).

The compound pinellin has been shown to have abortifacient activity (Lu et al. 1986).

No information on the safety of pinellia during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of unprocessed pinellia in mice is 0.325 g/kg after intraperitoneal administration and 42.7 g/kg after oral administration. No signs of toxicity were reported in mice orally administered 16 g/kg of processed pinellia every 3 hours for five doses (Chen and Chen 2004).

Piper cubeba L. f.

Piperaceae

SCN: cubeb
AN: *kankola*

Part: unripe fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with kidney inflammation (Felter and Lloyd 1898).

Drug and Supplement Interactions

See Pharmacological Considerations.

Notice

Piperine (Parmar et al. 1997); *see* Appendix 3.

Adverse Events and Side Effects

An Eclectic medical text indicated that, in "large" doses (standard dose listed as 0.6–4.0 g), cubeb occasionally causes nausea and vomiting, burning pain, griping, or even purging. Cubeb has been associated with skin rashes in some individuals (Felter and Lloyd 1898; Wood and LaWall 1926).

Pharmacological Considerations

The compound piperine has been shown to enhance the bioavailability of certain drugs (Hu et al. 2005; Srinivasan 2007; Wattanathorn et al. 2008).

Pregnancy and Lactation

No information on the safety of cubeb in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An Eclectic medical text indicated that, in "large" doses (standard dose listed as 0.6–4.0 g), cubeb occasionally causes nausea and vomiting, burning pain, griping, or even purging. Cubeb has been associated with skin rashes in some individuals (Felter and Lloyd 1898; Wood and LaWall 1926).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The ethyl acetate fraction of an aqueous extract of cubeb inhibited the drug-metabolizing isoenzyme CYP3A4 (Usia et al. 2005b, 2006). Subsequent testing indicated that methylenedioxyphenyl lignan compounds produced mechanism-based inhibition of CYP3A4 (Usia et al. 2005a).

No significant effects of a methanol extract of cubeb were observed on the drug-metabolizing isoenzymes CYP2D6 and CYP3A4 in human liver microsomes (Subehan et al. 2006).

An extract of cubeb demonstrated antagonistic activity in recombinant wild-type androgen receptors (Yam et al. 2008a).

An ethanolic extract of cubeb significantly inhibited growth induced by β-estradiol in estrogen receptor-positive human breast cancer cells (MCF-7) (Yam et al. 2008b).

IV. Pregnancy and Lactation

No information on the safety of cubeb during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Piper longum L.

Piperaceae

SCN: long pepper
AN: *pippali*
PN: *bi ba* (fruit)

OCN: jaborandi pepper
Part: fruit

Quick Reference Summary

Safety Class: 2b
Interaction Class: B

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Adhikary et al. 1990; Daware et al. 2000; Kholkute et al. 1979; Lakshmi et al. 2006).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Notice

Piperine (4–5%) (Tapadiya et al. 2009); *see* Appendix 3.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

The compound piperine has been shown to enhance the bioavailability of certain drugs (Hu et al. 2005; Srinivasan 2007; Wattanathorn et al. 2008). Some studies have indicated

that coadministration of piperine with certain drugs allowed for a reduction in the required dose of the drugs (Hu et al. 2005; Srinivasan 2007; Wattanathorn et al. 2008).

Pregnancy and Lactation

Animal studies of long pepper and the compound piperine have indicated some contraceptive activity of these materials (Adhikary et al. 1990; Daware et al. 2000; Kholkute et al. 1979; Lakshmi et al. 2006). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Another animal study indicated that piperine improved fertilization rates in artificially inseminated animals (Piyachaturawat and Pholpramool 1997).

No information on the safety of long pepper during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

In chickens orally administered 10 mg/kg of the drug oxytetracycline with or without pretreatment with an extract of long pepper (equivalent to 15 mg/kg of piperine) daily for 7 days, an increase in bioavailability and decrease in the elimination rate of oxytetracycline was observed. Long pepper reduced the required loading and maintenance doses by 33.3 and 39%, respectively (Singh et al. 2005).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic rats orally administered 300 mg/kg of an ethanol extract of long pepper daily for 45 days, a reduction in blood glucose levels was observed (Manoharan et al. 2007).

In Vitro Pharmacological Studies

Extracts of long pepper concentration-dependently inhibited platelet aggregation induced by U-46619 (a thromboxane A_2 receptor agonist). An ethanol extract was found to be more effective than a butanol extract (Iwashita et al. 2007b).

The compound piperlongumine concentration-dependently inhibited platelet aggregation induced by U-46619 but only slightly inhibited thrombin-induced aggregation (Iwashita et al. 2007a). The compounds piperine, pipernonaline, piperoctadecalidine, and piperlongumine concentration-dependently inhibited platelet aggregation induced by collagen, arachidonic acid, and platelet-activating factor, but not aggregation induced by thrombin. Piperlongumine was the most active of the compounds tested (Park et al. 2007).

The compound piperine was found to have MAO-inhibiting activity with inhibition of MAO-B greater than that of MAO-A (Lee et al. 2005).

IV. Pregnancy and Lactation

Animal studies have indicated that long pepper and compounds from long pepper have contraceptive activity (Adhikary et al. 1990; Kholkute et al. 1979; Lakshmi et al. 2006).

In mice orally administered 10 or 20 mg/kg of the compound piperine daily for 14 days, an increase in the period of the diestrous phase was observed, resulting in decreased mating performance and fertility. Postpartum litter growth was not affected by the piperine treatment. Considerable anti-implantation activity was recorded after 5 days postmating oral treatment with piperine (Daware et al. 2000).

In female hamsters orally administered 50 or 100 mg/kg of the compound piperine on days 1 through 4 of the estrus cycle, after superovulation and artificial insemination, the percent fertilization was significantly enhanced in the treated group (Piyachaturawat and Pholpramool 1997).

No information on the safety of long pepper during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in mice orally administered 0.5, 1, or 3 g/kg of an ethanol extract of long pepper (Shah et al. 1998).

In the brine shrimp lethality assay, the LC_{50} of an ethanol extract of long pepper is 6.9 µg/ml (Padmaja et al. 2002).

The LD_{50} of the compound piperine in male mice is 15.1 mg/kg after intravenous administration, 43 mg/kg after intraperitoneal administration, 200 mg/kg after subcutaneous administration, and 400 mg/kg after intramuscular administration. In female rats, the LD_{50} of piperine is 33.5 mg/kg after intraperitoneal administration (Piyachaturawat et al. 1983; Srinivasan 2007).

Short-Term Toxicity

In male rats orally administered 5 or 10 mg/kg of the compound piperine daily for 30 days, a reduction in the weight of the testes was observed at the 10 mg/kg dose. At the 5 mg/kg dose level, histological studies revealed partial degeneration of germ cell types, whereas at the 10 mg/kg dose, changes in the seminiferous tubules, Leydig cells, spermatocytes, and spermatids were observed (Malini et al. 1999).

Subchronic Toxicity

In mice orally administered 100 mg/kg of an ethanol extract of long pepper daily for 90 days, an increase in the weight of the lungs and spleen was observed. No external morphological, hematological, or spermatogenic changes or changes in body weight or other vital organ weights were recorded (Shah et al. 1998).

Piper methysticum G. Forst.

Piperaceae

SCN: kava
OCN: awa; kava kava; kava pepper; yangona

Part: rhizome, root

Quick Reference Summary

Safety Class: 2b, 2c
Interaction Class: B

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner.

Other Precautions

Concomitant use of alcohol and large doses of kava (1 g/kg) may produce additive inhibition of cognitive and motor function induced by alcohol (Foo and Lemon 1997).

Kava has been associated with a potential risk of rare but severe liver injury (Schmidt et al. 2005). Patients who have or have had liver problems, frequently use alcohol, or are taking any medications, especially those metabolized by the liver, are advised to consult with a healthcare professional prior to use.

Drug and Supplement Interactions

Kava may inhibit the drug-metabolizing isoenzyme CYP2E1, resulting in a slowed clearance and increased plasma levels of drugs metabolized by this enzyme (Gurley et al. 2005). *See* Cytochrome P450 in Appendix 3.

Editors' Note

The American Herbal Products Association has established a trade requirement (AHPA 2011) that products containing kava bear the following or significantly similar statement:

> Caution: U.S. FDA advises that a potential risk of rare, but severe, liver injury may be associated with kava-containing dietary supplements. Ask a healthcare professional before use if you have or have had liver problems, frequently use alcoholic beverages, or are taking any medication. Stop use and see a doctor if you develop symptoms that may signal liver problems (e.g., unexplained fatigue, abdominal pain, loss of appetite, fever, vomiting, dark urine, pale stools, yellow eyes or skin). Not for use by persons under 18 years of age, or by pregnant or breastfeeding women. Not for use with alcoholic beverages. Excessive use, or use with products that cause drowsiness, may impair your ability to operate a vehicle or dangerous equipment.

Standard Dose

The standard dose is 2 to 4 g as a decoction, up to three times daily (BHMA 1983); 60–600 mg kavalactones (kavapyrones) per day (Blumenthal and Busse 1998; Dentali 1997).

Adverse Events and Side Effects

Kava is reported as being generally well tolerated in clinical trials (Pittler and Ernst 2003). Cases of liver toxicity have been reported in association with kava use (Brauer et al. 2001, 2003; Bujanda et al. 2002; Campo et al. 2002; Gow et al. 2003; Humberston et al. 2003; Musch et al. 2006; Russmann et al. 2003; Sass et al. 2001; Schmidt et al. 2005; Stoller 2000). These reports have been subject to critical analysis by a number of organizations and individuals (Schmidt 2007; Schmidt et al. 2005; TMEC 2002; Waller 2002). A review of liver toxicity cases indicated that the reported cases represented unpredictable reactions, and that cases were best characterized as idiosyncratic reactions of the metabolic type (Teschke et al. 2008). Of 82 cases of liver toxicity reported through 2002, one case was assessed as being "certain" or "probable" by multiple reviewers, with up to 12 others being noted as "probable" (BfArM 2002; Schmidt 2007)

Excessive or extended consumption of kava is reported to cause a scaly, yellowing skin condition that resolves when use is discontinued (Blumenthal and Busse 1998; Bone 1993/1994; Grace 2005; Jappe et al. 1998; Lewin 1931; Norton and Ruze 1994; Pfeiffer et al. 1967; Schmidt and Boehncke 2000).

Pharmacological Considerations

Human studies have provided conflicting information on the effects of kava on the drug-metabolizing isoenzyme CYP1A2, with one study showing inhibition of CYP1A2 in heavy kava users (Russmann et al. 2005) and another study showing no effect (Gurley et al. 2005). Kava showed inhibition of CYP2E1 but had no effect on CYP2D6 or CYP3A4/5 (Gurley et al. 2005, 2008a, 2008b).

A human study showed no interaction between digoxin and kava (Gurley et al. 2007).

Trials with concomitantly administered bromazepam indicated no additive adverse effects of kava on motor or cognitive functioning (Herberg 1996). Trials with concomitantly administered alcohol gave mixed results on the additive adverse effects of kava on cognitive functioning, with one study showing a reduction in visual-motor function after high doses of kava and another study showing no additive effects after low doses of kava (Foo and Lemon 1997; Herberg 1993).

Pregnancy and Lactation

Animal studies have indicated no adverse effects of several compounds from kava administered during pregnancy (Hansel and Woelk 1994), and no information on the safety of kava during lactation was identified in the scientific or traditional literature.

In this work, the contraindications for use in pregnancy and lactation are based on concerns regarding the cases of hepatotoxicity reported in association with kava use, as the implications of these case reports and possible mechanisms of hepatotoxicity have yet to be fully understood.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

A study of bromazepam (9 mg/day) and kava (400 mg/day standardized extract) indicated that taking the two products together did not produce significant differences in well-being or mental performance as compared with bromazepam alone (Herberg 1996). In a study of ethanol (0.05 blood alcohol concentration) and kava (210 mg/

day), no additive effects of the kava were observed on safety-related parameters as compared with alcohol alone (Herberg 1993). Another study of alcohol (0.05 blood alcohol concentration) and a relatively high dose of kava (1 g/kg) showed that kava and alcohol taken together produced more significant decreases in cognitive and visual-motor functions than alcohol alone (Foo and Lemon 1997).

A trial of single doses of digoxin (0.5 mg) before and after 14 days supplementation with kava (1227 mg/day) indicated no statistically significant effects of kava on digoxin pharmacokinetics (Gurley et al. 2007).

Case Reports of Suspected Drug or Supplement Interactions

A 44-year-old man taking kava, valerian, paroxetine, and pantoprazole was reported to have a fever, malaise, headache, and confusion (Rubin et al. 2006).

A 54-year-old man taking kava, alprazolam, cimetidine, and terazosin was reported to have lethargy and disorientation (Almeida and Grimsley 1996). Cimetidine has been shown to slow the metabolism of alprazolam, a benzodiazepine that may cause sleepiness, dizziness, and confusion if overdosed (Greenblatt and Wright 1993).

A 52-year-old woman on long-term treatment with benzodiazepines experienced confusion and auditory and visual hallucinations within 2 days of starting to take kava (Cartledge and Rutherford 2001). Several case reports of possible dopamine antagonism suggest that kava may interact with central dopamine agonists or antagonists (Mills and Bone 2005; Schelosky et al. 1995).

Animal Trials of Drug or Supplement Interactions

A study of ethanol (3.5 g/kg) and kava (200 mg/kg) in mice showed that the two products taken together produced a significant increase in sleeping time compared to ethanol alone (Jamieson and Duffield 1990). The applicability of those animal data to humans is unknown.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a meta-analysis of 12 double-blind, randomized controlled trials (n = 700), adverse events associated with kava use were reported as being mild, transient, and infrequent (Pittler and Ernst 2003). Doses of up to 6 g/day of kava caused yellowing of the skin in some individuals after several weeks of administration (Pfeiffer et al. 1967).

Case Reports of Adverse Events

A number of case reports of hepatotoxicity in association with kava use have been reported in the medical literature and to pharmacovigilance centers. Reports include cases of fulminant liver failure, severe liver damage, necrotizing hepatitis, cholestatic hepatitis, liver cell impairment, and an increase in liver enzymes (Brauer et al. 2001, 2003; Bujanda et al. 2002; Campo et al. 2002; Gow et al. 2003; Humberston et al. 2003; Musch et al. 2006; Russmann et al. 2003; Sass et al. 2001; Schmidt et al. 2005; Stoller 2000). These reports have been subject to critical analysis by a number of organizations and individuals (Schmidt 2007; Schmidt et al. 2005; TMEC 2002; Waller 2002). Details of case reports recorded by pharmacovigilance centers can be found in reviews by Schmidt et al. (2005) and Schmidt (2007). The analyses include assessments of causality for the case reports, with reviewers using assessment schemes that generally categorize causality of the adverse event as certain, probable, possible, unlikely, conditional, or unassessable in relation to kava ingestion (Schmidt et al. 2005; Teschke et al. 2008). Reviewers have included varying numbers of case reports in reviews, with some looking only at cases reported to German pharmacovigilance centers and others examining all known cases. German and Swiss cases of hepatotoxicity assessed as "probable" range from 0% (Waller 2002) to 42% (BfArM 2002) of cases analyzed. Information was noted as insufficient to assess causality in a number of the case reports and, in multiple cases, patients were taking other medications that have been associated with liver damage (BfArM 2002; Schmidt et al. 2005; TMEC 2002; Waller 2002). Of the 82 cases of hepatotoxicity reported through 2002, one case was assessed as being "certain" or "probable" by multiple reviewers with up to 12 others being noted as "probable" (BfArM 200; Schmidt 2007).

Based on sales data for 2000 to 2002, the total number of daily doses of kava in Germany has been estimated at 70 million annually. With 12 cases of hepatotoxicity reported in Germany and Switzerland assessed by some reviewers as probable (BfArM 2002), the incidence of reported adverse events is 0.24 per 1 million daily doses (Schmidt et al. 2005).

Traditional daily use of aqueous extracts of kava in the Pacific Islands has not been associated with any increased incidence of hepatotoxicity (Schmidt et al. 2005). Hypotheses for causes of hepatotoxicity reported outside of, but not in, Pacific Island populations include differences in solvent extraction (acetone and ethanol extracts versus traditional aqueous preparations), improper plant parts being included in manufactured products (i.e., the inclusion of stem peelings that may contain toxic compounds), increased levels of other hepatotoxic substances in populations taking manufactured kava extracts (Currie and Clough 2003), and genetic differences (Russmann et al. 2001). A review of hepatotoxicity cases indicated that cases were reported after the use of aqueous, ethanolic, and acetonic kava extracts, suggesting a lack of association between the solvent and hepatotoxicity (Teschke et al. 2009).

Use of kava in Fijian and Australian aboriginal communities has been recorded to range from 100 to 500 g, and occasionally to 900 g, per week. Adverse reactions associated with kava use in these communities include scaly skin, weight loss, headache, and decreases in blood lymphocytes (Schmidt et

al. 2005). A condition known as kava dermopathy has been reported in heavy users of kava, with symptoms including yellow, scaly, leprosy-like eruptions of the skin and inflammation of the eyes (Norton and Ruze 1994). This condition is reported to resolve on discontinuation of kava (Blumenthal and Busse 1998; Bone 1993/1994; Lewin 1931).

Kava use has been associated with several other types of adverse reactions. Persistent Parkinsonism was reported in a 54-year-old woman with a family history of essential tremors after 10 days of kava use (65 mg/day); symptoms abated as kava was discontinued and medical treatment was started (Meseguer et al. 2002).

Several patients were reported to have episodes of dystonia and dyskinesia, and one patient with Parkinson's disease experienced an increase in motor oscillations. The reporting physicians indicated that dopamine antagonism was believed to be responsible for the adverse events (Schelosky et al. 1995).

Additional adverse reactions have been reported to include vertigo, nausea, and vomiting experienced by a 37-year-old man who drank several cups of "strong" kava tea (Perez and Holmes 2005); choreoathetosis in a 27-year-old man after occasions of consumption of "large quantities" of kava beverage (Spillane et al. 1997); acute urinary retention in a 61-year-old man who drank 1 liter of kava beverage (Leung 2004); and a case of "intoxication" in a 34-year-old man who drank up to 40 bowls of kava per day (Chanwai 2000).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Conflicting information exists showing significant inhibition of CYP1A2 in chronic kava consumers (Russmann et al. 2005) or showing no effect after 28 days of 1.18 g daily kava in a non-kava drinking population (Gurley et al. 2005). In healthy volunteers orally administered 0.4 or 2 g kava for 28 days, a significant reduction in phenotypic ratios of CYP2E1 was observed, with no effects on CYP2D6 (Gurley et al. 2005, 2008b). No changes in CYP3A4 activity were observed in healthy volunteers orally administered 0.4 or 3.6 g kava daily for 14 days (Gurley et al. 2005, 2008b).

No effect was observed on pharmacokinetics of single doses of digoxin (0.5 mg) before or after 14 days of kava consumption, suggesting that kava does not effect P-gp activity (Gurley et al. 2007).

In a study of a kava-drinking population, recent users of kava were observed to have higher liver enzyme levels of γ-glutamyl transferase (GGT) and alkaline phosphatase (ALP) but not alanine aminotransferase (ALT) or bilirubin. Baselines were reported at normal levels after abstinence from kava (Clough et al. 2003).

Animal Pharmacological Studies

Animal studies were identified but omitted due to presence of human data.

In Vitro Pharmacological Studies

In vitro studies were identified but omitted due to presence of human data.

IV. Pregnancy and Lactation

Administration of synthetic kavain to rats (100 and 500 mg/kg) and rabbits (20 and 200 mg/kg) on days 6 to 17 of gestation did not result in any fetal abnormalities. Similarly, in rats administered dihydromethysticin (50 mg/kg) intraperitoneally for 3 months, no fetal abnormalities were noted in the first two generations of offspring (Hansel and Woelk 1994).

No information on the safety of kava during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of a standardized kava extract (70% kavalactones) is 180 mg/kg in mice and 1600 mg/kg in rats. The intraperitoneal LD_{50} is 380 mg/kg in mice and 370 mg/kg in rats (Hansel and Woelk 1994).

Short-Term Toxicity

In mice and rats fed a corn oil extract of kava at doses to 2 g/kg daily for 11 days, abnormal breathing, ataxia, and lethargy were observed. Hepatic cellular hypertrophy was noted in some animals (Sparrow et al. 2004).

In mice orally administered 0.125, 0.25, 0.5, 1.0, or 2.0 g/kg kava extract daily for 14 weeks, analyses of gene functions and pathways indicated that the levels of expression of a number of genes involving drug metabolism were changed, and that the pathways involving xenobiotics metabolism, Nrf2-mediated oxidative stress response, mitochondrial functions, and others were altered (Guo et al. 2010).

In rats orally administered kava containing 38 or 380 mg/kg kavalactones daily (approximately 10 and 100 times the suggested human dose) for 8 days, expression of CYP1A1 mRNA was markedly enhanced in the high-dose group along with ethoxyresorufin O-deethylase activities and CYP1A1 immunoreactivities. A moderate increase in CYP1A2 mRNA expression was also observed in the high-dose group (Yamazaki et al. 2008).

In rats administered kava aqueous extract (200 or 500 mg/kg kavalactones) for 2 or 4 weeks, no elevated levels of any liver enzymes were observed. After 2 weeks of treatment, levels of ALT and AST were decreased, and after 4 weeks of treatment, ALT levels were decreased (Singh and Devkota 2003).

In rats orally administered 10 mg/kg pipermethystine, 100 mg/kg acetone-water extracts of kava, or both pipermethystine and the kava extract daily for 2 weeks, no changes in liver enzyme levels were observed, although levels of hepatic glutathione, cytosolic superoxide dismutase,

TNF-α, mRNA expression, CYP2E1, and CYP1A2 were increased (Lim et al. 2007).

Subchronic Toxicity

In rats fed ethanol or acetone extracts of kava at 31.25, 62.5, or 133 mg/kg added to the diet for 3 months, no evidence of liver injury was observed, including changes in serum markers of liver damage and serum lipid peroxide readings. After intraperitoneal administration of the hepatotoxin galactosamine, kava showed no signs of enhancing liver injury induced by galactosamine (DiSilvestro et al. 2007).

Chronic Toxicity

Rats fed 7.3 or 73 mg/kg kava extract for 3 to 6 months showed no signs of hepatotoxicity or other adverse effects (Sorrentino et al. 2006).

Cytotoxicity

An in vitro assay of aqueous and methanolic extracts of kava (root, leaf, and stem peeling) on human liver carcinoma cells indicated that the methanolic extract displayed significantly greater cytotoxicity than the aqueous extract. The compound flavokavain B was believed to be responsible for the toxic effects (Jhoo et al. 2006).

Piper nigrum L.

Piperaceae

SCN: pepper
AN: *maricha*
PN: *hu jiao*
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: B

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Notice

Contains piperine (5–9%) (Bhardwaj et al. 2002; Srinivasan 2007); *see* Appendix 3.

Alkenylbenzenes (safrole 0.01–0.09%) (Ames et al. 1990; Farag and Abo-Zeid 1997); *see* Appendix 1.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Large doses of pepper may irritate the urinary tract. Overdoses of pepper may cause abdominal heat and burning, thirst, vomiting, fever, and sometimes convulsions (Felter and Lloyd 1898).

Pharmacological Considerations

The compound piperine has been shown to enhance the bioavailability of certain drugs (Hu et al. 2005; Srinivasan 2007; Wattanathorn et al. 2008). Some studies have indicated that coadministration of piperine with certain drugs allowed for a reduction in the required dose of the drugs (Hu et al. 2005; Srinivasan 2007; Wattanathorn et al. 2008).

An animal study suggested that an alcohol extract of pepper increased triiodothyronine (T_3) and thyroxine (T_4) levels, while an aqueous extract had no effects on T_3 and T_4 levels (Panda and Kar 2003).

Pregnancy and Lactation

Animal studies of pepper and the compound piperine have indicated some anti-implantation activity of these materials (Alkofahi et al. 1996; Daware et al. 2000). Another animal study indicated that piperine improved fertilization rates in artificially inseminated animals (Piyachaturawat and Pholpramool 1997).

No information on the safety of pepper during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

P

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 4-year-old boy with a history of pica (a pattern of eating nonfood materials) experienced respiratory arrest, severe anoxia, and death after aspiration of an unknown amount of ground pepper (Sheahan et al. 1988).

Large doses of pepper may irritate the urinary tract. Overdoses of pepper may cause abdominal heat and burning, thirst, vomiting, fever, and sometimes convulsions (Felter and Lloyd 1898).

Urticaria has been associated with pepper use (Felter and Lloyd 1898).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In mice orally administered 4 mg/kg of water or alcohol extracts of pepper daily for 15 days, no adverse effects on liver or thyroid functions were observed in the group

administered the water extract. In the group receiving the alcohol extract, however, thyrotoxicosis was observed, as evidenced by increased concentrations of thyroxine and triiodothyronine. A concomitant increase in hepatic lipid peroxidation with a decrease in superoxide dismutase and/or catalase activities were also observed (Panda and Kar 2003).

In Vitro Pharmacological Studies

Inhibition of the drug-metabolizing isoenzyme CYP2D6 was observed in human liver microsomes treated with an ethanol extract of pepper (Subehan et al. 2006a, 2006b).

An ethyl acetate fraction of pepper inhibited the drug-metabolizing isoenzymes CYP3A4 (84% inhibition) and CYP2D6 (72% inhibition) in a radiometric assay (Cha 2003; Usia et al. 2006).

Analyses of fractionations of the ethyl acetate extract indicated that certain fractions markedly inhibited CYP3A4, but none of the fractions contained the compound piperine, indicating that the inhibitory activity may be due to compounds other than piperine (Cha 2003). The bisalkaloids dipiperamides D and E were identified as CYP3A4 inhibitors (Tsukamoto et al. 2002).

In human liver microsomes, no activity of an ethanol extract of pepper was observed on CYP3A4 (Subehan et al. 2006a).

Inhibition of acetylcholinesterase activity of a methanol extract of pepper at a concentration of 0.1 mg/ml was observed in a preliminary screening of plants (Ingkaninan et al. 2003).

A methanol extract of pepper inhibited tyrosinase activity (Khanom et al. 2000).

IV. Pregnancy and Lactation

In mice orally administered 50 mg (animals weighed 20–30 g) of an aqueous extract of pepper daily for 25 days, an increase in the number of fetal resorptions, with no significant changes in the number of implantations or the number of viable fetuses, was observed (Alkofahi et al. 1996).

In mice orally administered 10 or 20 mg/kg of the compound piperine daily for 14 days, an increase in the period of the diestrous phase was observed, resulting in decreased mating performance and fertility. Postpartum litter growth was not affected by the piperine treatment. Considerable anti-implantation activity was recorded after 5 days postmating oral treatment with piperine (Daware et al. 2000).

In female hamsters orally administered 50 or 100 mg/kg of the compound piperine on days 1 through 4 of the estrus cycle, after superovulation and artificial insemination, the percent fertilization was significantly enhanced in the treated group (Piyachaturawat and Pholpramool 1997).

A spasmolytic effect of an aqueous extract of pepper was observed in uteruses excised from pregnant and nonpregnant rats. At concentrations of 0.125–2 mg/ml, the pepper extract dose-dependently reduced the uterine contractions induced by KCl and oxytocin (Naseri and Yahyavi 2007).

No information on the safety of pepper during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a crude extract of pepper in mice is 3.714 g/kg after intraperitoneal administration and could not be determined at doses up to 5 g/kg after oral administration (Pires et al. 2004).

The LD_{50} of the compound piperine in male mice is 15.1 mg/kg after intravenous administration, 43 mg/kg after intraperitoneal administration, 200 mg/kg after subcutaneous administration, and 400 mg/kg after intramuscular administration. In female rats, the LD_{50} of piperine is 33.5 mg/kg after intraperitoneal administration (Piyachaturawat et al. 1983; Srinivasan 2007).

Subchronic Toxicity

Pepper, pepper oleoresin, or piperine fed to weanling rats at doses 5 to 20 times normal human intake did not cause any adverse effect on growth, food efficiency ratio and organ weights, blood cell counts, and the levels of blood constituents like hemoglobin, total serum proteins, albumin, globulin, glucose and cholesterol, activities of serum aminotransferases and phosphatases, or nitrogen balance (Bhat and Chandrasekhara 1986).

In mice topically and orally administered 2 mg of a pepper extract 3 days a week for 3 months, an increase in incidences of tumors was observed. A reduction in the increase of tumor formation was observed in rats orally and topically administered 5 or 10 mg of vitamin A palmitate twice weekly for 3 months during and after pepper administration. No impact on carcinogenesis was observed in mice fed diets containing 1.6% pepper (Shwaireb et al. 1990). Conversely, another study indicated that pepper inhibited chemically induced carcinogenesis in rats (Nalini 1998).

In toads (*Bufo regularis*) orally administered 2 mg of pepper three times a week for 5 months, liver tumors (hepatocellular carcinomas, lymphosarcomas, and fibrosarcomas) were observed in approximately 30% of animals (el-Mofty et al. 1991).

In toads (*Bufo regularis*) orally administered 20 mg ground pepper in a saline solution daily, or subcutaneously administered 2 mg/ml of an ethanol extract of pepper three times a week, an increase in primary and secondary tumors was observed after 13 weeks of administration (el-Mofty et al. 1988).

Genotoxicity

In mice intraperitoneally administered 7, 14, 28, or 56 mg/kg of an alcohol extract of pepper, an increase in sister-chromatid exchange frequency was observed in bone marrow

cells at all dose levels. A similar pattern with regard to cell proliferation kinetics was observed at all doses tested, but was not dose dependent (Madrigal-Bujaidar et al. 1997).

In human lymphocytes treated with an alcohol extract of pepper at concentrations of 25, 50, 75, or 100 µg/ml, an increase in the frequency of sister-chromatid exchange was observed. A reduction in the replicative index was observed at the two high doses (Madrigal-Bujaidar et al. 1997).

Conversely, antimutagenic activity of pepper was observed in the somatic mutation and recombination test in *Drosophila melanogaster* treated with the promutagen agent ethyl carbamate. Pepper was not effective, however, in inhibiting mutation events induced by the alkylating agent methyl methanesulfonate (El Hamss et al. 2003).

Plantago spp. — Plantaginaceae

Plantago lanceolata L.
SCN: English plantain
OCN: lance-leaf plantain; narrow-leaf plantain; ribgrass

Plantago major **L.**
SCN: plantain
PN: *che qian cao* (whole plant)
OCN: broad-leaf plantain; greater plantain

Plantago media **L.**
SCN: hoary plantain
OCN: plantain
Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Editors' Note
Instances of adulteration of *P. lanceolata* leaves with those of *Digitalis lanata* have been rarely reported (Slifman et al. 1998; Whitmore 1997).

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of plantain, English plantain, or hoary plantain leaf in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials
No adverse effects on the gastrointestinal tract, liver, kidneys, or hemopoiesis were observed in bronchitis patients administered a plantain leaf preparation for 25 days (Matev et al. 1982).

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of plantain leaf use during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
The LD_{50} of an orally administered plantain leaf extract in rats could not be determined at doses up to 4 g/kg, whereas the LD_{50} after intraperitoneal administration is 1 g /kg (Angelov et al. 1980).

An ethanol extract of plantain leaf was found to be toxic in the brine shrimp assay (Schmeda-Hirschmann et al. 1992).

Genotoxicity

Assays of the genotoxicity of plantain leaf extracts have provided mixed results. In the Ames test, a decoction of plantain had some mutagenic activity (Lim-Sylianco and Shier 1985), while a saline extract showed no mutagenic activity (Basaran et al. 1996). No toxicity of an alcohol extract of plantain leaf was shown in the plate incorporation assay with *Aspergillus nidulans* (Ruiz et al. 1996).

Syn: *Plantago psyllium* L.
OCN: black psyllium (seed); French psyllium (seed); Spanish psyllium (seed)

***Plantago asiatica* L.**
SCN: Asian plantain
PN: *che qian zi* (seed)
OCN: Asian psyllium (seed)

Plantago ovata Forssk.

SCN: Indian plantain
Syn: *Plantago ispaghula* Roxb. ex Fleming
OCN: blonde psyllium (seed); Indian psyllium; ispaghula (seed)
Note: The SCN of the seed of *P. afra*, *P. arenaria*, *P. asiatica*, and *P. ovata* is psyllium.
Part: seed, seed husk

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Contraindicated in bowel obstruction, esophageal stenosis, and abnormal intestinal narrowing (Bradley 1992; Brinker 2001; Wichtl 2004).

Other Precautions

Take with at least 250 ml (8 oz.) of liquid (CFR 2011; Wichtl 2004).

Drug and Supplement Interactions

Other drugs should be taken 1 hour prior to consumption of psyllium or several hours after consumption, as psyllium may reduce the absorption of certain drugs due to the mucilage content and the increased speed of passage through the intestines (Bradley 1992; Brinker 2001); *see* Mucilages in Appendix 3.

Notice

Bulk-forming laxative (Bradley 1992; Leung and Foster 1996; Martindale and Reynolds 1996; Wichtl 2004; Williamson 2003); *see* Appendix 2.

Mucilages (10–30%) (Leung and Foster 1996; Wichtl 2004); *see* Appendix 3.

Standard Dose

The standard adult dose is 2.5–7.5 g up to 3 times daily (Bradley 1992; Federal Register 1986).

Editors' Note

Specific labeling is required in the United States for all over-the-counter drug products containing psyllium (CFR 2011a, Federal Register 1986), and psyllium in granular form is not permitted in these products (CFR 2011b). *See* Bulk-forming laxatives in Appendix 2.

Adverse Events and Side Effects

Allergic sensitivity has been reported for psyllium products (Drake et al. 1991; Ford et al. 1992; Freeman 1994; Gauss et al. 1985; Hoffman 2006; Khalili et al. 2003; Lantner et al. 1990; Machado et al. 1979; Pozner et al. 1986; Schwartz et al. 1989; Scott 1987; Seggev et al. 1984; Suhonen et al. 1983; Sussman and Dorian 1990; Terho ja Martti Torkko 1980; Vaswani et al. 1996; Zaloga et al. 1984). Such sensitivity is most common among healthcare workers who have had repeated respiratory exposure to airborne psyllium powder (Freeman 1994).

Pharmacological Considerations

Human studies have demonstrated that psyllium may modify glucose regulation. People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use (Anderson et al. 1999; Frati Munari et al. 1998; Pastors et al. 1991).

Pregnancy and Lactation

Over-the-counter psyllium products are categorized as an FDA category B, indicating that the products are generally considered safe during pregnancy although no adequate and well-controlled studies in pregnant humans have been completed (PDR 2006). Psyllium is generally considered to be safe for use by nursing mothers (Ulbricht and Basch 2005).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No relevant clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

The addition of psyllium husk to the daily regimen of a woman taking lithium was associated with decreased blood levels of lithium (Perlman 1990).

Animal Trials of Drug or Supplement Interactions

No relevant animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Meta-analyses of psyllium preparations have not reported any adverse events associated with clinical trials of psyllium (Anderson et al. 2000; Brown et al. 1999; Olson et al. 1997).

Case Reports of Adverse Events

The bulking action of psyllium has resulted in gastrointestinal tract and, in rare occasions, respiratory tract obstructions (Angueira and Kadakia 1993; Berman and Schultz 1980; Frohna 1992; Herrle et al. 2004; Noble and Grannis 1984; Sauerbruch et al. 1980; Schapira et al. 1995; Schneider 1989). Some cases of obstructions have been reported in persons with some type of narrowing or restriction of the digestive tract (Angueira and Kadakia 1993; Herrle et al. 2004).

Reports of allergic reactions to psyllium included anaphylaxis, rashes, and asthma (Drake et al. 1991; Ford et al. 1992; Freeman 1994; Gauss et al. 1985; Hoffman 2006; Khalili et al. 2003; Lantner et al. 1990; Machado et al. 1979; Pozner et al. 1986; Schwartz et al. 1989; Scott 1987; Seggev et al. 1984; Suhonen et al. 1983; Sussman and Dorian 1990; Terho ja Martti Torkko 1980; Vaswani et al. 1996; Zaloga et al. 1984). Such reactions occur most commonly in healthcare workers, as sensitization to psyllium is thought to be caused by repeated respiratory exposure to powdered psyllium (Freeman 1994).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In type 2 diabetes mellitus and non-insulin-dependent diabetes mellitus (NIDDM) subjects, administration of single doses of psyllium before a meal significantly reduced postmeal glucose levels (Anderson et al. 1999; Frati Munari et al. 1998; Pastors et al. 1991).

In NIDDM subjects, administration of 5.1 g psyllium twice daily for 8 weeks significantly reduced proximate and postmeal glucose levels (Pastors et al. 1991).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Over-the-counter psyllium products are categorized as an FDA category B, indicating that the products are generally considered safe during pregnancy, although no adequate and well-controlled studies in pregnant humans have been completed (PDR 2006).

No evidence of adverse effects on reproduction was reported in rats or mice fed psyllium husk as 0, 1.25, or 5% of the diet for three generations (EMEA 2007). No evidence of adverse effects was observed in rabbits fed psyllium husk as

0, 2.5 5, or 10% of the diet on days 2 through 20 of gestation (EMEA 2007).

Psyllium-containing products are considered generally safe for use by nursing mothers (Ulbricht and Basch 2005).

V. Toxicity Studies

Acute Toxicity

No LD_{50} of orally administered psyllium husk could be determined at doses up to 2940 mg/kg in mice or in rats at doses up to 3360 mg/kg (EMEA 2007).

Short-Term and Subchronic Toxicity

In rats fed psyllium husk as 10% of the diet for 28 days or 13 weeks, with psyllium consumption ranging from 3876 to 11,809 mg/kg daily, lower serum total protein, albumin, globulin, total iron-binding capacity, calcium, potassium, and cholesterol, and higher aspartate transaminase (AST) and alanine transaminase (ALT) activities relative to control were observed (EMEA 2007). The reasons for the lower serum total protein, albumin, and globulin were not clear, but the absence of any increase in urinary protein, any evidence of gastrointestinal pathology which could account for protein loss, and any differences in growth or feed efficiency in psyllium fed rats suggests that psyllium does not adversely affect protein metabolism (EMEA 2007).

Platycladus orientalis (L.) Franco — Cupressaceae

SCN: oriental arborvitae
Syn: *Biota orientalis* (L.) Endl.; *Thuja orientalis* L.

PN: *ce bai ye* (leaf and branch tip)
Part: cacumen (leafy twig)

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for long-term use; do not exceed recommended dose (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 6 to 15 g, raw or charred, daily as a tea (Bensky et al. 2004; Chen and Chen 2004).

Notice

Thujone (50–60% of the essential oil) (Bensky et al. 2004; Chizzola et al. 2004); *see* Appendix 1.

Adverse Events and Side Effects

Allergic reactions to oriental arborvitae twig have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of oriental arborvitae twig in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose (standard dose is listed as a decoction of 6–15 g) or long-term use of oriental arborvitae twig has been associated with gastric discomfort, nausea, dizziness, and decreased appetite. In severe cases of overdose, vomiting of blood may occur (Bensky et al. 2004; Chen and Chen 2004).

Allergic reactions to oriental arborvitae twig have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In assays with rabbit platelets, an aqueous extract of oriental arborvitae twig was found to be a platelet-activating factor (PAF) receptor binding antagonist (Yang et al. 1995). Related studies indicated that the compound pinusolide is responsible for this activity (Han et al. 1998; Yang and Han 1998). Pinusolide inhibited ^{3}H-serotonin release from rabbit platelets induced by PAF, but showed no effect on ^{3}H-serotonin release induced by ADP, collagen, or thrombin (Kim et al. 1999).

IV. Pregnancy and Lactation

No information on the safety of oriental arborvitae twig during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in mice orally administered up to 60 g/kg of a decoction of oriental arborvitae twig (Chen and Chen 2004). The LD_{50} of a decoction of oriental arborvitae twig intraperitoneally administered in mice is 15.2 g/kg (Chen and Chen 2004; Zhu 1998).

Short-Term Toxicity

Reduced appetite and activity were observed in rats orally administered up to 48 g/kg of oriental arborvitae twig daily for 6 weeks (Zhu 1998).

PN: *bai zi ren* (seed)
Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with loose stools (Bensky et al. 2004; Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Editors' Note

Contamination by aflatoxins, toxic compounds produced by fungi that grow in grains, nuts, and other products, has been reported in oriental arborvitae seed (Bensky et al. 2004). Proper processing and storage can prevent aflatoxin formation (Kabak et al. 2006).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of oriental arborvitae seed in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Platycodon grandiflorum (Jacq.) A. DC. — Campanulaceae

SCN: platycodon
PN: *jie geng* (root)

OCN: balloon flower; Chinese bellflower; Japanese bellflower
Part: root

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with a tendency to cough up blood (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that platycodon may modify glucose regulation (Kwon et al. 2009; Zheng et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of platycodon in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No adverse effects have been reported within the normal dosage range (decoction of 3–9 g) of platycodon. Overdose may cause nausea and vomiting and, in severe cases, sweating on the limbs, exhaustion, and restlessness (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic mice orally administered 2 g/kg of platycodon or 0.2 g/kg of saponins from platycodon daily for 8 weeks, improvement of glucose homeostasis was observed. The saponin fraction was more active than the crude extract (Kwon et al. 2009).

In diabetic mice orally administered 150 or 300 mg/kg of an aqueous-ethanol extract of platycodon, a decrease in serum glucose levels was observed after a single dose and after daily dosing for 4 weeks. No changes in serum insulin levels were observed (Zheng et al. 2007).

Several animal studies have indicated that extracts of platycodon or saponins from platycodon prevented liver injury and changes in liver enzyme levels induced by ethanol or carbon tetrachloride. These studies indicated that inhibition of the drug-metabolizing isoenzyme CYP2E1 was responsible for this protection. Doses used in these studies were 10 to 100 mg/kg of an aqueous extract or 0.5 to 2 mg/kg of saponins (Khanal et al. 2009; Kim et al. 2007; Lee et al. 2008; Lee and Jeong 2002).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of platycodon during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered platycodon decoction in mice is 24 g/kg. The oral LD_{50} of the saponin fraction of

platycodon is 420 mg/kg in mice and over 800 mg/kg in rats (Zhu 1998).

Genotoxicity

No mutagenic activity of an aqueous extract of platycodon was observed in the Ames mutagenicity assay with *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation by S9 (Yin et al. 1991).

In the mouse micronucleus and chromosomal aberration assays, dose-dependent increases in polychromatic erythrocytes and in the incidences of chromosomal aberrations were observed in mice intraperitoneally administered an aqueous extract of platycodon at doses of 0.25, 0.5, 1.0, or 2.0 g/kg (Yin et al. 1991).

Podophyllum hexandrum Royle

Berberidaceae

SCN: Himalayan mayapple
Syn: *Podophyllum emodi* Wall. ex Hook. f. & Thomson

PN: *tao er qi* (root and rhizome)
Part: root and rhizome

P

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Didcock et al. 1952; Longstaff and von Krogh 2001).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Didcock et al. 1952; Longstaff and von Krogh 2001); *see* Appendix 2.

Emetic (Felter and Lloyd 1898); *see* Appendix 2.

Stimulant laxative (Felter and Lloyd 1898); *see* Appendix 2.

Adverse Events and Side Effects

Toxicity has been reported after topical and internal administration of products (podophyllin and podophyllotoxin) derived from Himalayan mayapple and included nausea, vomiting, peripheral neuropathy, difficulty breathing, lethargy, and coma. Some cases of toxicity have been fatal (Cassidy et al. 1982; McFarland and McFarland 1981).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Case reports and animal studies have indicated that compounds from Himalayan mayapple have abortifacient activity (Chamberlain et al. 1972; Didcock et al. 1952; Longstaff and von Krogh 2001). A safety assessment of the compounds podophyllotoxin and podophyllin indicated that the topical use of these compounds during pregnancy is strongly contraindicated (Longstaff and von Krogh 2001).

An animal study with aqueous extract of Himalayan mayapple indicated no adverse effects during pregnancy (Sajikumar and Goel 2003).

No information on the safety of Himalayan mayapple in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Adverse effects from topical application of podophyllin have been reported and include erythema, edema, chemical burns, and allergic sensitivity. Systemic toxicity may cause nausea, vomiting, respiratory stimulation, peripheral neuropathy, fever, acute confusional states, tachycardia, oliguria, adynamic ileus, leukopenia, elevation of liver enzymes, coma, and death (Miller 1985; Rudrappa and Vijaydeva 2002).

A 2-year-old girl experienced bouts of vomiting, convulsions, and altered perception followed by a grade III coma after being accidentally administered 1 teaspoon of a 20% podophyllin preparation intended for topical treatment of warts. The girl's heart rate and blood pressure were normal, liver function tests on day 4 after poisoning indicated a mild increase in liver enzymes, and examination revealed no neurological effects. After supportive therapy for four weeks, the child made a full recovery (Rudrappa and Vijaydeva 2002).

A 22-year-old man developed a severe sensorimotor neuropathy following ingestion of podophyllin that had been prescribed for topical application for genital condylomata. The initial toxic symptoms were vomiting and diarrhea, followed by peripheral neuropathy. The neuropathy was still present 18 months later. Nerve conduction studies and sural nerve biopsy confirmed the presence of axonal degeneration (O'Mahony et al. 1990).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Intravenous administration of 200 mg (per 200–250 g animal) of an aqueous extract of Himalayan mayapple to rats on day 16 of pregnancy demonstrated a protective effect against neuronal damage in offspring induced by exposure to radiation on day 17 of pregnancy (Sajikumar and Goel 2003).

A review of cases of adverse events associated with podophyllin use during pregnancy indicated that the adverse events were generally reported in young women with recent surgical procedures with or without general anesthesia, or in women who were taking other prescription or nonprescription drugs in addition to podophyllin use. The review concluded that podophyllin may be used topically during pregnancy without concern (Bargman 1988). A more recent review of the safety of the compounds podophyllin and podophyllotoxin indicates that these compounds are strongly contraindicated during pregnancy (Longstaff and von Krogh 2001).

A normal infant was born at term 3 months after the mother was accidentally administered 1 g of podophyllum resin orally (Balucani and Zellers 1964).

The child of a woman who had been topically treated with podophyllin on five occasions between weeks 23 and 29 of pregnancy was born with a simian crease and a preauricular skin tag. The mother had taken chloroquine and primaquine phosphate between weeks 19 and 22 of pregnancy (Karol et al. 1980). A comment on this case indicated that the podophyllin use was too late in pregnancy to cause the observed abnormalities (Bargman 1988; Fraser 1981).

In studies with rabbits, rats, and mice, administration of the compound podophyllotoxin to pregnant animals was associated with fetal resorption and abortifacient activity. Effects were observed in rats intravenously administered 2.5 mg/kg or subcutaneously administered 6 mg/kg, with no maternal mortality at these doses. In rabbits, subcutaneous doses of 18 mg/kg terminated pregnancy in two of five animals, while a dose of 35 mg/kg terminated pregnancy in

three of four animals with no maternal mortality reported in either group (Didcock et al. 1952).

No information on the safety of Himalayan mayapple in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a fractionated extract (with podophyllin and podophyllotoxin removed) of Himalayan mayapple in mice is 250 mg/kg after oral administration and 90 mg/kg after intraperitoneal administration (Gupta et al. 2008a, 2008b; Lata et al. 2009).

The LD_{50} of the compound podophyllotoxin orally administered to rats was less than 100 mg/kg. After intravenous administration, the LD_{50} of podophyllotoxin is 10 mg/kg in rats and could not be determined at doses up to 20 mg/kg in mice. The dermal LD_{50} of podophyllotoxin is greater than 200 mg/kg in rabbits and greater than 500 mg/kg in rats (Longstaff and von Krogh 2001).

Genotoxicity

The compound podophyllin increased bacterial revertants and abnormal chromosomal structures in a concentration-dependent manner, both with and without metabolic activation, and increased the incidence of micronuclei in imprinted control region mouse reticulocytes (Lin et al. 2009).

Podophyllum peltatum L.

Berberidaceae

SCN: mayapple
OCN: American mandrake

Part: root

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Cassidy

et al. 1982; Longstaff and von Krogh 2001; McFarland and McFarland 1981).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Chamberlain et al. 1972; Didcock et al. 1952; Longstaff and von Krogh 2001); *see* Appendix 2.

Emetic (Felter and Lloyd 1898); *see* Appendix 2.

Stimulant laxative (Felter and Lloyd 1898; Rosenstein et al. 1976; Wood and LaWall 1926); *see* Appendix 2.

Adverse Events and Side Effects

Mayapple toxicity has been reported after topical and internal use of mayapple and included nausea, vomiting, peripheral neuropathy, difficulty breathing, lethargy, and coma. Some cases of toxicity have been fatal (Cassidy et al. 1982; McFarland and McFarland 1981).

An Eclectic medical text indicated that mayapple may cause drooling and gastrointestinal pain. The fresh or recently dried root is reported to act as an "irritant poison" causing hypercatharsis, hyperemesis, griping, and other unpleasant symptoms. After inappropriate use, mayapple may cause prolonged gastrointestinal irritation and inflammation (Felter and Lloyd 1898).

Repeated topical application of the fresh or dried root may cause irritation followed by suppuration (Felter and Lloyd 1898).

Pharmacological Considerations

Although mayapple acts as a stimulant laxative, the plant is generally considered obsolete for this use (Rosenstein et al. 1976).

Pregnancy and Lactation

Case reports and animal studies have indicated that mayapple and compounds from mayapple have abortifacient activity (Chamberlain et al. 1972; Didcock et al. 1952; Longstaff and von Krogh 2001). A safety assessment of the compounds podophyllotoxin and podophyllin indicated that the topical use of these compounds during pregnancy is strongly contraindicated (Longstaff and von Krogh 2001).

No information on the safety of mayapple during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A review of cases of poisonings associated with mayapple use indicated that toxicity may occur after topical use or ingestion. Typical symptoms include nausea, vomiting, peripheral neuropathy, difficulty breathing, lethargy or coma, leukocytosis, and pancytopenia. Renal failure was reported in two fatal cases. Cases reviewed had topical doses of 150 to 1880 mg. Fatal poisoning was reported in a 60-year-old woman after application of 325 mg, while neuropathy was reported in an 18-year-old woman after application of 1800 mg. In persons who ingested 350 to 2800 mg of mayapple extracts, neuropathy with leukocytosis was observed after 350 mg, while coma with neuropathy was reported after a dose of 2800 mg (Cassidy et al. 1982; McFarland and McFarland 1981).

An Eclectic medical text indicated that mayapple may cause drooling, gastrointestinal pain, and griping. In overdose, violent vomiting and catharsis (diarrhea) may occur (Felter and Lloyd 1898). The fresh or recently dried root is reported to act as an "irritant poison" causing hypercatharsis, hyperemesis, griping, and other unpleasant symptoms. After inappropriate use, mayapple may cause prolonged gastrointestinal irritation and even inflammation (Felter and Lloyd 1898). Overdoses of mayapple have been lethal (Felter and Lloyd 1898). Repeated topical application of the fresh or dried root may cause irritation followed by suppuration (Felter and Lloyd 1898).

A 54-year-old alcoholic man with suicidal intent ingested a bottle of wine followed by a 10 to 11 g bottle of 25% mayapple in benzoin tincture. Treatment including ipecac, activated charcoal, and hemoperfusion was unsuccessful, and the poisoning was fatal (Cassidy et al. 1982).

A 20-year-old woman experienced nausea, vomiting, and an extended period of severe peripheral neuropathy

after ingestion of approximately 4 g of mayapple in tincture of benzoin (McFarland and McFarland 1981).

A 22-year-old man developed a severe sensorimotor neuropathy following ingestion of podophyllin that had been prescribed for genital condylomata. The initial toxic symptoms were vomiting and diarrhea, followed by peripheral neuropathy. The neuropathy was still present 18 months later. Nerve conduction studies and sural nerve biopsy confirmed the presence of axonal degeneration (O'Mahony et al. 1990).

Irritation of the mucous membranes, including conjunctival inflammation, has been reported in workers processing dried mayapple or mayapple resin (Felter and Lloyd 1898).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

An 18-year-old woman in her 34th week of pregnancy experienced severe peripheral neuropathy followed by intrauterine death of the fetus after professional application of a 25% solution of podophyllum resin in tincture of benzoin on vulval warts. A total of 7.5 ml (equivalent to 1.88 g podophyllum) was applied. The woman was under general anesthesia at the time of application. After 3 months, the woman was walking without aid and was able to type, but very slowly and clumsily. Complete recovery from neuropathy and a subsequent healthy pregnancy was reported (Chamberlain et al. 1972).

A review of cases of adverse events associated with podophyllin use during pregnancy indicated that the adverse events were generally reported in young women with recent surgical procedures with or without general anesthesia, or in women who were taking other prescription or nonprescription drugs. The review concluded that podophyllin may be used topically during pregnancy without concern (Bargman 1988). A more recent review of the safety of the compounds podophyllin and podophyllotoxin indicates that these compounds are strongly contraindicated during pregnancy (Longstaff and von Krogh 2001).

A normal infant was born at term 3 months after the mother was accidentally administered 1 g of podophyllum resin orally (Balucani and Zellers 1964).

The child of a woman who had been topically treated with podophyllin on five occasions between weeks 23 and 29 of pregnancy was born with a simian crease and a preauricular skin tag. The mother had taken chloroquine and primaquine phosphate between weeks 19 and 22 of pregnancy (Karol et al. 1980). A comment on the case indicated that the podophyllin use was too late in pregnancy to cause the observed abnormalities (Bargman 1988; Fraser 1981).

In studies with rabbits, rats, and mice, administration of the compound podophyllotoxin to pregnant animals was associated with fetal resorption and abortifacient activity. Effects were observed in rats intravenously administered 2.5 mg/kg or subcutaneously administered 6 mg/kg, with no maternal mortality at these doses. In rabbits, subcutaneous dose of 18 mg/kg terminated pregnancy in two of five animals, while a dose of 35 mg/kg terminated pregnancy in three of four animals with no maternal mortality in either group (Didcock et al. 1952).

No information on the safety of mayapple during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound podophyllotoxin orally administered in rats and rabbits could not be determined at doses up to 100 mg/kg. After intravenous administration, the LD_{50} of podophyllotoxin is 10 mg/kg in rats and could not be determined at doses up to 20 mg/kg in mice. The dermal LD_{50} of podophyllotoxin is greater than 200 mg/kg in rabbits and greater than 500 mg/kg in rats (Longstaff and von Krogh 2001).

Genotoxicity

The compound podophyllin increased bacterial revertants and abnormal chromosomal structures in a concentration-dependent manner, both with and without metabolic activation, and increased the incidence of micronuclei in imprinted control region mouse reticulocytes (Lin et al. 2009).

Polygala senega L. — Polygalaceae

SCN: Seneca snakeroot
OCN: senega snakeroot

Part: root

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Felter and Lloyd 1898).

Not for long-term use; do not exceed recommended dose (Felter and Lloyd 1898; Wichtl 2004).

Not for use in persons with gastritis or gastric ulcers (Bradley 1992).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Yamahara et al. 1979); *see* Appendix 2.

Emmenagogue (Felter and Lloyd 1898); *see* Appendix 2.

Standard Dose

The standard dose is 0.5–1.0 g three times daily (Bradley 1992); 1–3 g daily (Merck 1930; Wichtl 2004).

Adverse Events and Side Effects

Prolonged use or overdose of Seneca snakeroot may cause gastrointestinal irritation, nausea, vomiting, retching, and diarrhea (Felter and Lloyd 1898; Wichtl 2004).

Pharmacological Considerations

Animal studies have demonstrated that Seneca snakeroot and compounds from Seneca snakeroot may modify glucose regulation (Kako et al. 1996, 1997; Yoshikawa et al. 1995, 1996). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Seneca snake root has traditionally been used as an emmenagogue (Felter and Lloyd 1898). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of Seneca snake root in lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered 2 g/kg of a hydromethanolic extract of Seneca snakeroot, a 62% reduction in congestive edema was observed along with a significant increase in 24-hour urine volume (Yamahara et al. 1979).

A reduction in blood glucose levels was observed in healthy and in non-insulin-dependent diabetic mice intraperitoneally administered 5 mg/kg of the *n*-butanol fraction of Seneca snakeroot. No changes in glucose levels were observed in insulin-dependent diabetic mice (Kako et al. 1996). A reduction in blood glucose levels was observed in healthy and in non-insulin-dependent diabetic mice intraperitoneally administered the compounds senegin II and senegin III (Kako et al. 1997).

In the oral glucose tolerance test in rats, after oral administration of 100 mg/kg of the compounds *E,Z*-senegasaponins a or b, a reduction in plasma glucose levels was observed (Yoshikawa et al. 1995). Similar inhibition of glucose elevation was observed after animals were administered *E,Z*-senegins II, III, and IV and *E,Z*-senegasaponin c (Yoshikawa et al. 1996).

In Vitro Pharmacological Studies

In high-throughput enzyme inhibition screening assays, an ethanol extract of Seneca snakeroot inhibited the drug-metabolizing isoenzyme CYP2C19 (Scott et al. 2006).

IV. Pregnancy and Lactation

Based on the traditional use of Seneca snake root as an emmenagogue (Felter and Lloyd 1898), use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of Seneca snakeroot during lactation was identified.

V. Toxicity Studies

Genotoxicity

No mutagenic activity of aqueous or methanolic extracts of Seneca snakeroot was observed in the Ames mutagenicity test with *Salmonella typhimurium* strains TA98 and TA100 (Morimoto et al. 1982).

Polygala spp.

Polygalaceae

Polygala sibirica L.
SCN: polygala
PN: *yuan zhi* (root)
OCN: Siberian milkwort; Siberian polygala

***Polygala tenuifolia* Willd.**
SCN: polygala
PN: *yuan zhi* (root)
OCN: thin-leaf polygala
Part: root

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chen and Chen 2004).

Not for use in persons with gastritis or ulcers (Bensky et al. 2004; Chen et al. 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Chen and Chen 2004; Yamahara et al. 1979); *see* Appendix 2.

Adverse Events and Side Effects

Polygala may be irritating to the gastrointestinal tract (Bensky et al. 2004; Chen et al. 2004).

Allergic reactions to polygala have been reported (Bensky et al. 2004; Park et al. 2005).

Pregnancy and Lactation

A reference text on traditional Chinese medicine indicates that polygala should be used with caution during pregnancy, as water and alcohol extracts of polygala have exhibited uterine-stimulating activity in pregnant and nonpregnant animals (Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of polygala during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose (standard dose is listed as a decoction of 6–15 g) of polygala may cause nausea and vomiting (Bensky et al. 2004).

Allergic reactions to polygala have been reported (Bensky et al. 2004).

Occupational asthma and rhinitis induced by polygala were reported in a patient who had worked in an herb processing facility for 8 years. A skin prick test confirmed polygala as the causative agent (Park et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered 2 g/kg of a hydromethanolic extract of polygala, a 100% reduction in congestive edema was observed along with a significant increase in 24-hour urine volume (Yamahara et al. 1979).

Prolongation of hexobarbital-induced sleeping times was observed in mice intraperitoneally administered 6.25 to 50 mg/kg of the butanol-soluble fraction of a methanolic extract of polygala (Nikaido et al. 1982).

In Vitro Pharmacological Studies

No estrogenic activity of an ethanol extract of polygala was observed in a recombinant yeast assay system with a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

The compound tetrahydrocolumbamine exhibited dopamine receptor binding activity in several in vitro assays (Shen et al. 1994).

IV. Pregnancy and Lactation

Water and alcohol extracts of polygala have exhibited uterine-stimulating activity in pregnant and nonpregnant rabbits, cats, and dogs. Information on dose and route of administration was not reported in the available English language translation (Chen and Chen 2004).

No information on the safety of polygala during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of polygala orally administered in mice is 16.95 g/kg for the whole root, 10.03 g/kg for the root bark, and over 75 g/kg for the root core (Chang and But 1986).

Genotoxicity

No mutagenic activity of aqueous or methanolic extracts of polygala was observed in the Ames mutagenicity test with *Salmonella typhimurium* strains TA98 and TA100 (Morimoto et al. 1982).

Polygonatum biflorum (Walter) Elliott — Liliaceae

SCN: Solomon's seal
OCN: small Solomon's seal

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

In addition to medicinal use, the rhizomes of Solomon's seal were used by the Cherokee people as a food, being ground into a flour and made into bread or boiled and then eaten (Moerman 1998).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Solomon's seal in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of Solomon's seal during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Polygonatum odoratum (Mill.) Druce

Liliaceae

SCN: aromatic Solomon's seal
Syn: *Polygonatum officinale* All.
PN: *yu zhu* (rhizome)

OCN: fragrant Solomon's seal
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

An allergic reaction to aromatic Solomon's seal has been reported (Bensky et al. 2004).

Pharmacological Considerations

Animal studies have demonstrated that aromatic Solomon's seal may modify glucose regulation (Choi and Park 2002; Kato and Miura 1994; Miura and Kato 1995). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of aromatic Solomon's seal in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of aromatic Solomon's seal (standard dose listed as a decoction of 6–15 g) may cause nausea, vomiting, or diarrhea (Bensky et al. 2004).

An allergic reaction to aromatic Solomon's seal, including generalized pruritus and red papular rashes, has been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In healthy and in diabetic mice intraperitoneally administered 800 mg/kg of a methanol extract of aromatic Solomon's seal, a reduction in blood glucose levels was observed (Kato and Miura 1994; Miura and Kato 1995).

In 90% pancreatectomized rats orally administered 30 mg/kg of steroidal glycoside compounds from aromatic Solomon's seal daily for 13 weeks, no change in insulin secretion from pancreatic beta-cells was observed; however, mice were found to have an increased insulin sensitivity (Choi and Park 2002).

In Vitro Pharmacological Studies

No estrogenic activity of an ethanol extract of aromatic Solomon's seal was observed in a recombinant yeast assay system with a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of aromatic Solomon's seal during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in mice orally administered 10 g/kg of an aqueous extract of aromatic Solomon's seal (equivalent to 64.5 g/kg crude material) twice at 6 hour intervals (Chen et al. 2001).

The LD_{50} of an injectable preparation of aromatic Solomon's seal intraperitoneally administered in mice is 112.5 g/kg (Zhu 1998).

In a sperm aberration test, sexually mature male mice were orally administered 2.5, 5, or 10 g/kg of an aqueous extract of aromatic Solomon's seal daily for 5 days. Examination of sperm 30 days after the final aromatic Solomon's seal dose indicated no significant difference in the rates of sperm aberration between the control group and the extract-treated groups (Chen et al. 2001).

Subchronic Toxicity

In rats orally administered 4 or 16 g/kg of an aqueous extract of aromatic Solomon's seal (equivalent to 12.9 and 51.6 g/kg crude material) daily for 6 months, softened feces were noted in the 16 g/kg group. No signs of toxicity, including changes in behavior, appearance, diet, hematology, blood biochemistry, and histopathology, were observed (Chen et al. 2001).

Genotoxicity

In the mouse bone marrow micronucleus assay, mice were orally administered 2.5, 5, or 10 g/kg of an aqueous extract of aromatic Solomon's seal twice at a 24-hour interval. No significant changes in the rates of micronucleus cells in treated groups were observed (Chen et al. 2001).

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA97, TA98, TA100, or TA102 tested with and without metabolic activation by S9, no mutagenic activity of 0.2, 1, or 5 mg/plate of an aqueous extract of aromatic Solomon's seal was observed (Chen et al. 2001).

Polygonatum sibiricum F. Delaroche — Liliaceae

SCN: polygonatum
PN: *huang jing* (rhizome)
OCN: Siberian Solomon's seal
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
Animal studies have demonstrated that polygonatum may modify glucose regulation (Kato and Miura 1993; Miura and Kato 1995). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation
No information on the safety of polygonatum in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
In healthy and in diabetic mice intraperitoneally administered 800 mg/kg of a methanol extract of polygonatum, a reduction in blood glucose levels was observed, with the effect being more pronounced in diabetic animals. Serum insulin levels did not change in either group (Kato and Miura 1993; Miura and Kato 1995).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of polygonatum during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
In mice orally administered an aqueous extract of polygonatum at a dose corresponding to 450 g/kg, all mice administered an extract of the unprocessed herb died, but all of the mice administered an extract of the steam-processed root survived (Zhu 1998).

Polygonum bistorta L. — Polygonaceae

SCN: bistort
PN: *quan shen* (rhizome)
OCN: English serpentary
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (15 21%) (Remington and Wood 1918; Wattiez 1920); *see* Appendix 1.

Adverse Events and Side Effects

Mild side effects of bistort have been reported, including abdominal pain and diarrhea (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of bistort in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Mild side effects of bistort have been reported, including abdominal pain and diarrhea. These effects are thought to be due to irritation of the intestinal mucosa (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An ethanol extract of bistort induced activity of a substance showing interferon-like activity in cultures of monkey kidney cells (Smolarz and Skwarek 1999).

IV. Pregnancy and Lactation

No information on the safety of bistort during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Populus balsamifera L. ssp. *balsamifera* — Salicaeae

SCN: balsam poplar
Syn: *Populus candicans* Aiton; *Populus tacamahaca* Mill.

OCN: balm-of-gilead (leaf bud); tacamahac
Part: resinous leaf buds

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Salicylates (List and Hörhammer 1973); *see* Appendix 1.

Adverse Events and Side Effects

Hypersensitivity and allergic skin reactions to poplar buds have been reported and noted as rarely occurring (Blumenthal et al. 1998; Bradley 1992).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of balsam poplar in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

Portulaca oleracea L. — Portulacaceae

SCN: purslane
PN: *ma chi xian* (above-ground parts)

Part: above-ground parts

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004).

Other Precautions

Use with caution in persons with a history of kidney stones (McGuffin et al. 1997).

Drug and Supplement Interactions

None known.

Notice

Diuretic (Pagar et al. 2007; Yasuye and Honda 1944); *see* Appendix 2.

Editors' Note

Purslane is commonly consumed as a vegetable in many regions of the world (Ezekwe et al. 1999; Omara-Alwala et al. 1991).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that purslane may modify glucose regulation (Cui et al. 2005; Li et al. 2009). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Fresh purslane is commonly consumed as a vegetable in many regions of the world with no cautions listed for use as a food during pregnancy (Ezekwe et al. 1999; Omara-Alwala et al. 1991). Animal studies have provided conflicting data on the activity of purslane on the uterus (Chen and Chen 2004). Of two reference texts on traditional Chinese medicine, one indicates that purslane should not be used during pregnancy (standard dose listed is 9–15 grams of dried purslane) (Bensky et al. 2004) while the other text does not (Chen and Chen 2004). Texts on traditional medicine from India do not indicate any concern for use of purslane in pregnancy (Khory and Katrak 1887; Nadkarni 1954).

No information on the safety of purslane during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic and healthy rats orally administered 0.5, 2.5, or 5 g/kg of purslane powder daily for 21 days, a dose-dependent reduction in blood glucose levels was observed in diabetic but not in healthy rats (Cui et al. 2005).

In diabetic mice orally administered 200 or 400 mg/kg of polysaccharides from purslane daily for 28 days, a decrease in fasting blood glucose and increase in serum insulin levels were observed (Li et al. 2009).

In rats administered 200 or 400 mg/kg of a hydroethanolic extract of purslane, an increase in the volume of urine and urinary concentration of sodium, potassium, and chloride ions was observed at the 400 mg/kg dose. At the 200 mg/kg dose, no change in urine volume or urinary concentration of chloride ions was observed, although urinary

concentrations of sodium and potassium levels were elevated (Pagar et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Of two authoritative English-language texts on traditional Chinese medicine, one indicates that purslane should not be used during pregnancy (standard dose listed is 9–15 grams of dried purslane, approx. 195–326 g fresh) (Bensky et al. 2004) while the second text does not (Chen and Chen 2004). Texts on traditional medicine from India do not indicate any concern for use of purslane in pregnancy (Khory and Katrak 1887; Nadkarni 1954).

An extract of purslane was reported to have a stimulating effect on the smooth muscles of the intestines and uteruses of rats, rabbits, and guinea pigs. In another study, purslane was reported to have mixed effects on the uterus, with an extract of the stem stimulating the uterus and an extract of the leaves relaxing the uterus. Details on the extracts, doses, and routes of administration were not reported in the available English language translation (Chen and Chen 2004).

No information on the safety of purslane during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a methanol extract of purslane intraperitoneally administered in mice is 1.87 g/kg (Musa et al. 2007).

Genotoxicity

No mutagenic activity of an aqueous extract of purslane was observed in the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA100 with or without metabolic activation by S9 (Yen et al. 2001).

P

Potentilla erecta (L.) Räusch. — Rosaceae

SCN: cinquefoil
Syn: *Potentilla tormentilla* Stokes

OCN: erect cinquefoil; tormentil
Part: rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (15.0–20.0%) (Tomczyk and Latte 2009; Wichtl 2004); *see* Appendix 1.

Adverse Events and Side Effects

Cinquefoil may cause gastric discomfort in sensitive individuals (Huber et al. 2007; Wichtl 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of cinquefoil in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse effects were reported in a randomized, double-blind, placebo-controlled study of cinquefoil in children ages 3 months to 7 years with rotavirus diarrhea. Patients were orally administered 3 drops cinquefoil per year of age (~0.01 ml/kg), three times daily, for up to 5 days (Subbotina et al. 2003).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In an open-label dose escalation study in patients with ulcerative colitis, patients were orally administered 1200 mg, 1800 mg, 2400 mg, or 3000 mg of capsules containing an ethanolic dried extract of cinquefoil (containing 15 to 22% tannins) daily, divided into three doses. Adverse effects reported as likely related to the cinquefoil were stomach discomfort, heartburn, and nausea or fullness. Other adverse events reported as possible or "unclear" in relation to cinquefoil causality were abdominal cramps, rash on the arms and legs, and exacerbation of the ulcerative colitis (Huber et al. 2007).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of cinquefoil during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

After oral administration, no adverse effects were observed in rats administered 2.5 g/kg or mice administered 6.8 g/kg of cinquefoil extract. After intraperitoneal administration, no adverse effects were observed in rats administered 3.8 g/kg or mice administered 14.5 g/kg of cinquefoil extract (Subbotina et al. 2003).

Primula veris L. — Primulaceae

SCN: cowslip
Syn: *Primula officinalis* (L.) Hill

Part: flower, root

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with gastritis or gastric ulcers (ESCOP 2003).

Other Precautions

Use with caution in persons with hypersensitivity to *Primula* species (EMEA 2008).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Occasional stomach discomfort and nausea has been reported with the use of cowslip root or flower (ESCOP 2003; Wichtl 2004).

Cowslip flower may cause skin reactions in individuals sensitive to species of *Primula* (Wichtl 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of cowslip in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of cowslip root (standard dose: decoction of 0.5–1.5 g, 2–4 g of tincture) may cause upset stomach, nausea, vomiting, or diarrhea (Hänsel et al. 1993; Wichtl 2004).

The leaf of various species of *Primula* contains the compound primin, a potent sensitizer that causes contact dermatitis in sensitive persons (Aplin and Lovell 2001; Ingber and Menne 1990). Primula dermatitis typically manifests as linear streaks of erythema with vesicles and bullae on the forearms, vesicles on the fingers, and sometimes on the face (Zachariae et al. 2007). The underground parts of cowslip do not contain primin, and thus no cutaneous effects are expected after oral use of cowslip root (EMEA 2008; Hausen 1978).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of cowslip during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the saponin fraction of cowslip root intraperitoneally administered in mice is 24.5 mg/kg, whereas that of primula acid intravenously administered to rats is 1.2 mg/kg (Hänsel et al. 1993). The toxic effects of cowslip are generally attributed to the saponin content (EMEA 2008).

Prunella vulgaris L.

Lamiaceae

SCN: heal all
PN: *xia ku cao* (fruit spike)

OCN: self heal
Part: fruit spike

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to heal all have been reported (Bensky et al. 2004).

Pharmacological Considerations

An animal study demonstrated that heal all may modify glucose regulation (Zheng et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

In animal studies, antiestrogenic activity, with no adverse effects on fertility, was observed after treatment with heal all (Collins et al. 2009).

Pregnancy and Lactation

Limited information on the safety of heal all in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Rare cases of allergic reactions to heal all have been reported, with rashes, swelling of the throat, lips, and tongue, and gastrointestinal symptoms including nausea, vomiting, and diarrhea (Bensky et al. 2004). In an animal study, heal all demonstrated inhibition of immediate-type allergic reactions (Shin et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A dose-dependent reduction in blood glucose levels was observed in an acute glucose tolerance test with diabetic mice orally administered 50, 75, 100, or 125 mg/kg of an aqueous-ethanolic extract of heal all. No increase in plasma levels of insulin was observed. A synergistic reduction of blood glucose levels was observed in mice administered a 100 mg/kg dose of the same extract along with 5 mg/kg of the drug glibenclamide (Zheng et al. 2007).

Antiestrogenic activity of heal all was observed in ovariectomized mice administered an aqueous extract of heal all as the sole source of drinking water (estimated daily intake not specified). The mice were implanted with human endometrial xenografts that remain only when treated with estrogen. Mice treated with estrogen and heal all for 1 month had fewer and smaller xenograft implants compared with their estrogen-treated counterparts that drank only water (Collins et al. 2009).

No adverse effects on fertility were observed in mice administered an aqueous extract of heal all as the sole source of drinking water (estimated daily intake not specified) for 2 weeks prior to mating (Collins et al. 2009).

In Vitro Pharmacological Studies

In a hormone-responsive endometrial cell line (ECC-1), a methanolic extract of heal all exhibited antiestrogenic activity. Specifically, a reduction in alkaline phosphatase activity and cell proliferation in response to estrogen in a dose-dependent manner was observed. The expression of an estrogen-induced protein was blocked in the cell line both by a standard antiestrogen compound and by the heal all extract (Collins et al. 2009).

In an in vitro screening system, an extract of heal all exhibited some inhibition of the drug-metabolizing isoenzyme CYP3A4 (Lee et al. 2007).

IV. Pregnancy and Lactation

In excised rabbit uteruses, a decoction of heal all produced tonic contractions in uteruses from nonpregnant animals but had only a weak effect on uteruses from pregnant animals (Zhu 1998).

No information on the safety of heal all during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in mice orally administered 10 g/kg of an extract of heal all (Chen and Chen 2004).

Prunus armeniaca L.

Rosaceae

SCN: apricot
Syn: *Armeniaca vulgaris* Lam.
PN: *ku xing ren* (seed)

OCN: Chinese bitter almond
Part: seed

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004; Femenia et al. 1995).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Cyanogenic glycosides (up to 8% amygdalin) (Chen and Chen 2004; Encarna et al. 1998; FAO/WHO 2009; Femenia et al. 1995; Gunders et al. 1969); *see* Appendix 1.

Editors' Notes

"Sweet" varieties of apricot kernel, with very low levels of cyanogenic glycosides (<0.000005% cyanide) are available commercially (Bensky et al. 2004). Concerns stated here refer to the bitter apricot kernel (0.2–0.4% cyanide) and not the sweet apricot kernel.

Bitter varieties of almonds (*Prunus dulcis*), formerly marketed as a supplement for persons with cancer, also contain the cyanogenic glycoside amygdalin (0.2% cyanide), while commonly consumed sweet varieties of almonds have only trace amounts of the compound (Dicenta et al. 2002). Concerns listed for bitter apricot also apply to bitter almond (Shragg et al. 1982).

Oil extracted from apricot kernel does not contain cyanogenic glycosides (Alpaslan and Hayta 2006; Beyer and Melton 1990).

The U.K. Food Standards Agency suggested that a daily dose of 0.005 mg/kg of cyanide would be unlikely to cause acute effects (FSA 2006). A discussion paper from the FAO and WHO indicated that this estimate may be overly conservative and does not account for the different toxicokinetics for amygdalin (the cyanogenic glycoside present in apricot kernels) that involves bacterial enzymatic conversion to hydrocyanic acid once ingested (FAO/WHO 2009). Other organizations have indicated provisional tolerable daily intake levels of cyanide at 0.012 to 0.108 mg/kg (FAO/WHO 2009).

Bitter apricot kernel should not be sold in retail in bulk; labels on all products should state: Not for use by children (McGuffin et al. 1997).

Adverse Events and Side Effects

Cases of poisoning, both fatal and nonfatal, have been reported in children and adults after ingestion of apricot kernels (Bensky et al. 2004; Gunders et al. 1969; Lasch and Shawa 1981; Sayre and Kaymakcalan 1964; Suchard et al. 1998; Townsend and Boni 1975). The toxic dose for children has been reported as 10 to 20 seeds, while for adults 40 to 60 seeds may cause toxicity (Bensky et al. 2004; Chen and Chen 2004). Poisoning from the cyanogenic glycosides results in symptoms such as salivation, gastric discomfort, nausea, vomiting, abdominal pain, diarrhea, headache, dizziness, weakness, difficulty breathing, restlessness, terror, and palpitations. In severe cases, symptoms may include coma, convulsions, cyanosis, dilated pupils, and death by respiratory failure (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

An animal study indicted that in rats fed diets containing high-amygdalin apricot kernel, offspring survival, lactation indices, and weaning weights were reduced (Miller et al. 1981).

No information on the safety of apricot kernel during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

The toxic dose for children has been reported as 10 to 20 seeds; for adults, 40 to 60 seeds may cause toxicity. Ingestion of 50 to 120 seeds has resulted in fatal poisoning. Poisoning from the cyanogenic glycoside content results in symptoms such as salivation, gastric discomfort, nausea, vomiting, abdominal pain, diarrhea, headache, dizziness, weakness, difficulty breathing, restlessness, terror, and palpitations. In severe cases, symptoms may include coma, cyanosis, dilated pupils, and death by respiratory failure (Bensky et al. 2004; Chen and Chen 2004).

Within the normal dosage range (3–10 g as a decoction) and taken as a decoction, no toxic side effects are expected.

A suspension of the powdered kernel is considered four to five times as toxic as a decoction of the seed. Boiling reduces the toxicity of the kernel (Bensky et al. 2004).

Fatal cyanide poisoning occurred in a 3-year-old girl who ingested an unspecified number of apricot kernels. Analysis of apricot kernels from the same lot that caused the poisoning showed an average of 2.15 mg cyanide per kernel (Gunders et al. 1969).

A 41-year-old woman became weak and had difficulty breathing after ingesting 30 apricot kernels (estimated total, 15 g) purchased at a health food store. She became comatose and hypothermic but responded promptly to antidotal therapy for cyanide poisoning (Suchard et al. 1998).

Nonfatal cyanide poisoning was reported in a 49-year-old woman with lymphoma who had eaten 20 to 40 bitter apricot seeds (Suchard et al. 1998).

Other cases of cyanide poisoning in children and adults have been reported (Lasch and Shawa 1981; Sayre and Kaymakcalan 1964; Townsend and Boni 1975).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

P

IV. Pregnancy and Lactation

In pregnant rats fed diets containing 10% ground apricot kernel from cultivars of apricots containing low amygdalin (<500 mg/kg cyanide), moderate amygdalin (1000–2000 mg/kg cyanide), or high amygdalin (2000 mg/kg cyanide) for 18 weeks, 3-day survival indices of offspring were lower in the high-amygdalin group than the low-amygdalin group. Lactation indices and weaning weights were also lower in the high-dose group than in the low-dose group (Miller et al. 1981).

No information on the safety of apricot kernel during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of an aqueous extract of apricot kernel (amygdalin content not specified in English language abstract) in mice is 2.25 g/kg, whereas that of the compound amygdalin is 443 mg/kg (Yamashita et al. 1987).

The LD_{50} of the compound amygdalin in rats is 25 g/kg after intravenous injection, 8 g/kg after intraperitoneal administration, and 0.6 g/kg after oral administration. Hydrocyanic acid is produced from amygdalin in the presence of gastric acid; thus the oral route is the most toxic (Chen and Chen 2004).

Short-Term Toxicity

In rats fed diets containing 30% powdered pomace of apricot kernels (containing "low" levels of amygdalin) for 4 weeks, poor weight gain and food efficiency ratio were observed. If water was added to the meal prior to feeding, these effects were ameliorated. No histological manifestations were observed in the organs examined (Gandhi et al. 1997).

Subchronic Toxicity

In a toxicity test, rats were fed diets containing 10% ground apricot kernel from cultivars of apricots containing low amygdalin (<500 mg/kg cyanide), moderate amygdalin (1000–2000 mg/kg cyanide), or high amygdalin (2000 mg/kg cyanide) for 18 weeks. In female but not male rats, liver rhodanese activity and thiocyanate (SCN) blood levels increased with the high-amygdalin diet. Both males and females efficiently excreted thiocyanate, indicating efficient detoxification and clearance of cyanide hydrolyzed from dietary amygdalin. No changes in blood chemistry were observed (Miller et al. 1981).

Prunus persica (L.) Batsch

Rosaceae

SCN: peach
Syn: *Amygdalus persica* L.

PN: *tao ren* (seed)
Part: leaf, seed, twig

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Bensky et al. 2004; Holzbecher et al. 1984).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Cyanogenic glycosides (2–6% amygdalin in seed, ~0.5 to 1.5% in leaf) (Holzbecher et al. 1984; List and Hörhammer 1973; Machel and Dorsett 1970); *see* Appendix 1.

Editors' Notes

Peach kernel is generally taken as a decoction. If taken directly, in pills or powders, the kernels should be processed by peeling after being boiled in water for a short time. This processing reduces the toxicity (Bensky et al. 2004). The leaf and twig are less toxic than the kernel (Machel and Dorsett 1970).

Peach leaf and twig should be completely dried before use. The partially dried material contains higher levels of hydrocyanic acid than the fresh or fully dried material. Complete drying reduces the hydrocyanic acid content (Kingsbury 1964; Radostits et al. 2000).

Adverse Events and Side Effects

Overdose (standard dose is a decoction of 4.5–10 g of the kernel) of peach kernel, twig, or leaf may result in poisoning. In children under five, 5 to 10 kernels have caused adverse effects, and 20 kernels have been lethal (Bensky et al. 2004). Symptoms of overdose are similar to cyanide poisoning, including nausea, vomiting, irritation of the gastrointestinal mucosa, headache, dizziness, weakness, blurred vision, increased heart rate, and difficulty breathing (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that peach kernel should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of peach kernel during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of peach kernel, twig, or leaf (standard dose is a decoction of 4.5–10 g of the kernel) may result in poisoning. In children under five, 5 to 10 kernels have caused adverse effects, and 20 kernels have been lethal (Bensky et al. 2004). Symptoms of overdose are similar to cyanide poisoning, including nausea, vomiting, irritation of the gastrointestinal tract, headache, dizziness, weakness, blurred vision, increased heart rate, and difficulty breathing. In more severe cases, symptoms may include incontinence of the urine or stool, loss of consciousness, dilation of pupils, absence of pupillary reflexes, severe spasms, cyanosis, and shock (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered an aqueous extract (boiled for 3 hours) of peach kernel, inhibition of cholinesterase activity in the brain and plasma was observed. The inhibitory dose (ID50) for brain cholinesterase activity was 2.7 g/kg; for plasma cholinesterase activity inhibition, the ID50 was 18.6 g/kg (Suh et al. 2006).

In Vitro Pharmacological Studies

No estrogenic activity of ethanol extracts of peach kernel was observed in a recombinant yeast system with a human estrogen receptor expression plasmid and a reporter plasmid (Kang et al. 2006; Kim et al. 2008).

IV. Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that peach kernel should not be used during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of peach kernel during lactation was identified.

V. Toxicity Studies

The LD_{50} of an intramuscularly injected aqueous extract of peach kernel in mice is 222 g/kg (Chen and Chen 2004).

The oral LD_{50} of an aqueous extract containing the compound amygdalin in mice is 443 mg/kg (Yamashita et al. 1987).

Prunus serotina Ehrh.

Rosaceae

SCN: black cherry
OCN: wild black cherry

Part: dried bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Standard Dose
The standard dose is 2.0–4.0 g (Osol and Farrar 1955).

Notice
Cyanogenic glycosides (prunasin, yielding up to 0.15% hydrocyanic acid) (List and Hörhammer 1973); *see* Appendix 1.

Editors' Notes
Black cherry bark should be completely dried before use. The partially dried bark contains higher levels of hydrocyanic acid than the fresh or fully dried bark, while complete drying reduces the hydrocyanic acid content (Kingsbury 1964; Radostits et al. 2000).

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of black cherry in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

OCN: red sandalwood
Part: heartwood

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Use of this species as a food additive in the U.S. is limited to its function as a flavoring substance in alcoholic beverages (CFR 2011). Dietary ingredients for use in dietary supplements, however, are specifically excluded from the federal food additive definition (U.S.C. 2010).

Adverse Events and Side Effects

Allergic contact dermatitis from red saunders has been reported (Sandra et al. 1996).

Pharmacological Considerations

An animal study demonstrated that red saunders may modify glucose regulation (Kameswara Rao et al. 2001). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of red saunders in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis from red saunders has been reported (Sandra et al. 1996).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In healthy or diabetic rats orally administered 0.25, 0.5, 0.75, or 2.0 g/kg of the water, ethanol, or hexane fractions of red saunders bark, a reduction in blood glucose levels was observed in diabetic but not in healthy animals. The ethanol extract produced the maximum antihyperglycemic activity (Kameswara Rao et al. 2001).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of red saunders during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

In vitro studies with kudzu and the compound puerarin, and animal and in vitro studies of the compound puerarin, have shown that these substances may inhibit platelet aggregation (Choo et al. 2002; Pan et al. 2003; Zhu 1998). Although no cases of interactions have been reported, kudzu should be used with caution in persons taking anticoagulant or antiplatelet drugs (Chen and Chen 2004).

Several in vitro studies have indicated estrogenic activity of kudzu (Boue et al. 2003; Kang et al. 2006; Kim et al. 2008; Zhang et al. 2005), while another in vitro study and a human clinical trial indicated no estrogenic activity (Cherdshewasart et al. 2004; Malaivijitnond et al. 2006).

An animal study indicated that high doses of kudzu (2 or 4 g/kg) slowed the elimination of and increased exposure to the drug methotrexate (Chiang et al. 2005).

Pregnancy and Lactation

No information on the safety of kudzu in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

A decrease in the elimination rate and increase in exposure to the drug methotrexate were observed in rats administered 1 mg/kg intravenously or 5 mg/kg orally of methotrexate with 2 or 4 g/kg of orally administered kudzu (Chiang et al. 2005).

II. Adverse Events

Adverse Events Reported in Clinical Trials

In menopausal women orally administered an aqueous extract of kudzu containing 100 to 200 mg of isoflavones daily for 3 months, slight reductions in estradiol and follicle-stimulating hormone were observed, with no changes in luteinizing hormone (Woo et al. 2003).

Case Reports of Adverse Events

Large overdose of kudzu (standard dose is a decoction of 9–21 g) has been associated with arrhythmias (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In ovariectomized rats orally administered 10, 100, or 1000 mg/kg of kudzu daily for 14 days, an increase in vaginal cornification but no changes in vaginal epithelium were observed in animals in the 100 and 1000 mg/kg dose groups. An increase in uterine weight was observed in animals at the 1000 mg/kg dose (Malaivijitnond et al. 2006).

In rats intravenously administered the compound puerarin (dose not specified in available English language translation), a reduction in the viscosity of whole blood and plasma, blood yield stress, and the maximum rate of platelet aggregation was observed in animals with acute blood stasis (Pan et al. 2003).

In diabetic and healthy rats intravenously administered 15 mg/kg of the compound puerarin, a reduction in plasma glucose levels was observed. The effect was greater in diabetic than in healthy animals (Hsu et al. 2003).

In rats orally administered 100 or 200 mg/kg of the compound puerarin or 700 or 1400 mg/kg of kudzu, a "complex pattern of modulation" of drug-metabolizing isoenzymes was observed, with induction of the drug-metabolizing isoenzymes CYP1A2, CYP3A1, and CYP2B1 in rats treated with kudzu and induction of CYP2A1, 1CYPA1/2, CYP3A1, and CYP2C11 in animals administered puerarin. Both treatments were also reported to inactivate CYP3A, CYP2E1, and CYP2B1 (Guerra et al. 2000).

In Vitro Pharmacological Studies

Inhibition of ADP-induced platelet aggregation was observed in rat platelets treated with 0.25, 0.5, or 1 mg/ml of the compound puerarin. At concentrations of 0.5 to 3.0 mg/ml, puerarin inhibited rabbit, sheep, and human platelet aggregation induced by ADP or 5-HT (Zhu 1998).

Inhibition of ADP- and collagen-induced platelet aggregation was observed in the blood of rats that had been orally administered 1 g/kg of kudzu or 0.25 or 0.5 mg/kg of the compound puerarin (Choo et al. 2002).

An increase in cell proliferation was observed in estrogen receptor-positive human breast cancer cells (MCF-7) treated with a methanol extract of kudzu. The addition of an estrogen antagonist (ICI 182,780) suppressed cell proliferation induced by kudzu (Boue et al. 2003).

In estrogen receptor-positive human breast cancer cells (MCF-7) treated with kudzu, no proliferation and a mild antiproliferative effect was observed (Cherdshewasart et al. 2004).

Competitive binding of a methanol extract of kudzu to estrogen receptor β was observed in a competitive binding assay (Boue et al. 2003).

In assays using recombinant yeast systems with a human estrogen receptor expression plasmid and a reporter plasmid, estrogenic activity of kudzu was observed (Kang et al. 2006; Kim et al. 2008; Zhang et al. 2005).

The compound puerarin blocked L-type calcium channels and potassium channels in isolated guinea pig ventricular myocytes (Sun et al. 2007).

IV. Pregnancy and Lactation

No information on the safety of kudzu during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No evidence of toxicity was observed in mice orally administered up to 20 g/kg of an ethanol extract of kudzu daily for 3 days (Zhu 1998).

The LD_{50} of intravenously administered puerarin in mice is 738 mg/kg (Zhu 1998).

Short-Term Toxicity

In mice orally administered 2 g/kg of an ethanol extract of kudzu daily for 60 days, no pathological changes in organs were observed (Zhu 1998).

No toxic effects were observed in hypertensive dogs orally administered 2 g/kg of an ethanol extract of kudzu daily for 14 days (Zhu 1998).

Pulmonaria officinalis L.

Boraginaceae

SCN: lungwort

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Although the presence of pyrrolizidine alkaloids is common in the Boraginaceae family, and the presence of those compounds in lungwort has been suspected, analyses of plants containing pyrrolizidine alkaloids failed to detect any pyrrolizidine alkaloids in lungwort (Dobler et al. 2000; Williamson 2003).

A set of anticholinergic poisonings, improperly attributed to lungwort, was reported (Baca-Garcia et al. 2007). Lungwort does not contain compounds that would cause anticholinergic poisoning.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of lungwort in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A set of anticholinergic poisonings, improperly attributed to lungwort, was reported in three members of a family who consumed tea from what were believed at the time to be lungwort leaves. The identity of the leaves was not confirmed or analyzed for the presence of adulterants (Baca-Garcia et al. 2007). Lungwort does not contain compounds that would cause anticholinergic poisoning.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Punica granatum L. — Punicaceae

SCN: pomegranate
AN: *dadima*

PN: *shi liu pi* (fruit rind)
Part: fruit husk

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Gujral et al. 1960; Prakash et al. 1985).

Not for use in the early stages of diarrhea or dysentery, although one of the common therapeutic uses is in chronic diarrhea and dysentery (Bensky et al. 2004; Chen and Chen 2004).

Not for use in excess of 14 days.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (up to 28.0%) (List and Hörhammer 1973); *see* Appendix 1.

Editors' Note

Pomegranate fruit husk should not be mixed with oils or fats when taken to kill parasites (Bensky et al. 2004; Chen and Chen 2004).

Adverse Events and Side Effects

Allergic reactions to pomegranate fruit have been reported (Gaig et al. 1992, 1999; Igea et al. 1991).

In the normal dose range (decoction made from 3–10 g of husk), nausea, vomiting, diarrhea, abdominal pain, dizziness, tinnitus, and tremors have been reported as side effects (no further details available) (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

Extracts of whole pomegranate fruit have shown varying activity on drug-metabolizing enzymes in vitro (Subehan et al. 2006; Usia et al. 2006). The relevance of those data to human use of preparations made from pomegranate husk is not known.

Pregnancy and Lactation

Animal studies have indicated anti-implantation and antifertility activity of pomegranate fruit husk (Gujral et al. 1960; Prakash et al. 1985). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of pomegranate fruit husk during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions after ingestion of pomegranate fruit, confirmed by skin prick testing, have been reported (Gaig et al. 1992, 1999; Igea et al. 1991). Anaphylactic reactions to pomegranate fruit have been reported. Skin prick testing has indicated that the compound mannitol, naturally present in pomegranate, is responsible for this reaction (Hegde et al. 2002; Hegde and Venkatesh 2004).

In the normal dose range (decoction made from 3–9 g of husk), nausea, vomiting, diarrhea, abdominal pain, dizziness, tinnitus, and tremors have been reported as side effects (case details not available) (Bensky et al. 2004; Chen and Chen 2004). In overdose, pomegranate husk has been associated with vertigo, headache, blurred vision, tinnitus, weakness, and tremors. In severe cases, death due to respiratory paralysis has been reported (case details not available) (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Hypoglycemic activity of pomegranate husk extract was observed in diabetic rats administered doses of 2.5 g/kg (Zafar 1990).

In animal studies, gross overdose of pomegranate peel led to respiratory suppression (dose, product, and route of administration not reported in English language translation) (Chen and Chen 2004).

In Vitro Pharmacological Studies

No significant effects of 0.5 mg/ml of a m ethanolic extract of pomegranate fruit on CYP3A4 or CYP2D6 were observed in human liver microsomes (Subehan et al. 2006). In another study, however, a methanolic extract of the fruit significantly inhibited CYP3A4, with an inhibitory concentration (IC_{50}) of 35 µg/ml, and CYP2D6, with an IC_{50} of 32 µg/ml (Usia et al. 2006). The studies used an extract of the whole fruit, including juice, and findings may or may not apply to products made from pomegranate husk.

IV. Pregnancy and Lactation

Some antifertility activity was observed in rats and guinea pigs fed a d iet supplemented with pomegranate husk (Gujral et al. 1960). Anti-implantation activity of acetone, aqueous, and methanol extracts of pomegranate seed, root, or whole plant was observed in rats (Prakash et al. 1985).

Early studies indicated that the fruit pulp of pomegranate had a stimulatory effect on isolated rat uteri (Dhawan and Saxena 1958).

No information on the safety of pomegranate fruit husk during lactation was identified.

V. Toxicity Studies

Acute Toxicity

See Punica granatum juice entry (next entry).

Short-Term Toxicity

See Punica granatum juice entry.

Subchronic Toxicity

See Punica granatum juice entry.

Genotoxicity

In two human lymphoma cell lines, administration of a decoction of pomegranate husk did not induce chromosomal aberrations but did induce apoptotic DNA fragmentation (Settheetham and Ishida 1995).

Part: fruit juice

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Adverse Events and Side Effects

A review of six clinical studies of a pomegranate juice product indicated that no serious adverse events or changes in blood chemistry were observed (McCutcheon et al. 2008).

Pharmacological Considerations

Animal (Faria et al. 2007; Hidaka et al. 2005; Nagata et al. 2007) and in vitro (Farkas et al. 2007; Hidaka et al. 2005; Kim et al. 2006; Nagata et al. 2007; Subehan et al. 2006; Usia et al. 2006) studies have provided conflicting data on the effects of pomegranate juice on drug-metabolizing isoenzymes CYP3A, CYP2C9, and CYP2D6, with some studies showing inhibition of the enzymes and others showing no effects. One human study comparing pomegranate juice and grapefruit juice (a known CYP3A4 inhibitor), however, showed no effect of pomegranate juice on CYP3A4 (Farkas et al. 2007).

In vitro studies have indicated that pomegranate juice competitively binds to estrogen receptors (Kajiya et al. 2005; Maru et al. 2001). The relevance of the in vitro data to human use is not known.

Pregnancy and Lactation

An animal study of pomegranate juice during pregnancy and lactation indicated a strong protective effect of pomegranate juice in experimentally induced brain damage due to lack of oxygen and blood flow (hypoxia-ischemia) in the fetuses and nursing offspring (Loren et al. 2005).

No information on the safety of pomegranate fruit juice during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

See Human pharmacological studies.

Case Reports of Suspected Drug or Supplement Interactions

Rhabdomyolysis was reported in a 4 8-year-old man with possible underlying myopathy. The man had been successfully treated with ezetimibe 10 mg/day and rosuvastatin 5 mg every other day for 17 months. Three weeks before presentation, he began drinking 200 ml pomegranate juice twice weekly. Muscle pain and weakness is reported to occur in 1 to 5% of patients taking statin drugs such as rosuvastatin, and rhabdomyolysis also occurs (Wooltorton 2004). Ezetimibe has also been associated with rhabdomyolysis (Health Canada 2005). The authors of the

report indicated that pomegranate juice may increase the risk of rhabdomyolysis from rosuvastatin through inhibition of CYP3A4, although rosuvastatin is not metabolized by CYP3A4 (AstraZeneca 2003; Sorokin et al. 2006).

Animal Trials of Drug or Supplement Interactions

See Animal pharmacological studies.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No serious adverse events were reported in a phase II study of pomegranate juice in men being treated for prostate cancer. The men were administered 8 oz of pomegranate juice daily for 33 months (Pantuck et al. 2006). No changes in blood chemistry were observed in patients with atherosclerosis administered 50 ml of pomegranate juice daily for 1 to 3 years (Aviram et al. 2004).

Case Reports of Adverse Events

Allergic reactions after ingestion of pomegranate fruit, confirmed by skin prick testing, have been reported (Gaig et al. 1992, 1999; Igea et al. 1991). Anaphylactic reactions to pomegranate fruit have been reported. Skin prick testing has indicated that the compound mannitol, naturally present in pomegranate, is responsible for this reaction (Hegde et al. 2002; Hegde and Venkatesh 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers pretreated with pomegranate juice or grapefruit juice, no effects of pomegranate juice were seen on the activity of the drug-metabolizing isoenzyme CYP3A4. Grapefruit juice, however, significantly inhibited CYP3A4 (Farkas et al. 2007).

No adverse events were reported in a safety study of a pomegranate ellagitannin-enriched polyphenol extract in overweight patients administered capsules containing 710 mg (435 mg of gallic acid equivalents, GAEs) or 1420 mg (870 mg of GAEs) daily for 28 days (Heber et al. 2007). No serious adverse events were reported in a safety study of pomegranate juice in men with erectile dysfunction administered 8 oz of pomegranate juice daily for 28 days. Nonserious adverse events were similar in the pomegranate and control groups (Forest et al. 2007).

Animal Pharmacological Studies

In rats administered 3 ml of pomegranate juice, a significant increase in the area under the time-concentration curve of orally administered tolbutamide was observed, although the elimination half-life of tolbutamide was not affected, indicating that pomegranate juice impairs the function of intestinal but not hepatic CYP2C9 (Nagata et al. 2007).

In rats administered 2 ml of pomegranate juice, a significant increase in the area under the concentration-time curve of orally administered carbamazepine was observed, although the elimination half-life of carbamazepine was not affected, indicating that pomegranate juice impairs the function of intestinal but not hepatic CYP3A (Hidaka et al. 2005).

In mice administered pomegranate juice (made from whole fruit including seed) as the sole source of drinking water for 4 weeks, a decrease in total hepatic cytochrome P450 content and expression of CYP1A2 and CYP3A were observed (Faria et al. 2007).

An increase in uterine weight was reported in ovariectomized rats administered pomegranate juice (dose and duration not specified in English-language abstract) (Maru et al. 2001).

In Vitro Pharmacological Studies

In human liver microsomes preincubated with pomegranate juice, no inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed. Without preincubation, some inhibition was observed (Farkas et al. 2007). In another test in human liver microsomes, pomegranate juice was shown to inhibit CYP3A. The effect was less than that of grapefruit, black mulberry, wild grape, and black raspberry fruit juices (Kim et al. 2006).

Addition of pomegranate juice to human liver microsomes resulted in a dose-dependent inhibition of CYP3A and CYP2C9 activity, with a 5% (by volume) concentration providing almost complete inhibition of both enzymes. The effects on CYP3A were similar to that of grapefruit juice (Hidaka et al. 2005; Nagata et al. 2007).

No significant effects of 0.5 mg/ml of a methanolic extract of pomegranate fruit on CYP3A4 or CYP2D6 were observed in human liver microsomes (Subehan et al. 2006). In another study, however, a methanolic extract of the fruit significantly inhibited CYP3A4, with an inhibitory concentration (IC_{50}) of 35 µg/ml, and CYP2D6, with an IC_{50} of 32 µg/ml (Usia et al. 2006).

Pomegranate juice was reported to have competitive binding activity with 17β-estradiol for the estrogen receptor and to stimulate proliferation of the estrogen receptor-positive human breast cancer cell line MCF-7 (active concentrations not reported in English language abstract) (Maru et al. 2001). Another study of competitive binding indicated that pomegranate juice was more active in estrogen receptor (ER)-α than ER-β, and that the methanolic fraction of pomegranate juice showed more competitive binding against 17β-estradiol than the water fraction (Kajiya et al. 2005). A phytochemical analysis of pomegranate seed and juice failed to find any steroid-like compounds in either product (Choi et al. 2006).

IV. Pregnancy and Lactation

A neuroprotective effect of pomegranate juice was observed in a mouse model of neonatal hypoxic-ischemic brain injury in offspring of mothers administered pomegranate juice beginning at the third trimester of pregnancy

and continuing through lactation. The juice was provided alongside drinking water for consumption ad libitum in low, medium, or high concentrations (8, 16, or 32 µmol polyphenols daily estimated intake), with the high dose equivalent to a human dose of two 8 oz glasses of pomegranate juice daily. Ellagic acid, a polyphenolic component in pomegranate juice, was detected in plasma from treated but not control pups (Loren et al. 2005).

Early studies indicated that the fruit pulp of pomegranate had a stimulatory effect on isolated rat uteri (Dhawan and Saxena 1958).

No information on the safety of pomegranate fruit juice during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered whole plant (excluding roots) extract in rats is 250 mg/kg (Dhawan et al. 1977). The LD_{50} of an intraperitoneally administered standardized whole pomegranate fruit extract (30% punicalagins) in rats is 217 mg/kg and in mice is 187 mg/kg. The LD_{50} of an orally administered standardized whole pomegranate fruit extract (30% punicalagins) in rats and mice could not be determined at doses up to 5 g/kg (Patel et al. 2008). The LD_{50} of an intraperitoneally administered pomegranate whole fruit hydroalcoholic extract is 731 mg/kg in mice (Vidal et al. 2003).

In chick embryos, a dose of 0.1 mg pomegranate whole fruit hydroalcoholic extract per embryo was nontoxic (Vidal et al. 2003).

Short-Term Toxicity

No adverse effects were observed in rats intranasally administered 0.4 and 1.2 mg/kg pomegranate whole fruit hydroalcoholic extract daily for up to 35 days (Vidal et al. 2003).

In rats fed a diet containing 6% of the compound punicalagin (present in pomegranate juice at concentrations of 2 g/l) daily for 37 days, a decrease in food intake and growth rate was observed, attributed to the palatability of the supplemented food. Blood chemistry was normal with the exception of urea and triglycerides, which remained at low values throughout the experiment. Histopathological analysis of liver and kidney indicated no adverse effects on the organs (Cerda et al. 2003).

Subchronic Toxicity

No adverse effects were observed in rats orally administered a standardized whole pomegranate fruit extract (30% punicalagins) at doses of 60, 240 and 600 mg/kg daily for 90 days. Based on the results of the study, the authors indicated that the no-observed-adverse-effect level (NOAEL) for the standardized pomegranate fruit extract was 600 mg/kg daily (Patel et al. 2008).

Genotoxicity

A hydroalcoholic extract of whole pomegranate fruit showed genotoxic activity in *Salmonella typhimurium* strain TA100 and *Saccharomyces cerevisiae* with or without activation by S9 (Sanchez-Lamar et al. 2008). Administration of a hydroalcoholic extract of whole pomegranate fruit to mice at doses of 7 to 700 mg/kg (intraperitoneal) daily for 2 days resulted in some mutagenic activity in the bone marrow micronucleus assay and the sperm shape abnormality assay at doses over 70 mg/kg (Sanchez-Lamar et al. 2008). Antimutagenic effects of pomegranate extracts have also been shown in *Salmonella typhimurium* and in micronucleus assays in mice and rats (Alekperov 2002; Bala and Grover 1992).

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions to pomegranate fruit have been reported (Gaig et al. 1992, 1999; Igea et al. 1991). Ingestion of dried crushed seed has been associated with an increased risk of esophageal cancer in Iranian woman. The risk is believed to be due to repeated mechanical irritation of the esophagus, which is a recognized cause of esophageal cancer (Ghadirian et al. 1992).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Information on the safety of pomegranate seed use during pregnancy and lactation is limited. One study indicated that pomegranate seed is traditionally consumed by pregnant women in Iran (Ghadirian et al. 1992). Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

An increased risk of esophageal cancer in Iranian women was associated with the consumption of crushed pomegranate seed. As traditionally prepared for consumption, the seed pieces have sharp edges that mechanically irritate or damage the esophagus, which is a recognized cause of esophageal cancer (Ghadirian et al. 1992).

Allergic reactions after ingestion of pomegranate fruit, confirmed by skin prick testing, have been reported (Gaig et al. 1992, 1999; Igea et al. 1991). Anaphylactic reactions to pomegranate fruit have been reported. Skin prick testing indicated that the compound mannitol, naturally present in pomegranate, is responsible for the reaction (Hegde et al. 2002; Hegde and Venkatesh 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A significant reduction of blood glucose levels was observed in diabetic rats orally administered an extract of pomegranate seed at doses of 150, 300, or 600 mg/kg (Das et al. 2001).

Pomegranate seed oil administered orally or intramuscularly increased the uterine weight in ovariectomized mice and increased vaginal cornification in immature female rabbits (Sharaf 1969; Sharaf and Nigm 1964).

In Vitro Pharmacological Studies

A polyphenol-rich fraction of pomegranate seed oil inhibited 17β-hydroxysteroid dehydrogenase type 1 at concentrations ranging from 100 to 1000 µg/ml. The oil also inhibited proliferation of estrogen receptor (ER)-positive human breast cancer cells (MCF-7), inhibited invasion of MCF-7 across a membrane, and induced apoptosis in ER-negative human breast cancer cells (MDA-MB-435) (Kim et al. 2002). An older study indicated that dried pomegranate seed contains the compound estrone at a concentration of 17 mg/kg (Heftmann et al. 1966); a more recent analysis indicated that no estrone was present (Choi et al. 2006).

IV. Pregnancy and Lactation

Pomegranate seed is traditionally consumed by pregnant women in Iran (Ghadirian et al. 1992). No other information on the safety of pomegranate seed use during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered whole plant extract (excluding roots) in rats is 250 mg/kg (Dhawan et al. 1977).

Pomegranate seed oil was not toxic to brine shrimp larvae (Fatope et al. 2002).

Chronic Toxicity

A lack of adverse effects was noted in rats administered a diet containing 0.01 to 1% pomegranate seed oil for up to 32 weeks (Kohno et al. 2004).

Quassia amara L.

Simaroubaceae

SCN: quassia
OCN: Surinam quassia

Part: bark, root, wood

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Felter and Lloyd 1898; Remington and Wood 1918).

Not for use in children under 6 years of age (Felter and Lloyd 1898).

Not for internal use by men attempting to conceive (Faisal et al. 2006; Parveen et al. 2003; Raji and Bolarinwa 1997).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 1–2 g per day of the wood as a decoction; average dose, 0.5 g, 2 to 3 times daily (Merck 1930; Wichtl 2004).

Editors' Note

Quassia should not be confused with Jamaica quassia (*Picrasma excelsa*) or senna (*Senna* spp., formerly classified as *Cassia* spp.).

Adverse Events and Side Effects

Consumption of large amounts of quassia can irritate the mucous membrane of the stomach and lead to vomiting (List and Hörhammer 1973; Remington and Wood 1918; Wichtl 2004).

Pharmacological Considerations

Animal studies with quassia have demonstrated changes in sperm count, shape, and viability (Faisal et al. 2006; Parveen et al. 2003; Raji and Bolarinwa 1997). Changes were shown to return to normal several weeks after cessation of treatment (Raji and Bolarinwa 1997). No human studies on the safety or efficacy of quassia as a male contraceptive have been completed.

Pregnancy and Lactation

Although no information on the safety of quassia during pregnancy was identified, traditional use in the treatment of parasites suggests that quassia should not be used during pregnancy (Felter and Lloyd 1898; Remington and Wood 1918).

No information on the safety of quassia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in sperm counts and motility and an increase in sperm abnormalities were observed in mice intraperitoneally administered 25, 50, or 100 mg/kg of dried methanol extract of quassia (Faisal et al. 2006).

In mice (average animal weight 187 g) intramuscularly administered 1 ml of a chloroform extract of quassia daily for 15 days, a reduction in the weight of testis and epididymis was observed, along with marked decreases in the sperm count, motility, and viability and an increase in sperm abnormalities (Parveen et al. 2003).

In rats provided drinking water to give doses of 100, 1000, or 2000 mg/kg of a methanol extract of quassia or 0.1, 1.0, and 2.0 mg/kg of the compound quassin daily for 8 weeks, a decrease in the weights of the testes, seminal vesicles, and epididymides was observed. A dose-independent reduction of sperm counts was observed, although sperm counts returned to normal after 8 weeks (Raji and Bolarinwa 1997).

In Vitro Pharmacological Studies

A methanol extract of quassia concentration-dependently inhibited basal and luteinizing hormone-stimulated testosterone secretion by rat Leydig cells (Njar et al. 1995).

IV. Pregnancy and Lactation

Although no information on the safety of quassia during pregnancy was identified, traditional use in the treatment of parasites suggests that quassia should not be used during pregnancy (Felter and Lloyd 1898; Remington and Wood 1918).

No information on the safety of quassia during lactation was identified.

V. Toxicity Studies

Acute Toxicity

In mice orally administered 250, 500, 750, or 1000 mg/kg of an aqueous extract of quassia, no signs of acute toxicity were observed (Garcia Gonzalez et al. 1997).

In mice intraperitoneally administered 500 or 1000 mg/kg of an aqueous extract of quassia, signs of acute toxicity but no mortality were observed in the 500 mg/kg dose group, while 100% mortality was observed in the 1000 mg/kg dose group (Garcia Gonzalez et al. 1997).

Short-Term Toxicity

In mice (average animal weight 187 g) intramuscularly administered 1 ml of a chloroform extract of quassia daily for 15 days, no changes in bilirubin, aspartate aminotransferase, alanine aminotransferase, or hemoglobin levels were observed (Parveen et al. 2003).

SCN: oak
OCN: sessile oak

Quercus robur **L.**
SCN: oak
OCN: English oak
Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Topical use is cautioned in extensive cases of eczema or skin damage (Blumenthal et al. 1998).

Drug and Supplement Interactions

None known.

Notice

Tannins (6.0–20.0%) (List and Hörhammer 1973; Wichtl 2004); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of oak or white oak in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Several cases of occupational asthma due to oak wood dust have been reported in woodworkers (Malo et al. 1995).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of oak or white oak during pregnancy or lactation was identified.

V. Toxicity Studies

Genotoxicity

In the Ames test for mutagenicity, an extract of oak heartwood did not exhibit any mutagenic activity (Weissmann et al. 1989).

Rehmannia glutinosa (Gaertn.) Steud. — Orobanchaceae

SCN: rehmannia
PN: *sheng di huang* (unprocessed tuber)

Part: dried tuber

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with diarrhea (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Two forms of rehmannia tuber are used in traditional Chinese medicine, the dried tuber (*sheng di huang*), which is the subject of this entry, and the processed tuber (*shu di huang*), which is the subject of a separate entry. Processing reduces the content of the compound catalpol (an iridoid glycoside) such that the catalpol content of prepared rehmannia root is only 1/20–1/30 that of fresh rehmannia (Wang et al. 1997). Methods of proper processing and resulting chemical profiles are described in other texts and articles (Bensky et al. 2004; Wang et al. 1997).

Adverse Events and Side Effects

Occasional side effects of rehmannia tuber include diarrhea, abdominal pain, dizziness, fatigue, and heart palpitations (Bensky et al. 2004).

Allergic reactions to rehmannia tuber, including an anaphylactic reaction after a very high dose, have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Limited information on the use of rehmannia tuber in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reaction to rehmannia tuber, including an anaphylactic reaction after a 100 g dose, has been reported (Bensky et al. 2004).

Occasional side effects of rehmannia tuber include diarrhea, abdominal pain, dizziness, fatigue, and heart palpitations. Ingestion of very high doses (standard dose is a decoction of 9–15 g) has been associated with headache, dizziness, constricted pupils and loss of pupil reflexes, blue discoloration of the lips, low blood pressure, irregular heartbeat, and coma (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Several different extracts of rehmannia tuber, including an ethanol fraction of an aqueous extract, rehmannia oligosaccharide, and rehmannia glycoside D, showed hypoglycemic activity in healthy and diabetic rats and mice (Kiho et al. 1992; Kitagawa et al. 1971; Oshio and Inouye 1982).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A decrease in litter numbers was observed in mice subcutaneously administered 0.1 to 0.4 ml daily of an aqueous extract of rehmannia (condition of herbal material not stated) (Matsui et al. 1967).

No information on the safety of dried (unprepared) rehmannia tuber during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No deaths were reported in mice orally administered 60 g/kg daily of an aqueous or alcoholic extract of dried rehmannia tuber for 3 days (Chen and Chen 2004).

Short-Term Toxicity

No deaths were reported in rats orally administered 18 g/kg daily of an aqueous or alcoholic extract of dried rehmannia for 15 days. No adverse effects on internal organs were seen (Chen and Chen 2004).

Genotoxicity

Dried rehmannia tuber did not exhibit mutagenic activity in the Ames mutagenicity test or the micronucleus assays in mice (Yin et al. 1991).

Reynoutria multiflora (Thunb.) Moldenke

Polygonaceae

SCN: fo-ti
Syn: *Fallopia multiflora* (Thunb.) Haraldson; *Polygonum multiflorum* Thunb.

PN: *he shou wu* (cured root tuber)
OCN: fleeceflower
Part: prepared root tuber

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with loose stools or diarrhea (Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Editors' Notes

Two forms of fo-ti tuber are used in traditional Chinese medicine, the processed or prepared tuber (*zhi he shou wu*), which is the subject of this entry, and the dried tuber (*sheng he shou wu*), which is the subject of a separate entry (*see* next entry). The prepared tuber is used almost exclusively, while the dried tuber is not commonly used and is difficult to find commercially. The dried tuber contains stilbene glycosides and anthraquinone glycosides and is traditionally used for short periods of time as a stimulant laxative; the processed tuber is used as a tonic and has significantly lower anthraquinone glycoside content (Bensky et al. 2004; Leung and Foster 1996). The processing is responsible for this change in constituents, reducing the concentrations of free and conjugated anthraquinones by 42 to 96% (Avula et al. 2007; Leung and Foster 1996; Zhang et al. 2006). Methods of proper processing and resulting chemical profiles are described in other texts and articles (Avula et al. 2007; Bensky et al. 2004; Liu et al. 1991; PPRC 2005; Sionneau and Flaws 1995; Yi et al. 2007; Zhang et al. 2006).

Adverse Events and Side Effects

Several cases of acute hepatitis have been reported in persons taking fo-ti (Battinelli et al. 2004; But et al. 1996; Cardenas et al. 2006; Laird et al. 2008; Panis et al. 2005; Park et al. 2001). Although products in the case reports were marketed as processed fo-ti, analyses of some products indicated elevated levels of anthraquinone glycosides and stilbene glycosides (Battinelli et al. 2004; But et al. 1996; Laird et al. 2008; Panis et al. 2005). The hepatitis is believed to be due to long-term use of unprocessed or incompletely processed tuber, which is indicated only for short-term use (*see* Editors' Notes). The stilbene glycosides (Panis et al. 2005) and anthraquinone glycosides (Cardenas et al. 2006; Stickel et al. 2005; Vanderperren et al. 2005) in the unprocessed or incompletely processed tuber have been indicated as the compounds responsible for the hepatotoxicity, although the mechanism of action is not yet understood.

Pharmacological Considerations

In vitro, a mild estrogenic effect (Kang et al. 2006; Zhang et al. 2005) and inhibition of some CYP enzymes have been observed (Unger and Frank 2004).

Pregnancy and Lactation

No information on the safety of fo-ti in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Cases of acute hepatitis have been reported as follows: a woman who had taken 2 tablets daily of shen-min tablets (20% 12:1 extract of fo-ti and 40% fo-ti powder) for 8 weeks (Cardenas et al. 2006); a man who had taken fo-ti tablets at the recommended dose daily for 1 month (Battinelli et al. 2004); and a woman who had taken fo-ti tablets for 2 weeks

at the recommended dose (Park et al. 2001). In one case, the herbal product was analyzed and found to contain 0.14% by weight anthraquinones (Battinelli et al. 2004). The author of one of the reports indicated that the hepatotoxicity was an idiosyncratic reaction because the patient developed a fine maculopapular rash and mild eosinophilia, and did not overdose (Cardenas et al. 2006).

Recurrent hepatitis was reported in a 5-year-old girl who had taken 3 tablets daily of shou wu pian, a product made from fo-ti tuber, for 4 months. Elevated serum levels of bilirubin and liver enzymes were observed, and viral markers were used to rule out a number of diseases. Symptoms disappeared and liver function tests were normal 1 month after cessation of the product. The girl experienced hepatitis again after being administered 2 tablets daily of the same product for 1 month (Panis et al. 2005). The product identity was confirmed by nuclear magnetic resonance analysis and showed 2,3,5,4′-tetrahydroxystilbene-2-*O*-β-D-glucopyranoside, a stilbene glycoside, to be the main constituent. The anthraquinone emodin was present in trace amounts (Panis et al. 2005). Such a chemical composition indicates that raw or incompletely processed fo-ti was used.

Hepatitis was diagnosed in a 31-year-old pregnant woman who had been taking shou wu pian (dose unspecified), a proprietary product made from fo-ti tuber, for several weeks prior to the hepatitis. Elevated plasma levels of liver enzymes were observed, and viral hepatitis was ruled out. Liver enzyme levels returned to normal 3 weeks after cessation of the product. The identity of the product was confirmed by thin-layer chromatography, and two anthraquinones, emodin and physcion, were identified. The patient described a case of hepatitis that she had 2 years prior after taking a liquid extract prepared from fo-ti (But et al. 1996).

Acute hepatitis mimicking iron overload syndrome was reported in a 35-year-old man who had been taking fo-ti (dose and duration unspecified). Laboratory studies included alanine transferase 2714 U/l (normal <50 U/l), aspartate aminotransferase 1170 U/l (normal <50 U/l), AP 137 U/l (normal <130 U/l), total bilirubin 4.6 mg/dl (normal <1.4 mg/dl), direct bilirubin 3.0 mg/dl (normal <0.4 mg/dl), and ferritin 13,862 ng/ml (normal 8 to 282 ng/ml) and a fasting transferrin saturation of 86% (normal 20% to 60%). Analysis of the herbal supplement identified extracts from fo-ti including the anthraquinones emodin and physcion. The patient recovered after cessation of the herbal products, and liver function tests 4 months after hospitalization were normal (Laird et al. 2008).

A traditional Chinese medicine text lists the following adverse events reported in association with processed fo-ti tuber products (no details on cases are provided): mild abdominal pain, nausea, vomiting, mild jaundice, abnormal liver function studies, bleeding from the upper digestive tract, diarrhea, and melena. In extremely high doses, stimulation, agitation, tachycardia, clonic or tetanic spasms, and even death due to respiratory paralysis have been reported. A repetitive, malarial-like sequence of drug fevers, chills, sweating, and weakness has been observed. Allergic reactions have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

At concentrations greater than 0.1 μg/ml, a mild estrogenic effect of fo-ti was observed in vitro (Kang et al. 2006). The EC_{50} for fo-ti estrogenic activity in the recombinant yeast bioassay was 80 μg/ml (Zhang et al. 2005).

Inhibition of several CYP450 enzymes was observed in vitro at concentrations of 500 μg/ml, but not at concentrations of 20 or 100 μg/ml. The authors of the study indicated that the relevance of the in vitro results to in vivo situations is unknown (Unger and Frank 2004).

Fo-ti inhibited DNA synthesis and growth in human vascular epithelial cells under normal culture conditions at a concentration of 100 μg/ml (Ling et al. 2008).

IV. Pregnancy and Lactation

No studies were identified on the use of fo-ti during pregnancy or lactation. No contraindications for use during pregnancy or lactation are listed in two traditional Chinese medicine texts (Bensky et al. 2004; Chen and Chen 2004).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered alcohol extract of processed fo-ti tuber in mice is 164.9 g/kg (Leung and Foster 1996; Shen et al. 1982), whereas that of the intragastrically administered extract is over 1000 g/kg, with no deaths reported at that dose (Chen and Chen 2004; Shen et al. 1982).

Genotoxicity

No mutagenic activity of fo-ti aqueous extracts was reported in the Ames test for mutagenicity (Kam 1981). Antimutagenic activity of fo-ti was observed in a *Tradescantia* micronucleus assay (Zhang et al. 1999).

PN: *sheng he shou wu* (dried root tuber)
OCN: fleeceflower
Part: unprocessed root tuber

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Battinelli et al. 2004; But et al. 1996; Laird et al. 2008; Panis et al. 2005).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Stimulant laxative (Leung and Foster 1996); *see* Appendix 2.

Editors' Notes

Two forms of fo-ti tuber are used in traditional Chinese medicine, the dried tuber (*sheng he shou wu*), which is the subject of this entry, and the processed tuber (*zhi he shou wu*), which is the subject of a separate entry (*see* previous entry). The processed tuber is used almost exclusively, while the dried tuber is not commonly used and is difficult to find commercially. The dried tuber contains stilbene glycosides and anthraquinone glycosides and is traditionally used for short periods of time as a stimulant laxative (Avula et al. 2007; Leung and Foster 1996; Zhang et al. 2006).

Adverse Events and Side Effects

Although no cases of adverse events associated explicitly with unprocessed fo-ti have been reported in the English language literature, analysis of fo-ti products marketed as processed fo-ti and associated with cases of hepatitis showed levels of anthraquinone glycosides or stilbene glycosides that suggested incomplete processing (Battinelli et al. 2004; But et al. 1996; Laird et al. 2008; Panis et al. 2005).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No studies on the use of unprocessed fo-ti during pregnancy or lactation were identified. No contraindications for use during pregnancy or lactation are listed in two traditional Chinese medicine texts (Bensky et al. 2004; Chen and Chen 2004). Based on stimulant laxative activity and an incomplete understanding of reports of hepatotoxicity associated with the incompletely processed tuber, use during pregnancy or lactation is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Although no cases of adverse events associated explicitly with unprocessed fo-ti have been reported in the English language literature, analysis of fo-ti products marketed as processed fo-ti and associated with cases of hepatitis showed levels of anthraquinone glycosides or stilbene glycosides that suggested incomplete processing (Battinelli et al. 2004; But et al. 1996; Laird et al. 2008; Panis et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats fed peroxidized corn oil, administration of stilbene components (100 mg/kg piceid or 50 or 100 mg/kg 2,3,5,4′-tetrahydroxystilbene-2-*O*-D-glucoside) isolated from fo-ti tubers was found to partly inhibit the deposition of lipid peroxides in the liver, providing a h epatoprotective effect, and to reduce the elevation of glutamic oxaloacetic transaminase (GOT) and glutamic pyruvate transaminase (GPT) levels in the serum (Kimura et al. 1983).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No studies on the use of unprocessed fo-ti during pregnancy or lactation were identified. No contraindications for use during pregnancy or lactation are listed in two traditional Chinese medicine texts (Bensky et al. 2004; Chen and Chen 2004). Based on stimulant laxative activity and an incomplete understanding of reports of hepatotoxicity associated with the incompletely processed tuber, use during pregnancy or lactation is not recommended except under the supervision of a qualified healthcare practitioner.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered alcohol extract of unprocessed fo-ti tuber in mice is 2.7 g/kg, whereas that of an intragastrically administered extract is 50 g/kg (Leung and Foster 1996; Shen et al. 1982).

Rhamnus cathartica L. — Rhamnaceae

SCN: buckthorn

Part: fruit

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Bradley 1992; Chadha 1988; Roth et al. 1984; Wichtl 2004).

Not for use in persons with intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (i.e., appendicitis, colitis, Crohn's disease, irritable bowel syndrome, and melanosis coli) (Bradley 1992; De Smet 1993; Wichtl 2004).

Not for use in children less than 12 years of age (Bradley 1992; De Smet 1993).

Not for use in excess of 8 consecutive days (Bradley 1992; De Smet 1993; Leung and Foster 1996; Weiss and Meuss 2001; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Notice

Stimulant laxative (Bradley 1992; Chadha 1988; De Smet 1993; Felter and Lloyd 1898; Leung and Foster 1996; Martindale and Reynolds 1996; Roth et al. 1984; Weiss and Meuss 2001; Wichtl 2004); *see* Appendix 2.

Standard Dose

The individually correct dose is the smallest dose necessary to produce a comfortable, soft stool (ESCOP 2003).

Editors' Note

The American Herbal Products Association has established a trade requirement (AHPA 2011) that products containing this herb in sufficient quantity to warrant such labeling bear the following label statement:

> NOTICE: Do not use this product if you have abdominal pain or diarrhea. Consult a health care provider prior to use if you are pregnant or nursing. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use.

Adverse Events and Side Effects

Discoloration of the urine by buckthorn metabolites may occur but is not clinically significant. Abdominal spasms and pain have been reported (ESCOP 2003).

Pharmacological Considerations

Concomitant use of buckthorn is cautioned with antiarrhythmic drugs and botanicals containing cardiac

glycosides, as long-term use of buckthorn as a laxative can cause potassium loss, leading to increased toxicity of those drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Concomitant internal use of buckthorn is cautioned with thiazide diuretics, corticosteroids, or licorice and long-term use of buckthorn as a laxative may increase the potassium loss induced by those drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Use of stimulant laxatives, such as buckthorn, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

While most stimulant laxatives have traditionally been contraindicated in pregnancy due to concerns regarding stimulation of the uterus, a number of stimulant laxatives, including buckthorn, have shown a lack of adverse effects on pregnancy or the fetus when used according to the recommended dosage schedule (De Smet 1993; ESCOP 2003). Thus, these laxatives are now considered appropriate for use during pregnancy (De Smet 1993; ESCOP 2003; Prather 2004). Due to the potential genotoxicity of certain anthraquinones, however, it is recommended that use of certain anthranoid laxatives, including buckthorn, should be avoided in the first trimester of pregnancy or used under professional supervision (ESCOP 2003).

No information on the safety of buckthorn during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Not for use in intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (i.e., appendicitis, colitis, Crohn's disease, irritable bowel syndrome, and melanosis coli) (Bradley 1992; De Smet 1993; Martindale and Reynolds 1996; Roth et al. 1984; Wichtl 2004), or during menstruation (Bensky et al. 2004; Chen and Chen 2004).

Not for use in excess of 8 consecutive days (Bradley 1992; De Smet 1993; Leung and Foster 1996; Weiss and Meuss 2001; Wichtl 2004).

Not for use in children less than 12 years of age (Bradley 1992; De Smet 1993).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Standard Dose

The standard dose is 1 to 5 g daily, directly consumed or as a tea (Bradley 1992). Traditional Chinese medicine texts indicate that the standard dose is 3 to 10 g daily as a tea, with up to 20 g in severe cases, and that the dose should be reduced by half when the powdered product is taken internally (Bensky et al. 2004; Chen and Chen 2004).

Notice

Stimulant laxative (Bensky et al. 2004; Bradley 1992; De Smet 1993; ESCOP 2003; Felter and Lloyd 1898; Leung and Foster 1996; Weiss and Meuss 2001); *see* Appendix 2.

Tannins (4.0–11.0%) (Bradley 1992; Tang and Eisenbrand 1992); *see* Appendix 1.

Editors' Notes

Although not used in medicine, the leaf blade of Chinese rhubarb contains oxalic acid, which can cause precipitation of calcium oxalate in the renal tubules, thus causing kidney failure (Bensky et al. 2004).

Some compounds in Chinese rhubarb produce a purgative action. These compounds are highly sensitive to heat and may be removed by different forms of processing (Chen and Chen 2004).

The American Herbal Products Association has established a trade requirement (AHPA 2011) that products containing this herb in sufficient quantity to warrant such labeling bear the following label statement:

> NOTICE: Do not use this product if you have abdominal pain or diarrhea. Consult a health care provider prior to use if you are pregnant or nursing. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use.

Adverse Events and Side Effects

Gastrointestinal cramping may occur during Chinese rhubarb use (Wichtl 2004). Metabolites of Chinese rhubarb may cause the urine to have a red-brown or bright yellow coloration (Wichtl 2004). Side effects of nausea, vomiting, and poor appetite have been reported (Bensky et al. 2004).

Pharmacological Considerations

Long-term use of Chinese rhubarb and other anthranoid laxatives may cause pseudomelanosis coli, a brownish pigmentation of the colon. Although pseudomelanosis coli has been regarded as harmless (Leng-Peschlow 1992; Wichtl 2004), some researchers have suggested a possible relationship between the condition and an increased risk of development of colon cancer (Siegers et al. 1993). The risk, however, may be due to other confounding factors such as chronic constipation or diet (Sonnenberg and Müller 1993; van Gorkom et al. 1999).

Concomitant use of Chinese rhubarb is cautioned with antiarrhythmic drugs and botanicals containing cardiac glycosides, as long-term use of Chinese rhubarb as a laxative can cause potassium loss, leading to increased toxicity of those drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Concomitant internal use of Chinese rhubarb is cautioned with thiazide diuretics, corticosteroids, or licorice, and long-term use of Chinese rhubarb as a laxative may increase the potassium loss induced by those drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003; Wichtl 2004).

Use of stimulant laxatives, such as Chinese rhubarb, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

A reference text on traditional Chinese medicine indicated that Chinese rhubarb should be used with great caution and only when absolutely necessary during pregnancy and lactation (Bensky et al. 2004). Based on this information, use during pregnancy or lactation is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Acute renal failure was reported in a 23-year-old woman after 6 weeks of use of an herbal slimming pill that contained Chinese rhubarb (amount unspecified). The woman had begun taking diclofenac, a nonsteroidal anti-inflammatory drug (NSAID) that has been associated with kidney failure (Juhlin et al. 2004; Revai and Harmos 1999; Rossi et al. 1985; Rubio Garcia and Tellez Molina 1992). The authors of the report indicated that although NSAIDs are well recognized as a major cause of kidney dysfunction, such dysfunction is usually associated with dehydration, with consequent hemodynamically mediated renal impairment (Kwan et al. 2006).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdoses of Chinese rhubarb can cause a toxic reaction, especially if the fresh herb is used. Symptoms include diarrhea, nausea, vomiting, dizziness, abdominal colic, and jaundice. Long-term use may cause severe damage to the large intestine, cirrhosis of the liver, and potassium loss (Bensky et al. 2004).

Allergic reactions to Chinese rhubarb have also been reported, usually after large doses (30 g), and include flushing, pruritus, papular rashes, asthma, and tachypnea (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In guinea pig stomachs, an aqueous extract of Chinese rhubarb dose-dependently increased the resting tension and contractile frequency of gastric body circular muscle. The authors indicated that the exciting action of Chinese rhubarb was partly mediated via the cholinergic M receptor, the cholinergic N receptor, and the L-type calcium channel (Yu et al. 2005).

The compound rhapontin exhibited growth inhibition and induced apoptosis in human stomach cancer cells (Hibasami et al. 2007). The compound rhein induced apoptosis and blocked cell cycle progression in the G_1 phase in human liver cancer cells (Kuo et al. 2004).

An extract of Chinese rhubarb induced estrogenic activity at a concentration of 0.1 mg/ml in a yeast-based estrogen receptor activity assay (Kang et al. 2006).

IV. Pregnancy and Lactation

A reference text on traditional Chinese medicine indicates that Chinese rhubarb should be used with great caution, and only when absolutely necessary, during pregnancy and lactation (Bensky et al. 2004).

Rheum spp.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered Chinese rhubarb decoction in mice is 153 g/kg (Chen and Chen 2004).

Subchronic Toxicity

In rats orally administered 140, 794, or 4500 mg/kg daily of anthraquinones isolated from rhubarb for 13 weeks, nephrotoxicity developed in the group administered 4500 mg/kg, and tubule epithelial cells swelled and denatured (Yan et al. 2006).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the use of Sicilian sumac or smooth sumac in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An ethyl acetate extract of Sicilian sumac inhibited alpha-amylase, a g lycoside hydrolase, indicating hypoglycemic activity of this extract. The IC_{50} was 28.7 µg/ml (Giancarlo et al. 2006).

IV. Pregnancy and Lactation

No information on the use of Sicilian sumac or smooth sumac during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Part: fruit, leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Notice
Diuretic (leaf) (Rácz-Kotilla and Rácz 1977; Wichtl 2004); *see* Appendix 2.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of black currant in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
In rats orally administered a fluid extract of black currant leaf at a dose equivalent to 1.5 g/kg of the dried leaf, a diuretic action (diuretic quotient of 1.56) was observed and was similar to a 50 mg/kg dose of furosemide (Rácz-Kotilla and Rácz 1977).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of black currant during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
No adverse effects were observed in mice orally administered 2 g/kg of an extract of the outer layer of black currant fruit (Kyerematen and Sandberg 1986).

The LD_{50} of a fluid extract (1:1) of black currant leaf in mice is 49 g/kg (Rácz-Kotilla and Rácz 1977).

The LD_{50} of a freeze-dried hydroethanolic extract of black currant leaf in mice is 1.09 g/kg after intraperitoneal administration and could not be determined at doses up to 3 g/kg after oral administration (Mongold et al. 1993).

Short-Term Toxicity
No adverse effects, including gastric ulceration or signs of toxicity, were observed in rats orally administered a freeze-dried hydroethanolic extract of black currant leaf (1 g of extract equivalent to 1.8 g of leaf) at doses of 2 g/kg daily for 21 days or 1.34 g/kg daily for 28 days.

Ricinus communis L. — Euphorbiaceae

SCN: castor
AN: *eranda*
PN: *bi ma you* (seed oil)
OCN: palma christi
Part: seed oil

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Lippert and Mueck 2002; Martindale and Reynolds 1996; McFarlin et al. 1999; Nabors 1958; Osol and Farrar 1955).

Not for use in intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (i.e., appendicitis, colitis, Crohn's disease, irritable bowel syndrome, and melanosis coli) (Bradley 1992; De Smet 1993; Martindale and Reynolds 1996; Roth et al. 1984; Wichtl 2004).

Not for use in excess of 8 consecutive days.

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Standard Dose

Adults: 5.0–20.0 ml per dose, not to exceed 60.0 ml per day. Children: 4.0–12.0 ml (Leung and Foster 1996; Osol and Farrar 1955; Williamson 2003).

Notice

Stimulant laxative (Chadha 1988; Felter and Lloyd 1898; Leung and Foster 1996; List and Hörhammer 1973; Martindale and Reynolds 1996); *see* Appendix 2.

Editors' Notes

Castor seed contains the highly toxic compound ricin. Ricin is removed in the process of oil extraction and thus is not present in castor oil (Audi et al. 2005; Doan 2004; Lord et al. 2003; Wilbur 2007). Several hundred cases of poisoning after ingestion of castor seed have been reported in the literature. Symptoms of poisoning include acute gastroenteritis, fluid and electrolyte depletion, gastrointestinal bleeding, hemolysis, and hypoglycemia (Challoner and McCarron 1990).

Adverse Events and Side Effects

Adverse events and side effects reported in association with castor oil include thrombosed hemorrhoids, precipitous labor, nausea, vomiting, diarrhea, intestinal colic, flatulence, disturbances of electrolyte balance, dehydration, hemorrhagic gastritis, hyperemia of the pelvic organs, hemolysis, and liver cell necrosis (Lippert and Mueck 2002; McFarlin et al. 1999).

Allergic reactions to castor oil, including cheilitis and dermatitis, confirmed by patch testing, have been reported after topical application of personal care products containing castor oil (Aplin and Eliseo 1997; Brandle et al. 1983; Di Berardino and Della Torre 2003; Fisher 1991; Kalavala et al. 2007; le Coz and Ball 2000; Lodi et al. 1992; Sai 1983; Taghipour et al. 2008; Tan et al. 1997; Wakelin et al. 1996; Wilbur 2007).

Pharmacological Considerations

Concomitant use of castor oil is cautioned with antiarrhythmic drugs and botanicals containing cardiac glycosides, as long-term use of castor oil as a laxative can cause potassium loss, leading to increased toxicity of those drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003).

Concomitant internal use of castor oil is cautioned with thiazide diuretics, corticosteroids, or licorice, and long-term use of castor oil as a laxative may increase the potassium loss induced by those drugs and botanicals (Brinker 2001; De Smet 1993; ESCOP 2003; Wichtl 2004).

Use of stimulant laxatives, such as castor oil, may reduce the gastrointestinal transit time and thus reduce the

absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

Castor oil has traditionally been used for the induction of labor (McFarlin et al. 1999). Human studies have indicated that castor oil can be used safely for labor induction, although the studies provide mixed results for the need for cesarean sections in castor oil-treated groups versus control groups (Davis 1984; Garry et al. 2000). Possible side effects and case reports of adverse events have led some reviewers to caution against the use of castor oil as a labor inducer (Lippert and Mueck 2002; Nabors 1958), although castor oil is the most commonly used natural product for labor induction among certified nurse midwives that use natural products for labor induction (McFarlin et al. 1999). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

An Eclectic medical text notes that castor oil is "the most suitable laxative for constipation of pregnant women" (Felter and Lloyd 1898), and a more recent survey of gastroenterologists and obstetricians indicated that 26% of gastroenterologists and 38% of obstetricians would prescribe castor oil as a laxative to pregnant patients (Vinod et al. 2007). Other texts note that castor oil must be used with caution in pregnancy (Martindale and Reynolds 1996; Osol and Farrar 1955).

A case of an amniotic fluid embolism causing a maternal cardiorespiratory arrest was temporally associated with ingestion of castor oil by a woman at week 40 of gestation, although causality could not be determined (Steingrub et al. 1988).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

In dogs intravenously administered toxic doses of methyprylon with or without a large oral dose of castor oil, no significant difference was observed in the sleep times of the dogs treated with castor oil, or in the methyprylon pharmacokinetics, as compared to controls (Gwilt et al. 1982).

II. Adverse Events

Case Reports of Adverse Events

Cutaneous reactions to castor oil, including cheilitis and dermatitis, confirmed by patch testing, have been reported after topical application of personal care products containing castor oil (Aplin and Eliseo 1997; Brandle et al. 1983; Di Berardino and Della Torre 2003; Fisher 1991; Kalavala et al. 2007; le Coz and Ball 2000; Lodi et al. 1992; Sai 1983; Taghipour et al. 2008; Tan et al. 1997; Wakelin et al. 1996; Wilbur 2007).

An anaphylactic reaction to polyethoxylated castor oil, confirmed by intradermal testing, was reported in a woman who had been intravenously administered cyclosporine with a vehicle of polyethoxylated castor oil (Ebo et al. 2001).

A case of epoxydicarboxylic aciduria was reported in a woman excreting large amounts of 3,6-epoxyoctanedioic, 3,6-epoxydecanedioic, and 3,6-epoxydodecanedioic acids, the presence of which was traced to factitious ingestion of castor oil (Hagenfeldt et al. 1986).

Also see Pregnancy and Lactation for this entry.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Skin irritation tests on rats, guinea pigs, and pigs have shown that topical application of castor oil for 10 to 56 days is generally well tolerated (Butcher 1951; Meyer et al. 1976; Motoyoshi et al. 1979; Wilbur 2007).

In rabbits, one irritation test showed severe irritation after several doses of castor oil (Motoyoshi et al. 1979), while other studies indicated that daily application for up to 54 days was well tolerated (Guillot et al. 1979; Rantuccio et al. 1981).

Castor oil did not promote chemically induced skin tumors in mice treated topically with castor oil twice a week for 20 weeks (Shubik 1950).

Slight epidermal hyperplasia was observed in mice treated topically with castor oil 4 times in a 2-week period (Shubik 1950).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In a study of pregnant women with premature rupture of the membranes, who were between weeks 37 and 42 of gestation, administration of castor oil increased the rates of spontaneous labor, decreased the need for cesarean section, and decreased the need for labor induction with oxytocin as compared to women not administered castor oil. No significant adverse events were reported in the mothers. The

authors of the study concluded that castor oil is safe for the induction of labor (Davis 1984).

No adverse outcomes for mother or fetus were identified in a study of pregnant women administered a single 60 ml dose of castor oil to induce labor. The rate of cesarean sections was 19% in the group receiving castor oil and 8% in the untreated control group (Garry et al. 2000).

In pregnant women between gestational weeks 38 and 41 orally administered single doses of 71 ml of castor oil, an increase in the contractile work of the uterus was observed. Effects on fetal health were not reported (Mathie and Dawson 1959).

In a study of amniotic fluid at the time of rupture of the membranes, meconium passage was significantly more common among women who had recently taken castor oil as compared with women that did not use castor oil (Mitri et al. 1987).

A survey of American certified nurse midwives that used natural products to induce labor (90 midwives responded) indicated that castor oil was the most commonly used product for the induction of labor, with 93% of midwives using castor oil. Adverse events reported in association with castor oil use were thrombosed hemorrhoids, precipitous labor, nausea, vomiting, diarrhea, and flatulence, and two midwives reported an increase in meconium-stained fluid (McFarlin et al. 1999).

A survey of attending gastroenterologists and obstetricians at a New York hospital (75 physicians responded) indicated that 26% of gastroenterologists and 38% of obstetricians would prescribe castor oil as a laxative to pregnant patients (Vinod et al. 2007).

A review of the use of castor oil for labor induction lists possible side effects of castor oil as follows: nausea, vomiting, intestinal colic, diarrhea, disturbances of electrolyte balance, dehydration, hemorrhagic gastritis, hyperemia of the pelvic organs, hemolysis, and liver cell necrosis (Lippert and Mueck 2002).

A woman at 39 weeks of gestation, with a history of a previous cesarean delivery, had severe abdominal pains and rupture of membranes shortly after ingesting 5 ml of castor oil. Forty-five minutes later, repetitive variable decelerations prompted a cesarean delivery. At surgery, a portion of the umbilical cord was protruding from a 2 cm rupture of the lower transverse scar. The reporting authors indicated that the risk of uterine rupture in women with a low transverse incision from a previous cesarean section is 0.2 to 1.5% (Sicuranza and Figueroa 2003).

A case of an amniotic fluid embolism causing a cardiorespiratory arrest was temporally associated with ingestion of 30 ml castor oil by a woman at week 40 of gestation. Approximately 1 hour after ingestion, the woman experienced spontaneous rupture of the membranes and suffered cardiorespiratory arrest. The reporting authors noted that the association between castor oil ingestion and the adverse events was temporal but that causality could not be determined (Steingrub et al. 1988).

V. Toxicity Studies

Acute Toxicity

Damage to the duodenal and jejunal mucosa was observed from 1 to 7 hours after oral administration in rats of single doses of 2 ml of castor oil per 160 to 180 g animal. Injury was not observed at 0.5 or 9 hours after dosing (Capasso et al. 1994).

In ponies administered 2.5 ml/kg castor oil via nasogastric tubes, hyperemia of the intestinal mucosa was observed 24, 48, and 72 hours postdosing. Dosing was associated with transient diarrhea, neutrophilic inflammation, and mucosal erosion in the cecum and ventral colon (Johnson et al. 1993).

No toxic effects on the renal tubular epithelium were observed in rats in which castor oil was injected into proximal tubules (Langer et al. 1968).

Short-Term Toxicity

No adverse effects or catharsis were observed in rats fed a diet containing 10% castor oil daily for 5 weeks (Masri et al. 1962).

Subchronic Toxicity

No toxicity to any specific tissue, organ system, or organ was observed in mice and rats fed a diet of up to 10% castor oil daily for 13 weeks. A dose-related increase in alkaline phosphatase was observed on days 5, 12, and at the end of the study (NTP 1992). The no-observed-adverse-effect levels (NOAEL) in the study were estimated as 5 g/kg daily for rats and 7.5 g/kg daily for mice (Burdock et al. 2006).

Genotoxicity

No evidence of induction of micronuclei in peripheral erythrocytes was observed in mice fed diets of up to 10% castor oil for 13 weeks (NTP 1992).

No induction of sister-chromatid exchanges was observed in Chinese hamster ovary cells incubated with castor oil at concentrations up to 5000 µg/ml with or without metabolic activation (NTP 1992).

No mutagenic activity was observed in *Salmonella* strains TA97, TA98, TA100, TA102, TA1535, and TA1537 with or without metabolic activation with castor oil at concentrations of up to 10,000 µg/plate (Hachiya 1987; Zeiger et al. 1988).

No genotoxic activity of polyoxyethylene hydrogenated castor oil was observed in the micronucleus test in mice, or in the reverse mutation test in bacteria and the chromosome aberration test in vitro, with or without metabolic activation (Hirai et al. 1994).

Cytotoxicity

At concentrations of 100 and 5000 µg/plate, with and without metabolic activation, castor oil exhibited cytotoxicity against an *E. coli* strain (Hachiya 1987).

Rorippa nasturtium-aquaticum (L.) Hayek

Brassicaceae

SCN: watercress
Syn: *Nasturtium officinale* W.T. Aiton; *Sisymbrium nasturtium-aquaticum* L.

PN: *xi yang cai gan* (herb)
Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in cases of gastric and duodenal ulcers, inflammatory kidney disorders, and in children under 4 years of age (Wichtl 2004).

Drug and Supplement Interactions

A decrease in blood levels of acetaminophen was observed after pretreatment with a l arge dose (50 g) of watercress (Chen et al. 1996).

No significant changes in coumarin metabolism were observed after several large doses (57 g each) of watercress (Murphy et al. 2001).

Adverse Events and Side Effects

Irritation of the gastric mucosa may develop if watercress is taken in large amounts or for an extended time (Wichtl 2004).

Pharmacological Considerations

In human studies, watercress inhibited the drug-metabolizing isoenzyme CYP2E1 in one study but had no effect on this isoenzyme in a second study (Desager et al. 2002; Leclercq et al. 1998).

Pregnancy and Lactation

Limited information on the safety of watercress in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In healthy volunteers orally administered coumarin before or after ingestion of four doses of 56.8 g each of fresh watercress over the course of 24 hours, a marginal inhibitory effect on coumarin metabolism was observed. In approximately 30% of volunteers, a decrease in urinary excretion of coumarin was observed in the first 2 hours after coumarin administration, although the mean excretion of coumarin during that time for all test subjects was not significantly different from the control. Total excretion of the coumarin metabolite was not affected by watercress (Murphy et al. 2001).

In healthy volunteers orally administered 50 g of watercress homogenates 10 hours prior to a single dose of acetaminophen, a reduction in serum levels of acetaminophen was observed. Total urinary excretion of Cys-acetaminophen was also reduced, although pharmacokinetic processes and the urinary excretion of acetaminophen, acetaminophen glucuronide, and acetaminophen sulfate were not altered (Chen et al. 1996).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

R

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered chlorzoxazone (a substrate of the drug-metabolizing isoenzyme CYP2E1) before or after 50 g fresh watercress homogenate, an increase in chlorzoxazone plasma concentration was observed. Similarly, chlorzoxazone elimination half-life was prolonged after watercress ingestion. The effects of watercress were one-third to one-half the effects of the CYP2E1 inhibitor isoniazid (Leclercq et al. 1998).

In healthy volunteers orally administered 50 g fresh watercress homogenate 10 hours or 1 hour prior to ingestion of ethanol (a substrate of the drug-metabolizing isoenzyme CYP2E1), no significant effects on ethanol metabolism were observed, although ethanol absorption was delayed by ingestion of watercress just prior to ethanol consumption. Ingestion of watercress was associated with a weak inhibition of acetaldehyde (a metabolite of ethanol) metabolism (Desager et al. 2002).

Although the compound phenethyl isothiocyanate, found in watercress and vegetables such as cabbage, was found to inhibit the drug-metabolizing isoenzyme CYP2D6 in vitro, a study in healthy human volunteers indicated no effects on CYP2D6. In the human study, phenotyping was performed on healthy volunteers before and after ingestion of 50 g of fresh watercress. No significant changes in CYP2D6 metabolism were observed (Caporaso et al. 1994).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In rats orally administered 200, 400, or 800 mg/kg of an aqueous extract of watercress daily on days 1 to 6 of pregnancy, a reduction in the number of viable fetuses and increase in the number of resorptions were observed (Elbetieha et al. 1996).

No information on the safety of watercress during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Small hairs on fresh or dried whole rose hips may cause mechanical irritation in the mouth, throat, and other areas. Commercial processing removes the hairs.

Adverse Events and Side Effects

A systematic review of clinical trials on rose fruit products indicated that rose fruit was generally well tolerated with no significant adverse events reported in the trials (Chrubasik et al. 2006). No case reports of adverse events were identified for any of the rose species.

Allergic reactions to rose fruit have been reported (Chrubasik et al. 2008; Lleonart et al. 2007).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of *Rosa* species in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of clinical trials on dog rose fruit (5 g daily for over 3 months) did not indicate any adverse events in clinical trials (Chrubasik et al. 2006).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No studies on the use of rose fruit during pregnancy or lactation were identified.

V. Toxicity Studies

Acute Toxicity

No toxicity of ethyl acetate, *n*-butanol, or ethanol extracts of dog rose fruit was observed after oral administration of 919 mg/kg to mice (Orhan et al. 2007).

Rosmarinus officinalis L.

Lamiaceae

SCN: rosemary

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Chadha 1988); *see* Appendix 2.

Editors' Note

Concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Topical allergic reactions to rosemary, confirmed by patch testing, have been reported (Armisen et al. 2003; Fernandez et al. 1997; Guin 2001; Inui and Katayama 2005; Klarman 1958; Serra et al. 2005).

Pharmacological Considerations

Absorption of nonheme iron was reduced in healthy women who ingested a phenolic-rich extract of rosemary with a test meal (Samman et al. 2001).

Animal studies have indicated that rosemary reduced serum glucose levels in both healthy and diabetic animals (Bakirel et al. 2008; Erenmemisoglu et al. 1997). An ethnobotanical survey indicated that rosemary is traditionally used in Morocco to treat diabetes and hypertension (Tahraoui et al. 2007). Thus, diabetic persons using insulin or oral hypoglycemic drugs should continue to monitor glucose levels during rosemary use.

Induction of the drug-metabolizing isoenzymes CYP1A1, CYP1A2, and CYP2B1,2 was observed in rats administered an aqueous extract of rosemary or rosemary essential oil (Debersac et al. 2001a, 2001b).

Inhibition of platelet aggregation was observed in one animal and two in vitro studies (Lee et al. 2007; Yamamoto et al. 2005).

Pregnancy and Lactation

Information on the safety of rosemary during pregnancy is conflicting. While some older references indicate that rosemary (perhaps referring to rosemary essential oil) was used to induce abortions (Casey 1960; Chadha 1988; Greshoff 1913), animal studies of rosemary or compounds isolated from rosemary have not indicated such activity. One animal study showed no significant adverse effects of a rosemary aqueous extract administered to pregnant rats, although a small, statistically insignificant increase in preimplantation loss was observed (Lemonica et al. 1996). No teratogenic effects of the compounds D-camphor or 1,8-cineol were observed in other studies (Jori and Briatico 1973; Leuschner 1997). In rats administered the compound 1,8-cineol during pregnancy, 1,8-cineol was shown to cross the placenta, suggesting that caution is warranted for use during pregnancy

(Jori and Briatico 1973). Although dried rosemary or rosemary tea may be safe in pregnancy, the essential oil and other concentrated extracts should not be used.

In rats administered the compound 1,8-cineol during or after pregnancy, 1,8-cineol was shown to cross the placenta but was reported not to cross into breast milk (Jori and Briatico 1973).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Several cases of topical allergic reactions, including cheilitis and eczema, after ingestion of rosemary or topical application of products containing rosemary, confirmed by patch testing, have been reported (Armisen et al. 2003; Fernandez et al. 1997; Guin 2001; Inui and Katayama 2005; Klarman 1958; Serra et al. 2005). In two cases, the patients also tested positive to thyme (*Thymus vulgaris*) in skin patch tests (Armisen et al. 2003; Martinez-Gonzalez et al. 2007). Photopatch tests produced stronger reactions than standard tests (Armisen et al. 2003). A case of occupational contact dermatitis was reported, with the compound carnosol identified as the major allergen (Hjorther et al. 1997).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Absorption of nonheme iron was significantly reduced in healthy women who ingested a phenolic-rich extract of rosemary with a test meal. The effect of rosemary was less than that of green tea (Samman et al. 2001).

An ethnobotanical survey of diabetic and hypertensive people in Morocco indicated that rosemary is commonly used in the treatment of both conditions (Tahraoui et al. 2007).

Animal Pharmacological Studies

In healthy and diabetic rabbits orally administered an ethanolic extract of rosemary at doses of 50, 100, or 200 mg/kg, the 200 mg/kg dose caused a lowering of blood glucose in both healthy and diabetic animals, and the 100 and 200 mg/kg doses caused increases in serum insulin levels in diabetic animals (Bakirel et al. 2008). A decrease in serum glucose levels was observed in healthy or diabetic mice provided aqueous extracts of rosemary ad libitum for 3 months. No changes in liver enzymes were observed in either the treatment or control groups (Erenmemisoglu et al. 1997).

Antithrombotic activity in the laser-induced thrombosis test was observed in mice orally administered a juice extract of fresh rosemary at doses of 3.85 ml/kg. No effect on vasodilation was observed (Yamamoto et al. 2005).

In male rats orally administered 250 or 500 mg/kg of a concentrated ethanol extract of rosemary daily for 63 days, a significant decline in spermatogenesis in testes was observed due to a decrease in the number of spermatocytes and spermatids in the high-dose group, which was attributed to a decrease in testosterone. Sperm motility and density also decreased in this group. No changes in the weights of testes were observed, although a weight decrease in some other reproductive tissues was noted. The treated male rats were mated with untreated females, and an increase in the number of fetal resorptions was observed in the females that had been mated with males from the high dose group (Nusier et al. 2007).

An increased weight of seminal vesicles was reported in male rats orally administered 582 mg/kg of rosemary aqueous extract daily for 5 days. No other changes in organ weights or sperm production were observed at that dose, and no adverse effects were observed in rats administered 291 mg/kg (Waseem et al. 2006).

The compound 1,8-cineol was detected in the blood of rats after inhalation of 0.5 ml of rosemary essential oil (Kovar et al. 1987).

In Vitro Pharmacological Studies

Rosemary extract inhibited the drug-metabolizing isoenzyme CYP1A1 by 70 to 90% (Offord et al. 1995).

The addition of a methanol-extracted fraction of rosemary at a concentration of 16.5–82 mg/ml significantly increased the intracellular accumulation of doxorubicin and vinblastine in drug-resistant P-glycoprotein-expressing MCF-7 cells (Plouzek et al. 1999).

An aqueous extract of rosemary inhibited angiotensin-converting enzyme (ACE) activity in vitro (Kwon et al. 2006).

An aqueous extract of rosemary enhanced the permeability of Caco-2 cells to furosemide but not verapamil, metoprolol, ketoprofen, or paracetamol (Laitinen et al. 2004).

The juice extracted from fresh rosemary inhibited platelet aggregation as assessed by a shear-induced in vitro

platelet function test (Yamamoto et al. 2005). The compound carnosic acid produced a dose-dependent inhibition of collagen-, arachidonic acid-, U46619- and thrombin-induced washed rabbit platelet aggregation in a concentration-dependent manner, with IC_{50} values of 29 to 48 µ*M* (Lee et al. 2007).

IV. Pregnancy and Lactation

In rats orally administered an aqueous extract of rosemary leaf, flower, and stem at doses of 26 mg (13 mg/ml of solids) on days 1 to 6 (preimplantation) or 6 to 15 (organogenic period) of pregnancy, no differences between the rosemary and control groups were observed for postimplantation loss or number of malformations, although a nonsignificant increase in preimplantation loss was observed in the rosemary group (Lemonica et al. 1996).

No teratogenic effects of the compound D-camphor were observed in rats orally administered the compound at doses up to 1000 mg/kg daily during the organogenesis period of pregnancy, or in pregnant rabbits administered doses up to 681 mg/kg daily (Leuschner 1997).

Some references indicate that rosemary has been used as an abortifacient. Details on that use are lacking, including whether crude extracts or the essential oil were used (Casey 1960; Chadha 1988; Greshoff 1913).

In rats subcutaneously administered the compound 1,8-cineol (eucalyptol) on gestational days 10 to 14, the last 4 days of pregnancy, or on postnatal days 2 through 6, treatment enhanced microsomal enzyme activity of the mothers and induced the enzyme activity in fetal livers, but it did not induce microsomal activity of the suckling newborn rats, suggesting that 1,8-cineol is able to cross the placenta but does not cross into breast milk (Jori and Briatico 1973).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered rosemary essential oil in rats is 5 ml/kg (Opdyke 1974).

No toxic effects of an alcoholic rosemary extract were observed in rats and mice intraperitoneally administered 2 g/kg (Mongold et al. 1991). In rats orally administered 2 g/kg of a supercritical fluid extract of rosemary, no adverse effects, including changes in hematological and serum chemistry values, organ weights, or gross histological characteristics, were noted during a 2-week observation period (Anadon et al. 2008).

Toxicity studies on the compound eucalyptol (1,8-cineol) are reviewed in the *Eucalyptus globulus* leaf essential oil entry.

Subchronic Toxicity

A rosemary extract inhibited tumor promotion in mice with initiated skin tumors topically treated with 3.6 mg of rosemary acetone extract twice a week for 19 weeks (Ho et al. 1994). A similar inhibition of tumor growth was observed in rats with induced mammary carcinoma fed a diet of 1% rosemary extract daily for 21 weeks (Singletary and Nelshoppen 1991).

Hepatotoxicity

Significant hepatoprotective activity of orally or intraperitoneally administered aqueous and ethanolic extracts of rosemary have been observed in mice treated with the hepatotoxic compounds carbon tetrachloride or azathioprine (Fahim et al. 1999; Hoefler et al.; Rusu et al. 2005; Sotelo-Felix et al. 2002; Waseem et al. 2006).

No change in liver enzymes was observed in male rats administered 250 or 500 mg/kg of rosemary daily for 63 days (Nusier et al. 2007).

Genotoxicity

Antimutagenic activity of rosemary extracts has been observed in the Ames mutagenicity assay and in rats (Fahim et al. 1999; Minnunni et al. 1992; Wolleb et al. 1992).

Rubia cordifolia L. — Rubiaceae

SCN: Indian madder
AN: *manjishtha*
PN: *qian cao gen* (root)
OCN: Bengal madder
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
Animal studies have demonstrated that Indian madder may modify glucose regulation (Patil et al. 2006; Somani et al. 2007). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation
Although one animal study showed some anti-implantation activity of relatively high doses (250 mg/kg) of Indian madder (Sharma et al. 1983), reference texts on traditional Chinese medicine do not caution against the use of Indian madder during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of Indian madder during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
A reduction in blood sugar was observed in healthy and diabetic mice orally administered single or repeated (for 2 weeks) doses of an alcohol extract of Indian madder (Somani et al. 2007). A reduction in blood sugar was observed in diabetic mice intraperitoneally administered 100, 200, or 400 mg/kg of an alcohol extract of Indian madder (Patil et al. 2006).

In Vitro Pharmacological Studies
A partially purified fraction of Indian madder inhibited PAF-induced, but not thrombin-induced, platelet aggregation in rabbit platelets (Tripathi et al. 1993).

IV. Pregnancy and Lactation
In rats orally administered relatively large doses (250 mg/kg) of an ethanolic extract of Indian madder on days 1 to 7 of pregnancy, a reduction in the number of implanted fetuses was observed (Sharma et al. 1983).

No information on the safety of Indian madder during lactation was identified.

V. Toxicity Studies

Acute Toxicity
No deaths were reported in mice orally administered 150 g/kg of an Indian madder decoction. At a dose of 175 g/kg, one of five mice died (Zhu 1998).

The LD_{50} of an alcohol extract of Indian madder intraperitoneally administered to mice could not be determined at doses up to 1 g/kg (Patil et al. 2006).

The LD_{50} of the compound rubidate in mice is 3 g/kg after intraperitoneal administration (Zhu 1998).

Chronic Toxicity

The compound 1-hydroxyanthraquinone is a metabolite of the compound alizarin primeveroside that is found in Indian madder. In rats fed diets containing 1% 1-hydroxyanthraquinone daily for 480 days, an increase in incidences of tumors in the colon and intestines was observed (Mori et al. 1990).

Notice

Tannins (8–14% in *R. fruticosus*) (Mullen et al. 2002; Wichtl 2004); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that blackberry leaf may modify glucose regulation (Alonso et al. 1980; Jouad et al. 2002). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

Human studies have indicated no adverse effects of raspberry leaf on fetal or maternal health with doses of 2.4 g daily from week 32 until birth in a double-blind, randomized, placebo-controlled trial, and in a retrospective study with women taking one to eight raspberry leaf tablets or one to six cups of raspberry leaf tea daily (Parsons et al. 1999; Simpson et al. 2001).

An animal study indicated a lengthening of gestation in animals treated with raspberry leaf (Johnson et al. 2009).

No information on the safety of blackberry or raspberry leaf during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in blood glucose levels was observed in healthy and diabetic rabbits orally administered 5 g/kg of an aqueous extract of blackberry leaf (Alonso et al. 1980). Similar effects were observed in healthy and diabetic rats orally administered 100 mg/kg of an aqueous extract of blackberry leaf as a single dose or the same dose daily for 9 days (Jouad et al. 2002).

In Vitro Pharmacological Studies

Extracts of raspberry leaf prepared with different solvents (*n*-hexane, ethyl acetate, chloroform, and methanol) exhibited a relaxant effect on isolated guinea pig ileum. The methanol extract was the most active (Rojas-Vera et al. 2002).

IV. Pregnancy and Lactation

In a double-blind, randomized, placebo-controlled trial, healthy pregnant women were orally administered tablets containing 2.4 g raspberry leaf daily from 32 weeks of gestation until birth. No adverse effects on fetal or maternal health were observed, including length of gestation, medical augmentation of labor, need for pain relief during labor, time of the stages of labor (shorter second stage in the raspberry leaf group), blood loss during labor, and diastolic blood pressure in the mother. Other observed parameters included meconium stained fluid, Apgar score at 5 minutes of age, birth weight, transfer of baby to special care, and rate of emergency caesarean sections. Slightly more women in the placebo group had forceps or vacuum-assisted birth (Simpson et al. 2001).

In a retrospective study of mothers who used raspberry leaf during pregnancy, no adverse effects on pregnancy or on fetal or maternal health were observed. Doses ingested ranged from one to six cups of raspberry leaf tea daily or one to eight tablets of raspberry leaf (tablet size not specified) daily. Findings from this study suggest that raspberry leaf might decrease the likelihood of preterm and post-term gestation. Women who ingested raspberry leaf were less likely to receive an artificial rupture of their membranes or require a caesarean section, forceps birth, or vacuum birth than the women in the control group (Parsons et al. 1999).

In rats orally administered 10 mg/kg raspberry leaf daily for the full gestational period, gestation was an average of 1.6 days longer in the raspberry group as compared to control. In offspring of treated animals, the time to vaginal opening was 2 days earlier than control group animals (Johnson et al. 2009).

Studies examining the effects of intravenous administration of raspberry leaf extract to cats and rabbits, and the effects of the same extract on isolated uterine strips from dogs, cats, rabbits, and guinea pigs, indicated that raspberry leaf toned smooth muscles that were relaxed and relaxed muscles that were contracted (Burn and Withell 1941).

In isolated uterine strips from pregnant and nonpregnant rats and pregnant and nonpregnant humans (pathological uterine tissue, removed for therapeutic purposes), treatment with an aqueous extract of raspberry leaf had little or no effect on nonpregnant uteruses. In strips from pregnant uteruses, inhibition of contractions was observed along with a more regular rhythm of contractions (Bamford et al. 1970).

Raspberry leaf extracts applied to isolated uterine tissue produced a spasmolytic effect (Beckett et al. 1954).

No information on the safety of blackberry or raspberry leaf during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered blackberry leaf aqueous extract in mice is 8.1 g/kg (Jouad et al. 2002).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Fatal oxalate poisoning was reported in a 53-year-old insulin-dependent diabetic man who had ingested 1 kg of yellow dock (part not specified) along with his family members. Other family members who ingested smaller amounts of yellow dock had only mild symptoms of poisoning and recovered within several days (Reig et al. 1990).

Oxalate poisoning was reported in a flock of sheep within 40 hours of being set to graze in a lot that contained significant amounts of yellow dock leaf. Clinical signs of toxicosis included excess salivation, tremors, ataxia, and recumbency. Affected ewes were markedly hypocalcemic and azotemic. Samples of yellow dock contained 6.6 to 11.1% oxalic acid on a dry-weight basis, a concentration comparable with that in other oxalate-containing plants that have caused acute oxalate toxicosis (Panciera et al. 1990).

Ruscus aculeatus L. — Lilaceae

SCN: butcher's broom
OCN: box holly

Part: root and rhizome

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

A review of the literature on butcher's broom indicated that no side effects or other undesirable effects are expected (ESCOP 2003).

Contact allergy to butcher's broom and extracts of butcher's broom has been reported and confirmed by patch testing (Breuil et al. 1989; Elbadir et al. 1998; Landa et al. 1990; Ramirez-Hernandez et al. 2006).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Information on the safety of butcher's broom during pregnancy is limited. A small human study indicated that suppositories containing ruscogenin were well tolerated, with no adverse effects on pregnancy or on fetal or maternal health (Anger and Neietsch 1981).

No information on the safety of butcher's broom during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Contact allergy to butcher's broom and extracts of butcher's broom has been reported and confirmed by patch testing (Breuil et al. 1989; Elbadir et al. 1998; Landa et al. 1990; Ramirez-Hernandez et al. 2006).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In a human COX inhibitor screening assay, a methanol extract of butcher's broom exhibited COX-1 inhibition at 2.09 mg/ml (IC_{50}) and COX-2 inhibition at 6.83 mg/ml (IC_{50}) (Seaver and Smith 2004).

IV. Pregnancy and Lactation

Ruscogenin-containing suppositories were well tolerated in a study with 30 pregnant women. No adverse effects on newborns were reported (Anger and Neietsch 1981).

No information on the safety of butcher's broom during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered butcher's broom fluid extract in mice is 4.6 g/kg, and in rats could not be determined at doses up to 4.6 g/kg (Seidenberger et al. 1974). The LD_{50} of ruscogenins (combined ruscogenin and neoruscogenin) orally administered to mice and rats could not be determined at doses up to 3 g/kg (Capra 1972).

The oral LD_{50} of a fluid extract of butcher's broom rhizome is 2.2 ml/kg in rats and 29.21 ml/kg in mice. After intraperitoneal administration, the toxicity is 10- to 20-fold higher. An extract of the root was reportedly more toxic than that of the rhizome (Boucard et al. 1967).

An ethanol extract of butcher's broom intravenously administered to dogs was fatal at doses from 830 to 1800 mg/kg. In guinea pigs intraperitoneally administered the same extract, no toxic signs were observed at doses up to 1.5 g/kg, whereas doses over 2 g/kg were fatal (Caujolle et al. 1953; Moscarella 1953).

Subchronic Toxicity

In rabbits orally administered 2 or 5 g/kg of a butcher's broom extract daily for 26 weeks, no changes in body weight or blood count were observed (Roux 1969).

In rats orally administered 300 mg/kg of ruscogenin or saponins from butcher's broom daily for 8 weeks, no signs of toxicity were observed in any of the parameters measured, including body and organ weights, blood glucose and liver function levels, and histological examination of organs (Capra 1972).

Ruta graveolens L. — Rutaceae

SCN: rue
PN: *chou cao* (herb)
OCN: common rue; herb-of-grace
Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Al-Mahmoud et al. 2003; Ciganda and Laborde 2003; de Freitas et al. 2005; Wood and LaWall 1918).

Other Precautions

Avoid prolonged exposure to sunlight after ingestion (McGuffin et al. 1997; Zobel and Brown 1990).

Drug and Supplement Interactions

None known.

Notice

Abortifacient (Ciganda and Laborde 2003; Conway and Slocumb 1979; Felter and Lloyd 1898; Wood and LaWall 1918); *see* Appendix 2.

Emmenagogue (Chadha 1988; Conway and Slocumb 1979; Felter and Lloyd 1898); *see* Appendix 2.

Photosensitizing (Milesi et al. 2001; Zobel and Brown 1990); *see* Appendix 2.

Editors' Notes

Rue is identified as generally recognized as safe by the U.S. FDA when present in all categories of food at concentrations that do not exceed 2 ppm (CFR 2011a). Although an associated regulation states that other uses in foods would require a food additive regulation (CFR 2011b), dietary ingredients for use in dietary supplements are specifically excluded from the federal food additive definition (U.S.C. 2010).

Adverse Events and Side Effects

Rue contains furanocoumarin compounds known to cause phytophotodermatitis after topical application followed by exposure to sunlight or UVA light (Furniss and Adams 2007; Milesi et al. 2001; Schempp et al. 1999).

At standard therapeutic doses, ingestion of rue has been associated with melancholic mood, sleep disorders, drowsiness, dizziness, and cramps (Weiss and Fintelmann 2000). Rue may cause gastrointestinal irritation (Felter and Lloyd 1898; Remington and Wood 1918).

A review of cases of women who attempted to use rue as an abortifacient (doses not listed, but likely represent overdose) indicated that adverse effects of rue included abdominal pain, vomiting, genital hemorrhage, anemia, jaundice, liver enlargement, neurological depression, respiratory distress, and elevated liver enzyme levels (Ciganda and Laborde 2003).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Rue has traditionally been used as an abortifacient (Ciganda and Laborde 2003; Conway and Slocumb 1979). Animal studies have indicated that rue decreased birth rates and increased fetal resorption rates (Al-Mahmoud et al. 2003; de Freitas et al. 2005). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of rue during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 78-year-old woman with a history of heart problems developed bradycardia, acute renal failure with hyperkalemia, and coagulopathy after 3 d ays of consuming a decoction made from rue. Each dose was made from 50 g of fresh rue in 1000 ml of water, made into 250 ml of decoction

taken twice daily. The woman had a 5-year history of non-obstructive type hypertrophic cardiomyopathy, and was taking bisoprolol, diltiazem, and amiloride. Her heart rate was around 76 beats per minute in the previous 6 months (Seak and Lin 2007).

Phytophotodermatitis from rue has been reported after contact with the fresh plant (Asefi et al. 1999; Gawkrodger and Savin 1983; Heskel et al. 1983) or after topical application of infusions or ointments containing rue (Arias-Santiago et al. 2009; Morais et al. 2008; Wessner et al. 1999). Some cases have produced severe bullae (Eickhorst et al. 2007; Schempp et al. 1999).

A 2-year-old developed acute phytophotodermatitis with systemic upset after contact with rue (Furniss and Adams 2007).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In sperm immobilization tests with human sperm, dose-dependent immobilization of sperm was observed after treatment with a freeze-dried aqueous extract of rue, with 100% immobilization at a concentration of 100 mg/ml. No effects were observed on viability of cells, DNA status, or mitochondrial activity. After washing, motility was returned to approximately 30% of sperm cells. The part of the extract responsible for immobilization of the sperm cells was stable on boiling (Harat et al. 2008).

IV. Pregnancy and Lactation

A review of cases of herbal infusion ingestion with abortive intent received by a poison control center in Uruguay indicated that rue was one of the most commonly used herbs. In women who attempted to use rue as an abortifacient, reported symptoms of toxicity included abdominal pain, vomiting, genital hemorrhage, anemia, jaundice, liver enlargement, a decrease in urine production, neurological depression, respiratory distress, potassium levels less than 3.5 mEq/l, thrombocytes lower than 140,000, leukocytes higher than 10,000, elevated levels of aspartate aminotransferase (AST) and alanine aminotransferase (ALT), and increased creatinine. No information on doses used or method of preparation was given (Ciganda and Laborde 2003).

In mice orally administered 1 g/kg of a dried hydroalcoholic extract of rue daily on days 1 to 3, 4 to 6, or 7 to 9 of pregnancy, no significant differences in preimplantation or in fetal resorptions were observed in treated animals as compared to control. The fetal death rate was 8% in animals treated on days 7 to 9, and similar to control for other treatment periods. Birth rates were 91% for animals treated on pregnancy days 1 to 3, 82% in animals treated on days 4 to 6, 64% for days 7 to 9, and 76% for the control group (de Freitas et al. 2005).

In rats orally administered 800 mg/kg of water, methanol, ethanol, hexane, ether, or dichloromethane extracts of rue daily on days 1 to 6 of pregnancy, no anti-implantation activity was observed for the water, methanol, or ethanol extracts; significant anti-implantation activity was observed for the hexane, ether, and dichloromethane extracts. At the 800 mg/kg dose, the ether extract produced severe toxicity in the mothers. At 400 mg/kg, an increase in the number of fetal resorptions was observed in animals treated with the water, ethanol, or hexane extracts. A reduction in fetal weight gain was observed after treatment with water, methanol, or dichloromethane extracts. After administration of the same extracts and doses on days 6 to 15 of pregnancy, an increase in fetal mortality was observed (Al-Mahmoud et al. 2003).

To determine the effects of rue on embryo implantation and development, superovulated mated female mice were provided with aqueous extracts of rue at concentrations of 5, 10, or 20% as the sole source of drinking water for 4 days after mating. Examination of embryos 98 hours after superovulation treatment indicated that in the 10% group, 37% of embryos were abnormal while in the 20% group, 64% were abnormal. Cell number was diminished and embryo transport was slightly delayed in the high-dose group (Gutierrez-Pajares et al. 2003).

Rue is listed as an ingredient in four of six abortifacient formulas from ancient Persia (Madari and Jacobs 2004).

No information on the safety of rue during lactation was identified.

V. Toxicity Studies

Acute Toxicity

In goats orally administered 5 g/kg of rue leaf daily, tremor, dyspnea, frequent urination, incoordination of movement, ataxia, and recumbency, with death after 1 to 7 days, were observed (el Agraa et al. 2002).

Short-Term Toxicity

In male rats orally administered 500 mg/kg of an aqueous extract of rue daily for 60 days, decreases in the weight of reproductive organs, sperm motility, density in cauda epidydimides and testicular ducts, and spermatogenesis in the seminiferous tubules were observed. Ingestion of the extract was associated with a suppression of sexual behavior in adult males (Khouri and El-Akawi 2005).

In goats orally administered 1 g/kg of rue leaf daily for 40 days, animals had pallor of the visible mucous membranes and loss in condition, with one animal dying on day 17. Changes in serum aspartate transaminase, creatine kinase, total protein, cholesterol, urea and other serum constituents were observed (el Agraa et al. 2002).

In rats orally administered 500 mg/kg of rue daily for 3 weeks, significant increases in body weight with remarkable increase in total food intake and protein efficiency ratio were observed. No significant changes were observed in other biochemical and nutritional parameters except an elevation of alkaline phosphatase (Al-Okbi et al. 2002).

Genotoxicity

In mice orally administered 400 or 1000 mg/kg of a hydromethanolic extract of rue daily for 30 days, damage to cellular DNA was observed in the comet assay at the 1000 mg/kg dose. Damage was observed at day 30 but not at day 20 or earlier. In the chromosomal aberration test with animals on the same treatment regimen, a dose-dependent increase in aberrations was observed (Preethi et al. 2008).

In the Ames test for mutagenicity in *Salmonella typhimurium* strains TA98 and TA100, a strong mutagenic effect was observed in TA98 without metabolic activation. With metabolic activation, only a weak mutagenic response was observed. Moderate mutagenic effects were detected with and without metabolic activation by S9 mix (Paulini et al. 1987).

Compounds isolated from rue have demonstrated mutagenic activity and photomutagenic activity (Paulini and Schimmer 1989; Schimmer et al. 1991; Schimmer and Kuhne 1990).

Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use in persons with sensitivity to aspirin or other salicylate-containing drugs is cautioned (ESCOP 2003; Mills and Bone 2005; Wichtl 2004).

Use in persons with G6PD deficiency (a hereditary disease also known as favism) is cautioned (Baker and Thomas 1987; Brinker 2001; Mills and Bone 2005).

Drug and Supplement Interactions

White willow has been hypothesized to increase the risk of bleeding in persons on anticoagulant medication. Human studies, however, have indicated that the antiplatelet effect of white willow is mild compared to that of aspirin (Higgs et al. 1987; Krivoy et al. 2001; Meier and Liebi 1990).

Notice

Salicylates (1.5–11.0%) (Bradley 1992; List and Hörhammer 1973; Wichtl 2004; Williamson 2003); *see* Appendix 1.

Tannins (8.0–20.0%) (List and Hörhammer 1973; Wichtl 2004); *see* Appendix 1.

Editors' Note

Other species of *Salix* are used in trade, with salicylate content ranging from 1.5 to 11% (Bradley 1992; Wichtl 2004).

Adverse Events

Preparations of white willow have been generally well tolerated in clinical trials, with only mild and transient adverse events reported (ESCOP 2003; Marz and Kemper 2002).

Pharmacological Considerations

Theoretical concerns have been reported for the use of white willow bark in children or adolescents with viral infections due to the possibility of Reye's syndrome, an acute inflammatory disease in children that has been linked with use of aspirin and other salicylate-containing medications during acute viral infections (Clauson et al. 2005; Mills and Bone 2005; Upton 1999). Data to support or refute such a concern are lacking, and the U.S. Food and Drug Administration has indicated that no association has been identified between nonaspirin salicylates and Reye's syndrome (FDA 2003).

Only mild inhibition of platelet aggregation has been observed, indicating that white willow cannot be used as an antiplatelet medication, and that white willow is not likely to present any additive effects on antiplatelet medications (Krivoy et al. 2001; Meier and Liebi 1990).

Pregnancy and Lactation

No information on the safety of willow in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical trials on three different white willow extracts indicated that mild adverse events were reported in 3.7% of persons in the white willow groups (ESCOP 2003). Another review of clinical trials of 120 to 240 mg daily of white willow indicated only mild adverse events associated with white willow use. Adverse events were reported by 3.8 to 35.8% in treatment groups and 2.8 to 35.2% of persons in the placebo groups (Marz and Kemper 2002). Adverse events in these two reviews included nausea, stomach ache, dizziness, fatigue, sweating, skin rash, and allergic reactions (ESCOP 2003; Marz and Kemper 2002).

Case Reports of Adverse Events

A massive intravascular hemolysis was reported in a woman with G6PD deficiency who had taken an herbal product containing *Salix caprea*, a willow species that contains salicin (Baker and Thomas 1987). In patients with G6PD deficiency, aspirin can cause hemolytic anemia (Colonna 1981).

An anaphylactic reaction to an herbal product containing white willow bark was reported in a woman with a history of allergy to acetylsalicylic acid (Boullata et al. 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A clinical trial of white willow bark extract (240 mg daily salicin) for 4 weeks resulted in a mild inhibition of platelet aggregation, as compared to control and 100 mg daily acetylsalicylate (Krivoy et al. 2001). A review of salicin-containing plants indicated that salicin does not elicit the same irreversible inhibition of platelet aggregation that acetylsalicylic acid in aspirin does (Meier and Liebi 1990).

No gastric injury was observed after administration of a single dose of 5 mmol/kg salicin to rats. In the same study, saligenin and sodium salicylate induced severe gastric lesions (Akao et al. 2002).

Animal Pharmacological Studies

Administration of salicylate (200 mg/kg) or aspirin (200 mg/kg) to rats demonstrated that salicylate had a much weaker effect than aspirin on thromboxane B_2 production in blood clotting, indicating that salicylate is not an effective inhibitor of platelet aggregation (Higgs et al. 1987).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of willow in pregnancy or lactation was identified.

Low concentrations of salicylates are excreted into breast milk (Bailey et al. 1982; Bennett 1988). Although the World Health Organization Working Group on Human Lactation has advised against the use of acetylsalicylic acid (a salicylate) during lactation (Bennet 1988), the American Academy of Pediatrics has recommended that "aspirin (salicylates)" should be given to nursing mothers with caution (Ressel 2002).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered white willow ethanolic extract in mice is 28 ml/kg (Leslie 1978).

Salvia miltiorrhiza Bunge

Lamiaceae

SCN: Chinese salvia
PN: *dan shen* (root)
OCN: Chinese sage; red-root sage
Part: root

Quick Reference Summary

Safety Class: 2b
Interaction Class: C

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004).

Other Precautions

Chinese salvia should be used with caution in any situation associated with bleeding, including menstruation, nosebleeds, or blood in the urine, or if blood is expectorated during coughing (Chen and Chen 2004).

Drug and Supplement Interactions

Chinese salvia has been shown to slow the metabolism of warfarin, increasing plasma levels of the drug (Chan et al. 1995; Izzat et al. 1998; Lo et al. 1992).

A review of the literature on the use of Chinese salvia suggested that this herb may act synergistically with digitalis, cardiac glycosides, and hypotensive drugs, and that the dosage of these drugs may need to be modified if used concurrently with Chinese salvia (Wu et al. 2008).

Adverse Events and Side Effects

A review of Chinese salvia studies and case reports indicated that adverse events are rare relative to the extent of use of this herb. Adverse events reported in association with Chinese salvia and fufang danshen (a combination of Chinese salvia, *Panax notoginseng*, and *Cinnamomum camphora*) were anaphylactic reactions, abdominal discomfort, loss of appetite, pruritus, low blood pressure, dizziness, and headache (Wu et al. 2008).

A small percentage of persons taking Chinese salvia are reported to experience dry mouth, dizziness, nausea, weakness, shortness of breath, numbing or coldness of the hands, anxiety, or tachycardia (Bensky et al. 2004).

Pharmacological Considerations

Case reports and animal studies have indicated that concomitant use of Chinese salvia and warfarin slows the metabolism and increases blood levels of warfarin (Chan 1995; Chan et al. 1995; Izzat et al. 1998; Lo et al. 1992; Yu et al. 1997).

A human study indicated no interaction between Chinese salvia and theophylline (Qiu et al. 2008). One animal study indicated that Chinese salvia can decrease plasma levels of diazepam (Qiao et al. 2003).

Inhibition of platelet aggregation and a decrease in blood viscosity have been reported in animal studies and in vitro (Hou et al. 2007; Liu et al. 2002; Qiu et al. 2008; Wang et al. 1982).

Pregnancy and Lactation

A reference text on traditional Chinese medicine indicates that Chinese salvia is contraindicated in pregnancy (Bensky et al. 2004).

No information on the safety of Chinese salvia during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No effects on theophylline metabolism were observed in healthy volunteers before and after administration of 12 tablets (1 g each) of Chinese salvia for 14 days (Qiu et al. 2008).

Case Reports of Suspected Drug or Supplement Interactions

Several published case reports have suggested an interaction between Chinese salvia and warfarin. In all cases, the patients were on long-term warfarin therapy and were taking other drugs and/or herbs. They all experienced increased INR (a standardized scale used to report the results of blood coagulation tests; increased INR indicates slowed blood clotting and increased risk of bleeding) temporally related to the consumption of Chinese salvia. None of the cases report the dose of Chinese salvia taken by the patients, and some suggest that patients were using other herbs, but no details were provided (Chan 2001).

Case one was a 66-year-old man also taking digoxin and propanolol (Tam et al. 1995). Five days prior to admission due to melena (dark-colored feces) and chest pain, and 2 days prior to treatment, the man had self-treated with a topically applied medicated oil that contained 15% methyl salicylate. Methyl salicylate has been shown to augment the anticoagulant effect of warfarin (Chan 1995, 1998; Chow et al. 1989; Joss and LeBlond 2000; Yip et al. 1990).

Case two was a 48-year-old woman also taking furosemide, digoxin, mefenamic acid, and theophylline (Yu et al. 1997). She had consumed Chinese salvia and "other herbs" every other day for approximately 1 month prior to elevated INR.

Case three was a 62-year-old man also taking digoxin, captopril, and furosemide (Izzat et al. 1998). The man had consumed a decoction of Chinese salvia daily for 2 weeks prior to hospital admission for a massive pleural effusion and large pericardial effusion.

Animal Trials of Drug or Supplement Interactions

A significant increase in the plasma levels of (*R*)- and (*S*)-warfarin was observed in rats stabilized on warfarin (2 mg/kg daily) and then intraperitoneally administered 5 g/kg of a Chinese salvia extract twice daily for 3 days. A corresponding significant increase in prothrombin time was observed (Chan et al. 1995).

In rats administered warfarin (2 mg/kg) with or without pretreatment with intraperitoneal administration of 5 g/kg of an aqueous extract of Chinese salvia twice daily for 3 d ays, the absorption rate, volume of distribution, and elimination half-life of warfarin were significantly decreased, while the maximum concentration was significantly increased in the group treated with Chinese salvia. No significant changes in prothrombin time were observed (Lo et al. 1992).

An increase in clearance and decrease in plasma levels of orally administered diazepam (15 mg/kg single dose) were observed in rats orally pretreated with a Chinese salvia extract at a dose of 100 mg/kg daily for 15 days (Qiao et al. 2003).

Cyclosporine-induced nephropathy was reduced by administration of Chinese salvia extract to rats (Peng et al. 2006; Qiao et al. 2001). Extracts of Chinese salvia attenuated adriamycin-induced cardiac and hepatic toxicity in healthy rats (You et al. 2007) and vanadium-induced gastrointestinal stress and metal accumulation in diabetic rats (Zhang et al. 2008).

II. Adverse Events

Adverse Events Reported in Clinical Trials

A meta-analysis of clinical trials on Chinese salvia and fufang danshen (a standard formula containing Chinese salvia, *Panax notoginseng*, and *Cinnamomum camphora*) indicated that "literally thousands" of studies on Chinese salvia for the treatment of heart attack had been published, and adverse events were rarely reported. The route of administration in the studies reviewed included intravenous and oral. Reviewing the literature, adverse events reported in association with Chinese salvia and fufang danshen were anaphylactic reactions, abdominal discomfort, loss of appetite, pruritus, low blood pressure, dizziness, headache, and, with excessive use, an increased risk of bleeding. Bleeding events were bleeding in the skin or mucous membranes or excessive menstrual bleeding. An increase in serum aminotransferase has also been reported. Details on doses and preparations associated with the specific adverse events were not included with the review (Wu et al. 2008).

No differences in adverse events between treatment and control groups were reported in a meta-analysis of Chinese salvia for acute ischemic stroke. Compound dan shen injection, a formula derived from an aqueous extract of Chinese salvia, was the primary intervention used, usually administered intravenously at doses of 20 or 30 ml, and sometimes administered orally (Wu et al. 2007).

Case Reports of Adverse Events

A small percentage of persons taking Chinese salvia may experience dry mouth, dizziness, nausea, weakness, shortness of breath, numbing or coldness of the hands, anxiety, or tachycardia. Allergic reactions to Chinese salvia have been reported. One case of liver damage and two cases of shock have been reported after injection of preparations made from Chinese salvia (details on dose and product were not reported) (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Extracts of Chinese salvia have been administered intravenously for the treatment of various neurological and cardiovascular conditions. No mention of adverse events was made in a report on the intravenous therapeutic use of Chinese salvia in 100 people (ages 5 to 60 years) with nerve deafness. The standard dose used was 20 to 30 ml in solution four times daily for two to four treatment courses of 2 weeks each, separated by 3-day intervals (Hu et al. 1992).

In a dosing study of Chinese salvia extract injections in patients with hepatitis B, doses of 8, 16, or 24 ml were administered for 60 days. Chinese salvia treatment was associated with a decrease in liver enzyme levels, including alanine aminotransferase and total bilirubin. All doses were apparently well tolerated, and no adverse events were reported in the English language abstract of this study (Ye et al. 2005).

Animal Pharmacological Studies

In aging guinea pigs fed a diet containing 75, 100, or 150 mg/kg daily of a water-soluble extract of Chinese salvia for 28 days, blood biochemical parameters of the aging guinea pigs remained unaffected, except that the fibrinogen levels of the group fed the high dose decreased. The medium dose significantly reduced erythrocyte membrane malondialdehyde (MDA) levels, although no improvement in erythrocyte aggregation, blood viscosity, and blood viscoelasticity could be observed. At the high dose, a significant decrease in whole blood viscosity was observed at high, medium, and low shear rates (Hou et al. 2007). A review of studies published in the Chinese literature indicated that intravenous administration of Chinese salvia extracts has been associated with antiplatelet activity in healthy rabbits, rats, and mice (doses not specified in English translations) (Chen and Chen 2004).

Inhibition of platelet aggregation was observed in rabbits intragastrically administered an extract of Chinese salvia (dose and product not specified in English language abstract) (Liu et al. 2002). A combination of Chinese salvia and *Panax notoginseng* increased inhibition of platelet aggregation as compared to Chinese salvia alone (dose and product not specified in English language abstract) (Liu et al. 2002). Bioavailability of orally administered Chinese salvia (5 g/kg) was increased by coadministration of an extract of fragrant rosewood (*Dalbergia odorifera*) (2.5 g/kg) (Zheng et al. 2007).

An increase in cytochrome P450 activity was observed in the livers of rats that had been orally administered 20 or 100 mg/kg of an aqueous extract of Chinese salvia daily for 15 days. The cytochrome activity was primarily induction of the drug-metabolizing isoenzyme CYP3A (Jinping et al. 2003). Induction of the drug-metabolizing isoenzymes CYP1A, CYP2C, and CYP3A was observed in mice orally administered an ethyl acetate extract of Chinese salvia, although no effects were observed in mice administered a water extract of Chinese salvia (Kuo et al. 2006).

In rats with bile duct ligation, administration of 0.4 g daily of an aqueous extract of Chinese salvia for 4 weeks significantly reduced histological grades of fibrosis and ameliorated the portal hypertensive state as compared with control. Treatment had no effect on plasma biochemical profiles of either bile duct ligated or normal rats (Huang et al. 2001).

The compound tanshinone IIA crossed the blood-brain barrier at a greater rate than that for sucrose, and the brain penetration was increased in the presence of a P-glycoprotein or the multidrug-resistance-associated protein (Mrp1/2) inhibitor (Chen et al. 2007).

Inhibition of calcium channels has been suggested as the mechanism of action for the vasorelaxant activity of Chinese salvia (Lam et al. 2005, 2006, 2007). Inhibition of cardiac aldosterone activity was observed in rats treated with Chinese salvia (dose and preparation not specified in English language abstract) (Han et al. 2002). Studies in rats and dogs have indicated a therapeutic effect of Chinese salvia in animal models of myocardial infarction (Liu and Lu 1999; Sun et al. 2005).

In rats administered Chinese salvia, differing effects on digoxin assays were observed, with one assay (microparticle enzyme immunoassay) showing falsely lower digoxin concentrations, a second showing falsely elevated levels (fluorescence polarization immunoassay), and a third showing no change (chemiluminescence assay) (Dasgupta et al. 2002).

In Vitro Pharmacological Studies

Dose-dependent inhibition of platelet aggregation by ADP or epinephrine was observed in platelets treated with an extract of Chinese salvia prepared for injectable use (Wang et al. 1982).

An ethyl acetate extract of Chinese salvia exhibited modest digoxin-like immunoreactivity with the fluorescence polarization immunoassay, but no apparent digoxin activity was exhibited in Roche and Beckman brand digoxin immunoassays (Chow et al. 2003).

Inhibition of estrogen receptor-positive breast cancer cells (MCF-7) was observed in cells treated with an ethanolic extract of Chinese salvia (Hsieh and Wu 2006).

IV. Pregnancy and Lactation

A reference text on traditional Chinese medicine indicates that Chinese salvia is contraindicated for use during pregnancy (Bensky et al. 2004).

No information on the safety of Chinese salvia in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered water-soluble extract of Chinese salvia in mice is 25.8 g/kg (TTPG 1998). No fatalities were reported in mice intraperitoneally administered 43 g/kg of a decoction of Chinese salvia (Chen and Chen 2004).

Short-Term Toxicity

No adverse effects were observed in mice intraperitoneally administered 2.4 g/kg of a decoction of Chinese salvia daily for 14 days (Chen and Chen 2004).

Subchronic Toxicity

No toxic effects were observed in rats orally administered 2.5 g/kg of a water-soluble extract of Chinese salvia daily for 90 days (TTPG 1998).

Salvia officinalis L.

Lamiaceae

SCN: sage
OCN: Dalmatian sage; garden sage; common sage

Part: leaf

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Wichtl 2004).

Do not exceed recommended dose (Mills and Bone 2005).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 3 to 12 g of dried leaf as a tea (Mills and Bone 2005; Wichtl 2004).

Notice

Thujone (0.5–1.5%) (Farrell 1990; Länger et al. 1996; Leung and Foster 1996); *see* Appendix 1. The essential oil contains up to 60% α-thujone and up to 25% β-thujone (Länger et al. 1996).

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Overdose of sage essential oil may cause vomiting, excessive salivation, or seizures (Burkhard et al. 1999; Millet et al. 1981).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Information on the use of sage in pregnancy and lactation is limited. The German Commission E c ontraindicates the use of the alcohol extract or essential oil of sage in pregnancy (Wichtl 2004). Sage is traditionally used to stop lactation and should not be used by women who are lactating and wish to continue to do so (Leung and Foster 1996; Mills and Bone 2005).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 54-year-old woman with no history of epilepsy experienced dystonic movements of the tongue, followed by a typical generalized tonic-clonic seizure and loss of consciousness, after ingesting a "large" (unmeasured accidental overdose) amount of sage essential oil. The woman had previously taken smaller amounts (reported as "a mouthful") of sage oil weekly for the past several years. With each intake she had experienced gastric burning, faintness, profuse sweating, dizziness, and rapid breathing, all of which receded after 10 minutes (Burkhard et al. 1999).

A 53-year-old man developed a g eneralized tonic-clonic seizure and loss of consciousness, followed by muscle aches, after ingesting 12 drops of sage essential oil. A follow-up 2 years later indicated no recurrence of seizures (Burkhard et al. 1999).

Overdose of sage essential oil may result in episodes of vomiting, excessive salivation, tonic and/or clonic convulsions, and cyanosis (blue discoloration of the skin). The episodes may be separated by periods of atonicity. The dose at which such effects may occur was not specified (Millet et al. 1981).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A methanolic extract of sage decreased serum glucose levels in diabetic but not in healthy rats after intraperitoneal administration of doses of 100 to 500 mg/kg. No effects on serum glucose levels were observed in rats administered 0.042 to 0.4 ml/kg of sage essential oil (Eidi et al. 2005).

In Vitro Pharmacological Studies

A sage-based product induced the drug-metabolizing isoenzyme CYP3A4 but had no effect on CYP1A2. Induction of the drug transporter protein MDR1 was also observed (Brandin et al. 2007). An ethanolic extract of sage induced the drug-metabolizing isoenzymes CYP1A2, CYP2D6, and CYP3A4 (Hellum et al. 2007).

The essential oil of sage showed mild inhibition of platelet aggregation induced by arachidonic acid but not by thrombin, ADP, or the thromboxane A_2 agonist U46619 (Tognolini et al. 2006).

An extract of sage inhibited α-glucosidase activity (Kwon et al. 2006).

IV. Pregnancy and Lactation

The German Commission E contraindicates the use of the alcohol extract or essential oil of sage in pregnancy (Wichtl 2004).

In an anti-implantation study, no adverse effects were observed in rats orally administered 250 mg/kg aqueous or ethanolic extracts of sage on postcoital days 1 to 10 (Kamboj and Dhawan 1982).

Sage is traditionally used to stop lactation and should not be used by women who are lactating and wish to continue to do so (Leung and Foster 1996; Mills and Bone 2005).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an orally administered sage essential oil in rats is 2600 mg/kg (Opdyke 1974). Convulsions in rats intraperitoneally administered sage essential oil were observed at doses between 300 and 500 mg/kg. Doses over 3200 mg/kg were lethal to the rats (Millet et al. 1981).

The LD_{50} of an intraperitoneally administered methanolic extract of sage in rats was 4000 mg/kg (Eidi et al. 2005).

Hepatotoxicity

An aqueous extract of sage, provided as the sole source of drinking water, increased liver damage from the liver toxin carbon tetrachloride (CCl_4) in rats. Sage ingestion increased GST activity, glutathione peroxidase, and the CYP2E1 protein (CCl_4 toxicity results from bioactivation mainly by CYP2E1) (Lima et al. 2007a).

Hepatoprotective activity of aqueous and methanolic extracts of sage was observed in human liver cells treated

with sage extract and/or *tert*-butyl hydroperoxide (*t*-BHP). The methanolic extract had a higher content of phenolic compounds than the water extract and conferred better protection in this in vitro model of oxidative stress. Both extracts significantly prevented *t*-BHP-induced lipid peroxidation and GSH depletion but not DNA damage as assessed by the comet assay (Lima et al. 2007b).

A protective effect against oxidative liver damage produced by azathioprine was observed in rats treated with an aqueous extract of sage (Amin and Hamza 2005).

Genotoxicity

A terpenoid fraction of sage exhibited a dose-dependent protective effect against mutagenicity induced by mitomycin C in rats (Vujosevic and Blagojevic 2004).

Cytotoxicity

Sage used at a concentration of 100 µl/kg was cytotoxic to mammalian cells (Vujosevic and Blagojevic 2004). No significant cytotoxicity of sage essential oil was observed in human melanoma, renal, and adenocarcinoma cell lines, although some inhibition of tumor growth was observed (Loizzo et al. 2007).

Salvia sclarea L. — Lamiaceae

SCN: clary sage
OCN: clary; muscatel sage

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of clary sage in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In 24- and 48-hour closed patch test studies, no positive reactions were observed after use of full strength clary sage essential oil alone or in 8% petrolatum. Further, there were no sensitization reactions observed in volunteers tested with 8% clary oil in petrolatum (Opdyke 1979).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The essential oil of clary sage showed mild inhibition of platelet aggregation induced by arachidonic acid but not by thrombin, ADP, or the thromboxane A_2 agonist U46619 (Tognolini et al. 2006).

IV. Pregnancy and Lactation

No information on the safety of clary sage in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered clary sage essential oil in rats has been reported as 5.0 and 6.3 g/kg. The acute dermal toxicity in rabbits could not be determined at doses up to 2 g/kg (Opdyke 1979).

Genotoxicity

No significant genotoxic activity of clary sage was observed in the *Bacillus subtilis rec* assay or the *Salmonella* microsome reversion assay (Zani et al. 1991).

Literature Cited

Opdyke, D.L.J. 1979. *Monographs on fragrance raw materials*. New York: Pergamon Press.

Zani, F., G. Massimo, S. Benvenuti, et al. 1991. Studies on the genotoxic properties of essential oils with *Bacillus subtilis* rec-assay and *Salmonella*/microsome reversion assay. *Planta Med.* 57(3):237-241.

Salvia spp.

Lamiaceae

Salvia columbariae Benth.
SCN: chia
OCN: California chia; California sage

***Salvia hispanica* L.**
SCN: chia
OCN: Spanish sage
Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

A study with diabetic patients indicated no adverse effects of chia on safety parameters including liver, kidney, and hemostatic function, or on fasting blood glucose levels (Vuksan et al. 2007).

Pregnancy and Lactation

No information on the safety of chia in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In type 2 diabetes patients given supplementation of diets with 33 to 41 g of chia daily for 12 weeks, no changes in safety parameters including liver, kidney, or hemostatic function, or in fasting blood glucose levels were observed (Vuksan et al. 2007).

Animal Pharmacological Studies

In dyslipemic rats fed diets containing 33% chia seed for 3 weeks, the onset of dyslipidemia and insulin resistance was prevented, with no change in glycemia (Chicco et al. 2008).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of chia during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Sambucus spp.

Caprifoliaceae

Sambucus nigra L.
SCN: European elder
OCN: black elder

***Sambucus nigra* L. ssp. *canadensis* (L.) Bolli**
SCN: American elder
Syn: *Sambucus canadensis* L.
OCN: sweet elder
Part: flower

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

The leaf, bark, seed, and raw unripe fruit of European elder, American elder, and related *Sambucus* species contain the cyanogenic glycoside sambunigrin, ingestion of which may cause vomiting or severe diarrhea (Buhrmester et al. 2000; Frohne and Pfander 2000; Nelson et al. 2006; Weiss and Meuss 2001; Wichtl 2004). Cooking or drying reduces the content of cyanogenic glycosides (FSANZ 2004).

Extracts of cooked elder flowers are traditionally used as a beverage flavoring (Leung and Foster 1996).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of elder flower in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Oral administration of 2 m l/kg of an aqueous extract of European elder flower reduced sleep onset time and increased duration of sleeping time induced by orally administered pentobarbitone (30 mg/kg, administered subcutaneously) but had no significant effects on the analgesic activity of morphine (5 mg/kg, administered subcutaneously) (Jakovljevic et al. 2001).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An aqueous extract of European elder flower exhibited insulin-like and insulin-releasing actions in isolated mouse abdominal muscles (Gray et al. 2000).

IV. Pregnancy and Lactation

No studies on the use of elder flower during pregnancy or lactation were identified.

V. Toxicity Studies

Short-Term Toxicity

No significant toxic effects were observed in rabbits intragastrically administered 39 mg/kg daily of an ethanolic extract of European elder flower for 3 days (Chibanguza et al. 1984).

Notice

Cyanogenic glycosides (Buhrmester et al. 2000; Frohne and Pfander 2000; Nelson et al. 2006; Weiss and Meuss 2001; Wichtl 2004); *see* Appendix 1.

Editors' Notes

The leaf, bark, seed, and raw unripe fruit of European elder, American elder, and related *Sambucus* species contain the cyanogenic glycoside sambunigrin, ingestion of which may cause vomiting or severe diarrhea (Buhrmester et al. 2000; Frohne and Pfander 2000; Nelson et al. 2006; Weiss and Meuss 2001; Wichtl 2004). Cooking or drying reduces the content of cyanogenic glycosides (FSANZ 2004).

Ripe elder fruit is used as a food and beverage ingredient (Jagendorf 1963; Nichols 1972; Osol and Farrar 1955; Rombauer and Becker 1975).

Adverse Events and Side Effects

No adverse events were reported in clinical trials of European elder fruit extracts (Murkovic et al. 2004; Zakay-Rones et al. 1995, 2004).

Nausea, vomiting, abdominal cramps, and weakness were reported after consumption of a juice made from elder fruit, leaf, and branches (MMWR 1984).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of elder fruit in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

No adverse events were reported in clinical trials of European elder fruit extracts at doses of 60 ml or 1200 mg daily (Murkovic et al. 2004; Zakay-Rones et al. 1995, 2004).

Case Reports of Adverse Events

Consumption of an improperly prepared juice, made with the fruit, leaf, and branches of wild elder plants in California (believed to be *S. mexicana*), resulted in acute gastrointestinal and neurological symptoms in 11 individuals. Symptoms of poisoning included nausea, vomiting, abdominal cramps, and weakness (MMWR 1984).

S

Sanguinaria canadensis L. — Papaveraceae

SCN: bloodroot
OCN: red puccoon; red root

Part: rhizome, root

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (McGuffin et al. 1997).

Other Precautions

May cause nausea and vomiting (Felter and Lloyd 1898; Osol and Farrar 1955; Remington and Wood 1918; Scudder 1898).

Drug and Supplement Interactions

None known.

Notice

Berberine (Salmore and Hunter 2001); *see* Appendix 1.

Emetic (Felter and Lloyd 1898; Osol and Farrar 1955; Remington and Wood 1918; Scudder 1898); *see* Appendix 2.

Editors' Note

Bloodroot contains the compound berberine, which is present in significantly smaller quantities than other alkaloids in the plant (Salmore and Hunter 2001).

Adverse Events and Side Effects

Vomiting has been caused by as little as 1 g of bloodroot (Felter and Lloyd 1898; Osol and Farrar 1955; Remington and Wood 1918; Scudder 1898). The presence of the toxic alkaloid sanguinarine suggests that the plant should not be used in large amounts (Leung and Foster 1996; List and Hörhammer 1973; Martindale and Reynolds 1996). Large doses of bloodroot may cause irritation of the gastrointestinal tract (Felter and Lloyd 1898; Scudder 1898).

An association between increased risk of oral leukoplakia (white patches that develop on a mucous membrane, sometimes precancerous) and use of a bloodroot-containing commercial toothpaste has been recognized and been the subject of significant study and debate (Allen 1999; Damm et al. 1999; Eversole et al. 2000; Mascarenhas et al. 2001, 2002; Munro et al. 1999). A review of human studies on oral care products that contain bloodroot extracts indicates that the products were generally well tolerated, with cases of soft tissue irritation being reported in a small number of trial participants (Munro et al. 1999). A more recent analysis of leukoplakia tissue samples from patients that used bloodroot-containing toothpaste indicated that the leukoplakia was precancerous (Anderson et al. 2005).

Bloodroot has traditionally been used as an ingredient in topical escharotic (an agent that destroys tissue and causes sloughing) preparations for the treatment of skin cancers, although bloodroot itself does not have escharotic activity. Cases of late recurrences and metastasis of cancers, due to incomplete removal of cancerous cells, in patients who are self-treating skin cancers have been reported (Affleck and Varma 2007; Laub 2008; McDaniel and Goldman 2002). Scarring, inflammation, escharotic activity, ulceration, and acute pain have been reported after repeated topical applications of escharotic products that contain bloodroot (Affleck and Varma 2007; Jellinek and Maloney 2005; Laub 2008; McDaniel and Goldman 2002; Moran and Helm 2008).

Pharmacological Considerations

In vitro studies on the compound sanguinarine have indicated antiplatelet, antiangiogenic, and apoptotic activity, and have shown either inhibition or no effect on the drug-metabolizing isoenzyme CYP1A1 (Adhami et al. 2004; Basini et al. 2007; Eun and Koh 2004; Hussain et al. 2007; Jeng et al. 2007; Karp et al. 2005; Zdarilová et al. 2006). The relevance of those in vitro findings to human use is not known.

Pregnancy and Lactation

Animal studies indicated no adverse effects on fetal development or on fertility in animals administered up to 100 mg/kg bloodroot extract daily. At a dose of 60 mg/kg in rats and 25 mg/kg in rabbits, some toxicity was observed in the pregnant animals. Reduced body weights in the offspring during lactation were observed at 100 mg/kg treatment level concomitant with maternal toxicity (Keller and Meyer 1989).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of human studies on oral care products that contain bloodroot extracts indicates that multiple 14-day, 28-day, 90-day, and 6-month studies on these products have been completed and that the products were generally well tolerated, with cases of soft tissue irritation being reported in a small number of trial participants (Munro et al. 1999).

Case Reports of Adverse Events

Bloodroot has traditionally been used in topical preparations as an escharotic (an agent that destroys tissue and causes sloughing) for the treatment of skin cancers. This use is based on a technique developed in the 1930s by physician Frederic Mohs. Dr. Mohs used a salve containing zinc chloride, antimony trisulfide, and bloodroot (reportedly included as an "organic stabilizer") as an escharotic and fixative prior to surgical removal of tumors (McDaniel and Goldman 2002).

While anecdotal evidence indicates successful elimination of cancerous cells in some patients, case reports indicate late recurrences and metastasis of cancers, due to incomplete removal of cancerous cells, in patients who were self-treating skin cancers (Affleck and Varma 2007; Laub 2008; McDaniel and Goldman 2002). Scarring, inflammation, escharotic activity, ulceration, and acute pain have been reported after repeated topical applications of escharotic products that contain bloodroot (Affleck and Varma 2007; Jellinek and Maloney 2005; Laub 2008; McDaniel and Goldman 2002; Moran and Helm 2008).

A 27-year-old man with a history of abnormal moles presented with necrotic ulcers after use of "black salve," a topical preparation containing bloodroot that is used as an escharotic in the treatment of skin cancers. Histological examination and excisional biopsy showed ulceration and extensive tissue necrosis (involving the epidermis, dermis, and subcutaneous tissue). A diffuse mixed neutrophilic and lymphocytic infiltrate was present in all layers of the skin and in subcutaneous tissues. Information on dose and duration of use was not reported (Moran and Helm 2008).

Internally, overdose of bloodroot extracts is reported to cause burning in the epigastrium with vomiting, tormenting thirst, faintness, vertigo, dimness of vision, and prostration (Remington and Wood 1918).

The manufacturers of Viadent, a toothpaste that, at the time, contained 0.075% bloodroot extract, commissioned a safety and toxicology review of bloodroot and the compound sanguinarine by an expert panel. The panel concluded that the available toxicology data confirmed the safety of bloodroot at the exposure level of Viadent (Frankos et al. 1990). Bloodroot is no longer an ingredient in Viadent, and all references here to adverse events are in relation to the formulation that included bloodroot.

More recent studies and case reports, however, have suggested an association between increased risk of oral leukoplakia (white patches that develop on a mucous membrane, sometimes precancerous) and use of Viadent (Allen et al. 2001), although this association has been the focus of much study and debate (Allen 1999; Damm et al. 1999; Eversole et al. 2000; Mascarenhas et al. 2001, 2002; Munro et al. 1999).

In a retrospective study of immunohistochemical assessment of Viadent-associated leukoplakia, normal, dysplastic, and Viadent-associated tissue samples from an oral pathology archive were evaluated. Biomarker profiles evaluated in this study consistently showed intermediate staining intensities for Viadent-related specimens relative to dysplastic and normal. Based on biomarker profiles, unique histology, and clinical behavior, the authors of this study concluded that Viadent-associated lesions are preneoplastic in nature (Anderson et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Dermal, ocular, and oral cheek pouch sensitization studies of the compound sanguinarine chloride in rabbits and dogs at concentrations of 0.1 to 1.0% indicated that the compound caused slight dermal irritation in rabbits (0.1% concentration), mild ocular irritation in rabbits (0.1% concentration), and was nonirritating in the oral cheek pouch test in dogs (1.0% concentration for 28 days) (Frankos et al. 1990).

No effect on ventricular pressure, diastolic pressure, or cardiac output and no changes in lead II EKG were observed after intra-arterial administration of 0.075 mg/kg of the compound sanguinarine to beagle dogs (Frankos et al. 1990; Schwartz 1986). In monkeys orally administered 0, 10, 30, and 60 mg/kg daily for 90 days, no electrocardiographic evidence of a drug effect was noted at any of the dose levels (Frankos et al. 1990).

In Vitro Pharmacological Studies

Sanguinarine inhibited platelet aggregation induced by arachidonic acid, collagen, U46619, and a subthreshold concentration of thrombin with IC_{50} (the half-maximal inhibitory concentration) concentrations of 4.4 to 8.3 μ*M*. Sanguinarine also inhibited platelet thromboxane B_2 production, but not platelet aggregation induced by higher concentration of thrombin. SQ22536, an adenylate cyclase inhibitor, attenuated the inhibitory effect of sanguinarine toward arachidonic acid-induced platelet calcium mobilization and aggregation (Jeng et al. 2007).

The compound sanguinarine inhibited both vascular endothelial growth factor (VEGF) production and VEGF-induced Akt activation in swine granulosa cells, and blocked vessel growth induced by VEGF. The authors of the study suggested that supplementation of livestock feed with sanguinarine should be carefully considered, since sanguinarine could be detrimental to follicular angiogenesis (Basini et al. 2007).

The compound sanguinarine was shown to activate polycyclic aromatic hydrocarbon-associated signaling and metabolic pathways, inducing AhR-associated gene expression and inhibiting CYP1A1 microsomal oxidative activity (Karp et al. 2005). Other studies have shown that sanguinarine did not activate aryl hydrocarbon receptor signaling pathways in rat hepatoma cells (Dvorák et al. 2006) and had no direct effect on CYP1A expression (Zdarilová et al. 2006).

The compound sanguinarine inhibited cell proliferation and induced apoptosis in a dose-dependent manner in several lymphoma cell lines (Hussain et al. 2007). Sanguinarine has been shown to inhibit angiogenesis in the membrane of chick embryos (Eun and Koh 2004). In human prostate cancer cell lines, the compound sanguinarine caused cell cycle blockade and apoptosis by modulation of cyclin kinase inhibitor-cyclin-cyclin-dependent kinase machinery (Adhami et al. 2004).

In rat liver microsomes, the compound sanguinarine was metabolized to a species that caused DNA adduct formation in a dose-dependent manner (Stiborová et al. 2002). In human colon cancer cells treated with the compound sanguinarine, a relative abundance of rapidly initiated DNA double strand breaks was observed and were believed to be the result of, rather than the cause of, apoptotic cell death. The results of the study indicated that apoptosis induced by sanguinarine is independent of p53 and most likely independent of DNA damage (Matkar et al. 2008). Several studies have shown that the compound sanguinarine intercalates with DNA (Faddeeva and Beliaeva 1997; Piehler et al. 1997; Saran et al. 1995; Schmeller et al. 1997).

The compound sanguinarine had a positive inotropic effect followed by contracture in rat ventricular and atrial strips. Sanguinarine also dose-dependently reduced the rate of spontaneous contractions of isolated right atria (Hu et al. 2005). Positive inotropic effects were also observed in isolated guinea pig atria treated with the compound sanguinarine (Seifen et al. 1979). A dose-dependent response in ventricular refractoriness was observed in anesthetized pigs after vascular infusion of up to 4 mg/kg of the compound sanguinarine (Whittle et al. 1980).

IV. Pregnancy and Lactation

In a set of reproductive and developmental toxicity studies, female rats were orally administered bloodroot extract (containing ~68% alkaloids) at doses of up to 100 mg/kg daily 14 days prior to mating, through weaning, or doses of up to 60 mg/kg on gestational days (GD) 6 to 15, or the same dose on GD 15 through lactation day 20. Rabbits were orally administered up to 75 mg/kg daily on GD 6 to 18. No developmental toxicity, including teratogenicity, was observed in the fetuses of rats following maternal administration of the 5 to 60 mg/kg doses. An increase in post-implantation loss was observed at maternally toxic dosage levels of 50 and 75 mg/kg in rabbits. Oral administration of bloodroot in perinatal and postnatal studies in rats caused no adverse effects on litter size, parturition, or lactation of female rats nor on survival or growth of their offspring at dosage levels of 5 to 60 mg/kg. Maternal oral toxicity thresholds were 60 mg/kg daily in rats and 25 mg/kg daily in rabbits (Keller and Meyer 1989).

No adverse effects on estrous cycling or female copulatory and fertility indices or gestation/lactation parameters were observed in rats administered 10 to 100 mg/kg of bloodroot daily. Reduced body weights in the offspring during lactation were observed at the 100 mg/kg treatment level concomitant with maternal toxicity (Keller and Meyer 1989).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered bloodroot extract in rats is 1440 mg/kg (Frankos et al. 1990). No mortalities were reported in rabbits dermally administered undiluted bloodroot extract at a dose of 200 mg/kg (Becci et al. 1987; Schwartz 1986).

The LD_{50} of the compound sanguinarine in rats has been reported as 1525 mg/kg or 1658 mg/kg after oral administration (Becci et al. 1987; Frankos et al. 1990; Schwartz 1986) and 29 mg/kg after intravenous administration (Becci et al. 1987; Schwartz 1986).

In rats intraperitoneally administered a single dose of 10 mg/kg of the compound sanguinarine, increased levels of liver enzymes (SGPT and SGOT)) were observed (Dalvi 1985). In mice intraperitoneally administered the same dose, significant decreases in liver glutathione and P450 enzyme activities were observed along with increased serum levels of alanine aminotransferase (Williams et al. 2000).

Short-Term Toxicity

No toxic effects were observed in rats fed up to 150 ppm of the compound sanguinarine in the diet for 14 days, or in rats orally administered up to 0.6 mg/kg daily for 30 days (Becci et al. 1987; Schwartz 1986).

In rats administered a bloodroot extract as part of the diet, with estimated daily doses of 0 to 405 mg/kg for 28 days, no mortality was observed. At the highest dose level, a reduction in body weight was observed (Frankos et al. 1990).

In cynomolgus monkeys orally administered bloodroot extract at doses of 0 to 200 mg/kg for 28 days, emesis, diarrhea, inappetence, reduction of body weight, and mortality was observed. The publicly available data from the

study do not specify at which doses these adverse effects were observed (Frankos et al. 1990). Dose-related emesis and diarrhea (due to gastrointestinal irritation) were reported in cynomolgus monkeys orally administered the compound sanguinarine chloride at doses of 0 to 60 mg/kg daily for 90 days. The emesis occurred only during the first 5 weeks of the study and was not observed in the last 8 weeks (Frankos et al. 1990).

Subchronic Toxicity

No changes in liver enzymes were observed in pigs administered the compounds sanguinarine and chelerythrine (3:1 ratio) as 0.0002 to 0.01% of the diet for 90 days (Kosina et al. 2004).

Genotoxicity

In mice intraperitoneally administered single doses of 1.35 to 21.6 mg/kg of the compound sanguinarine, a dose-dependent increase in DNA damage in blood and bone marrow cells was observed 24 hours after treatment (Ansari et al. 2005).

In the Ames mutagenicity assay, an extract of bloodroot tested weakly positive in *Salmonella typhimurium* (Ames assay) with metabolic activation, while no mutagenic activity of the compound sanguinarine was observed with or without metabolic activation. No mutagenic activity was observed in *E. coli* in the unscheduled DNA synthesis assay in rat hepatocytes (Frankos et al. 1990).

S

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Among patients with allergic reactions to fragrances, positive patch test results to sandalwood were observed in less than 3% of patients (An et al. 2005; Larsen et al. 1996; Romaguera et al. 1983; Trattner and David 2003).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of sandalwood in pregnancy was identified in the scientific or traditional literature.

While this review did not identify any concerns for pregnant women, safety has not been conclusively established.

Sandalwood essential oil is a commonly sold, highly concentrated extract of sandalwood. An animal study demonstrated that sandalwood oil crosses into breast milk (Chhabra and Rao 1993).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Among 422 patients with suspected contact allergy in Korea, 9.6% tested positive to a fragrance mix and 2.4% tested positive to sandalwood essential oil (An et al. 2005).

Among 167 patients with suspected fragrance allergy in a worldwide investigation of fragrance contact dermatitis, 6.6% were allergic to sandalwood, while 1.8% had irritation reactions to sandalwood (Larsen et al. 1996). Among 641 Israeli patients with eczema, none tested positive to sandalwood (Trattner and David 2003).

In an analysis of patch test reactions in 58,128 patients, 5539 patients were patch tested and 80 tested positive to the fragrance mix. Among these 80, only one tested positive to sandalwood essential oil (Romaguera et al. 1983).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No significant activity of a methanol extract or ethyl acetate fraction of sandalwood was observed on the drug-metabolizing isoenzymes CYP3A4 or CYP2D6 in human liver microsomes (Subehan et al. 2006; Usia et al. 2006).

IV. Pregnancy and Lactation

No information on the safety of sandalwood in pregnancy was identified.

Increases in hepatic glutathione S-transferase, glutathione reductase, and glutathione peroxidase activity were observed in the nursing pups of rats that were orally administered 5 or 10 µl of sandalwood essential oil daily for 14 or 21 days. A decrease in hepatic CYP450 content was observed in pups and dams treated with 10 µl of sandalwood oil for 21 days (Chhabra and Rao 1993).

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of sandalwood essential oil in rats is 5.58 g/kg (Opdyke 1979). The dermal LD_{50} of sandalwood essential oil in rabbits could not be determined at doses up to 5 g/kg (Opdyke 1979).

Genotoxicity

No genotoxicity of sandalwood essential oil was observed in *Bacillus subtilis* spore *rec* assays with H17 *Rec*$^+$ and M45 *Rec*$^-$ with or without metabolic activation by S9 (Burdock and Carabin 2008; Ishizaki et al. 1985; Watanabe 1994).

Saposhnikovia divaricata (Turcz.) Schischk. — Apiaceae

SCN: siler
Syn: *Ledebouriella divaricata* (Turcz.) Hiroe; *Ledebouriella seseloides* (Hoffm.) Wolff; *Siler divaricatum* (Turcz.) Benth. & Hook. f.
PN: *fang feng* (root)
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
Allergic reactions to siler, affecting the skin and digestive system, have been reported (Bensky et al. 2004).

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of siler in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
Allergic reactions to siler, affecting the skin and digestive system, have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
Inhibition of the drug-metabolizing isoenzyme CYP3A was observed in human liver microsomes treated with a decoction or infusion of siler (Guo et al. 2001).

No estrogenic activity of an ethanolic extract of siler was observed in a recombinant yeast system featuring a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation
No information on the safety of siler during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
The LD_{50} of orally administered siler in mice is 213.8 g/kg (type of extract not specified in available English language translation) (Chen and Chen 2004).

Sassafras albidum (Nutt.) Nees — Lauraceae

SCN: sassafras
Syn: *Sassafras officinale* T. Nees & C.H. Eberm.

Part: root

Quick Reference Summary

Safety Class: * 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Vesselinovitch et al. 1979).

Not for long-term use; do not exceed recommended dose (Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 4–7 g of the root bark as a tea (Remington and Wood 1918).

Notice

Alkenylbenzenes (safrole 5.0–8.0% in the root bark, <1.0% in the root, 80% of the essential oil) (Cook and Martin 1948; Craig 1953; JECFA 1981; List and Hörhammer 1973); *see* Appendix 1.

Editors' Notes

U.S. regulations allow the use of sassafras in foods only if safrole-free (CFR 2011).

Animal studies in the 1960s raised concern about the cancer-causing potential of the purified compound safrole when fed in relatively high amounts (0.01 to 0.1% of the diet) for extended periods of time (2 years, equivalent to approximately 68 years of human exposure) (Abbott et al. 1961; Hagan et al. 1965, 1967; Long et al. 1963), leading to the ban on safrole in foods (CFR 2011c). Although safrole is listed as insoluble in water, one study indicated that approximately 11% of the safrole is extracted in sassafras tea, and a much higher percentage is extracted by alcohol (Carlson and Thompson 1997; Merck 1999). The content of safrole in sassafras tea made from 3 g sassafras root powder or root bark powder is 90 to 4120 µg per cup (Carlson and Thompson 1997). Safrole is also present in black pepper. With an estimated intake of 400 mg of black pepper per person daily in the United States, daily individual intake of safrole is approximately 36 µg (Ames et al. 1990; Bhardwaj et al. 2002; Farag and Abo-Zeid 1997; Gold et al. 2001). While occasional consumption of sassafras tea is thought to be safe, use of alcohol extracts is discouraged.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of sassafras during pregnancy or lactation was identified. Studies with the compound safrole in pregnant and lactating rats indicated higher incidences of tumors in offspring of treated pregnant or lactating mice as compared to control groups (Vesselinovitch et al. 1979). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

* Safrole-free extracts of sassafras are commercially available. Concerns regarding the use of sassafras do not apply to safrole-free products.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Hot flashes and sweating were reported in a 72-year-old woman with a history of hypertension. The woman was taking furosemide, potassium chloride, and aspirin in addition to drinking up to 10 cups of sassafras tea daily for an unspecified amount of time. The hot flashes and sweating resolved after cessation of the tea (Haines 1991).

Vomiting, tachycardia, and tremulousness were reported in a 47-year-old woman who inadvertently ingested one teaspoon of sassafras essential oil (Grande and Dannewitz 1987). A fatal case of poisoning was reported in young man after ingestion of one teaspoon of sassafras essential oil. Symptoms of poisoning included vomiting, collapse, dilated pupils, and stupor (Cincinnati 1888). Several other cases of sassafras oil poisoning have been reported, although details are lacking. A review of essential oil poisonings reported that vomiting and signs of shock are common in sassafras poisoning (Craig 1953).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats subcutaneously administered 15 mg of an extract of sassafras (produced with a series of solvents that omitted safrole) once a week for up to 78 weeks, tumors developed in 11 of 15 males and 9 of 15 females. The types of tumors were not specified (Kapadia et al. 2002).

In partially hepatectomized rats, an increase in liver regeneration was observed after subcutaneous administration of 15 or 375 mg of sassafras essential oil or after administration of a diet containing 1.5 or 7% sassafras tea for 7 days postoperatively (Gershbein 1977).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Offspring of pregnant mice orally administered 120 µg/g of the compound safrole on gestational days 12, 14, 16, and 18 were sacrificed at 94 weeks of age. Among animals exposed in utero to safrole, renal epithelial tumors were observed in 7% of female offspring, with none in male offspring (Vesselinovitch et al. 1979).

After oral administration of 120 µg/g of the compound safrole to lactating mice every other day for 12 weeks, 34% of male offspring had hepatocellular tumors, but no tumors were observed in female offspring. This incidence was significantly lower than observed in 4-week-old offspring orally administered the same dose of safrole twice a week for 90 weeks. In these animals, hepatocellular tumors were observed in 48% of females and 8% of males (Vesselinovitch et al. 1979).

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of the compound safrole is 2350 mg/kg in mice and 1950 mg/kg in rats (Jenner et al. 1964).

Chronic Toxicity

In rats fed sassafras essential oil as 0.117% of the diet or safrole as 0.039% of the diet for 2 years, equivalent to approximately 68 years of human exposure, hepatocarcinomas were found in all animals along with changes in the kidneys, adrenals, thyroid, pituitary, and testes or ovaries. In animals sacrificed at 22 months, kidneys showed evidence of congestion, but no liver tumors were observed (Abbott et al. 1961).

In rats fed the compound safrole as 0, 0.1, 0.25, 0.5, or 1% of the diet for 2 years, growth was depressed at levels of 0.25% and above. None of the animals in the 1% group survived beyond 62 weeks. These animals showed testicular atrophy, changes in the stomach, and changes in the liver, including tumor formation. Similar types of liver changes were seen with the lower doses. Liver damage was slight at 0.1% and lacked tumors and cirrhosis, moderate at 0.25% but lacked cirrhosis, and severe at 0.5%, with cysts and tumors (Hagan et al. 1965, 1967).

In rats fed diets containing 0.01, 0.05, 0.1, or 0.5% of the compound safrole for 2 years, changes in the liver, including benign and malignant tumors, were observed. The liver injury was rated as very slight at the 0.01% safrole level, slight at 0.05% safrole, slight to moderate at 0.1% safrole, and moderate to severe at 0.5% safrole. Tumor incidence was significantly increased at 0.5%. Weight gain and survival were significantly decreased at the 0.5% level (Long et al. 1963).

Genotoxicity

A review of mutagenicity studies on the compound safrole indicated that safrole was generally inactive in mutagenicity studies in various strains of *Salmonella typhimurium* with or without metabolic activation, but has occasionally been reported to be weakly positive (JECFA 1981).

Safrole was positive in the following short-term tests for mutagenesis: mammalian cell transformation in culture, Rabin's test of degranulation of rough endoplasmic reticulum from rat liver, and mouse sebaceous gland suppression test. The compound was negative in the tetrazolium reduction and tissue reaction to subcutaneous implants in mice. Safrole was positive in mutagenicity assays with *Escherichia coli* and *Saccharomyces cerevisiae* and in the intraperitoneal host-mediated assay with *Salmonella typhimurium* strain TA1535 or *Saccharomyces cerevisiae*. Safrole was positive in the host-mediated assay with *Salmonella typhimurium* strains TA1950 and TA1952 (JECFA 1981).

Satureja spp.

Lamiaceae

Satureja hortensis L.
SCN: summer savory
OCN: annual savory

Satureja montana L.
SCN: winter savory
Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (*S. hortensis*) (Hajhashemi et al. 2002; Stanic and Samaržija 1993); *see* Appendix 2.

Emmenagogue (*S. hortensis*) (Felter and Lloyd 1898); *see* Appendix 2.

Editors' Note

The classifications and concerns for these herbs are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with their use as spices.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of summer savory or winter savory in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered 50 ml/kg of winter savory, an initial decrease in diuresis with a subsequent mild stimulation of diuresis was observed. Administration of a 10% aqueous extract or 0.1% essential oil solution resulted in more pronounced diuretic activity. Tests with the essential oil indicated that a 0.1% solution of essential oil was considered to be a diuretic dose, whereas 0.5% and 1% solutions caused toxic symptoms (Stanic and Samaržija 1993).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of summer savory or winter savory during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of summer savory essential oil in rats is 1.37 g/kg after oral administration (Opdyke 1979).

Genotoxicity

No mutagenic activity of the essential oils of winter savory and summer savory was observed in the *Bacillus subtilis rec* assay and *Salmonella* microsome reversion assay (Zani et al. 1991).

Saussurea costus (Falc.) Lipsch.

Asteraceae

SCN: costus
Syn: *Aucklandia costus* Falc.; *Aucklandia lappa* Decne.; *Saussurea lappa* (Decne.) C.B. Clarke
AN: *kushtha*
PN: *mu xiang* (root)
OCN: aucklandia
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Costus, which is sold as *mu xiang*, is sometimes confused with the aristolochic acid-containing *Aristolochia* species, which are sometimes traded as *qing mu xiang* (Shum et al. 2007). Methods for differentiation of *Saussurea* and *Aristolochia* species and for detection of aristolochic acid have been developed (Shum et al. 2007; Upton 2006; Yamasaki et al. 2009).

Adverse Events and Side Effects

Allergic reactions to costus have been reported (Bensky et al. 2004; Cheminat et al. 1981).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of costus in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Costus essential oil is used in perfumery and has been responsible for a number of cases of contact dermatitis (Cheminat et al. 1981). Sesquiterpene lactone compounds are believed to be responsible for the reaction (Cheminat et al. 1981; Pandey et al. 2007; Robinson et al. 2008; Sun et al. 2003).

An allergic reaction was reported in a person who ingested a decoction containing 10 g of costus. The reaction was confirmed with an oral rechallenge (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No estrogenic activity of costus was observed in a recombinant yeast system featuring a human estrogen receptor expression plasmid and a reporter plasmid (Kim et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of costus during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound costuslactone is 300 mg/kg in rats after intraperitoneal administration (Chen and Chen 2004).

Subchronic Toxicity

No adverse effects were observed in rats orally administered 1.77 mg/kg (males) or 2.17 mg/kg (females) of costus daily for 90 days (Chen and Chen 2004).

Genotoxicity

In a mutagenicity assay with *Salmonella typhimurium* strains TA98, TA100, TA1535, and TA1537, an extract of costus exhibited some mutagenic activity in TA98 (Riazuddin et al. 1987).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (10–14%) (Morton 1978); *see* Appendix 1.

Adverse Events and Side Effects

Rashes have been reported in persons coming in contact with the resin, wood, and, less frequently, the fruit of Brazilian peppertree (Morton 1978).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Emmenagogue properties are attributed to the bark and leaf of the Peruvian peppertree in Argentina and also to the fruit and leaf in Iraq (Hieronymus 1882; Dellacassa 2010).

No information on the safety of Brazilian or Peruvian peppertree bark in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Animal Pharmacological Studies

No relevant human pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A review of the economic botany of Argentina records that emmenagogue properties are attributed to the bark and leaf of the Peruvian peppertree (Hieronymus 1882).

No information on the safety of Brazilian or Peruvian peppertree bark in lactation was identified.

V. Toxicity Studies

Genotoxicity

In a series of cell-free and bacterial assays, an extract of Brazilian peppertree bark was negative in a cell-free plasmid DNA test, indicating that it did not directly break DNA. Positive results were obtained in the SOS chromotest, in a forward mutagenesis assay employing strains of *Escherichia coli*, and in the *Salmonella* reversion assay with strains TA97, TA98, TA100, and TA102. All the bacterial tests were performed without metabolic activation. The authors indicated that results suggest that Brazilian peppertree bark produces DNA damage and mutation in bacteria, and that oxidative damage may be responsible for the genotoxicity (de Carvalho et al. 2003).

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Consumption of the fruit should not exceed small amounts for use as a c ondiment (Morton 1978; Watt and Breyer-Brandwijk 1962).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Gastrointestinal irritation after ingestion of Brazilian and Peruvian peppertree fruit has been reported (Morton 1978; Watt and Breyer-Brandwijk 1962).

Rashes have been reported in persons coming in contact with the resin, wood, and, less frequently, the fruit of Brazilian peppertree (Morton 1978). An irritant compound, cardanol, was identified in Brazilian peppertree fruit (Stahl et al. 1983).

Pharmacological Considerations

None known.

Pregnancy and Lactation

An animal study with an ethanolic extract of fruit of Peruvian peppertree indicated stimulant activity in isolated rabbit and rat uterus (Zaidi et al. 1970). Emmenagogue properties are attributed to the fruit and leaf of the Peruvian peppertree in Iraq (Dellacassa 2010).

No information on the safety of Brazilian or Peruvian peppertree fruit in lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Eaten "in quantity" (no more specific information was given), the fruit of Peruvian peppertree has been reported to cause gastrointestinal irritation in children, accompanied by vomiting, diarrhea, headache and fatigue, and the same effects but with "more severe exhaustion" have been reported in association with eating Brazilian peppertree fruit (Watt and Breyer-Brandwijk 1962). Cases of poisoning from eating the fruit of the Peruvian peppertree were reported to include irritation in the throat, vomiting and purging (Watt and Breyer-Brandwijk 1962). Eating more than a few of the ripe or unripe fruits of Brazilian peppertree was reported to cause digestive upset and vomiting (Morton 1978).

Rashes have been reported in persons coming in contact with the resin, wood, and, less frequently, the fruit of Brazilian peppertree (Morton 1978). A researcher preparing extracts of fresh ripe Brazilian peppertree fruit experienced headaches, swollen eyelids, shortness of breath, and chest pains (Morton 1978).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

An irritant compound, cardanol, was identified in Brazilian peppertree fruit. A skin test showed that the substance had a strong skin irritating effect after a relatively long latency period (Stahl et al. 1983).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

A study with a specially prepared extract of the fruit of Peruvian peppertree indicated stimulant activity on isolated rabbit and rat gravid uterus, but not in virgin uterus. The extract used was concentrated at 1 g/ml. Although described as an aqueous extract, it was prepared with ethanol (95%), then dried, mixed with chloroform and distilled water in several steps, neutralized to a pH of 6.8 with dilute ammonia solution, and subjected to charcoal filtration (Zaidi et al. 1970). Emmenagogue properties are attributed to the fruit and leaf of the Peruvian peppertree in Iraq (Dellacassa 2010).

No information on the safety of Brazilian or Peruvian peppertree fruit in lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of Brazilian peppertree fruit in mice is 3.5 g/kg after intraperitoneal administration and could not be determined at doses up to 5 g/kg after oral administration (Pires et al. 2004).

No toxic effects were observed in rats fed 2 g/kg of an ethanol extract of Peruvian peppertree fruit in the diet for 1 day (Ferrero et al. 2007).

Short-Term Toxicity

No toxic effects or histopathological changes in the brain, liver, kidney, lung, heart, stomach, or intestines were observed in rats fed diets containing a daily dose of 1 g/kg of an ethanol extract of Peruvian peppertree fruit for 14 days (Ferrero et al. 2007).

Genotoxicity

PN: *nan wu wei zi* (fruit)
OCN: schizandra
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: C

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

In human studies, schisandra has been shown to increase the plasma levels of tacrolimus and talinolol, and is thought to inhibit the drug metabolizing isoenzyme CYP3A and the drug transporter protein P-gp, leading to increased plasma levels of drugs metabolized by CYP3A or transported by P-gp (Fan et al. 2009; Jiang et al. 2010; Xin et al. 2007; Xin et al. 2009). *See* Cytochrome P450 in Appendix 3.

Adverse Events and Side Effects

Heartburn has been reported as a side effect in some individuals. Allergic reactions to schisandra have been reported (Bensky et al. 2004).

Pharmacological Considerations

Large doses (500 mg/kg) of schisandra increased the metabolism rate of intravenously administered warfarin in rats (Mu et al. 2006). Animal studies have indicated that schisandra berry induced the drug-metabolizing isoenzyme CYP1A2 and inhibited CYP3A4 (Makino et al. 2006; Zhang et al. 2002).

Pregnancy and Lactation

A reduction in postpartum hemorrhaging and no adverse effects on maternal or fetal health were reported in pregnant women that took a schisandra extract during pregnancy (Gaistruk and Taranovskij 1968). In one study, schisandra was used to induce labor in women with prolonged labor (Trifonova 1954).

No information on the safety of schisandra during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In healthy patients orally administered 100 mg talinolol before and after oral administration of 600 mg schisandra extract daily for 14 days, an increase in plasma levels of the talinolol was observed after the schisandra administration (51% increase in the maximum plasma concentration). Talinolol is a substrate of the drug transporter protein P-glycoprotein (P-gp), and inhibition of P-gp was proposed as the mechanism of interaction (Fan et al. 2009).

In liver transplant patients taking tacrolimus, a dose dependent increase in blood levels of tacrolimus was observed after treatment with two capsules of schisandra (each containing 11.25 mg deoxyschizandrin) extract along with one of two doses of tacrolimus, 0.1 to 0.15 mg/kg daily or 0.5 to 3 mg/person daily. Increases in the maximum plasma concentration of tacrolimus were 339% for the 0.1 to 0.15 mg/kg dose and 262% for the 0.5 to 3 mg/person dose. A decrease in diarrhea and agitation, two side effects typically observed with tacrolimus treatment, was noted along with improvement in liver function (Jiang et al. 2010).

Increased bioavailability of midazolam was observed in healthy volunteers orally administered three capsules schisandra extract (each containing 11.25 mg deoxyschizandrin) twice daily for seven days. As compared to pretreatment levels, an 85% increase in the maximum plasma concentration of midazolam and a 52% decrease in the oral clearance of this drug was observed after administration of a single dose of 15 mg midazolam. The authors indicated that inhibition of CYP3A was the likely mechanism of interaction (Xin et al. 2009).

An increase in the bioavailability of tacrolimus was observed in healthy volunteers orally administered three capsules schisandra extract (each containing 11.25 mg deoxyschizandrin) twice daily for 13 days. The maximum plasma concentration of tacrolimus increased by 227% as compared to tacrolimus administered prior to treatment with schisandra. Tacrolimus is metabolized by CYP3A4 and CYP3A5, and P-gp is important in the absorption metabolism of this drug. The authors suggested that inhibition of CYP3A and P-gp by schisandra were likely responsible for the observed interaction (Xin et al. 2007).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

In rats orally administered an aqueous extract of schisandra at a dose equivalent to 500 mg/kg of dried fruit daily for 5 days, the clearance rate of intravenously administered warfarin (2 mg/kg) was significantly larger than that seen in the control group. Related assays indicated that the interaction was due to induction of the pregnane X receptor (Mu et al. 2006).

The compounds schisandrol A and B and schisandrin B and C increased pentobarbital- and barbital-induced sleeping time in mice (Bao et al. 1980; Liu 1991).

II. Adverse Events

Case Reports of Adverse Events

Schisandra may occasionally cause heartburn (Bensky et al. 2004). Allergic rashes affecting the eyelids, back of the hands, chest, and lower back have been reported (Bensky et al. 2004; Sandberg 1993). Overdoses of schisandra (standard dose listed as a decoction of 3–6 g) have been associated with abdominal discomfort and burning, cold and sore sensations in the epigastrium, stomach pain, and reduced appetite (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Administration of an aqueous extract of schisandra (dose not specified in English language abstract) in rats for 3 or 6 days increased the metabolism of imipramine, a CYP1A2 substrate (Zhang et al. 2002). An aqueous extract of schisandra berry inhibited the drug-metabolizing isoenzyme CYP3A4 to a greater extent than grapefruit juice (Makino et al. 2006). In rats orally administered a single dose of schisandra equivalent to 3 g/kg of dried herb, examination of excised livers indicated an increase in total CYP450 expression (Mu et al. 2006).

In a study of the potential of schisandra to restore hepatic drug metabolism in rats with liver damage, rats were orally

administered the hepatotoxin carbon tetrachloride with or without pretreatment with 160 mg/kg of a lignan fraction of schisandra. In rats administered carbon tetrachloride alone, metabolism of antipyrine was significantly reduced, but rats pretreated with schisandra metabolized antipyrine at rates similar to those of control animals, indicating a protective effect of schisandra on phase I metabolism (Zhu et al. 1999).

Schisandra exhibited a significant protective effect against adriamycin-induced cardiotoxicity in rats (You et al. 2006).

In Vitro Pharmacological Studies

An ethanol extract of schisandra induced the drug-metabolizing isoenzymes CYP3A4 and CYP1A2, and MDR1 (Brandin et al. 2007). Aqueous extracts of schisandra induced the drug-metabolizing isoenzymes CYP3A4 and CYP2C9 in human liver cells (Mu et al. 2006). Dose-dependent induction of CYP3A4 via the pregnane X receptor was observed in human liver cells (Hua et al. 2007; Mu et al. 2006).

A study on different compounds isolated from schisandra berry indicated that the compound gomisin C is a mechanism-based inhibitor that competitively inhibits and irreversibly inactivates CYP3A4 with inhibitory effects greater than those of the drug ketoconazole (Iwata et al. 2004). The compounds schisandrin A and B and schisantherin A inhibited P-glycoprotein (Pan et al. 2006; Qiangrong et al. 2005).

An extract of schisandra activated the estrogen-responsive luciferase gene in cells transiently transfected with estrogen receptors and reporter plasmids (Lee et al. 2004).

IV. Pregnancy and Lactation

Administration of 20 to 25 drops of schisandra tincture three times daily, during three consecutive hours, for three consecutive days was effective in inducing labor in women with prolonged labor. No adverse effects were observed on blood pressure, elimination of the placenta, or postnatal health of mother and infant (Trifonova 1954).

In hypotensive or normotensive pregnant women administered 30 to 40 drops of schisandra tincture three times daily for an unspecified number of days, no adverse effects on maternal or fetal health were observed. Blood pressure was increased in hypotensive women and unchanged in normal women. A reduction in postpartum hemorrhaging was observed in women treated with schisandra, with 2.3% of women in the schisandra group and 12.4% of women in the control group experiencing hemorrhaging (Gaistruk and Taranovskij 1968).

Increases in uterine tension and the amplitude of uterine contractions were observed in rabbits subcutaneously administered 0.1 ml/kg of a schisandra tincture (Trifonova 1954).

No information on the safety of schisandra during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in mice orally administered 15 or 21 g/kg of schisandra extracts (Chen and Chen 2004; Hancke et al. 1999). The LD_{50} of a petroleum-ether extract containing 10% of the compound schisandrin in mice is 10.5 g/kg after oral administration and 4.4 g/kg after intraperitoneal administration (Volicer et al. 1966). The LD_{50} of a petroleum-ether extract orally administered in mice is 2.8 g/kg for an extract containing 40% schisandrin and 1.4 g/kg for an extract containing 80% schisandrin (Volicer et al. 1966).

The LD_{50} of orally administered schisandra essential oil in mice is 8.75 mg/kg (Chen and Chen 2004). Another reference indicates that oral administration of 280 mg/kg of the essential oil to mice caused depression, dyspnea, ataxia, and death (Chang and But 1986).

The LD_{50} of the compound schizandrol B in mice is 878 mg/kg after oral administration and 855 mg/kg after subcutaneous administration (Hänsel et al. 1994). In mice orally administered compounds isolated from schisandra, no deaths occurred after administration of 2 g/kg of schisandrins A, B, and C, 2 g/kg schisandrer A, 0.5 g/kg schizandrol A, or 0.25 g/kg of schizandrol B or schisandrer B (Bao et al. 1980). Another study indicated that mice died 7 days after oral administration of 2 g/kg of schisandrins A and C (Hänsel et al. 1994).

Short-Term Toxicity

No adverse effects were observed after oral administration of the compound schisandrin B for 30 days in mice at a dose of 200 mg/kg daily, or in dogs at a dose of 10 mg/kg daily (Chang and But 1986).

Oral administration of 1.3 g/kg of schisandra berries daily to mice for 10 days resulted in only mild toxic effects, including piloerection, apathy, and increased body weight (Sandberg 1993).

Subchronic Toxicity

No adverse effects, including changes in blood chemistry, were observed in piglets orally administered a standardized extract of schisandra at doses of 70, 360, or 720 mg/kg daily for 90 days. No changes in the liver, heart, kidneys, intestine, lungs, spleen, and gonads were seen (Burgos and Hancke 1992).

Hepatotoxicity

Significant hepatoprotective activity of extracts of schisandra and compounds isolated from schisandra have been observed in mice, rats, and rabbits treated with hepatotoxic compounds (Hancke et al. 1999; Ko et al. 2002; Nakagiri et al. 2003; Zhu et al. 1999, 2000).

Genotoxicity

No mutagenic effects of the compound schisandrin B were observed in the Ames mutagenicity test. Schisandrin B decreased the mutagenic effects of benzo[*a*]pyrene and 2-acetylaminofluorene in this assay (Liu 1991). However, in mice administered a diet containing 5% of an ethanol extract of schisandra, increased mutagenicity of benzo[*a*]pyrene and aflatoxin were observed in liver microsomes from the animals (Hendrich and Bjeldanes 1986).

Part: herb, root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
While some earlier literature cautions against the use of figwort in persons with ventricular tachycardia (Mitchell 1983), this concern is believed to be theoretical in nature. No studies have been completed to support or refute this concern.

Pregnancy and Lactation
No information on the safety of figwort in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
The compound harpagoside demonstrated negative chronotropic and positive inotropic effects in isolated rabbit hearts (Circosta et al. 1984; Sesterhenn et al. 2007).

IV. Pregnancy and Lactation
No information on the safety of figwort during pregnancy or lactation was identified.

V. Toxicity Studies
No toxicity studies were identified.

Scutellaria baicalensis Georgi — Lamiaceae

SCN: Chinese skullcap
PN: *huang qin* (root)
OCN: Baikal skullcap; scute
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: B

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

Chinese skullcap may decrease plasma levels of the immune-suppressant drug cyclosporine (Lai et al. 2004).

Adverse Events and Side Effects

Allergic reactions to Chinese skullcap have been reported (Bensky et al. 2004). Diarrhea and stomach discomfort have been reported after ingestion of Chinese skullcap (Bensky et al. 2004).

Pharmacological Considerations

Coadministration of Chinese skullcap and cyclophosphamide potentiated the antimetastatic effect of cyclophosphamide in mice (Kaplya et al. 2004; Razina et al. 1987).

In vitro studies indicate that Chinese skullcap can inhibit the drug-metabolizing isoenzyme CYP1A2 (Kim et al. 2001; Kim et al. 2002).

The compound baicalin was found to decrease plasma levels of rosuvastatin and to induce the drug metabolizing isoenzyme CYP2B6 (Fan et al. 2008, 2009).

Pregnancy and Lactation

In traditional Chinese medicine, Chinese skullcap is commonly used during pregnancy (Chen and Chen 2004).

Very large doses (25 g/kg) of Chinese skullcap produced some developmental abnormalities in offspring of pregnant mice administered Chinese skullcap during pregnancy. Lower doses (0.25 and 12.5 g/kg) did not produce any adverse effects (Kim et al. 1993).

No information on the safety of Chinese skullcap during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In healthy volunteers, the compound baicalin was found to decrease plasma levels of rosuvastatin. Volunteers were orally administered 20 mg rosuvastatin before or after oral administration of 150 mg baicalin daily for 14 days. After baicalin treatment, the area under the plasma concentration-time curve ($AUC_{0\text{-}72}$) of rosuvastatin decreased by 1.7 to 47%, depending on the haplotype of the volunteer. Rosuvastatin is a substrate of the organic anion-transporting polypeptide 1B1 (OATP1B1), which was proposed as the mechanism of interaction (Fan et al. 2008).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

A reduction in the plasma levels of orally administered cyclosporine was observed in rats orally administered a decoction of Chinese skullcap at doses of 1 or 2 g/kg. No changes in cyclosporine levels were observed after intravenous administration of the drug (Lai et al. 2004).

In rats administered the compounds baicalin or baicalein at doses of 112 mmol/kg, an increase in serum cyclosporine levels was observed (Lai et al. 2004).

Coadministration of 1 m l/kg of Chinese skullcap extract for 12 days and a single dose of 125 mg/kg cyclophosphamide potentiated the antimetastatic effect of cyclophosphamide in mice with grafted tumors. The effect was attributed to modulated cytotoxic activity of natural killer cells and peritoneal macrophages during tumor growth (Kaplya et al. 2004; Razina et al. 1987).

II. Adverse Events

Case Reports of Adverse Events

Diarrhea and stomach discomfort have been reported after ingestion or injection of Chinese skullcap. Details on dose and preparation were not reported (Bensky et al. 2004).

Allergic reactions to Chinese skullcap have been reported, including flushing of the skin and macular erythema, mainly in the face and on the exposed areas of the limbs (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers, the compound baicalin was found to induce the drug metabolizing isoenzyme CYP2B6. Volunteers were orally administered 150 mg of the CYP2B6 substrate bupropion before and after receiving 1.5 g baicalin daily for seven days. After treatment with baicalin, the maximum plasma concentration of hydroxybupropion (the metabolized form of bupropion) was increased by 73%, and the area under the time-concentration time curve ($AUC_{0-\infty}$) of hydroxybupropion increased by 87%, with no change in the elimination half-life of hydroxybupropion (Fan et al. 2009).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In human liver microsomes, individual flavonoid compounds isolated from Chinese skullcap inhibited the drug-metabolizing isoenzyme CYP1A2 at concentrations ranging from 0.7 to 51.3 µ*M*. No effects on the drug-metabolizing isoenzymes CYP2B1, CYP2C19, CYP2D6, or CYP2E1 were observed. The compound baicalein inhibited CYP3A4 and the compound oroxylin A inhibited CYP2C9 (Kim et al. 2002).

In human and rat liver microsomes, an aqueous extract of Chinese skullcap inhibited the drug-metabolizing isoenzyme CYP1A2 (Kim et al. 2001). An extract of Chinese skullcap inhibited the drug-metabolizing isoenzyme CYP3A4 (Lee et al. 2007).

Platelet aggregation induced by platelet-activating factor was attenuated by the compound baicalein (Michibayashi 2002). Baicalein has been shown to inhibit platelet lipoxygenase (Sekiya and Okuda 1982).

IV. Pregnancy and Lactation

Offspring of rats orally administered 0.25, 12.49, or 24.98 g/kg of a water extract concentrate of Chinese skullcap on gestational days 7 to 11 demonstrated a dose-dependent increase in the incidence of skeletal variations, while urinary system abnormalities were observed in the two higher dose groups, with an equivalent number of abnormalities in each group. No changes in hematological or other developmental parameters were observed at any of the dose levels (Kim et al. 1993).

In traditional Chinese medicine, Chinese skullcap is commonly used during pregnancy (Chen and Chen 2004).

No information on the safety of Chinese skullcap in lactation was identified.

V. Toxicity Studies

Acute Toxicity

No nausea or vomiting was observed in dogs orally administered a Chinese skullcap extract at a dose of 15 g/kg (Chen and Chen 2004).

The LD_{50} of intraperitoneally administered baicalein in mice is 3 g/kg (Chen and Chen 2004). The LD_{50} of intravenously administered wogonin in rats is 286 mg/kg (Qi et al. 2009).

Short-Term Toxicity

Loose stools were observed in dogs orally administered 5 g/kg of Chinese skullcap extract daily for 8 weeks (Chen and Chen 2004).

Subchronic Toxicity

In rats intravenously administered 30, 60, or 120 mg/kg of the compound wogonin daily for 90 days, no macroscopic changes in heart, liver, spleen, lung, kidney, adrenal gland, thymus, thyroid gland, brain, uterus, testis, ovary, or prostate were observed. In the high-dose group, microscopic investigation revealed myofibrosis cordis and interstitial fibroblast, histiocyte, and inflammatory cell infiltrate in the hearts of rats (Qi et al. 2009).

Hepatotoxicity

The compound baicalein has demonstrated hepatoprotective effects against damage induced by *tert*-butyl hydroperoxide, carbon tetrachloride, and acetaminophen (Hwang et al. 2005; Jang et al. 2003; Park et al. 2008).

Genotoxicity

Chinese skullcap provided a protective effect against liver mutagenesis induced by aflatoxin B1 in rats (de Boer et al. 2005).

Scutellaria lateriflora L. — Lamiaceae

SCN: skullcap
OCN: blue skullcap; scullcap

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Cases of toxicity reported in association with use of products labeled as skullcap are likely due to adulteration with germander (*Teucrium* spp.), which has been reported to cause liver toxicity. A text on herbal safety cites an "increasing number of case reports to suggest that the ingestion of skullcap-containing preparations can induce hepatoxic reactions." Yet an appended clarification acknowledges the adulteration of skullcap with species of *Teucrium*. This adulteration, along with more recent reports of hepatitis associated with *Teucrium* consumption, led to the conclusion that it is "unclear at the moment, whether the hepatotoxic effects that have been associated with preparations containing skullcap should be attributed to *Scutellaria*, *Teucrium*, or both" (De Smet 1993).

A more recent analysis of the literature (Mills and Bone 2005) on liver damage caused by diterpenes isolated from germander species and hepatic effects of related diterpenes isolated from skullcap indicated that, although both sets of diterpenes demonstrated hepatotoxic activity in mice, adverse effects of the skullcap diterpenes were limited to a few liver cells in a small percentage of tested animals, whereas germander diterpenes caused toxicity that was characterized as extensive and severe. Skullcap neoclerodane diterpenes lack the furan ring that is a structural requirement for the hepatotoxicity caused by the compound teucrin A from germander (Fau et al. 1997; Furbee et al. 2006; Haouzi et al. 2000; Lekehal et al. 1996).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of skullcap in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a trial of freeze-dried skullcap preparations at doses of up to 400 mg, no adverse events were reported in the skullcap group, and one adverse event was reported in the placebo group (Wolfson and Hoffmann 2003).

Case Reports of Adverse Events

Several cases of hepatotoxicity have been reported in persons taking products labeled to contain skullcap, usually in combination with other herbs. In most cases, skullcap was suggested as the herb responsible for the hepatotoxicity (Enlow 1996; Hullar et al. 1999; MacGregor et al. 1989); however, skullcap is botanically similar to two species of germander (*Teucrium canadense* and *T. chamaedrys*), plants that contain a hepatotoxic compound. A number of sources acknowledge that germander species have been common adulterants of skullcap (Applequist 2006; De Smet 1993; Gafner et al. 2003; Mills and Bone 2005; Sundaresan et al. 2006). The hepatotoxicity in the case reports above is most likely not due to skullcap but instead to germander, other herbs in the consumed formulas, such as mistletoe (*Viscum album*), or other causes (Wolfson and Hoffmann 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In male rat hepatocytes incubated with 100 µg/ml of diterpenoids from skullcap, the compounds caused apoptosis. Reactive metabolites formed by CYP3A depleted cellular thiols, increasing cellular calcium and opening the mitochondrial permeability transition pore (MPTP). Cyclosporine A, an inhibitor of MPTP opening, prevented cytochrome *c* release, caspase activation, and apoptosis, and caspase inhibitors also prevented apoptosis (Haouzi et al. 2000).

Ethanol, glycerin, and water extracts of skullcap showed significant inhibition of the drug-metabolizing isoenzyme CYP3A4 (Awad et al. 2003).

IV. Pregnancy and Lactation

No information on the safety of skullcap in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

In mice administered a single 20 mg dose (per 28–30 g animal) of diterpenoids isolated from skullcap, an increase in hepatic caspases was observed as compared to controls. In one skullcap-treated mouse, apoptosis affected a few hepatocytes, while in two other skullcap-treated mice, necrosis affected a few hepatocytes. No adverse effects were observed in the 13 other skullcap-treated mice. No apoptosis or necrosis was observed in the control group, nor in a group administered skullcap and pretreated with a caspase inhibitor (Haouzi et al. 2000).

Selenicereus grandiflorus (L.) Britton & Rose

Cactaceae

SCN: night-blooming cereus
Syn: *Cactus grandiflorus* L.; *Cereus grandiflorus* (L.) Mill.

OCN: queen-of-the-night
Part: flower, stem

Quick Reference Summary

Safety Class: 2d
Interaction Class: B

Contraindications

Do not exceed recommended dose (Felter and Lloyd 1898; Mitchell 2003; Yarnell and Abascal 2003).

Other Precautions

None known.

Drug and Supplement Interactions

Historical records of the cardiac activity of night-blooming cereus (Felter and Lloyd 1898) suggests that it be used with caution in persons on heart medications.

Notice

Diuretic (Felter and Lloyd 1898; Parke Davis 1894); *see* Appendix 2.

Standard Dose

The standard dose is 10 to 20 drops of tincture twice daily (Mitchell 2003).

Editors' Notes

Although one reference (Williamson 2003) reports a mild positive inotropic effect for the alkaloid hordenine, another reference indicates that hordenine is noncumulative (List and Hörhammer 1973). The long history of use and the lack of reports of human toxicity suggest that such an effect is likely to be minimal.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of night-blooming cereus in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Not for use in persons with intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (i.e., appendicitis, colitis, Crohn's disease, irritable bowel syndrome, and melanosis coli) (Bradley 1992; De Smet 1993; Martindale and Reynolds 1996; Wichtl 2004).

Not for use in excess of 8 consecutive days (Bradley 1992; De Smet 1993; Leung and Foster 1996; List and Hörhammer 1973; Weiss and Meuss 2001; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Use of stimulant laxatives, such as senna or sickle-pod senna, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Standard Dose

Senna leaf: 0.5–3.0 g infused in hot water for 10–15 minutes (Bensky et al. 2004; Weiss and Meuss 2001; Wichtl 2004).

Senna fruit or leaf containing the following dose of the compounds sennosides A a nd B: Adults and children 12 years of age and over, oral dosage is 12–50 mg of sennosides once or twice daily; children 6 to under 12 years of age, oral dosage is 6–25 mg of sennosides once or twice daily; children 2 to under 6 years of age, oral dosage is 3–12.5 mg of sennosides once or twice daily (FDA 1985).

Senna leaf typically contains 1.5–3% dianthrone glucosides, consisting primarily of sennosides A and B (Khan and Abourashed 2011).

Pharmacopeias of Europe, India, and China specify that senna leaf must contain a minimum of 2.5% hydroxyanthracene glycosides, calculated as sennoside B. Senna fruit typically contains 3–5% sennosides. Pharmacopeias of Europe and India recognize *Senna alexandrina* as two species, *S. angustifolia*, which must contain a minimum of 3.4%, and *S. acutifolia*, which must contain a m inimum of 2.2% hydroxyanthracene glycosides, calculated as sennoside B.

The proportion of anthraquinone glycosides is higher in the leaves than in the pods, with the composition of the laxative compounds differing in the leaf and pod (Wichtl 2004).

Notice

Stimulant laxative (Bradley 1992; De Smet 1993; FDA 1985; Leng-Peschlow 1992a; Leung and Foster 1996; List and Hörhammer 1973; Martindale and Reynolds 1996; Weiss and Meuss 2001; Wichtl 2004; Williamson 2003); *see* Appendix 2.

Editors' Notes

Records of use, case reports, research papers, and recommendations for appropriate use of senna products often do not differentiate between the fruit (pod) or the leaf, and numerous references are addressed to the sennosides contained in both of these plant parts. Unless otherwise specified, the information in this entry is relevant to both senna fruit and senna leaf.

Several authorities note that preparations of senna fruit act more gently than senna leaf (Weiss and Meuss 2001; Wichtl 2004). However, concerns regarding the long-term use of stimulant laxatives are relevant to both the fruit and the leaf.

The American Herbal Products Association has established a trade requirement (AHPA 2011) that products containing this herb in sufficient quantity to warrant such labeling bear the following label statement:

> NOTICE: Do not use this product if you have abdominal pain or diarrhea. Consult a health care provider prior to use if you are pregnant or nursing. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use.

Adverse Events and Side Effects

In overdose, senna may cause griping and severe diarrhea with consequent loss of fluid and electrolytes (ESCOP 2003).

Cases of hepatitis have been associated with chronic use of senna fruit and leaf (Beuers et al. 1991; Seybold et al. 2004; Soyuncu et al. 2008).

Accidental exposure to senna-containing laxatives in children under 6 years old has resulted in severe diaper rash, blistering, and skin sloughing after ingestion of doses containing 15 mg of sennosides (the standard adult dose) or more (Spiller et al. 2003).

Allergic reactions to senna have been reported in workers routinely exposed to senna pod dust (Marks et al. 1991) and to senna used in hair dyes (Helin and Makinen-Kiljunen 1996), such as *Senna italica* (syn. *S. obovata*).

Pharmacological Considerations

Long-term use of senna and other anthraquinone laxatives may cause pseudomelanosis coli, a brownish pigmentation of the colon. Although pseudomelanosis coli has been regarded as a harmless condition (Leng-Peschlow 1992c), some researchers have suggested a possible relationship between the condition and an increased risk of the development of colon cancer (Siegers et al. 1993b). This risk, however, may be due to other confounding factors such as chronic constipation or diet (Sonnenberg and Müller 1993; van Gorkom et al. 1999).

Concomitant use of senna or sickle-pod senna is cautioned with antiarrhythmic drugs, thiazide diuretics, corticosteroids, licorice, and botanicals containing cardiac glycosides, as long-term use of senna or sickle-pod senna as a laxative can cause or exacerbate potassium loss (Brinker 2001; De Smet 1993; ESCOP 2003).

Use of stimulant laxatives, such as senna or sickle-pod senna, may reduce the gastrointestinal transit time and thus reduce the absorption of orally administered drugs (Brinker 2001; De Smet 1993).

Pregnancy and Lactation

Some references advise cautious or supervised use of senna fruit or the contained seed and senna leaf during pregnancy (Bradley 1992; Chen and Chen 2004; ESCOP 2003).

A review of human studies of senna in pregnancy indicated that the use of senna for 2 weeks to 9 months showed good laxative efficacy with few side effects. Senna was not associated with stimulating uterine contractions, even in high-risk pregnancies, including those with a tendency to premature labor or to bleeding late in pregnancy (Leng-Peschlow 1992b). Epidemiological studies have shown a lack of birth defects in infants whose mothers used senna-based laxatives during pregnancy (Ács et al. 2009; Ács et al. 2010).

An evaluation of the safety of a variety of laxatives concluded that senna, without differentiation between the fruit and the leaf, is the laxative of choice in pregnancy and lactation (Gattuso and Kamm 1994).

Animal studies have indicated a lack of abortifacient, teratogenic, or fetotoxic effects, and one study in sheep indicated that senna did not stimulate uterine contractions (Garcia-Villar 1988; Mengs 1986).

The American Academy of Pediatrics lists senna as a product that is usually compatible with breast-feeding (AAP 2001). Although laxative compounds from senna have been shown to cross into breast milk, no laxative effects have been observed in nursing infants whose mothers took sennosides (Baldwin 1963; Faber and Strenge-Hesse 1988; Werthmann and Krees 1973).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Near fatal bleeding was reported in a woman who had been stable on warfarin for 7 years and had initiated use of a "senna-based laxative" (plant part not stated) several months prior to the bleeding event. An increase in INR (a standardized scale used to report the results of blood coagulation tests; increased INR indicates slowed blood clotting) was reported in conjunction with the bleeding and was associated with senna-induced diarrhea subsequent to a significant increase in senna use for three weeks. The reporting physicians indicated that diarrhea can reduce absorption of vitamin K and increase the risk of bleeding (Kittisupamongkol et al. 2008).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 52-year-old woman developed severe hepatotoxicity after ingestion of 1 liter per day of tea made from 70 g of dried senna fruit for over 3 years (Vanderperren et al. 2005). High levels of cadmium and mercury were found in the woman's urine, though analysis of the senna product indicated no cadmium or mercury contamination (Vanderperren et al. 2005).

Hepatitis was reported in a 28-year-old woman with a variant of the drug-metabolizing isoenzyme CYP2D6. The woman had recently been consuming 3 to 4 liters of beer per week, and had also been consuming an herbal tea containing senna leaf (dose, duration, and presence of other ingredients not specified). Re-exposure to the tea led to elevated liver enzyme levels (Seybold et al. 2004).

Hepatitis was reported in a 26-year-old woman who had been taking 10 g senna leaf tea twice a week for an unspecified length of time, and began also taking senna fruit containing 100 mg sennoside B daily 1 month prior to the hepatitis. This combined dose of senna products was noted as being 10 times the recommended dose. Liver enzyme levels returned to normal after cessation of senna products (Beuers et al. 1991).

Portal vein thrombosis was reported in a 42-year-old woman who had taken 200 ml of senna leaf tea (amount of senna used to make tea was not specified) daily for 2 years (Soyuncu et al. 2008).

Paralytic ileum was reported in an 85-year-old man who had been taking a tea with senna leaf and fruit (with licorice, mallow, fennel, "balum," and caraway) every other day for 2 months. At the time the condition was diagnosed, the man was being hospitalized for transitory ischemic stroke. He had a history of high blood pressure, chronic obstructive bronchopneumopathy, and cholelithiasis, and a 5-year history of constipation, for which lactulose, bisacodyl, and sodium picosulfate were taken, with enemas used every 15 to 30 days (Sossai et al. 2007).

A study of cases of accidental exposure to senna-containing laxatives in children under 6 years of age reported that 33% experienced severe diaper rash, and 10% developed blisters and skin sloughing. The mean dose ingested was 105 mg (presumably measured as sennosides), with a range of 15 to 375 mg. Approximately 12% of children ingested only a single dose, and several of those children experienced severe diaper rash or developed blisters and skin sloughing. Symptoms were significantly worse in children who wore diapers as compared to those who were fully toilet trained (Spiller et al. 2003).

Clubbing of fingers and toes has been reported in association with long-term abuse of senna, primarily in patients with anorexia nervosa (Armstrong et al. 1981; Levine et al. 1981; Lim et al. 2008; Malmquist et al. 1980; Prior and White 1978; Silk et al. 1975).

IgE-mediated occupational asthma, allergy, and rhinoconjunctivitis have been reported in workers routinely exposed to senna pod dust (Marks et al. 1991) and to species of senna used in hair colors (Helin and Makinen-Kiljunen 1996).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A prospective cohort study of the risk of anthraquinone laxatives use for the development of colorectal neoplasms indicated no statistically significant risk of anthranoid use for the development of colorectal adenomas or carcinomas. Macroscopic and high-grade microscopic melanosis coli were not significant risk factors for the development of adenomas or carcinomas (Nusko et al. 2000).

In a retrospective study of 2277 patients who underwent colonoscopy, the correlation between patients' laxative use or melanosis coli and colorectal neoplasms was examined. Increases in colorectal adenomas were observed in patients with melanosis coli and in patients with a history of laxative use (Nusko et al. 1993).

Animal Pharmacological Studies

No effects of senna on intestinal platelet-activating factor were observed in rats, mice, and guinea pigs orally administered senna in single or repeated doses of 60 to 240 mg/kg (Capasso et al. 1993; Mascolo et al. 1992).

No chronic changes in colonic motility were observed in rats orally administered 10 or 40 mg/kg sennosides daily for 23 weeks (Fioramonti et al. 1993).

No significant damage of myenteric neurons in the colon of rats or mice was observed after animals were given purgative doses of sennosides in drinking water for 4 or 5 months (Kiernan and Heinicke 1989).

In guinea pigs intragastrically administered sennosides daily for 14 days, the mucosa of the cecum and upper colon became brown, and microscopic examination revealed cytoplasmic degeneration and increased apoptosis in the colonic surface epithelium (Mengs and Rudolph 1993).

No induction of aberrant crypt foci (considered putative preneoplastic lesions) or increases in incidence of chemically induced aberrant crypt foci were observed in rats fed diets containing up to 0.2% anthraquinone glycosides from senna for 56 days (Mereto et al. 1996).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Some references advise cautious or supervised use of senna fruit or the contained seed and senna leaf during pregnancy (Bradley 1992; Chen and Chen 2004; ESCOP 2003).

A review of the safety of senna in pregnancy indicated that nine human studies on senna or a combination of various senna preparations and psyllium seed for 2 weeks to 9 months showed good laxative efficacy with few side effects. Senna was not associated with stimulating uterine contractions, even in high-risk pregnancies, including those with a tendency to premature labor or bleeding late in pregnancy (Leng-Peschlow 1992b).

In an epidemiological study of congenital malformations, 22,843 infants with congenital malformations were included. Of these, 506 had mothers who had taken senna during pregnancy. An additional 38,151 normal infants were identified whose mothers also used senna during pregnancy. Daily dosage ranged between 10 and 30 mg of sennoside A and B, and most pregnant women used 20 mg per day. The authors concluded that senna treatment was not associated with a higher risk of congenital abnormalities in the offspring of pregnant women with constipation (Ács et al. 2009).

No abortifacient, teratogenic, or fetotoxic effects were observed in rats or rabbits administered sennosides, even when large doses were administered (Mengs 1986). Electromyographic studies in pregnant sheep did not show any stimulation of uterine contractions by sennosides, and a slight inhibition of contraction frequency was observed in some animals (Garcia-Villar 1988).

The American Academy of Pediatrics lists senna as a product that is usually compatible with breast-feeding (AAP 2001).

In lactating women administered doses of senna containing 15 mg sennosides daily for 3 days, approximately 0.007% of the sennoside dose (calculated as rhein) was detected in breast milk. No effects of the treatment on infant bowel habits were observed (Faber and Strenge-Hesse 1988).

In lactating women administered a single dose of senna containing 8.6 mg of sennosides A and B, some infants had diarrhea. Doubling the dose administered to the women, however, did not cause diarrhea, suggesting that the diarrhea observed was due to a cause other than maternal laxative ingestion (Werthmann and Krees 1973).

No effects on infant bowel habits were observed after nursing mothers were administered 1 teaspoon of a granular product made from senna, described as equivalent to the total active constituents of 450 mg of senna fruit. The authors indicated that this study is not indicative of whether laxative compounds are excreted in breast milk, but only indicates the lack of effect on infant bowel habits (Baldwin 1963).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered sennosides in mice and rats is 5 g/kg, with death attributed to loss of water and electrolytes after severe diarrhea (Mengs 1988).

Short-Term Toxicity

No significant adverse effects were observed in rats orally administered sennosides at doses of 5, 10, or 20 mg/kg daily for 4 weeks. In the 20 mg/kg group, a low-grade laxative effect was observed, along with an increase in kidney weight (Mengs 1988).

No adverse effects were observed in dogs orally administered up to 500 mg/kg sennosides daily for 4 weeks (Mengs 1988).

In goats orally administered fresh fruit and leaf of senna at doses of 1, 5, and 10 g/kg daily, several goats died within 30 days. Serum levels of aspartate aminotransferase, ammonia, urea, and total cholesterol were increased, while total protein was decreased (El Sayed et al. 1983).

Subchronic Toxicity

In rats administered senna pods via oral gavage at doses of 100, 300, 750, or 1500 mg/kg daily for up to 13 weeks, dose- and treatment-related clinical signs included abnormal feces, which were seen to varying degrees in animals administered 300 mg/kg or more. In animals receiving 750 or 1500 mg/kg, notable changes in electrolytes in both serum and urine were observed, along with an increase in absolute and relative kidney weights, and a darkening of the kidneys. However, there were no indications in laboratory parameters of any renal dysfunction (Mengs et al. 2004).

No promotion of chemically induced colorectal tumors was observed in mice administered a diet containing 0.03% sennosides daily for 20 weeks, and no significant changes

in serum electrolytes or parameters of hepatotoxicity and nephrotoxicity were observed (Siegers et al. 1993a).

Chronic Toxicity

No induction of aberrant crypt foci was observed in rats administered 30 or 60 mg/kg of senna fruit extract daily for 2 years. Administration of the senna fruit extract inhibited tumor development in animals treated with a tumor initiating agent (Borrelli et al. 2005).

An increase in the appearance of chemically induced tumors was observed in rats administered a dose of 100 mg/kg senna fruit extract (a dose that induced chronic diarrhea) daily for 13 to 28 weeks. No induction of aberrant crypt foci was observed in rats administered 10 mg/kg of senna fruit extract daily (a dose that produced laxation), and no promotion of chemically induced tumors was seen at that dose (Mascolo et al. 1999).

In rats administered 5, 15, or 25 mg/kg of a purified senna extract via the drinking water daily for 2 years, no increases in tumor incidences in the gastrointestinal tract, liver, kidney, or adrenal gland were observed (Lyden-Sokolowski et al. 1993).

In male rats orally administered 25 or 100 mg/kg sennosides daily for 6 months, the low dose caused slightly softer stools than normal, while the high dose resulted in severe diarrhea. No significant hematological or urinary differences were observed (Mengs 1988).

Genotoxicity

No elevated levels of micronuclei in bone marrow cells were observed in mice orally administered 2 g/kg of a senna extract (equivalent to 119 mg/kg rhein, 5.74 mg/kg aloe-emodin, and 0.28 mg/kg emodin) (Mengs et al. 1999).

No mutagenic effects of sennosides were observed in the Ames mutagenicity test (concentration up to 5000 µg/plate), the mouse lymphoma forward mutation assay (up to 5000 µg/ml without metabolic activation and 4000 µg/ml with activation), or the mice micronucleus assay (doses up to 2.5 mg/kg) (Mengs 1988).

In the *Salmonella typhimurium* reversion assay, senna glycosides were inactive in all strains, except for a slight but significant increase in mutant frequency in TA102 in the absence and presence of liver microsomes. Extracts of senna fruit and senna leaf demonstrated weak activity in TA97a, TA100, and TA102 in the presence of liver microsomes, and in TA97a and TA102 in the absence of liver microsomes. A strong increase in mutant frequency (three- to five-fold above background frequency) was observed with all extracts in TA98 in the presence of liver microsomes. This activity increased further following enzymatic hydrolysis with hesperidinase of extracts of senna fruit from one source, and could be correlated to the release of kaempferol and quercetin, suggesting that mutagenicity cannot be attributed solely to the anthraquinone content of these plant materials. A strong increase in mutant frequency (three- to five-fold above background frequency) was observed with all extracts in TA98 in the presence of liver microsomes (Sandnes et al. 1992).

Genotoxicity tests were performed with senna fruit, senna leaf extract, sennosides, rhein, and aloe-emodin. Senna fruit, sennosides, and rhein did not increase mutation frequencies in the following test systems: bacterial systems, mammalian cell culture tests, mouse lymphoma test, chromosome aberration test with Chinese hamster ovary (CHO) cells, bone marrow micronucleus test, chromosome aberration tests, and melanoblast cell test. With aloe-emodin, mutagenic effects were observed only in vitro in the chromosome aberration test with CHO cells and in the *Salmonella* reverse mutation test. In the in vitro gene mutation test with V79 cells, no mutagenic potential of aloe-emodin was observed. In vivo studies indicated no mutagenic activity of aloe-emodin, and aloe-emodin did not induce unscheduled DNA synthesis in an ex vivo assay performed with hepatocytes of male rats (Heidemann et al. 1993).

An aqueous extract of senna leaf was tested in four different assays for genotoxic and mutagenic effects: *E. coli* cultures, bacterial growth inhibition, reverse mutation test, and DNA strand break analysis in plasmid DNA. The extract produced single and double strand breaks in plasmid DNA in a cell-free system but was not cytotoxic or mutagenic in the *E. coli* strains tested (Silva et al. 2008).

In mice orally administered anthraquinones from senna or their equivalent amount in senna extracts, no increase in the number of chromosomal aberrations or aberrant cells in bone marrow was observed (Mukhopadhyay et al. 1998).

No clastogenic activity of the compound chrysophanol was observed in the Chinese hamster ovary cell assay at concentrations up to the limit of solubility, with or without metabolic activation (Mengs et al. 2001).

Serenoa repens (W. Bartram) Small — Arecaceae

SCN: saw palmetto

Syn: *Sabal serrulata* (Michx.) Nutt. ex Schult. & Schult. f.; *Serenoa serrulata* (Michx.) G. Nichols.
OCN: sabal palm
Part: fruit

S

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Most contemporary research on saw palmetto fruit is specific to one or another brand of extract, usually standardized to 85% or more of the fruit's naturally occurring fatty acids. Unless otherwise stated, the references cited below identify standardized saw palmetto fruit extracts.

Adverse Events and Side Effects

Systematic reviews and meta-analyses of saw palmetto clinical trials and case reports indicate that saw palmetto was generally well tolerated, with adverse events reported similar to those of placebo (Agbabiaka et al. 2009; Tacklind et al. 2009; Wilt et al. 2002). A human study on the safety of saw palmetto indicated no significant differences between saw palmetto and treatment groups for adverse events, bilirubin levels, urine tests, or prostate-specific antigen levels (Avins et al. 2008).

An allergic reaction to topical application of "an unlabelled extemporaneous preparation that [the patient] was told contained saw palmetto" has been reported (Sinclair et

al. 2002). Single cases of pancreatitis (Jibrin et al. 2006) and hemorrhage during surgery (Cheema et al. 2001) have been reported in persons taking saw palmetto (no additional description provided). A case of cholestatic hepatitis was associated with a multi-ingredient product including saw palmetto, which the treating physician described as "presumably the most active ingredient" due to its "estrogenic and antiandrogenic effect" (Hamid et al. 1997).

Pharmacological Considerations

No effects of saw palmetto on the drug-metabolizing isoenzymes CYP3A4, CYP2D6, CYP1A2, or CYP2E1 were observed in human studies (Gurley et al. 2004; Markowitz et al. 2003).

Pregnancy and Lactation

No information on the safety of saw palmetto in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

The typical use of saw palmetto is for prostate health concerns; thus use by pregnant or lactating women is very uncommon.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a meta-analysis of saw palmetto clinical trials, data from 3139 men in 21 randomized trials lasting 4 to 48 weeks were assessed. Adverse effects in the saw palmetto groups were reported as generally minor and similar to those of placebo. Withdrawal rates in the studies were 8.9% for saw palmetto, 7.1% for placebo, and 9.0% for the drug finasteride. Specific adverse events were reported in 11 of the clinical trials. The most common event was impotence, with incidences reported at 1.1% for saw palmetto, 0.7% for placebo, and 4.9% for finasteride. Gastrointestinal side effects were reported in 1.3% of men on saw palmetto, 0.9% on placebo, and 1.5% on finasteride (Wilt et al. 2002).

In a study on the safety of 320 mg saw palmetto daily for 1 year in men with benign prostatic hyperplasia, no significant differences in serious or nonserious adverse events were reported between the saw palmetto and placebo groups. No clinically significant differences in sexual functioning, bilirubin levels, urine tests, or prostate-specific antigen levels were observed between the saw palmetto and placebo groups (Avins et al. 2008).

Case Reports of Adverse Events

A systematic review of adverse events reported in association with saw palmetto indicated that saw palmetto is well tolerated by most users and is not associated with serious adverse events. Reported adverse events were characterized as mild, infrequent, and reversible and included abdominal pain, diarrhea, nausea, fatigue, headache, decreased libido, and rhinitis (Agbabiaka et al. 2009).

One case of hemorrhage during surgery was reported in a man taking saw palmetto (Cheema et al. 2001). Single cases of pancreatitis (Jibrin et al. 2006) and protracted cholestatic hepatitis (Hamid et al. 1997) have been reported. A single case of allergic reaction, confirmed by patch testing, was reported (Sinclair et al. 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In human clinical trials, saw palmetto extracts did not affect the drug-metabolizing cytochrome P450 isoenzymes CYP3A4, CYP2D6, CYP1A2, or CYP2E1 (Gurley et al. 2004; Markowitz et al. 2003). In a trial on the effects of saw palmetto on testosterone, follicle-stimulating hormone, and luteinizing hormone in men, saw palmetto had no effect on hormone levels (Casarosa et al. 1988).

In healthy volunteers orally administered saw palmetto capsules at the manufacturer's recommended dose (amount not specified) daily for two weeks, no effects on platelet function or other hematological parameters were observed, including prothrombin time, partial thromboplastin time, thrombin time, bleeding time, the collagen/epinephrine assay, or the collagen/adenosine diphosphate assay. Aspirin (325 mg daily) was used as a positive control and markedly inhibited platelet function (Beckert et al. 2007).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In high-throughput *in vitro* screening, saw palmetto extract caused significant inhibition of CYP3A4, CYP2D6, and CYP2C9 (Yale and Glurich 2005).

IV. Pregnancy and Lactation

The typical use of saw palmetto is for prostate health concerns; thus use by pregnant or lactating women is not expected.

V. Toxicity Studies

Acute Toxicity

In toxicity tests in mice, rats, and guinea pigs, the LD_{50} could not be determined at doses up to 10 g/kg of an ethanolic extract of saw palmetto (Mills and Bone 2005).

Short-Term Toxicity

In a hepatotoxicity test in rats, rats fed 9 or 23 mg/kg/day of a hexane extract of saw palmetto for 2 weeks did not develop any signs of hepatotoxicity (Singh et al. 2007).

Chronic Toxicity

Chronic toxicity tests of an ethanolic extract of saw palmetto in rats for 6 weeks at 360 times the standard human dose and 6 months at 80 times the standard human dose did not cause any adverse effects. In the 6-month toxicity trial, fertility was reported as unaffected (Mills and Bone 2005). In the Ames test, no evidence of mutagenicity was found (Degenring et al. 2001).

Sesamum indicum L.

Pedaliaceae

SCN: sesame
Syn: *Sesamum orientale* L.

AN: *tila*
Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Sesame is a relatively common cause of food allergy (Aaronov et al. 2008; Agne et al. 2004; Gangur et al. 2005). Severe allergic reactions, including anaphylactic reactions, to sesame have been reported and confirmed by skin prick testing (Agne et al. 2004; Asero et al. 1999; Caminiti et al. 2006; Dalal et al. 2003; Derby et al. 2005; Gangur et al. 2005; James et al. 1991; Morisset et al. 2003; Panizzolo et al. 2005).

Pharmacological Considerations

An animal study indicated that a diet very high in sesame (10% of diet) counteracted the effects of the estrogen receptor antagonist tamoxifen in mice with estrogen receptor-positive human breast cancer tumors (Sacco et al. 2007).

Pregnancy and Lactation

No information on the safety of sesame in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Ovariectomized athymic mice under premenopausal-simulated conditions and estrogen receptor-positive human breast cancer cells (MCF-7) were fed a diet containing 10% sesame seed and implanted with tamoxifen pellets (5 mg; 60-day release). Results indicated that sesame did not inhibit tumor growth and tended to negate the tumor inhibitory effect of tamoxifen. Sesame alone and combined with tamoxifen enhanced femur biomechanical strength but caused no differences in bone mineral content or bone mineral density in either the femur or lumbar vertebrae (Sacco et al. 2007).

II. Adverse Events

Case Reports of Adverse Events

Sesame has been characterized as a relatively common food allergen. A review on sesame allergy indicated that most sesame allergy was presented in one of two forms. The first form was an immediate hypersensitivity, often expressed as systemic anaphylaxis, associated with positive skin prick test and/or immunoglobulin E (IgE) antibody test results to sesame proteins. The second form was delayed hypersensitivity to lignin-like compounds in sesame oil, which appeared clinically as allergic contact dermatitis. Several cases of immediate hypersensitivity to sesame were negative in skin prick and/or IgE antibody tests but were confirmed by oral challenge tests (Gangur et al. 2005).

Anaphylactic reactions to sesame have been reported (Agne et al. 2004; Asero et al. 1999; Dalal et al. 2003; Derby et al. 2005; James et al. 1991; Morisset et al. 2003; Panizzolo et al. 2005).

Severe allergic reactions, including vomiting, tightness in the chest, cough, sneezing, generalized itching, facial erythema, breathlessness, and laryngeal edema, were reported in a woman with a known allergy to sesame who accidentally consumed sesame paste (tahini) on two occasions (Caminiti et al. 2006).

In Israeli children with suspected food allergies, sesame was one of the four most common allergens among those tested, with 30 of 234 children testing positive for sesame allergy. Of these 30, 70% had an atopic background. Reactions to sesame were generally IgE-mediated (Aaronov et al. 2008; Dalal et al. 2003).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in plasma glucose and serum insulin levels was observed in diabetic mice fed diets containing 4% of a hot water extract of defatted sesame daily for 4 weeks (Takeuchi et al. 2001).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of sesame during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Sida cordifolia L.

Malvaceae

SCN: heart-leaf sida
AN: *bala*

OCN: country mallow; fanpetals; flannelweed; llima
Part: leaf, root, seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Heart-leaf sida contains 0.29 to 0.97% of the compound ephedrine (Gunatilaka et al. 1980; Marchei et al. 2006). The U.S. Food and Drug Administration declared in 2004 that dietary supplements containing ephedrine alkaloids are adulterated, and identified heart-leaf sida as containing ephedrine alkaloids (FDA 2004). In establishing this ban for ephedrine in dietary supplements, however, FDA stated that it does not apply to "traditional Asian medicine" that contains ephedrine alkaloids (FDA 2004).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of heart-leaf sida in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats intravenously administered 5 to 40 mg/kg of the aqueous fraction of a hydroalcoholic extract of heart-leaf sida, a reduction in heart rate and blood pressure was observed (Medeiros et al. 2006). The activity has been traced to the compound vasicine, which caused hypotension and a marked reduction in heart rate after intravenous administration to rats at doses of 2.5 to 10 mg/kg (Silveira et al. 2003).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of heart-leaf sida during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an aqueous extract of heart-leaf sida orally administered to mice could not be determined at doses up to 3 g/kg (Franzotti et al. 2000).

The LD_{50} of a hydroalcoholic extract of heart-leaf sida in mice is 2.639 g/kg after intraperitoneal administration and could not be determined at doses up to 5 g/kg after oral administration (Franco et al. 2005). Similarly, the oral LD_{50} of a methanol extract could not be determined at doses up to 5 g/kg in mice (Philip and Venkataraman 2001).

Chronic Toxicity

No adverse effects were reported in mice chronically administered an oral dose of 500 mg/kg of a methanol extract of heart-leaf sida (Philip and Venkataraman 2001).

Silybum marianum (L.) Gaertn. — Asteraceae

SCN: milk thistle
OCN: Mary's thistle

Part: seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic reactions, including anaphylactic reactions, to milk thistle products have been reported (Geier et al. 1990; Mironets and Krasovskaia 1990).

Pharmacological Considerations

Human studies have demonstrated that milk thistle may modify glucose regulation (Huseini et al. 2006; Velussi et al. 1997). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Human studies have indicated no interactions between milk thistle and indinavir (DiCenzo et al. 2003; Mills et al. 2005; Piscitelli et al. 2002), digoxin (Gurley et al. 2006b), or irinotecan (van Erp et al. 2005).

Human studies have shown a lack of clinically significant effects of milk thistle on the CYP450 drug-metabolizing isoenzymes (Fuhr et al. 2007; Gurley et al. 2004, 2006a, 2008; Rajnarayana et al. 2004; Rao et al. 2007). Human studies on the effects of the compound silymarin on the drug-metabolizing isoenzyme CYP3A4 have given conflicting results, with one study showing induction of the enzyme and another study showing no effect (Fuhr et al. 2007; Rao et al. 2007).

Pregnancy and Lactation

Limited human and animal studies on use of the compound silymarin during pregnancy have indicated no adverse effects (Gonzalez et al. 1988; Hahn et al. 1968). No adverse effects were reported in a study of nursing women taking the compound silymarin (Di Pierro et al. 2008).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No interaction between digoxin and milk thistle was observed in healthy volunteers orally administered a single dose of 0.4 mg of digoxin before or after 900 mg of a standardized extract of milk thistle daily for 14 days (Gurley et al. 2006b).

No interaction between indinavir and milk thistle was observed in healthy volunteers orally administered four 800 mg doses of indinavir before or after oral administration of 525 mg milk thistle (containing 459 mg silymarin) daily for 21 days (Piscitelli et al. 2002) or before or after oral administration of 1350 mg milk thistle daily for 30 days (Mills et al. 2005).

No interaction between indinavir and the compound silymarin was observed in healthy volunteers orally administered four 800 mg doses of indinavir before or after oral administration of 480 mg silymarin daily for 14 days (DiCenzo et al. 2003).

No interaction between irinotecan and milk thistle was observed in patients undergoing chemotherapy with irinotecan (125 mg/m^2) once a week along with 200 mg of orally administered milk thistle daily for 14 days (van Erp et al. 2005).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In systematic reviews of clinical trials, adverse events reported in the milk thistle groups were noted as being low in frequency, minor in nature, and indistinguishable from adverse events reported in placebo groups (Jacobs et al. 2002; Mulrow et al. 2000).

Case Reports of Adverse Events

One woman experienced repeated attacks of sweating, nausea, colicky abdominal pain, diarrhea, vomiting, weakness, and collapse after taking a milk thistle product (Adverse Drug Reactions Advisory Committee 1999). Other cases of adverse events, reported without details, include a case of abdominal pain, nausea, listlessness, and insomnia and one case of thrombocytopenia (Adverse Drug Reactions Advisory Committee 1999). The symptoms in these reports are similar to those associated with liver disease, for which the patients may have been taking milk thistle.

A case of an anaphylactic reaction after milk thistle tea consumption and a case of urticaria after consumption of a silymarin product have been reported (Geier et al. 1990; Mironets and Krasovskaia 1990).

Exacerbation of hemochromatosis (an inherited disease in which excessive iron accumulates in the body) was reported in a 68-year-old woman with a history of type 2 diabetes, asthma, hypothyroidism, borderline hypertension, borderline diastolic dysfunction, and a fatty liver. The women had been taking 200 mg of milk thistle daily for over a year, along with two extra-strength acetaminophen pills every 2 to 3 days, and a can of cola (presumably a diet cola) every day (Whittington 2007). A letter regarding this case noted that elevated liver enzymes, reported as a sign of hemochromatosis exacerbation, may occur with regular acetaminophen use (Kidd 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In two human studies, the compound silymarin (600 mg daily) significantly decreased fasting blood glucose levels in alcoholic cirrhosis patients with non-insulin-dependent diabetes mellitus and in type 2 diabetic patients (Huseini et al. 2006; Velussi et al. 1997).

Human studies indicated no significant effects of milk thistle on the drug-metabolizing isoenzymes CYP1A2, CYP2D6, CYP2E1, and CYP3A4 at doses of 900 mg milk thistle daily for 14 days or 350 mg milk thistle daily for 28 days (Gurley et al. 2004, 2006a, 2008).

Human studies of the compound silymarin on the drug-metabolizing isoenzyme CYP3A4 have yielded conflicting results. One study found that administration of 140 mg silymarin daily for 9 days resulted in significant induction of CYP3A4 (using metronidazole as the substrate) (Rajnarayana et al. 2004), while no effect of silymarin on CYP3A4 (using nifedipine as the substrate) was observed after administration of two doses of 280 mg each or after 7 days of administration of 420 mg daily (Fuhr et al. 2007; Rao et al. 2007).

In a dose escalation study of the compound silymarin in patients with noncirrhotic hepatitis C, no adverse effects were reported after oral administration of up to 2.1 g silymarin daily (Hawke et al. 2010).

Animal Pharmacological Studies

In healthy and diabetic rats orally administered 100 mg/kg daily of silymarin or 1.2 g/kg daily of an ethanol extract of milk thistle, non-significant decreases in blood glucose levels were observed for both silymarin and the milk thistle extracts in diabetic rats (Vessal et al 2010).

In Vitro Pharmacological Studies

A number of in vitro studies on the effects of milk thistle and compounds isolated from milk thistle on CYP450 drug-metabolizing isoenzymes have been completed and provide conflicting information on activity. In human hepatocytes, milk thistle has been shown to inhibit CYP2C8 and CYP3A4 (Etheridge et al. 2007), but it has also been shown to inhibit CYP3A4 at low concentrations while inducing the enzyme at high concentrations (Budzinski et al. 2007). The compound silybin has shown significant inhibition of CYP2C9 (Sridar et al. 2004) and no effect to significant inhibition of CYP3A4 (Kosina et al. 2005; Sridar et al. 2004; Zuber et al. 2002). Silybin moderately inhibited CYP1A1 (Awad et al. 2003), CYP2C8 (Dvorak et al. 2006; Jancova et al. 2007), CYP2D6 (Zuber et al. 2002), and CYP2E (Zuber et al. 2002). No effect to moderate inhibition from silybin was observed for CYP1A2 (Jancova et al. 2007; Kosina et al. 2005). Inhibition of CYP3A4 was observed after treatment with the compound silibinin (Budzinski et al. 2007).

A study with the compounds silybin A and silybin B indicated a possible interaction between these compounds and warfarin, with CYP2C9 noted as the mechanism of interaction (Brantley et al. 2010).

The compound silybin has been shown to have significant iron-chelating activity in vitro (Borsari et al. 2001). The implications of this to human clinical use are unclear. The binding may enhance or impair iron absorption (Mills and Bone 2005).

IV. Pregnancy and Lactation

In a study of women with cholestasis of pregnancy, no adverse effects were noted when the compound silymarin (210 mg daily) was taken for 15 days (Gonzalez et al. 1988). No teratogenic effects were observed after pregnant rabbits were administered the compound silymarin on days 8 to 17 of gestation, and when it was administered to pregnant rats on days 8 to 12 of gestation (Hahn et al. 1968).

No adverse effects were reported in nursing women taking 420 mg daily of the compound silymarin for 63 days during lactation (Di Pierro et al. 2008).

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in dogs administered a single dose of 1 g/kg of the compound silymarin (Hahn et al. 1968).

Short-Term Toxicity

No adverse effects were observed in mice administered the compound silymarin, 20 g/kg daily for 7 days. No adverse effects were observed in rats administered silymarin, 1 g/kg daily for 2 weeks (Hahn et al. 1968).

Chronic Toxicity

No adverse effects were observed in rats administered the compound silymarin at 100 mg/kg daily for 22 weeks (Hahn et al. 1968).

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Although the German Commission E reported that sarsaparilla could increase the absorption of digitalis glycosides, bismuth, or hypnotic drugs (Blumenthal et al. 1998), no information was found to support or refute this assertion.

Pregnancy and Lactation

No information on the safety of sarsaparilla in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of sarsaparilla during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No adverse effects were observed in rats orally administered up to 3 g/kg of a sarsaparilla extract (Rafatullah et al. 1991).

Subchronic Toxicity

No adverse effects were observed in rats orally administered up to 100 mg/kg of a sarsaparilla extract daily for 90 days. Observed parameters included body weight and hematological values (Rafatullah et al. 1991).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Use with caution in persons with hypersensitivity to the active substance or to other plants of the Asteraceae family (EMEA 2008).

Drug and Supplement Interactions

None known.

Notice

Diuretic (Chodera et al. 1991; Felter and Lloyd 1898; Remington and Wood 1918); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Canadian goldenrod, early goldenrod, or European goldenrod in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

S

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In a screening of different herbal products for effects on the cytochrome P450 drug-metabolizing isoenzymes CYP1A2 and CYP3A4 and the transporter protein MDR1, no effects of a h ydroethanolic extract of European goldenrod were observed on CYP1A2 or MDR1. An inducing effect on CYP3A4 was observed (Brandin et al. 2007).

IV. Pregnancy and Lactation

No information on the safety of Canadian goldenrod, early goldenrod, or European goldenrod during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered European goldenrod leaf extract (solvent not specified) in mice is 11.2 (g/kg presumably, dose units not specified for toxicity test), while that of the flower extract is 20.8 (g/kg presumably) (Racz-Kotilla and Racz 1978).

Sophora flavescens Aiton

Fabaceae

SCN: shrubby sophora
PN: *ku shen* (root)

OCN: light-yellow sophora
Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Occasional side effects such as mild dizziness, nausea, vomiting, and constipation may occur (Bensky et al. 2004; Chen and Chen 2004). The nausea and vomiting are usually related to the very bitter taste of shrubby sophora (Chen and Chen 2004).

Allergic reactions to shrubby sophora have been reported (Bensky et al. 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of shrubby sophora in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Occasional side effects such as mild dizziness, nausea, vomiting, and constipation may occur. In cases of overdose (standard dose is a decoction of 3–10 g), symptoms may include irritability, spasms or cramps, disturbance of speech, and irregular breathing. In cases of gross overdose, respiratory failure has been reported (Bensky et al. 2004; Chen and Chen 2004).

Allergic reactions to shrubby sophora have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats with arrhythmias induced by myocardial infarction (MI), the compound matrine exhibited antiarrhythmic activity along with a shortening of the MI-induced prolonged action potential duration (Li et al. 2009).

In Vitro Pharmacological Studies

Some estrogenic activity of an ethanolic extract of shrubby sophora was observed in a recombinant yeast assay system with a human estrogen receptor expression plasmid and a reporter plasmid (Kang et al. 2006; Kim et al. 2008).

A methanol extract of shrubby sophora inhibited mouse brain monoamine oxidase (MAO) (Hwang et al. 2005).

Compounds isolated from shrubby sophora had no activity on the drug transporter protein P-gp (Choi et al. 1999).

An extract of shrubby sophora inhibited the drug-metabolizing isoenzyme CYP3A4 (Lee et al. 2007).

In aortic smooth muscle tissue, the compound matrine was found to inhibit phenylephrine-induced contractions by inhibiting activation of α-adrenoceptors and interfering with the release of intracellular calcium and the influx of extracellular calcium (Zheng et al. 2009).

IV. Pregnancy and Lactation

No information on the safety of shrubby sophora during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of shrubby sophora in mice is 14.5 g/kg after oral administration and 14.4 g/kg after intramuscular injection (Chen and Chen 2004).

The LD_{50} of the total alkaloids from shrubby sophora in mice is 1.18 g/kg after oral administration (Zhu 1998). The LD_{50} of the compound oxymatrine in mice is 521 mg/kg after intraperitoneal administration (Zhu 1998).

Short-Term Toxicity

No significant damage to the heart, spleen, or kidneys was observed in mice intraperitoneally administered 100 to 500 mg/kg of the compound oxymatrine daily for 2 to 4 weeks (Zhu 1998).

Genotoxicity

In the mouse micronucleus and chromosomal aberration assays, mutagenic activity was observed in mice intraperitoneally administered an aqueous extract of shrubby sophora at doses of 0.24 to 3.6 or 0.1 to 2 g/kg. A dose-dependent increase in the incidence of chromosomal aberrations was observed at doses of 0.24 to 3.6 g/kg. In the micronucleus assay, an increase of polychromatic erythrocytes was observed at the 0.5 to 2 g/kg dose levels (Yin et al. 1991).

No mutagenic activity of an aqueous extract of shrubby sophora was observed in the Ames mutagenicity assay with *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation by S9 (Yin et al. 1991).

Spigelia marilandica (L.) L.

Loganiaceae

SCN: spigelia
OCN: Indian pink; pinkroot; woodland pinkroot; wormgrass

Part: root

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Felter and Lloyd 1898; Wood and LaWall 1918).

Not for long-term use (McGuffin et al. 1997).

Do not exceed recommended dose (McGuffin et al. 1997).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

Adults: 2 to 5 g, morning and evening, given with a strong purgative, such as senna (Wren et al. 1988).

Children over 4 years: 0.5 to 4 g, morning and evening, given with a strong purgative, such as senna (Wren et al. 1988).

Editors' Note

Historically, adulteration of spigelia with species of *Ruellia* or *Phlox* has been reported (Grieve 1971). No recent cases of adulteration have been reported.

Adverse Events and Side Effects

Texts from the early 1900s report that in standard doses, and when catharsis is produced either by spigelia or a coadministered stimulant laxative, no adverse effects are expected (Felter and Lloyd 1898; Osol and Farrar 1955; Wood and LaWall 1918). In large doses and without catharsis, spigelia may have a purgative effect, also producing various unpleasant symptoms such as increased action of the heart and arteries, dizziness, dilation of the pupils, and muscular spasms, often terminating in convulsions. Spasmodic twitching of the eyelids has been reported as one of the more frequent effects (Felter and Lloyd 1898; Wood and LaWall 1918). A later text reported that spigelia was commonly used throughout the United States as a vermifuge, and side effects were "almost unheard of" (Osol and Farrar 1955).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although no information on the safety of spigelia during pregnancy was identified, traditional use as a vermifuge (used to expel worms) suggests that spigelia should not be used during pregnancy (Felter and Lloyd 1898; Wood and LaWall 1918).

No information on the safety of spigelia during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Case Reports of Adverse Events

Texts from the early 1900s report that in standard doses, and when catharsis is produced either by spigelia or a coadministered stimulant laxative, no adverse effects are expected (Felter and Lloyd 1898; Osol and Farrar 1955; Wood and LaWall 1918). In large doses and without catharsis, spigelia may have a purgative effect, also producing various unpleasant symptoms such as increased action of the heart and arteries, dizziness, dilation of the pupils, and muscular spasms, often terminating in convulsions. Spasmodic twitching of the eyelids has been reported as one of the more frequent effects (Felter and Lloyd 1898; Wood and LaWall 1918). A later text reported that spigelia

was commonly used throughout the United States as a vermifuge, and side effects were "almost unheard of" (Osol and Farrar 1955).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Although no information on the safety of spigelia during pregnancy was identified, traditional use as a v ermifuge (used to expel worms) suggests that spigelia should not be used during pregnancy (Felter and Lloyd 1898; Wood and LaWall 1918).

No information on the safety of spigelia during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Rats injected with doses of 100 mg/kg or more of spilanthes had tonic-clonic seizures (Moreira et al. 1989, 1991), although mice orally administered doses up to 1500 mg/kg experienced no adverse effects (Ratnasooriya et al. 2004).

Pregnancy and Lactation

Although no studies on the safety of spilanthes in pregnancy or lactation were identified, traditional use of spilanthes in south Asia as a cooked vegetable or salad ingredient provides some indication of the relative safety of this herb (Burdock and Fenaroli 2005 ; Facciola 1990).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats intraperitoneally administered doses of 50 to 150 mg/kg of a hexane extract of spilanthes, minor behavioral changes (grooming and "wet dog shakes") were observed in animals administered 50 or 75 mg/kg. At doses of 100 to 150 mg/kg, full tonic-clonic seizures were induced in a dose-dependent manner (Moreira et al. 1989). Testing of the convulsant activity of different parts of spilanthes plants indicated that the flower was most active, followed by root and then a leaf and stem combination (Moreira et al. 1991).

A diuretic effect of a cold water extract of spilanthes flower was observed in rats orally administered doses of 1500 mg/kg. Doses of 500 or 1000 mg/kg did not significantly alter urine output. The extract caused a marked increase in urinary sodium and potassium levels and a reduction in the osmolarity of urine, suggesting that the activity is as a loop diuretic (Ratnasooriya et al. 2004).

In Vitro Pharmacological Studies

An ethanol extract of spilanthes inhibited CYP2E1, with alkylamides isolated from spilanthes showing greater activity (Raner et al. 2007).

IV. Pregnancy and Lactation

Although no studies on the safety of spilanthes in pregnancy or lactation were identified, traditional use of spilanthes in south Asia as a cooked vegetable or salad ingredient provides some indication of the relative safety of this herb (Burdock and Fenaroli 2005 ; Facciola 1990).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered hexane extract of spilanthes in rats is 150 mg/kg (Moreira et al. 1989).

Pregnancy and Lactation
No information on the safety of chickweed in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A case report indicated a positive patch test result to chickweed in a patient allergic to a number of common weeds. Analysis of the plant material used for the testing indicated the presence of borneol, menthol, linalool, and 1,8-cineole, all compounds that are not known to be present in chickweed, bringing into doubt the identity of the material tested (Jovanovi et al. 2003).

There is one report of an alleged case of nitrate toxicity associated with chickweed that resulted in a mild form of paralysis (Chadha 1988). The standard nitrate content of chickweed is 0.1% (Guil et al. 1997), suggesting that the toxicity case was due to environmental factors, such as harvesting from fields where synthetic fertilizers had been used.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of chickweed during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an ethanol extract of chickweed intraperitoneally administered to mice is 1 g/kg (Sharma et al. 1978).

Stephania tetrandra S. Moore

Menispermaceae

S

SCN: stephania
PN: *han fang ji* (root)

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Chen and Chen 2004); *see* Appendix 2.

Editors' Notes

Cases of nephrotoxicity were reported from ingestion of weight-loss products sold in Europe that listed *Stephania* as an ingredient (Vanherweghem et al. 1993). These were

analyzed and found to contain the nephrotoxic compound aristolochic acid (Schmeiser et al. 1996), which is not a constituent of stephania (Chen et al. 1990; Wu et al. 2007; Zhu and Phillipson 1996). Stephania, which is sold as *han fang ji*, is sometimes confused with the aristolochic acid-containing herb *Aristolochia fangchi*, which is traded as *guang fang ji* (Bensky et al. 2004; Chen and Chen 2004; Wu et al. 2007). Methods for differentiation of *Stephania* and *Aristolochia* species and for detection of aristolochic acid have been developed (Joshi et al. 2008; Koh et al. 2006; Sorenson and Sullivan 2007).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that stephania may modify glucose regulation. People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use (Tsutsumi et al. 2003, 2008).

Pregnancy and Lactation

A compound from stephania has been demonstrated in an animal study to have a therapeutic effect on fetal lung malformations (Xu et al. 2009). No other information on the safety of this herb in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No adverse effects are expected within the normal dosage range (4.5–9 g). Overdoses of stephania (15–30 g) have been associated with symptoms including headache, dizziness, numbness and tremor of the upper extremities, fainting, an oppressive feeling in the chest, and palpitations (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

A reduction in blood glucose levels was observed in diabetic rats orally administered 60 mg/kg of an aqueous extract of stephania (Tsutsumi et al. 2008).

A dose-dependent reduction in blood glucose levels was observed in diabetic mice orally administered 0.3 to 3 mg/kg of the compound fangchinoline. The activity of fangchinoline was greater than that of an aqueous extract of stephania (Tsutsumi et al. 2003).

In Vitro Pharmacological Studies

The compounds tetrandrine and fangchinoline inhibited platelet-activating factor (PAF)-induced human platelet aggregation. The IC_{50} of tetrandrine was 28.6 µ*M*, whereas that of fangchinoline was 21.7 µ*M*. Tetrandrine and fangchinoline also inhibited PAF-, thrombin- and arachidonic acid-induced thromboxane B_2 formation in human washed platelets. In the PAF-receptor binding assay, neither compound showed any inhibitory effects on the specific binding of PAF to its receptor (Kim et al. 1999).

The compound tetrandrine had a synergistic effect on the cytotoxicity of the chemotherapeutic agents 5-fluorouracil, oxaliplatin, and docetaxel in two gastric cancer cell lines (Wei et al. 2007).

IV. Pregnancy and Lactation

In rat fetuses with a model of congenital diaphragmatic hernia, oral administration of 30 mg/kg (based on maternal weight) of the compound tetrandrine to the pregnant mothers led to an improvement of morphological parameters (percentage of alveoli area, counting bronchus) in treated animals as compared to controls (Xu et al. 2009).

No information on the safety of stephania during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the total alkaloids of stephania intraperitoneally administered to mice is 113 mg/kg (Zhu 1998).

The LD_{50} of the compound tetrandrine in mice is 82.5 mg/kg after intravenous administration, 1450 mg/kg after intramuscular administration, and 3700 mg/kg after oral administration (Zhu 1998).

Stevia rebaudiana (Bertoni) Bertoni

Asteraceae

SCN: stevia
Syn: *Eupatorium rebaudianum* Bertoni

OCN: candyleaf; Paraguayan sweet herb; sweetleaf
Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Stevia has been extensively used as a sweetener for beverages, originally in Paraguay and, in the twentieth century, in other South American countries and Asia (Leung and Foster 1996).

Adverse Events and Side Effects

Reviews of stevia and compounds from stevia have indicated a lack of adverse effects (Carakostas et al. 2008; Chatsudthipong and Muanprasat 2009).

Pharmacological Considerations

Although two animal studies reported reductions in male or female fertility after large doses of stevia (Mazzei

Planas and Kuc 1968; Melis 1999), no adverse effects on fertility were observed in four other studies (Akashi and Yokoyama 1975; Mori et al. 1981; Sinchomi and Marcorities 1989; Yodyingyuad and Bunyawong 1991).

Pregnancy and Lactation

Animal studies have shown no adverse effects of large doses (up to 3 g /kg) of the compound stevioside on pregnancy or fetal and maternal health (Mori et al. 1981; Takanaka et al. 1991; Usami et al. 1995; Yodyingyuad and Bunyawong 1991).

No information on the safety of stevia during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Adverse events reported in three clinical trials of stevia leaf or leaf extract were similar in the stevia and placebo groups (Chan et al. 2000; Ferri et al. 2006; Hsieh et al. 2003).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In female rats orally administered an aqueous extract of 5 g stevia daily (~40 ml/kg) for 18 days, a reduction in fertility was observed. Fertility remained reduced during the 60-day post-treatment period (Mazzei Planas and Kuc 1968). A number of subsequent studies have not shown any effects of stevia, or the compound stevioside, on fertility or reproduction (Akashi and Yokoyama 1975; Mori et al. 1981; Sinchomi and Marcorities 1989; Yodyingyuad and Bunyawong 1991).

In male rats orally administered an aqueous extract of 2.66 g stevia daily for 60 days, a decrease in the concentration of spermatozoa stored in the cauda epididymides was observed along with decreases in the weights of the cauda epididymides and the seminal vesicles (Melis 1999).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In three successive generations of hamsters orally administered 0.5, 1, or 2.5 g/kg of the compound stevioside daily, no adverse effects on growth or reproduction were observed. Histological examinations of reproductive tissues from all three generations revealed no evidence of abnormality (Yodyingyuad and Bunyawong 1991).

In rats fed diets containing 0.15, 0.75, or 3% (equivalent to 150, 750, or 3000 mg/kg body weight daily) of the compound stevioside for 14 days before mating and for 7 days during gestation, no effects on fertility or fetal development were observed. At the highest dose, a slight increase in the number of fetal resorptions was observed (Mori et al. 1981).

In pregnant rats orally administered 250, 500, or 1000 mg/kg of the compound stevioside daily on gestational days 6 to 15, no adverse effects on fetal development or maternal health were observed (Takanaka et al. 1991; Usami et al. 1995).

No information on the safety of stevia during lactation was identified.

V. Toxicity Studies

Reviews of safety and toxicity information on stevia and the compound stevioside indicate that both are generally safe, with no adverse effects noted (Geuns 2002, 2003).

Acute Toxicity

The LD_{50} of orally administered stevia extract in rats is 17 g/kg (Mitusuhashi 1976). The LD_{50} of the compound stevioside orally administered to mice, rats, and hamsters could not be determined at doses up to 15 g/kg (Toskulkao et al. 1997).

Subchronic Toxicity

An increase in renal plasma flow was observed in rats administered stevia (4 ml of extract daily) for 60 days; no effects on mean arterial pressure were observed. The authors of the study suggested that stevia may induce vasodilation, low blood pressure, and increased urination (Melis 1995).

A decrease in the weight of seminal vesicles, but no effects on thyroid function or other parameters, were observed in male rats administered stevia (53 g/kg) for 60 days (Oliveira-Filho et al. 1989). A second study with similar stevia dose and duration indicated similar results but with some decrease in male fertility noted (Melis 1999).

In rats fed diets containing 25,000, 50,000, 75,000, or 100,000 ppm (~3, 6, 9, or 12 g/kg body weight) of the compound rebaudioside A for 13 weeks, a reduction in body weight gain, attributed to taste aversion and lower caloric density of the diet, was observed in the high-dose groups. Inconsistent reductions in serum bile acids and cholesterol were attributed to physiological changes in bile acid metabolism due to excretion of high levels of rebaudioside A. All other liver function test results and liver histopathology were within normal limits. No significant changes were observed in other clinical pathology results, including organ weights, and macroscopic and microscopic examinations of all organs, including testes and kidneys. The no-observed-adverse-effect level (NOAEL) was determined to be 4.4 g/kg (Curry and Roberts 2008).

In rats orally administered 500, 1000, or 2000 mg/kg of the compound rebaudioside A daily for 90 days, no treatment-related adverse effects were observed in clinical observations, hematology, serum chemistry, or urinalysis. Macroscopic and microscopic findings revealed no treatment-related effects on any organ evaluated. A reduction in body weight gain was noted in males at the 2000 mg/kg dose level (Nikiforov and Eapen 2008).

Chronic Toxicity

In rats fed diets containing the compound stevioside at a concentration of 0.2, 0.6, or 1.2% (equivalent to 100, 300, or 600 mg/kg body weight daily) for 2 years, no treatment-related changes were observed in hematological, urinary, or clinical biochemical values. The incidence and severity of non-neoplastic and neoplastic changes were unrelated to the concentration of stevioside in the diet. The no-observed-effect level was equivalent to 600 mg/kg per day (Xili et al. 1992).

Genotoxicity

A review of the genetic toxicity of the compounds steviol and stevioside indicated that the majority of the findings show no evidence of genotoxic activity for either of the compounds, and that neither stevioside nor steviol have been shown to react directly with DNA or demonstrate genotoxic damage in assays relevant to human risk (Brusick 2008).

Stillingia sylvatica Garden ex L.

Euphorbiaceae

SCN: stillingia
OCN: queen's delight; queen's root; yaw root

Part: root

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Felter and Lloyd 1898; Winston 2010; Wood and LaWall 1918).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 2 to 5 drops of tincture, 2 to 3 times daily (Winston 2010).

Adverse Events and Side Effects

Overdose of stillingia may cause symptoms such as vomiting and purging, sometimes accompanied by a burning sensation in the stomach or other part of the gastrointestinal tract (Felter and Lloyd 1898; Wood and LaWall 1918). Stillingia use has been associated with tachycardia (rapid heart rate) (Winston 2010).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Although no information on the safety of stillingia during pregnancy or lactation was identified, the side effects listed above suggest that stillingia should not be used during pregnancy or lactation (Felter and Lloyd 1898; McGuffin et al. 1997; Wood and LaWall 1918).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of stillingia may cause symptoms such as vomiting and purging, sometimes accompanied by a burning sensation in the stomach or other part of the gastrointestinal tract (Felter and Lloyd 1898; Wood and LaWall 1918).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Although no information on the safety of stillingia during pregnancy or lactation was identified, the side effects listed above suggest that stillingia should not be used during pregnancy or lactation (Felter and Lloyd 1898; Wood and LaWall 1918).

V. Toxicity Studies

No toxicity studies were identified.

Styrax spp. Styracaeae

Styrax benzoin Dryand.
SCN: benzoin tree
OCN: Benjamin tree; Sumatra benzoin
PN: *an xi xiang*

Styrax parallelloneurum **Perkins**
SCN: benzoin tree
OCN: haminjon toba; Sumatra benzoin

Styrax tonkinensis **(Pierre) Craib ex Hartwich**
SCN: benzoin tree
OCN: Siam styrax
PN: *an xi xiang*
Part: gum resin

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Among other products, benzoin is used in tincture of benzoin, which contains benzoin resin and alcohol, and compound tincture of benzoin, which contains benzoin resin, aloe resin, storax resin, and balsam of tolu resin in alcohol (Scardamaglia et al. 2003).

Adverse Events and Side Effects

Allergic contact dermatitis to benzoin has been reported and confirmed by patch testing (Coskey 1978; Hoffman and Adams 1978; Klein et al. 2009; Spott and Shelley 1970).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of benzoin in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

IV. Pregnancy and Lactation

No information on the safety of benzoin during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered benzoin in rats is 10 g/kg (Opdyke 1979).

Genotoxicity

A review of genotoxicity testing of benzoin indicated that the product showed mutagenic activity in 2 of 12 assays with rodents (Ashby and Shelby 1989).

Boraginaceae

SCN: comfrey
OCN: common comfrey; healing-herb; knitbone

Part: leaf, root

Quick Reference Summary

Safety Class: 2a, 2b, 2c
Interaction Class: A

Contraindications

For external use only (Bradley 1992; De Smet 1992; Wichtl 2004).

Not for use during pregnancy or lactation (Chan et al. 1994; De Smet 1992; Panter and James 1990).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Pyrrolizidine alkaloids (0.012–0.16% in leaf; 0.3–0.6% in dried root) (Altamirano et al. 2005; Betz et al. 1994; Cao et al. 2008; Couet et al. 1996; Dąbska et al. 1980; Mattocks 1980; Oberlies et al. 2004; Roitman 1981; Stickel and Seitz 2000; Tittel et al. 1979; Vollmer et al. 1988); *see* Appendix 1.

Editors' Notes

Pyrrolizidine alkaloid compounds in comfrey have been associated with cases of liver toxicity (see Adverse Events and Side Effects below). The American Herbal Products Association has established a trade requirement (AHPA 2011) that all products with botanical ingredients that contain toxic pyrrolizidine alkaloids, including comfrey, are not offered for sale for internal use and display the following cautionary label: "For external use only. Do not apply to broken or abraded skin. Do not use when nursing."

Considering the lower concentration of alkaloids in comfrey leaf and the absence of echimidine in most samples of the species (Couet et al. 1996; Roitman 1981), the

[*] Extracts of comfrey that have had the pyrrolizidine alkaloids removed (PA-free comfrey) are commercially available. Concerns regarding the internal use of comfrey products do not apply to PA-free products.

limitation to external use recommended above may be overly cautious for the leaf. One reference states, without differentiation of the species, that chronic internal use of *Symphytum* preparations may cause severe hepatic damage (De Smet 1992).

Adulteration of comfrey may occur with *Symphytum* species that contain echimidine (one of the most toxic of the pyrrolizidine alkaloids), such as *S. asperum* and *S. uplandicum* (Wichtl 2004). A chemical analysis of *Symphytum* species indicated a lack of echimidine in *S. officinale* (Huizing et al. 1982), although a more recent analysis reported echimidine to be present in one-quarter of tested samples of *S. officinale,* in a range reported as from a "generally very small quantity" up to "a rather high echimidine content comparable to concentrations found in *Symphytum asperum*" (Awang et al. 1993).

German authorities have recommended that external application of comfrey be limited to 4 to 6 weeks per year with a daily exposure at or below 100 µg unsaturated pyrrolizidine alkaloids (Wichtl 2004).

Adverse Events and Side Effects

Cases of veno-occlusive liver disease (blockage of some very small veins in the liver) have been reported in persons taking comfrey leaf or root (Bach et al. 1989; Huxtable et al. 1986; Ridker et al. 1985; Weston et al. 1987; Yeong et al. 1990). This type of liver disease is caused by consumption of unsaturated pyrrolizidine alkaloids (Cao et al. 2008).

The leaves of comfrey and foxglove (*Digitalis purpurea*) are similar in appearance. Several cases of poisoning have been reported in persons who accidentally ingested foxglove instead of comfrey (Awang et al. 1993; Bain 1985; Routledge and Spriggs 1989; Turley and Muir 2008).

Pharmacological Considerations

Rats fed diets containing 2 or 8% comfrey root for 12 weeks did not develop liver toxicity but did have a higher mutation rate in liver and lung cell genes, and expressed genes that were involved in liver injury and abnormalities, including liver fibrosis and cancer development (Mei et al. 2005, 2006; Mei and Chen 2007).

In contrast to case reports of liver disease, no evidence of liver damage was found in regular consumers (1 to 10 years of regular use) of comfrey (species not identified) leaf (Anderson and McLean 1989).

In one animal study, topical administration of comfrey resulted in excretion of PA metabolites (*N*-oxides) 20 to 50 times lower than that seen after oral administration (Brauchli et al. 1982).

Pregnancy and Lactation

Data from animal studies indicates that pyrrolizidine alkaloid compounds present in comfrey can cross the placenta and are present in the breast milk of animals that have consumed comfrey (Chan et al. 1994; Panter and James 1990). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

Support for the cytochrome P450-mediated activation of pyrrolizidines into their corresponding toxins comes from the observation that potent microsomal enzyme inducers, such as the anticonvulsant phenobarbital, can enhance the toxicity of pyrrolizidines (McLean 1974).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Consumption of comfrey tea has been associated with liver damage, primarily veno-occlusive disease, a nonthrombotic obliteration of small hepatic veins leading to cirrhosis and eventually liver failure. Patients have presented with either acute or chronic clinical signs, with portal hypertension, hepatomegaly, and abdominal pain as the main features (Stickel and Seitz 2000). In the case reports below, the species of comfrey consumed was generally not reported.

A 49-year-old woman was diagnosed with veno-occlusive disease, a form of Budd-Chiari syndrome. The patient had portal hypertension associated with obliteration of the smaller hepatic venules. A liver biopsy specimen showed centrilobular necrosis and congestion. The woman had been regularly taking two products that contained comfrey, one for 6 months and the other for 4 months. Analyses of products taken indicated an estimated intake of pyrrolizidine alkaloids of 0.49 to 1.45 µg/kg daily. Other supplements being taken by the woman included a number of vitamins, minerals, and sterotrophic adrenal bovine extract (Ridker et al. 1985).

Veno-occlusive disease was reported in a 13-year-old boy with Crohn's disease who was "regularly" administered comfrey leaf tea (dose, duration, and frequency not specified) (Weston et al. 1987). Veno-occlusive disease was reported in a 47-year-old woman who had been consuming

10 cups of comfrey tea daily for approximately 4 years (part and dose used not specified) (Bach et al. 1989).

Hepatic veno-occlusive disease leading to death was reported in a 23-year-old man who ingested 4 to 5 cooked comfrey leaves daily for 1 to 2 weeks (Yeong et al. 1990). Two cases of veno-occlusive disease were reported in women who took comfrey-pepsin tablets for 6 months. The daily doses included 280 mg/kg total pyrrolizidine alkaloids in one patient and 988 mg/kg total pyrrolizidine alkaloids in the other patient (Huxtable 1987).

The leaves of comfrey and foxglove (*Digitalis purpurea*) are similar in appearance. Several cases of poisoning have been reported in persons who accidentally ingested foxglove instead of comfrey (Awang et al. 1993; Bain 1985; Routledge and Spriggs 1989; Turley and Muir 2008).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No evidence of liver damage was found in regular consumers of comfrey leaf (species not identified). Liver function tests showed slightly elevated levels of bilirubin in two patients and aspartate aminotransferase (AST) in one patient. Most volunteers (72%) had used comfrey for 1 to 10 years (mean intake 3.0 g dry leaf/day); 17% used it for 11 to 20 years (mean intake 2.6 g dry leaf/day); and 10% used it for 21 to 30 years (mean intake 11 g dry leaf/day). The estimated intake of pyrrolizidine alkaloids was 0.015 to 0.15 mg/kg daily (Anderson and McLean 1989).

Animal Pharmacological Studies

In rats topically administered a dose of an ethanolic comfrey extract corresponding to 194 mg/kg of alkaloid *N*-oxides (with 7-acetylintermedine and 7-acetyllycopsamine as the main constituents along with lycopsamine, intermedine, symphytine, and traces of two unidentified alkaloids), the excretion of *N*-oxides in the urine was in the range of 0.1 to 0.4% of the dose, indicating that the dermally absorbed *N*-oxides are either not, or only to a small extent, converted to free alkaloids. Oral administration led to a 20 to 50 times higher excretion of *N*-oxides and free alkaloids in the urine (Brauchli et al. 1982).

In rats orally administered 1 mg/kg of the compound riddelliine (a pyrrolizidine alkaloid) 5 days per week or fed a daily diet of 8% comfrey root for 12 weeks, gene expression and biological processes observed were significantly different between the comfrey and riddelliine groups, although a number of genes related to carcinogenesis were expressed in both groups (Guo et al. 2007).

Unsaturated pyrrolizidine alkaloids, such as those found in comfrey, are metabolized by the CYP3A drug-metabolizing isoenzymes (Fu et al. 2004; Wang et al. 2005; Yarnell and Abascal 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Offspring of rats administered the pyrrolizidine alkaloid riddelliine during pregnancy and lactation had lower weight than control animals. The authors of the study indicated that riddelliine may cross the placenta and may be found in milk (Chan et al. 1994).

Pyrrolizidine alkaloids, including those present in comfrey, have been shown to be present in milk of animals that have consumed plants that contain these compounds (Panter and James 1990). Cases of veno-occlusive disease have been reported in infants of lactating women who consumed species of plants containing pyrrolizidine alkaloids (Sperl et al. 1995).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered symphytine is 300 mg/kg in mice (Culvenor et al. 1980) and 130 mg/kg in rats (Hirono et al. 1979).

Short-Term Toxicity

In rats administered a diet consisting of 5, 10, or 30% comfrey (part unspecified) for 21 days, those on the 30% comfrey diet gained less weight than control animals. Rats fed 10 or 30% comfrey or 30% alfalfa (*Medicago sativa*) in the diet exhibited an increase in hepatic aminopyrine N-demethylase activity but had no change in hepatic glutathione S-transferase or epoxide hydrolase activities, as compared to rats fed a control diet (Garrett et al. 1982).

Chronic Toxicity

A dose-dependent induction of liver tumors was observed in rats fed a diet of 8, 16, or 33% comfrey leaf for 600 days or a diet of 33% comfrey for 480 days. Liver tumors were also observed in rats fed a diet of 1 to 8% comfrey root for varying periods of time. The 8% comfrey root diet was administered until the rats died, while the 1, 2, and 4% diets were administered for 180 to 275 days with a reduced content of comfrey root (0 to 2%) administered for a total of 245 days or until the rats died (Hirono et al. 1978).

Hepatotoxicity

In rats fed a diet of 2% comfrey root daily for 12 weeks, a higher mutation rate was observed in liver and lung *cII* genes than in rats fed a control diet. No signs of liver toxicity were observed (Mei et al. 2005; Mei and Chen 2007). Riddelliine, one of the pyrrolizidine alkaloids of comfrey, was previously shown to dose-dependently induce mutations in the *cII* gene after oral administration to rats at doses of 0.1, 0.3, and 1.0 mg/kg (Mei et al. 2004). A gene expression profile of rats administered a diet of 8% comfrey root indicated that differentially expressed genes in the livers of treated animals were involved in metabolism, injury of endothelial cells, and liver injury and abnormalities, including liver fibrosis and cancer development (Mei et al. 2006).

In rats orally administered riddelliine at doses up to 10 mg/kg and in mice administered riddelliine at doses up to 25 mg/kg 5 days a week for 13 weeks, dose-related hepatopathy and intravascular macrophage accumulation in rats and hepatocytomegaly in mice were observed. Some animals were given a 14-week recovery period after treatment, and during that time, hepatic foci of cellular alteration in male rats and bile duct proliferation in female rats and male and female mice increased in severity (Chan et al. 1994).

Genotoxicity

Formation of DNA adducts was observed in female rats orally administered extracts of comfrey root but not comfrey leaf. The compound riddelliine caused formation of a significantly larger number of adducts than comfrey root (Chou and Fu 2006).

In the Ames mutagenicity test, comfrey produced "toxic responses" in *Salmonella typhimurium* strains TA98 and TA100 in the absence of microsomal activation, but showed no adverse effects in the presence of microsomal activation (White et al. 1983).

An alkaloid extract of comfrey induced sister-chromatid exchanges (SCE) and chromosomal aberrations at concentrations of 140 and 1400 µg/ml but not at concentrations of 1.4 or 14 µg/ml. In the presence of S9 mix, the clastogenic activity and SCE-inducing effect were enhanced (Behninger et al. 1989).

No mutagenic effects of comfrey leaf were observed in *Drosophila* (Clark 1982).

Symphytum spp.

Boraginaceae

Symphytum asperum Lepechin
SCN: prickly comfrey
OCN: rough comfrey

Symphytum uplandicum **Nyman**
SCN: Russian comfrey
OCN: prickly comfrey; Quaker comfrey
Part: leaf, root

S

Quick Reference Summary

Safety Class:[*] 2a, 2b, 2c
Interaction Class: A

Contraindications

For external use only (Bradley 1992; De Smet 1992; Wichtl 2004).

Not for use during pregnancy or lactation (Chan et al. 1994; De Smet 1992; Panter and James 1990).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Pyrrolizidine alkaloids (0.01–0.15% in leaf; up to 0.37% in root) (Culvenor et al. 1980; De Smet 1992; Mattocks 1980; Roitman 1981; Stickel and Seitz 2000; Wuilloud et al. 2004); *see* Appendix 1.

Editors' Notes

Pyrrolizidine alkaloid compounds in comfrey have been associated with cases of liver toxicity (see Adverse Events and Side Effects below). The American Herbal Products Association has established a t rade requirement (AHPA 2011) that all products with botanical ingredients that contain toxic pyrrolizidine alkaloids, including prickly comfrey

[*] Extracts of prickly comfrey and Russian comfrey that have had the pyrrolizidine alkaloids removed are commercially available. Concerns regarding the internal use of comfrey products do not apply to PA-free products.

and Russian comfrey, are not offered for sale for internal use and display the following cautionary label: "For external use only. Do not apply to broken or abraded skin. Do not use when nursing."

Along the alkaloids found in different species of comfrey, the pyrrolizidine alkaloid echimidine has exhibited a more toxic effect than other alkaloids (Culvenor et al. 1980). Russian comfrey and prickly comfrey contain echimidine in greater amounts than comfrey (*S. officinale*) (Awang et al. 1993; Jaarsma et al. 1989). Pyrrolizidine alkaloids and their metabolites are of particular interest, since these compounds are associated with toxicity (Stickel and Seitz 2000). Reports indicate that prickly comfrey contains from 0.14 to 0.37% pyrrolizidine alkaloids (Mattocks 1980), while the concentration in a commercial extract of Russian comfrey was reported as 0.0001% (Cao et al. 2008).

Symphytum uplandicum is a hybrid of *S. asperum* and *S. officinale* (Culvenor et al. 1980).

Adverse Events and Side Effects

Cases of liver disease have been reported in persons taking the leaf or root of *Symphytum* species (Bach et al. 1989; Huxtable et al. 1986; Ridker et al. 1985; Weston et al. 1987; Yeong et al. 1990). These case reports generally do not identify the species of comfrey consumed. Liver disease is caused by consumption of unsaturated pyrrolizidine alkaloids (Cao et al. 2008).

The leaves of comfrey and foxglove (*Digitalis purpurea*) are similar in appearance. Several cases of poisoning have been reported in persons who accidentally ingested foxglove instead of comfrey (Awang and Kindack 1989; Bain 1985; Routledge and Spriggs 1989; Turley and Muir 2008).

Pharmacological Considerations

In contrast to case reports of liver disease, no evidence of liver damage was found in regular consumers (1 to 10 years of regular use) of comfrey (species not identified) leaf (Anderson and McLean 1989).

Dose-dependent impairment of liver function has been observed in rats orally administered mixtures of alkaloids extracted from Russian comfrey (Culvenor et al. 1980; Yeong et al. 1991).

Pregnancy and Lactation

Data from animal studies indicates that pyrrolizidine compounds present in comfrey can cross the placenta and are present in the breast milk of animals that have consumed comfrey (Chan et al. 1994; Panter and James 1990). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

The leaves of comfrey and foxglove (*Digitalis purpurea*) are similar in appearance. Several cases of poisoning have been reported in persons who accidentally ingested foxglove instead of *Symphytum* species (Awang and Kindack 1989; Bain 1985; Routledge and Spriggs 1989; Turley and Muir 2008).

Also see Case reports of adverse events in entry for *Symphytum officinale* leaf and root.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No evidence of liver damage was found in regular consumers of comfrey leaf (species not identified). Liver function tests showed slightly elevated levels of bilirubin in two patients and AST in one patient. Most volunteers (72%) had used comfrey for 1 to 10 years (mean intake 3.0 g dry leaf/day); 17% used it for 11 to 20 years (mean intake 2.6 g dry leaf/day); and 10% used it for 21 to 30 years (mean intake 11 g dry leaf/day). The estimated intake of pyrrolizidine alkaloids was 0.015 to 0.15 mg/kg daily (Anderson and McLean 1989).

Animal Pharmacological Studies

In rats orally administered 1 mg/kg of the compound riddelliine 5 days per week or fed a daily diet of 8% comfrey root for 12 weeks, gene expression and biological processes observed were significantly different between the comfrey and riddelliine groups, although a number of genes related to carcinogenesis were expressed in both groups. The study authors concluded that the pyrrolizidine alkaloids contained in comfrey are the main active components responsible for carcinogenicity of the plant (Guo et al. 2007).

Unsaturated pyrrolizidine alkaloids, such as those found in comfrey, are metabolized by the CYP3A

drug-metabolizing isoenzymes (Fu et al. 2004; Wang et al. 2005; Yarnell and Abascal 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Offspring of rats administered the pyrrolizidine alkaloid riddelliine during pregnancy and lactation had lower weight than control animals. The authors of the study indicated that riddelliine may cross the placenta and may be found in milk (Chan et al. 1994). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Pyrrolizidine alkaloids, including those present in comfrey, have been shown to be present in the milk of animals that have consumed plants that contain these compounds (Panter and James 1990). Cases of veno-occlusive disease have been reported in infants of lactating women who consumed species of plants containing pyrrolizidine alkaloids (Sperl et al. 1995).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered extract of the alkaloids of Russian comfrey in young rats is 284 mg/kg (Culvenor et al. 1980).

The LD_{50} of the compound echimidine administered intraperitoneally to rats is 200 mg/kg (Bull et al. 1968). The LD_{50} of intraperitoneally administered symphytine is 300 mg/kg in mice (Furuya and Araki 1968) and 130 mg/kg in rats (Hirono et al. 1979).

Short-Term Toxicity

In rats orally administered 50 mg/kg daily of Russian comfrey-derived alkaloids for 6 weeks, sinusoidal fibrosis, sloughing of endothelial cells, and hepatocyte membrane damage were observed (Yeong et al. 1993).

In rats orally administered pyrrolizidine alkaloids isolated from Russian comfrey at a single dose of 200 mg/kg, or 100 mg/kg 3 days per week for 3 weeks, or 50 mg/kg 3 days per week for 3 weeks, all rats showed evidence of liver damage, the severity of which was dose dependent (Yeong et al. 1991).

In rats administered alkaloids derived from Russian comfrey, a dose of 71 mg/kg administered intraperitoneally three times per week resulted in severely impaired liver function and death within 3 to 4 weeks. Plasma protein and the albumin/globulin ratio were reduced by 40% or more, with only small increases in liver enzymes (Culvenor et al. 1980).

Symplocarpus foetidus (L.) Salisb. ex Nutt. — Araceae

SCN: skunk cabbage
Syn: *Dracontium foetidum* L.

Part: herb, root

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Do not exceed recommended dose (Felter and Lloyd 1898; Wood and LaWall 1918).

Other Precautions

Individuals with a history of kidney stones should use skunk cabbage with caution (McGuffin et al. 1997).

Drug and Supplement Interactions

None known.

Standard Dose

Tincture of the fresh root: 3 to 8 drops two or three times daily, diluted in a full cup of juice or water (Winston 2010).

Tincture of the dried root: 15 to 30 drops two or three times daily, diluted in a full cup of juice or water (Winston 2010).

Adverse Events and Side Effects

Large doses of skunk cabbage have been associated with nausea and vomiting, headache, dizziness, and dimness of vision (Felter and Lloyd 1898; Wood and LaWall 1918).

Skunk cabbage contains calcium oxalate crystals, microscopic needlelike structures that mechanically irritate the skin and mucous membranes, causing a painful burning sensation of the lips and mouth after ingestion (Genua and Hillson 1985; Higley 1880; Keating 2004; Nelson et al. 2006; Rowlee and Nichols 1896). Ingestion may cause an inflammatory reaction, often with edema and blistering, sometimes resulting in hoarseness and difficulty swallowing (Nelson et al. 2006).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of skunk cabbage in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Part: flower bud

S

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications

Do not exceed recommended dose (Bensky et al. 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 1 to 5 g as a decoction (Bensky et al. 2004; Chen and Chen 2004), 120 to 300 mg of powder (Martindale and Reynolds 1967).

Editors' Notes

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Clove should not be confused with clove essential oil, which is also available commercially. Although the oil has

long been used as a topical pain reliever for toothaches and is regarded as safe for this use (Alqareer et al. 2006), ingestion of large amounts may cause toxicity (Hartnoll et al. 1993).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

The compounds eugenol and acetyleugenol inhibited platelet aggregation in vitro (Laekeman et al. 1990; Saeed et al. 1995; Srivastava and Malhotra 1991).

In one animal study, some changes in sperm formation were reported after administration of clove extract (Mishra and Singh 2008).

Pregnancy and Lactation

Limited information on the safety of clove in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No adverse reactions to clove have been reported in the normal dosage range (a decoction of 1–3 g). Overdose of clove has resulted in symptoms of nausea, diarrhea, vomiting, and upper gastrointestinal hemorrhage. Cases of severe overdoses have been reported to cause changes in liver function, difficulty breathing, loss of consciousness, or death (Bensky et al. 2004).

A 2-year-old boy that ingested 5 to 10 ml of clove essential oil experienced coma, fits, a coagulopathy, and acute liver damage (Hartnoll et al. 1993).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

An increase in muscle propulsion in the gastrointestinal tract was observed in fasted mice and rats orally administered 300 or 700 mg/kg of an aqueous extract of clove (Agbaje 2008).

In mice orally administered 15, 30, or 60 mg/kg of a hexane extract of cloves daily for 35 days, the 15 mg/kg dose increased the activities of hydroxysteroid dehydrogenases and serum level of testosterone. At the 30 and 60 mg/kg dose, inhibition of these parameters was observed, along with induction of nonuniform degenerative changes in the seminiferous tubules associated with a decrease in daily sperm production and depletion of round and elongated spermatid populations (Mishra and Singh 2008).

In Vitro Pharmacological Studies

A methanol extract of clove inhibited the human drug-metabolizing isoenzyme CYP3A4 in a radiometric assay (Usia et al. 2006).

In human plasma, the compound eugenol strongly inhibited platelet aggregation induced by platelet-activating factor. A weaker inhibition was observed on platelet aggregation induced by arachidonic acid or collagen (Saeed et al. 1995). Inhibition of arachidonic acid-induced platelet inhibition was also observed in rabbit plasma (Laekeman et al. 1990).

The compounds eugenol and acetyleugenol inhibited platelet aggregation induced by arachidonic acid, adrenaline, and collagen in platelet-rich human plasma (IC_{50} values of 0.8 µ*M* for eugenol and 2 µ*M* for acetyleugenol), with effects on arachidonic acid-induced aggregation being greater than that of aspirin (IC_{50} of 28 µ*M*). A combination of the two compounds had an additive effect (Srivastava and Malhotra 1991).

Two polysaccharides isolated from clove were found to have antithrombotic activity (Lee et al. 2001).

IV. Pregnancy and Lactation

In mice fed diets containing 0.25% clove essential oil (estimated daily intake of 375 mg/kg) for 2 weeks and then mated, examination of 4-day-old embryos indicated an increase in cell death rate. The number of embryos and the rate of pregnancy were higher in the clove group than in the control group (Domaracky et al. 2007).

No information on the safety of clove during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of clove essential oil orally administered in rats is reported as 2.65 and 3.72 g/kg (Opdyke 1979). The dermal LD_{50} for clove essential oil is 5 g/kg (Opdyke 1979).

The oral LD_{50} of the compound eugenol is 3 g/kg in mice, 1.9 or 2.7 g/kg in rats, and 2.1 g/kg in guinea pigs (JECFA 1982). Clove essential oil is approximately 90% eugenol (Chaieb et al. 2007).

The Joint FAO/WHO Expert Committee on Food Additives determined that the acceptable daily intake for the compound eugenol is 2.5 mg/kg. This group also indicated that 250 mg/kg was the level causing no effect in the diet of rats (JECFA 1982).

Short-Term Toxicity

In rats orally administered 35 or 70 mg of clove essential oil daily for 8 weeks, the doses were reported as well tolerated. At a dose of 105 mg, severe liver and kidney damage was observed after 2 to 3 weeks. A single dose of 140 mg was fatal (Opdyke 1979).

Genotoxicity

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA100, an ethanol extract of clove exhibited strong mutagenic activity in strain TA100 and weak activity in TA98 (Mahmoud et al. 1992).

An ethanol extract of clove showed no mutagenic activity in the Ames test but gave a strong positive result in the *Bacillus subtilis rec* assay (Morimoto et al. 1982).

In *Salmonella typhimurium* strain TA100, clove essential oil was mutagenic without metabolic activation, but not mutagenic after metabolic activation by S9 (Park 2002). Another study with TA100 indicated that no mutagenic activity of clove essential oil was observed without metabolic activation and that mutagenic effect was stronger after the addition of S9 (Shoeibi et al. 2009).

An aqueous extract of clove showed no mutagenic activity in the SOS chromotest and in the *Salmonella reversion* assay using strains TA97a, TA98, TA100, and TA102. In a forward mutagenesis assay, an increase in mutagenesis was observed with the CC104 *mutMmutY* strain, suggesting that oxidative DNA damage occurred (dos Santos et al. 2008).

In the mouse bone marrow micronucleus assay, mice fed diets containing 0.5 or 2% clove for 10 days did not have any induced micronuclei (Kumari 1991).

Phenylpropanoid compounds from clove exhibited antimutagenic activity after induction of the SOS response in *Salmonella typhimurium* TA1535/pSK1002 treated with various mutagens (Miyazawa and Hisama 2003). A methanol extract of clove showed a suppressive effect on the SOS-inducing activity of furylfuramide in the *Salmonella typhimurium* TA1535/pSK1002 umu test (Miyazawa and Hisama 2001).

Syzygium cumini (L.) Skeels

Myrtaceae

SCN: jambolan
Syn: *Eugenia jambolana* Lam.; *Syzygium jambolana* DC.
AN: *jambu*

OCN: Java plum; jumbul
Part: bark, seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that jambolan seed and bark may modify glucose regulation (Mallick et al. 2006; Pandey and Khan 2002; Ravi et al. 2004; Saravanan and Pari 2008; Sharma et al. 2003, 2008; Sridhar et al. 2005; Villaseñor and Lamadrid 2006). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of jambolan in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In diabetic rats orally administered 800 mg/kg of a methanolic extract of jambolan seed daily for 14 days, corrections in fasting blood glucose levels and plasma insulin levels were observed (Mallick et al. 2006).

In diabetic rats orally administered 100 mg/kg of an ethanol extract of jambolan seed, a significant decrease in

blood glucose levels and glucose tolerance was observed (Ravi et al. 2004).

In rats with mild or severe diabetes, oral administration of 500 mg/kg of a flavonoid-rich extract of jambolan seed resulted in a reduction in fasting blood glucose and peak blood glucose levels (Sharma et al. 2008).

In rabbits with moderate or severe diabetes, oral administration of 100 mg/kg of an ethanol extract of jambolan seed daily for 15 days resulted in a significant reduction in fasting blood glucose and peak blood glucose and an increase in serum insulin levels (Sharma et al. 2003).

In diabetic rats fed diets containing 15% jambolan seed powder daily for 21 days, significantly lowered blood glucose levels were observed along with improved oral glucose tolerance (Pandey and Khan 2002).

In diabetic rats orally administered 250, 500, or 1000 mg/kg of jambolan seed powder daily for 15 days, decreases in fasting blood glucose and in post-treatment fasting and peak blood glucose were observed at the 500 and 1000 mg/kg doses (Sridhar et al. 2005).

In nondiabetic mice orally administered 250 mg/kg of a methanol extract of jambolan bark, a significant decrease in the blood glucose level was observed in the oral glucose tolerance test (Villaseñor and Lamadrid 2006).

In diabetic rats orally administered 75, 150, or 300 mg/kg of an aqueous extract of jambolan bark daily for 45 days, significant decreases in levels of blood glucose and urine sugar were observed. The activity of the 300 mg/kg dose was greater than that of the 75 and 150 mg/kg doses (Saravanan and Pari 2008).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of jambolan during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

No mortality or abnormalities were observed in rats orally administered single doses of 2.5 or 5 g/kg of jambolan seed powder (Sridhar et al. 2005).

Short-Term Toxicity

In diabetic rats orally administered 800 mg/kg of a methanolic extract of jambolan daily for 14 days, decreases in hepatic and renal GOT and GPT activity were observed (Mallick et al. 2006).

Tabebuia impetiginosa (Mart. ex DC.) Standl. — Bignoniaceae

SCN: pau d'arco
Syn: *Tabebuia avellanedae* Lorentz ex Griseb.; *Tabebuia heptaphylla* (Vell.) Toledo; *Tecoma impetiginosa* Mart. ex DC.

OCN: ipe roxo; lapacho; taheebo
Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Much of the research related to pau d'arco has been done on the compound lapachol, which is reported by one reference to be present in the heartwood at a concentration of 2 to 7%, with less in the bark (Taylor 2005). An analysis of commercial pau d'arco wood and bark products, however, indicated that the lapachol content in the wood was 0.001%, with no lapachol detected in bark products (Awang et al. 1994). Similarly, no lapachol was identified in an aqueous extract of pau d'arco inner bark (Steinert et al. 1996). Publications on lapachol, including those cited here, may therefore have little or no relevance to products that contain pau d'arco.

Adverse Events and Side Effects

Occupational asthma and allergic contact dermatitis have been reported in woodworkers exposed to pau d'arco dust (Algranti et al. 2005; Estlander et al. 2001).

At doses of the compound lapachol over 1.5 g/day, nausea and vomiting were reported as adverse events in one clinical trial (Block et al. 1974).

Pharmacological Considerations

At doses of 2 g daily of the compound lapachol, a prolonged thrombin time was observed, while other tests of clotting gave normal results (Block et al. 1974).

Pregnancy and Lactation

While animal studies indicated mixed effects of the compound lapachol (*see* Editors' Note) in pregnant animals, no information on the safety of pau d'arco in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Occupational asthma and allergic contact dermatitis have been reported in woodworkers exposed to pau d'arco wood dust (Algranti et al. 2005; Estlander et al. 2001).

Adverse Events Reported in Clinical Trials

At doses of 2 g d aily of the compound lapachol, thrombin time was prolonged and required correction with vitamin K. Other tests of clotting gave normal results (Block et al. 1974). No toxicity was observed at doses up to 1.5 g daily. At doses over 1.5 g/day, nausea and vomiting were reported as adverse events (Block et al. 1974).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

The compound lapachol had contact-sensitizing effects in guinea pigs (Schulz et al. 1977).

An increase in thrombin time but no change in clotting time were observed in dogs administered the compound lapachol (Morrison et al. 1970).

A decrease in weight of seminal vesicles but no changes in body weight or other organs were observed in male rats administered 100 mg/kg daily of hydroalcoholic solution of lapachol for 5 days (de Cassia da Silveira and Guerra 2007).

Also see Pregnancy and Lactation for this entry.

In Vitro Pharmacological Studies

Lapachol and lapachol derivatives exhibited cytotoxicity against A549 human breast cancer cells in vitro. The IC_{50} of lapachol was 0.78 m*M* (Oliveira et al. 2002).

The compounds lapachol and β-lapachone have been shown to be cytotoxic to cancer cells in animal studies and at micromolar concentrations in vitro in certain human cancer cell lines (Li et al. 1999; Menacho-Marquez and Murguia 2006; Ough et al. 2005; Pardee et al. 2002; Perez-Sacau et al. 2007; Queiroz et al. 2008). β-lapachone has been shown to have inhibitory activity on DNA topoisomerase (Lee et al. 2005), and cell death may also be caused by activation of a futile cycling of the drug by the cytoplasmic two-electron reductase NAD(P)H:quinone oxidoreductase (Ough et al. 2005; Pardee et al. 2002).

IV. Pregnancy and Lactation

No studies on the safety of pau d'arco in pregnancy or lactation were identified though a number of studies have examined the effects of the compound lapachol on reproduction in mice and rats.

In rats orally administered doses of 55 mg/kg or 110 mg/kg of lapachol on days 8 to 12 of pregnancy, 99 and 100% fetal mortality rates, respectively, were observed at the two dose levels, although no maternal toxicity was seen (Guerra et al. 1999, 2001). Fetal growth retardation but no effects on implantation or occurrences of resorption were observed in rats orally administered 100 mg/kg lapachol on days 17 to 20 of pregnancy (Felicio et al. 2002). Inhibition of pregnancy was observed in mice intramuscularly administered 20 mg/kg lapachol daily for 2 to 7 days. A 100% inhibition of pregnancy was observed in mice treated with lapachol on days 1 to 7 of pregnancy, while a 71% inhibition was observed in mice treated on days 1 to 3 (Sareen et al. 1995). No fetal resorption was observed in rats orally administered 100 mg/kg of lapachol daily for days 14 to 19 of pregnancy, although the same product and dose administered on days 7 to 12 of pregnancy resulted in a 79% fetal resorption rate (Rodrigues de Almeida et al. 1988). No effects on implantation and no resorptions were observed in rats orally administered lapachol at doses of 100 to 200 mg/kg daily on days 3 to 5 of pregnancy (Almeida et al. 1999).

V. Toxicity Studies

Acute Toxicity

No LD_{50} of pau d'arco concentrated aqueous extract could be determined at doses up to 5 g/kg orally administered to mice (de Miranda et al. 2001).

In tumor-bearing mice treated with β-lapachone, doses of 2 and 5 mg/kg had no effects on survival. Toxicity was evident at the 5 mg/kg dose with the death of 33% of treated tumor-bearers in the first 24 hours after β-lapachone administration, as compared to the 17-day delay in the onset of death of nontreated tumor-bearing mice (Queiroz et al. 2008).

The LD_{50} of orally administered lapachol in mice is 621 mg/kg, and in rats is 2.4 g/kg (Morrison et al. 1970). The LD_{50} for intraperitoneally administered lapachol in mice is 1.6 g/kg (de Santana et al. 1968).

In monkeys orally administered lapachol at doses of 0.0625, 0.125, 0.25, 0.5, or 1 g/kg daily, death occurred after six doses of 0.5 g/kg and after five doses of 1 g/kg. Severe anemia and elevated alkaline phosphatase levels were observed at the higher doses (Morrison et al. 1970).

Short-Term Toxicity

In dogs orally administered lapachol at doses of 0.25, 0.5, 1, or 2 g/kg daily six times per week for 4 weeks, no lethal effects were observed, but severe anemia and elevated alkaline phosphatase levels occurred (Morrison et al. 1970).

Genotoxicity

In the Ames test, lapachol had no mutagenic activity (Hakura et al. 1994).

Tanacetum parthenium (L.) Sch. Bip. — Asteraceae

SCN: feverfew
Syn: *Chrysanthemum parthenium* (L.) Bernh.

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (De Smet 1992; Mitchell 1983; Yao et al. 2006).

Other Precautions

Persons with allergies to other members of the Asteraceae family (such as chamomile) should exercise caution with feverfew, as allergic cross-reactivity is common to Asteraceae plants (Hausen and Osmundsen 1983; Upton 2007).

Persons discontinuing feverfew should reduce the dosage gradually over a 1-month period to avoid "post-feverfew syndrome" (Johnson et al. 1985; Mills and Bone 2005; Upton 2007).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Systematic reviews of clinical trials on feverfew indicate that the herb is generally well tolerated with few adverse effects (Ernst and Pittler 2000; Pittler and Ernst 2004). No adverse effects were observed in a dose escalation study of a standardized feverfew extract at doses up to 1 g daily (Curry et al. 2004).

Daily consumption of fresh feverfew leaves, but not the CO_2 extract of the leaf (Diener et al. 2005; Pfaffenrath et al. 2002; Upton 2007), may cause canker sores that have been shown to resolve after discontinuation of the herb (Johnson 1984).

"Post-feverfew syndrome" has been reported after cessation of feverfew in approximately 10% of long-term feverfew users, with symptoms of aches and pains, joint and muscle stiffness, anxiety, and poor sleep (Johnson et al. 1985).

Pharmacological Considerations

While some in vitro studies have indicated that feverfew can inhibit platelet aggregation (Loesche et al. 1988; Makheja and Bailey 1982), no effects on aggregation were observed in the one human study of feverfew and aggregation (Biggs et al. 1982), and no cases of bleeding in association with feverfew have been reported (Stargrove et al. 2008).

Pregnancy and Lactation

Limited information on the safety of feverfew during pregnancy and lactation is available. Animal studies with high doses of feverfew in pregnant rats or on isolated rat fetuses have shown some adverse effects on the fetus (Yao et al. 2006). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of clinical trials of feverfew monopreparations, including six clinical trials, characterized feverfew as generally well tolerated with only mild and transient adverse events. In two of the six trials, adverse events were higher in the placebo group, and in a third trial, adverse events were equivalent in the placebo and feverfew groups (Ernst and Pittler 2000). One study indicated a higher incidence of mouth ulcers in the placebo group than in the feverfew group (Murphy et al. 1988).

In a survey of 270 migraine patients who had been self-treating their headaches by chewing several feverfew leaves daily for 2 to 4 years, 18% of respondents reported adverse effects. The most frequent complaint was canker sores reported by 11.3% of respondents, although only 7% discontinued therapy. Other complaints included sore tongue, abdominal pain, indigestion, tingling sensation, urinary problems, and headaches (Johnson 1983). Canker sores are believed to be a systemic effect that resolves within a week of discontinuing feverfew (Johnson 1984). Canker sores and ulceration have not been reported in any clinical trials using a CO_2 extract of feverfew (Diener et al. 2005; Pfaffenrath et al. 2002; Upton 2007).

"Post-feverfew syndrome" has been reported after cessation of feverfew in approximately 10% of long-term feverfew users. Symptoms included aches and pains, joint and muscle stiffness, anxiety, and poor sleep (Johnson et al. 1985).

Case Reports of Adverse Events

Chewing fresh leaves may induce a generalized inflammation of oral mucosa (Johnson et al. 1985), which is likely due to the sesquiterpene lactone compounds in the plant. These compounds were suggested as the cause for contact allergy to live feverfew plants (Hausen and Osmundsen 1983).

Occasional side effects, such as mouth ulceration or gastric disturbance, have been observed in 6 to 15% of users, usually in the first week of use (Bradley 1992; De Smet 1992; Martindale and Reynolds 1996; Williamson 2003). No adverse effects have been reported from long-term consumption (Bradley 1992).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

A small study of long-term feverfew users (3.5 to 8 years of use) indicated that aggregation responses to ADP and thrombin were identical to a control group that had not taken feverfew for at least 6 months (Biggs et al. 1982). A review on feverfew indicated that the herb does not appear to affect blood pressure, heart rate, or other hematological parameters (Johnson et al. 1985).

In a dose escalation trial of a standardized feverfew product (500 µg parthenolide per 125 mg capsule), doses

up to 4 mg of parthenolide daily, taken orally, were well tolerated with no dose-limiting toxicity observed during 4 weeks of treatment (Curry et al. 2004).

Animal Pharmacological Studies

No relevant animal pharmacological trials were identified.

In Vitro Pharmacological Studies

A methanolic extract of feverfew indicated some inhibition of CYP1A2, CYP2C9, CYP2C8, CYP2C19, CYP2D6, and CYP3A4 (Unger and Frank 2004). An ethanolic extract exhibited very low inhibitory action on CYP3A4, while the compound parthenolide significantly inhibited CYP3A4 (Budzinski et al. 2000).

Extracts of feverfew have inhibited human platelet aggregation in vitro (Groenewegen and Heptinstall 1990; Heptinstall et al. 1987, 1988; Loesche et al. 1988; Makheja and Bailey 1982).

IV. Pregnancy and Lactation

When pregnant rats were administered 839 mg/kg of feverfew daily on gestational days 1–8 or 8–15, fetuses from the group that received feverfew later in pregnancy were smaller than fetuses in the control group (Yao et al. 2006). The dose used in this study was 60 times the recommended human dose (Upton 2007). Feverfew demonstrated toxicity when 10-day-old fetuses were cultured for 26 hours in rat serum with feverfew extract (Yao et al. 2006). Low doses of feverfew used prophylactically against migraines might not elicit any adverse effects, but prudence suggests that feverfew should not be used in pregnancy until more evidence is available (Upton 2007).

No information on the safety of feverfew during lactation was identified.

V. Toxicity Studies

Acute Toxicity

No LD_{50} of feverfew has been reported. The highest nontoxic acute dose in rats was reported at 860 mg/kg (Yao and Brown-Woodman 2001).

Short-Term Toxicity

No toxic effects were reported in guinea pigs or rats fed 100 to 150 times the daily human dose for 5 to 7 weeks (Johnson 1983).

Genotoxicity

A study of the genotoxicity of feverfew in humans examined the number of sister-chromatid exchanges in feverfew users compared with nonusers and indicated that no adverse effects of feverfew were found. The mutagenicity of urine samples from feverfew users was tested using the Ames mutagenicity test. The frequency of chromosomal aberrations was lower in the feverfew group than in the control group (Johnson et al. 1987).

Tanacetum vulgare L. — Asteraceae

SCN: tansy
Syn: *Chrysanthemum vulgare* (L.) Bernh.

Part: herb

Quick Reference Summary

Safety Class: 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Felter and Lloyd 1898; Wood and LaWall 1918).

Do not exceed recommended dose (Felter and Lloyd 1898; Opdyke 1979; Wood and LaWall 1918).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

1 to 2 g as an infusion up to 3 times daily (Mitchell 1983).

1 to 2 ml of the fluid extract (1:1) up to 3 times daily (Mitchell 1983).

0.6 to 1.5 ml of the tincture (1:5) up to 3 times daily (Mills and Bone 2005).

Notice

Abortifacient (Felter and Lloyd 1898; Wood and LaWall 1918); *see* Appendix 2.

Emmenagogue (Felter and Lloyd 1898; Wood and LaWall 1918); *see* Appendix 2.

Diuretic (Lahlou et al. 2007); *see* Appendix 2.

Thujone in some chemotypes (0–73.5% α-thujone and 0–97.7% β-thujone in the essential oil) (Dragland et al. 2005; Holopainen et al. 1987; Rohloff et al. 2004); *see* Appendix 1.

Editors' Notes

A number of different chemotypes (plants that are botanically identical but chemically different) of tansy have been identified. The compounds in these chemotypes vary widely, with α-thujone ranging from 0 to 73.5% of the essential oil and β-thujone ranging from 0 to 97.7% of the essential oil. The essential oil content of the plant ranges from 0.04 to 0.19 ml/kg (Dragland et al. 2005; Holopainen et al. 1987; Rohloff et al. 2004). This chemical variation leads to challenges for safe dosing of tansy (Blumenthal et al. 1998; List and Hörhammer 1973).

Adverse Events and Side Effects

Contact dermatitis from tansy has been reported and is attributed to sesquiterpene lactone compounds in the plant. Cross-reactivity has been reported between sesquiterpene lactone-containing plants in the Asteraceae family including tansy, dandelion, feverfew, and yarrow (Guin and Skidmore 1987; Hausen 1996; Hausen and Osmundsen 1983; Killoran et al. 2007; Mark et al. 1999; Opdyke 1979; Paulsen et al. 1993, 2001).

Pharmacological Considerations

An animal study indicated that tansy has diuretic activity (Lahlou et al. 2007).

Pregnancy and Lactation

Tansy and tansy essential oil have been used in attempted abortions. Several texts report that such use is "highly dangerous and generally ineffectual," with some fatal cases of tansy essential oil use reported (Felter and Lloyd 1898; Whitehill 1906; Wood and LaWall 1918). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of tansy during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis from tansy has been reported. Patch testing has indicated cross-reactions to a number of sesquiterpene lactone-containing plants in the Asteraceae family including tansy, dandelion, feverfew, and yarrow. The dermatitis is generally attributed to the sesquiterpene lactone compounds in tansy (Guin and Skidmore 1987; Hausen 1996; Hausen and Osmundsen 1983; Killoran et al. 2007; Mark et al. 1999; Paulsen et al. 1993, 2001).

In overdose, tansy and tansy essential oil have been reported to cause abdominal pain, vomiting, convulsions, seizures, coma, dilated pupils, irregular respiration, and fast and weak pulse. Some cases of overdose have been fatal (Felter and Lloyd 1898; Opdyke 1979; Wood and LaWall 1918).

Also see Pregnancy and Lactation for this entry.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In rats orally administered single doses of 100 mg/kg of an aqueous extract of tansy or 10 mg/kg of the drug furosemide, an increase in urine output was observed. Increases in urinary levels of sodium and potassium were also observed in the tansy group, while furosemide increased urinary levels of potassium. Despite changes in urinary excretion of the electrolytes, plasma levels of sodium and potassium were unaffected. In an 8-day study, both substances induced significant diuresis and natriuresis, but only tansy increased urinary potassium excretion (Lahlou et al. 2007).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Tansy and tansy essential oil have been used in attempted abortions. Several texts report that such use is "highly dangerous and generally ineffectual," with some fatal cases of tansy essential oil use reported (Felter and Lloyd 1898; Wood and LaWall 1918).

Convulsions and seizures were reported in an 18-year-old woman who had taken two or three doses of tansy essential oil over the course of one evening in an attempted abortion. The pregnancy was not interrupted (Whitehill 1906).

No information on the safety of tansy during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of tansy essential oil is 1.15 g/kg in rats and 3 g/kg in dogs (Opdyke 1979).

The LD_{50} of a freeze-dried aqueous extract of tansy leaf in mice is 9.9 g/kg after oral administration and 2.8 g/kg after intraperitoneal administration (Lahlou et al. 2008).

Subchronic Toxicity

In mice orally administered 100, 300, or 600 mg/kg of a freeze-dried aqueous extract of tansy leaf daily for 90 days, no significant adverse effects or changes in biological or hematological parameters were observed (Lahlou et al. 2008).

Taraxacum officinale Weber ex F.H. Wigg. — Asteraceae

SCN: dandelion
Syn: *Taraxacum dens-leonis* Desf.; *Taraxacum vulgare* (Lam.) Schrank

OCN: lion's tooth
Part: leaf, root

Quick Reference Summary

T

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Clare et al. 2009; Mitchell 1983; Racz-Kotilla et al. 1974; Schutz et al. 2006); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Human and animal studies have indicated that dandelion leaf is a diuretic (Clare et al. 2009; Racz-Kotilla et al. 1974).

Due to the choleretic activity of dandelion, caution has been suggested for persons with gallstones (Mills and Bone 2005; Schutz et al. 2006; Wichtl 2004).

Pregnancy and Lactation

No information on the safety of dandelion in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Contact dermatitis from fresh dandelion leaf has been reported and confirmed by patch testing. These reactions are generally attributed to the sesquiterpene lactone compounds in dandelion (Guin and Skidmore 1987; Hausen 1982; Ingber 2000; Jovanovic et al. 2003; Mark et al. 1999; Paulsen et al. 2008; Wakelin et al. 1997).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered 8 ml of a hydroethanolic extract of dandelion leaf every 5 hours for three doses, an increase in the frequency of urination was observed after the first dose, and an increase in the excretion ratio (urination volume:fluid intake) was observed after the second dose. No changes were observed after the third dose (Clare et al. 2009).

Animal Pharmacological Studies

No significant changes in urine volume were reported in saline-loaded mice orally administered 50 ml/kg of different extract fractions of dandelion root. Excretion of sodium and potassium were higher in animals given certain extract fractions (petroleum ether and chloroform) than in control animals. A crude methanol extract increased potassium concentration in the urine similar to levels observed with furosemide treatment (37.5 mg/kg), although sodium excretion was significantly lower after dandelion than furosemide (Hook et al. 1993).

In studies with mice and rats, increases in urine output and salt excretion were observed after administration of dandelion leaf fluid extract. A dose corresponding to 8 g/kg of the dried herb demonstrated activity equivalent to 80 mg/kg of the diuretic furosemide (Racz-Kotilla et al. 1974).

Inhibition of the drug-metabolizing isoenzyme CYP2E1 was observed in rats provided with drinking water containing 2% dandelion root tea (Maliakal and Wanwimolruk 2001).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of dandelion during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered dandelion leaf fluid extract (1:1) in mice is 28.8 g/kg, while that of the root is 36.6 g/kg (Racz-Kotilla et al. 1974).

No adverse effects were observed in rabbits orally administered doses equivalent to 6 g/kg of dried whole dandelion (Akhtar et al. 1985). An ethanol extract of dandelion root demonstrated very low toxicity in mice and rats orally administered a dose equivalent to 10 g/kg of the dried herb or intraperitoneally administered a dose equivalent to 4 g/kg of the dried herb (Tita et al. 1993).

Taxus brevifolia Nutt.

Taxaceae

SCN: Pacific yew

Part: needles

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Krag 1976).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Krag 1976); *see* Appendix 2.

Editors' Notes

Pacific yew should not be confused with botanically similar species, *T. baccata* (English yew) and *T. cuspidata* (Japanese yew), that are recognized as toxic due to effects on heart rate and rhythm (Rowinsky et al. 1990; Vance et al. 2001). Effects on the heart are caused by taxine compounds, present at 0.5 to 1% in *T. baccata* as compared to 0.0007% in Pacific yew (Jenniskens et al. 1996; Tyler 1960).

Pacific yew is a source of the compound taxol, used in chemotherapy of several types of cancers. The concentration of taxol in Pacific yew needles is approximately 0.006% and 0.01% in the bark (Witherup et al. 1990).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Pacific yew has traditionally been used as an emmenagogue (Krag 1976).

No information on the safety of Pacific yew during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Pacific yew has traditionally been used as an emmenagogue (Krag 1976).

No information on the safety of Pacific yew during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of Pacific yew powder orally administered to rats could not be determined at doses up to 5 g/kg (PSL 1999).

Terminalia arjuna (Roxb. ex DC.) Wight & Arn. — Combretaceae

SCN: arjuna
AN: *arjuna*

Part: bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Gupta et al. 1989; Pole 2006).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (12–24%) (Chadha 1988; Dwivedi 2007); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

An animal study indicated that some extracts of arjuna reduced the number of viable fetuses (Gupta et al. 1989). A text on Ayurvedic medicine indicates that arjuna should not be used during pregnancy (Pole 2006). Based on this information, use during pregnancy is not recommended except under the supervision of a q ualified healthcare practitioner.

No information on the safety of arjuna during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In a phase II open label study of arjuna in patients with severe refractory heart failure, patients stabilized on digitalis and/or diuretic and vasodilator drugs were orally administered 500 mg of a hydroalcoholic extract of arjuna bark every 8 hours for 4 months. Biochemical, electrocardiographic, radiological, and echocardiographic parameters were monitored. No adverse events were reported, and in all cases patients were able to reduce the diuretic dosage to the minimum necessary to keep symptom free (Bharani et al. 1995).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No relevant animal studies of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical trials of arjuna bark and bark extracts in patients with cardiovascular disorders indicated that arjuna bark is generally well tolerated at doses of 1 to 2 g daily. At those doses, only minor adverse events were reported, including mild gastritis, headache, and constipation (Dwivedi 2007). *Also see* Clinical trials of drug or supplement interactions above.

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant pharmacological studies were identified.

Animal Pharmacological Studies

A dose-dependent reduction in blood glucose levels was observed in diabetic rats orally administered 250 or 500 mg/kg of an ethanol extract of arjuna daily for 30 days (Ragavan and Krishnakumari 2006).

In Vitro Pharmacological Studies

In platelets from healthy persons and patients with coronary artery disease (CAD), the effect of an ethanol extract of arjuna on platelet function indices was determined by incubating the platelets with arjuna extract in a time- and dose-dependent (concentrations of 25 to 100 µg/ml) manner in the presence and absence of adenosine diphosphate (ADP). Arjuna was able to significantly inhibit platelet aggregation in platelets from CAD patients and from healthy controls. Significant attenuation of intracellular free calcium release and expression of CD62P was also observed after treatment with arjuna (Malik et al. 2009).

IV. Pregnancy and Lactation

In rats orally administered 200 or 400 mg/kg of a freeze-dried ethanol extract of arjuna on gestational days 1 to 7, no anti-implantation activity was observed. In animals administered the same dose on days 12 to 14, a dose-dependent increase in the number of fetal resorptions was observed. Hexane (10 mg/kg) and butanol (100 mg/kg) fractions of the extract and the compounds arjunolone (5 mg/kg) and baicalein (25 mg/kg), but not chloroform (50 mg/kg) or benzene (50 mg/kg) fractions, also produced an increase in the number of fetal resorptions (Gupta et al. 1989).

A text on Ayurvedic medicine indicates that arjuna should not be used during pregnancy (Pole 2006).

No information on the safety of arjuna during lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

No signs of toxicity were observed in diabetic rats orally administered up to 500 mg/kg of an ethanol extract of arjuna daily for 30 days (Ragavan and Krishnakumari 2006).

Terminalia chebula Retz. — Combretaceae

SCN: chebulic myrobalan
AN: *haritaki*
PN: *he zi* (fruit)
OCN: black myrobalan; true myrobalan
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Notice
Tannins (25–32%) (Chadha 1988; List and Hörhammer 1973); *see* Appendix 1.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
Animal studies and traditional human use have demonstrated that chebulic myrobalan may modify glucose regulation (Kumar et al. 2006; Murali et al. 2007; Rao and Nammi 2006). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation
No information on the safety of chebulic myrobalan in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
In diabetic rats orally administered 200 mg/kg of an ethanol extract of chebulic myrobalan daily for 30 days, a significant reduction in blood glucose and glycosylated hemoglobin was observed. Determination of plasma insulin levels revealed the insulin-stimulating action of the fruit extract (Kumar et al. 2006). In diabetic rats orally administered 100, 200, or 300 mg/kg of a chloroform extract of chebulic myrobalan seed daily for up to 8 weeks, a dose-dependent reduction in blood glucose levels was observed (Rao and Nammi 2006). A reduction in blood glucose levels was observed in diabetic rats orally administered 200 mg/kg of arjuna aqueous extract daily for 2 months. Related in vitro studies with pancreatic islets showed that the insulin release was nearly two times more in treated than in untreated diabetic animals (Murali et al. 2007).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of chebulic myrobalan during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
The LD_{50} of an orally administered aqueous extract of arjuna in rats could not be determined at doses up to 3 g/kg. At doses up to 3 g/kg, no changes in blood parameters for liver and kidney function were observed including total

protein, alkaline phosphatase, SGPT, SGOT, total bilirubin, and creatinine (Murali et al. 2007).

Short-Term Toxicity

In rats fed a diet containing 25% chebulic myrobalan seed powder daily for 10 to 14 days, early centrilobular vein disruption and centrilobular sinusoidal congestion were observed (Arseculeratne et al. 1985).

Genotoxicity

In the Vitotox assay, no mutagenic activity of chebulic myrobalan was observed, whereas an increase in DNA damage was observed in the comet assay with an extract of chebulic myrobalan at a concentration of 500 ppm. The authors noted that these differing results are not considered contradictory because DNA damage in the alkaline comet assay may not be permanent and hence may not necessarily result in mutations; chebulic myrobalan was previously found to have significant antimutagenic activity in the Ames assay (Arora et al. 2005).

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of tilia estrella during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a tilia estrella methanol extract intraperitoneally administered to mice is 1.05 g/kg (Aguilar-Santamaria and Tortoriello 1996).

Literature Cited

Aguilar-Santamaria, L., and J. T ortoriello. 1996. Anticonvulsant and sedative effects of crude extracts of *Ternstroemia pringlei* and *Ruta chalepensis*. *Phytother. Res.* 10(6):531-533.

Tetradium ruticarpum (A. Juss.) T.G. Hartley — Rutaceae

SCN: evodia
Syn: *Euodia ruticarpa* (A. Juss.) Benth.

PN: *wu zhu yu* (unripe fruit)
Part: unripe fruit

Quick Reference Summary

Safety Class: 2d
Interaction Class: B

Contraindications

Not for long-term use (Bensky et al. 2004; Chen and Chen 2004).

Do not exceed recommended dose (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

See Pharmacological Considerations.

Editors' Notes

Unprocessed evodia is sometimes used topically, whereas material for internal use should be processed. Processing of evodia, which reduces the toxicity, is typically done by cooking the unripe fruit with licorice (Bensky et al. 2004; Chen and Chen 2004; Hong et al. 2008). Other methods of processing are sometimes used (Bensky et al. 2004).

Adverse Events and Side Effects

Large doses (standard dose listed as a decoction of 1.5–5 g) have a stimulating effect on the central nervous system and can lead to visual disturbances and hallucinations (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

Animal studies have indicated that evodia and compounds from evodia may affect the metabolism of theophylline, acetaminophen, chlorzoxazone, and caffeine (Bista et al. 2008; Jan et al. 2005; Lee et al. 2007; Tsai et al. 2005). In all of these studies, evodia or a compound from evodia was administered orally, while the drugs were administered intravenously. The relevance of those studies to human oral use is not known.

Animal studies have indicated that evodia and compounds from evodia may induce the drug-metabolizing isoenzymes CYP1A1, CYP1A2, and CYP2E1 (Bista et al. 2008; Jan et al. 2005, 2006; Lee et al. 2004, 2007; Tsai et al. 2005; Ueng et al. 2001, 2002a, 2002c).

Pregnancy and Lactation

Limited information on the safety of evodia in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

A decrease in serum levels and a dose-dependent increase in the rate of clearance of the drug theophylline was observed in rats orally administered 1 or 2 g/kg of an ethanol extract of evodia or 50 mg/kg of the compound rutaecarpine daily for 3 days prior to intravenous administration of 2 mg/kg theophylline, a CYP1A2 substrate (Jan et al. 2005; Ueng et al. 2005).

A decrease in serum levels and an increase in the clearance rate of caffeine was observed in rats orally administered 1 g/kg daily of a hydroalcoholic extract of evodia, or 25 mg/kg daily of the compound rutaecarpine daily, for 3 days prior to the intravenous administration of 5 mg/kg caffeine, a CYP1A2 substrate (Tsai et al. 2005).

A decrease in serum levels of chlorzoxazone was observed in rats orally administered 80 mg/kg of the compound rutaecarpine daily for 3 days prior to the intravenous administration of 20 mg/kg chlorzoxazone, a CYP2E1 substrate (Bista et al. 2008).

A decrease in serum levels of acetaminophen was observed in rats orally administered 40 or 80 mg/kg of the compound rutaecarpine daily for 3 days prior to intravenous administration of acetaminophen (Lee et al. 2007).

II. Adverse Events

Case Reports of Adverse Events

Overdoses (standard dose is a decoction of 1.5–5 g) of evodia or internal use of the unprocessed herb have been associated with abdominal pain, diarrhea, visual disturbances, dizziness, hair loss, headache, a sense of oppression in the chest, and rashes (Bensky et al. 2004; Chen and Chen 2004).

Allergic reactions, primarily in the form of scarlatiniform rashes, have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In mice orally administered 2 g/kg of methanolic or aqueous extracts of evodia daily, immunoblot analyses showed that the methanol extract increased the levels of the drug-metabolizing isoenzymes CYP1A1, CYP1A2, and CYP2B and GSTYb-immunoreactive proteins while the aqueous extract increased only CYP1A2 protein levels (Ueng et al. 2002c).

A significant increase in activity of the drug-metabolizing isoenzymes CYP1A1 and CYP1A2 was observed in mice orally administered 50 mg/kg of the compound rutaecarpine daily for 3 days. No effect on CYP3A was observed (Ueng et al. 2001).

Induction of the drug-metabolizing isoenzyme CYP1A2 was observed in mice orally administered 3.5 mg/kg daily of the compound rutaecarpine or 0.77 g/kg per day of a concentrate of evodia; the compounds evodiamine and dehydroevodiamine had no significant effects on CYP1A2 activity (Ueng et al. 2002a).

Induction of the drug-metabolizing isoenzymes CYP1A and CYP2B was observed in mice orally administered 20, 40, or 80 mg/kg of the compound rutaecarpine daily for 3 days (Lee et al. 2004).

The drug-metabolizing isoenzymes CYP1A and CYP2B, but not CYP3A, were found to play major roles in the hydroxylation of rutaecarpine in mice (Jan et al. 2006).

Also see Animal trials of drug or supplement interactions for this entry.

In Vitro Pharmacological Studies

Significant inhibition of the drug-metabolizing isoenzyme CYP1A2 was observed in mouse and human liver microsomes treated with the compound rutaecarpine. The compounds evodiamine and dehydroevodiamine were also tested, but no significant activity of the compounds on CYP1A2 was observed (Ueng et al. 2002b).

Mechanism-based inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed in human liver microsomes treated with the compounds rutaecarpine or limonin, with activity reported as preincubation time dependent (Iwata et al. 2005).

Moderate modulation of the drug transporter P-glycoprotein (P-gp) was observed in the calcein assay in porcine brain capillary endothelial cells treated with the compounds rutaecarpine or evodiamine. The compound evocarpine had no effect on P-gp (Adams et al. 2007).

The essential oil of evodia enhanced percutaneous absorption of ibuprofen (Luo et al. 2007).

In human platelet-rich plasma, inhibition of aggregation induced by collagen, ADP, adrenaline, and arachidonic acid was observed after treatment with the compound rutaecarpine (40–200 μ*M*) (Sheu et al. 1996).

IV. Pregnancy and Lactation

In an in vitro uterotonic assay, the compounds rutaecarpine and dehydroevodiamine demonstrated uterotonic activity. No uterotonic activity of evodiamine hydrochloride was observed (King et al. 1980).

No information on the safety of evodia during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered aqueous and ethanolic extracts of evodia could not be determined at doses up to 10 g/kg (Yang 2008). The LD_{50} of aqueous extracts of processed (cooked with a licorice decoction) or unprocessed evodia could not be determined at doses up to 40 g/kg (route of administration not specified in English language abstract) (Hong et al. 2008).

The LD_{50} values for compounds isolated from evodia and intravenously administered to mice are 65.0 mg/kg for rutaecarpine, 77.8 mg/kg for evodiamine, 64.9 mg/kg for 1-methyl-2-undecyl-4(1*H*)-quinoline, 36.0 mg/kg for 2-undecyl-4(1*H*)-quinolone, and 47.6 mg/kg for 1-methyl-2-undecanone-10′-4(1*H*)-quinolone. The LD_{50} of the total quinolones of evodia is 14 mg/kg after intravenous administration (Yang et al. 2006).

In the mouse sperm aberration test, no abnormalities were observed in the sperm of mice orally administered up to 5 g/kg of aqueous or ethanolic extracts of evodia daily for 5 days (Yang 2008).

Genotoxicity

No mutagenic activity of aqueous or ethanolic extracts of evodia was observed in the Ames test for mutagenicity or in the mouse bone marrow micronucleus test. The Ames test examined effects in *Salmonella typhimurium* strains TA97, TA98, TA100, or TA102. In the mouse bone marrow micronucleus test, animals were administered up to 5 g/kg of the evodia extracts daily for 2 days (Yang 2008).

Thuja occidentalis L. — Cupressaceae

SCN: thuja
OCN: eastern white cedar; eastern arborvitae; northern white cedar; swamp cedar

Part: leaf

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Felter and Lloyd 1898; Osol and Farrar 1955).

Not for long-term use; do not exceed recommended dose (Wood and LaWall 1926).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 1–3 g as a tea (Remington and Wood 1918).

Notice

Abortifacient (Felter and Lloyd 1898; Osol and Farrar 1955); *see* Appendix 2.

Thujone (0.76–2.4% of herb; essential oil contains approximately 55% α-thujone and 16% β-thujone) (Naser et al. 2005; Svajdlenka et al. 1999); *see* Appendix 1.

Editors' Notes

Use of thuja as a food additive in the United States is subject to a limitation that the finished food or beverage is thujone-free (CFR 2011). Dietary ingredients for use in dietary supplements, however, are specifically excluded from the federal food additive definition (U.S.C. 2010).

Adverse Events and Side Effects

Seizures have been reported after overdose of thuja essential oil (Friesen and Phillips 2006; Millet et al. 1981).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Thuja has historically been used as an abortifacient, although more recent reviews have indicated that such use was ineffective and often highly toxic (Felter and Lloyd 1898; Harnischfeger and Stolze 1983; Naser et al. 2005; Osol and Farrar 1955). Thuja and thuja essential oil should not be used internally or externally during pregnancy.

No information on the safety of thuja during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Seizures were reported in a 2-year-old girl who ingested up to 15 ml of 0.1% thuja essential oil. The two seizures, each lasting 5 min, occurred within 20 minutes of ingestion (Friesen and Phillips 2006). A tonic seizure was reported in a 50-year-old woman who had taken 20 drops of thuja essential oil twice daily for 5 days (Millet et al. 1981).

In children who have eaten the fresh shoots or cones of thuja, gastrointestinal pain was reported. In some instances, the pain was accompanied by bloody vomiting. Quantities ingested were not reported in the available English language translation (Schulte 2002).

Allergic contact dermatitis to thuja has been reported (Grimm 1991).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Thuja has historically been used as an abortifacient, although more recent reviews have indicated that such use was ineffective and often highly toxic (Felter and Lloyd 1898; Harnischfeger and Stolze 1983; Naser et al. 2005; Osol and Farrar 1955).

No information on the safety of thuja during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of the compound thujone (mixture of α- and β-thujone) is 500 mg/kg after oral administration to rats, 87.5 mg/kg after subcutaneous administration to mice, 240 mg/kg after intraperitoneal administration to rats, and 0.031 mg/kg after intravenous administration to rabbits (EMEA 1999; Naser et al. 2005).

In the brine shrimp lethality assay, the LC_{50} of an alcohol extract of thuja is 11.94 µg/ml (Lagarto Parra et al. 2001).

Genotoxicity

No mutagenic activity of thuja tinctures was observed in the *Salmonella*/mammalian microsome assay and the SOS-chromotest (Valsa and Felzenszwalb 2001).

Thymus vulgaris L. — Lamiaceae

SCN: thyme
OCN: common thyme; garden thyme

Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chadha 1988; Felter

and Lloyd 1898; Watt and Breyer-Brandwijk 1962; Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Chadha 1988; Felter and Lloyd 1898; Watt and Breyer-Brandwijk 1962); *see* Appendix 2.

Editors' Note

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Adverse Events and Side Effects

Allergic reactions to thyme have been reported, sometimes with cross-sensitivity to rosemary or oregano (Armisen et al. 2003; Benito et al. 1996; Le Roy et al. 1981; Lorenzi et al. 1995; Martinez-Gonzalez et al. 2007).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Several authors list thyme as an emmenagogue or abortifacient and note that thyme essential oil should not be used in pregnancy (Chadha 1988; Felter and Lloyd 1898; Watt and Breyer-Brandwijk 1962; Wichtl 2004). Large doses of the compound thymol (which comprises approximately 51% of thyme essential oil) have been associated with abortifacient activity (Gillespie 1973; Sollman 1948). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of thyme during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to thyme, confirmed by patch testing, have been reported (Benito et al. 1996; Le Roy et al. 1981; Lorenzi et al. 1995). In some cases, patients exhibited cross-sensitivity to oregano or rosemary (Armisen et al. 2003; Benito et al. 1996; Martinez-Gonzalez et al. 2007).

Relative to urban-dwelling control groups, respiratory ailments and sensitivity to microbial allergens were increased in thyme farmers regularly exposed to airborne thyme dust (Golec et al. 2003, 2005). Occupational airborne contact dermatitis caused by thyme dust was reported in some farmers during threshing of thyme (Spiewak et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Induction of phase I and phase II enzymes was observed in mice fed a diet containing up to 2% thyme or treated orally with thymol (200 mg/kg) or carvacrol (up to 200 mg/kg) daily for 7 days. Bioactivity was attributed to the thymol and carvacrol content of thyme (Sasaki et al. 2005).

In Vitro Pharmacological Studies

Thyme essential oil inhibited arachidonic acid-induced platelet aggregation at a concentration of 7 µ*M*, and ADP-induced aggregation at a concentration of 100 µ*M*, but had no effect on U46619-induced aggregation (Tognolini et al. 2006). The compound thymol inhibited platelet aggregation induced by collagen, ADP, arachidonic acid, and thrombin (Okazaki et al. 2002).

An aqueous-ethanolic extract of thyme bound competitively to estradiol and progesterone receptors (Zava et al. 1998).

IV. Pregnancy and Lactation

No adverse effects on development were observed in 4-day-old embryos from pregnant mice that were administered a diet of 0.25% thyme essential oil (approximate dose of 375 mg/kg daily) for 2 weeks prior to pregnancy until day 4 of pregnancy (Domaracky et al. 2007).

Large doses (over 1 g) of the compound thymol may cause abortion (Sollman 1948). In the 1970s, a combination of thymol, potassium iodide, soap, and astringents was applied as a topical irritant to produce abortion. This practice was considered high risk, and a number of maternal deaths were associated with the use of this combination (Gillespie 1973).

No information on the safety of thyme during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered thyme essential oil in rats is reported as 2.48 and 4.7 g/kg (Opdyke 1974; Skramlik 1959).

In mice orally administered doses of 0.5 to 3 g/kg of a concentrated thyme extract (equivalent to 4.3 to 25.8 g/kg thyme), a decrease in locomotor activity and modest slowing of the respiratory system were observed (Qureshi et al. 1991).

Short-Term Toxicity

No significant adverse effects, including differences in weight gain, were observed in piglets administered a diet of 1% dried thyme (duration of feeding not specified in English language abstract) (Jugl-Chizzola et al. 2005).

Subchronic Toxicity

In mice administered 100 mg/kg of a concentrated thyme extract (equivalent to 900 mg/kg thyme) daily for 3 months, an increase in liver and testes weight was noted, but no spermatotoxic effects were observed (Qureshi et al. 1991).

Chronic Toxicity

No significant adverse effects were observed in rats fed a diet supplemented with thyme essential oil (providing 42.5 mg/kg daily) for 28 months (Youdim and Deans 1999).

Genotoxicity

No mutagenic effects of thyme essential oil or the compound thymol were observed in the Ames mutagenicity assay (Azizan and Blevins 1995; Zani et al. 1991). Similarly, no mutagenic effects of thyme essential oil were observed in the *Bacillus subtilis rec* assay (Zani et al. 1991).

Tilia spp. — Tiliaceae

Tilia cordata **Mill.**
SCN: linden
OCN: small-leaf lime tree

Tilia platyphyllos **Scop.**
SCN: linden
OCN: large-leaf linden; tilia

Tilia vulgaris **Hayne**
SCN: linden
Syn: *Tilia europaea* L.
OCN: European linden; European lime tree; tilia
Part: flower, leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
An allergic reaction to linden pollen in a linden flower tea was reported and confirmed by patch testing (De Smet 1993; Faillers 1989). A case of contact urticaria after use of a linden-containing shampoo was reported and confirmed by patch testing (Picardo et al. 1988).

Pharmacological Considerations
Coadministration of linden flower tea and iron-fortified bread reduced absorption of the iron (Hurrell et al. 1999).

Pregnancy and Lactation
No information on the safety of linden in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
Contact urticaria was reported after use of a shampoo containing a linden extract. Patch testing with linden elicited a positive reaction (Picardo et al. 1988).

An allergic reaction to linden pollen in a linden flower tea was reported in a woman allergic to multiple types of tree pollen. The reaction was confirmed by patch testing (De Smet 1993; Faillers 1989).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Coadministration of iron-fortified bread and linden flower tea reduced absorption of the iron by 52%, an effect that was less pronounced than that of black tea, cocoa, or teas made with peppermint, European pennyroyal, or European vervain, but greater than the inhibitory effect of chamomile tea (Hurrell et al. 1999).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of linden during pregnancy or lactation was identified.

V. Toxicity Studies

Genotoxicity

No mutagenic activity of an aqueous extract of linden was observed in the somatic mutation and recombination test (SMART) in *Drosophila melanogaster* (Romero-Jimenez et al. 2005).

Tinospora cordifolia (Willd.) Miers — Menispermaceae

SCN: Indian tinospora
AN: *guduchi*

Part: leaf, root, starch, stem

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Kapoor 2001; Nayampalli et al. 1988; Remington and Wood 1918); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Animal studies have demonstrated that Indian tinospora may modify glucose regulation (Grover et al. 2000; Kar et al. 2003; Panchabhai et al. 2008; Stanely et al. 2000, 2003). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Pregnancy and Lactation

No information on the safety of Indian tinospora in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy male volunteers orally administered 50 to 1520 mg of an aqueous extract of Indian tinospora daily for 4 days, an increase in urine volume was observed. A reduction in serum potassium and chloride levels was observed in one of the ten study subjects. No significant changes in liver enzyme levels or other serum biochemical parameters were observed. All study subjects noted an increase in appetite (Nayampalli et al. 1988).

Animal Pharmacological Studies

A dose-dependent reduction in blood glucose levels was observed in diabetic rats orally administered 25, 50, or 100 mg/kg of an alcohol extract of Indian tinospora daily for 42 days (Stanely et al. 2003). Similarly, a reduction in blood glucose levels was observed in diabetic rats orally administered 2.5 or 5 g/kg of an aqueous extract of Indian tinospora daily for 42 days (Stanely et al. 2000). In diabetic mice and rats, a reduction in blood sugar levels was observed after administration of 400 mg/kg of an aqueous extract of Indian tinospora daily for 15 weeks (Grover et al. 2000). A reduction in blood glucose levels was observed in diabetic rats orally administered a single dose of 250 mg/kg of an ethanol extract of Indian tinospora (Kar et al. 2003).

In male rats orally administered 100 mg/animal of a methanolic extract of Indian tinospora daily for 60 days, decreases in the weight of testis, epididymis, seminal vesicle, and ventral prostate were observed. Sperm motility and density were significantly reduced, resulting in complete infertility (Gupta and Sharma 2003).

In mice with cyclophosphamide-induced immunosuppression, oral administration of 100 mg/kg of an aqueous extract of Indian tinospora resulted in an increase in the number of leukocytes. Indian tinospora was found to inhibit cyclophosphamide-induced immunosuppression (Manjrekar et al. 2000).

In rats orally administered 100 mg/kg of an aqueous extract of Indian tinospora, an increase in urine output was observed. As compared to 2.5 mg/kg of hydrochlorothiazide, Indian tinospora produced a greater loss of sodium and potassium (Nayampalli et al. 1988).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of Indian tinospora during pregnancy or lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

In mice orally administered 400 mg/kg of the freeze-dried powder of an aqueous extract of Indian tinospora daily for 60 days, no significant changes were observed in white and red blood cell counts, hemoglobin, mean corpuscular volume, or hematocrit (Grover et al. 2000).

Genotoxicity

No genotoxicity of an aqueous extract of Indian tinospora was observed in any of four different genotoxicity tests. Tests included the Ames test with *Salmonella typhimurium* strains TA97a, TA98, TA100, TA102, and TA1535 at concentrations of extract up to 5000 µg/plate, the chromosome aberration assay, the rodent bone marrow micronucleus assay, and the comet assay. For the bone marrow micronucleus and comet assays, mice were orally administered the extract for 7 days at doses of 150, 200, and 250 mg/kg (Chandrasekaran et al. 2009).

Tribulus terrestris L. — Zygophyllaceae

SCN: tribulus
AN: *gokshura*
PN: *bai ji li* (fruit)

OCN: puncturevine caltrop; small caltrops
Part: fruit

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Chen and Chen 2004; Wright et al. 2007); *see* Appendix 2.

Editors' Note

Tribulus fruit contains trace amounts of β-carboline alkaloids (e.g., harmane, harmine, and harmol). Analyses indicate that the content of these alkaloids in the fruit is approximately 0.000045% (Tsuchiya et al. 1999).

Adverse Events and Side Effects

Topical application of tribulus fruit has been associated with rash and itching (Chen and Chen 2004).

Allergic reactions, including anaphylactic reactions, to tribulus fruit have been reported (Bensky et al. 2004; Chen and Chen 2004).

Pharmacological Considerations

A 20-day human study on a tribulus product reported to contain both tribulus fruit extract and tribulus aerial parts showed a temporary increase in testosterone levels after the first 10 days (Milašius et al. 2010).

Pregnancy and Lactation

A text on traditional Chinese medicine indicates that tribulus fruit should be used with caution during pregnancy (Bensky et al. 2004), while another text indicates that it may cause miscarriage and should not be used during pregnancy (Chen and Chen 2004). Due to the above cautions listed in the traditional Chinese literature, use should be discontinued at the time of attempted conception.

No information on the safety of tribulus fruit during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of tribulus fruit (standard dose is a decoction of 6–15 g) has been associated with dizziness, weakness, drowsiness, nausea, vomiting, heart palpitations, increased breathing and heart rates, and blue coloration of the skin. In severe cases of overdose, pulmonary edema and respiratory failure have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered 625 mg of a tribulus product three times daily for 20 days, an increase in blood levels of testosterone was observed after the first 10 days of treatment, but the levels returned to near baseline at the end of the study (Milašius et al. 2010). The tested product is reported to contain a proprietary blend of tribulus fruit extract and tribulus aerial parts (Optimum Nutrition 2012).

Animal Pharmacological Studies

Hypotensive activity of tribulus was observed in rats with high blood pressure orally administered 10 mg/kg of a freeze-dried aqueous extract of tribulus fruit daily for 4 weeks (Sharifi et al. 2003).

Diuretic activity of tribulus was observed in rats orally administered 5 g/kg of an aqueous extract of a combination of tribulus fruit and leaf (Al-Ali et al. 2003).

In Vitro Pharmacological Studies

A methanol extract of tribulus fruit was shown to inhibit prostaglandin E_2 production (Hong et al. 2002).

IV. Pregnancy and Lactation

A text on traditional Chinese medicine indicates that tribulus fruit should be used with caution during pregnancy (Bensky et al. 2004), while another text indicates that it may cause miscarriage and should not be used during pregnancy (Chen and Chen 2004).

No information on the safety of tribulus fruit during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Tribulus terrestris L.

Zygophyllaceae

SCN: tribulus
AN: *gokshura*
OCN: puncturevine caltrop; small caltrops
Part: above-ground parts

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Animals grazing on live tribulus stems and leaves sometimes develop a condition known as geeldikkop, which includes photosensitivity, jaundice, and facial edema (Aslani et al. 2004; Smith and Henderson 1991). No such activity has been associated with human consumption of tribulus.

Pharmacological Considerations

Human studies on the effect of tribulus on reproductive hormone levels (testosterone and related hormones) have provided conflicting results. One study reported to contain both tribulus fruit extract and tribulus aerial parts showed a temporary increase in testosterone levels after the first 10 days (Milašius et al. 2010). Other human studies on products derived just from the aerial parts have shown no effects on hormone levels (Neychev and Mitev 2005; Saudan et al. 2008). Animal studies of tribulus aerial parts have also provided conflicting results (Gauthaman and Ganesan 2008; Martino-Andrade et al. 2010).

A 20-day human study on a tribulus product reported to contain both tribulus fruit extract and tribulus aerial parts showed a temporary increase in testosterone levels after the first 10 days (Milašius et al. 2010; Optimum Nutrition 2012).

Pregnancy and Lactation

Tribulus is reported to sometimes be used to promote fertility (Romm 2010).

No information on the safety of tribulus aboveground parts during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A case of gynecomastia was reported in a 21-year-old male, identified as a "keen weight-trainer," who was reportedly taking tribulus. The specific product used, dose, and duration of use were not specified, though the product was described as derived from the aboveground parts of the plant. Testing revealed decreased levels of follicle-stimulating hormone, luteinizing hormone, and testosterone that returned to normal after cessation of the product. The man had a history of atypical ductal hyperplasia, although it was not clear from the case report whether the hyperplasia began during or prior to tribulus use (Jameel et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy young men orally administered 10 or 20 mg/kg daily for 4 weeks of a tribulus extract standardized to 60% steroid saponins, no changes in serum hormone levels were observed, including testosterone, androstenedione, or luteinizing hormone (Neychev and Mitev 2005).

Conversely, oral administration in thirty-two 20- to 22-year-old athletes of 625 mg of a tribulus product three times daily for 20 days measured an increase in blood levels of testosterone after the first 10 days of treatment; the levels returned to near baseline at the end of the study (Milašius et al. 2010). The tested product is reported to contain a proprietary blend of tribulus fruit extract and tribulus aerial parts (Optimum Nutrition 2012).

No changes in urinary levels of hormones were observed in two healthy female volunteers who ingested 500 mg of a tribulus extract three times daily for 2 days (Saudan et al. 2008).

Animal Pharmacological Studies

In baboons and rhesus monkeys intravenously administered single doses of 7.5, 15, or 30 mg/kg of an extract of the aerial parts of tribulus, a brief rise in testosterone level 15 minutes after administration was observed, followed by a return to near but above control levels. A similar pattern was observed for dihydrotestosterone, whereas serum levels of dehydroepiandrosterone sulfate were generally higher than control. For all three hormones, the effects of the tribulus extract were not dose dependent. No significant changes in blood pressure occurred. Electrocardiograms indicated no significant changes in heart rate or beat (Gauthaman and Ganesan 2008).

In rats and rabbits orally administered 2.5, 5, or 10 mg/kg of the same tribulus extract daily for 8 weeks, an increase in dihydrotestosterone was observed in rabbits at the 5 and 10 mg/kg doses. In castrated rats orally administered 5.5 mg/kg of the tribulus extract daily for 8 weeks, an increase in serum testosterone levels was observed (Gauthaman and Ganesan 2008).

No changes in levels of androgen hormones were observed in male rats or ovariectomized female rats orally administered 11, 42, or 110 mg/kg of a dry ethanolic extract of tribulus aerial parts daily for 28 days, or in castrated male rats for 7 days (Martino-Andrade et al. 2010).

Sheep and goats grazing on live tribulus plants sometimes develop a condition known as geeldikkop, which includes photosensitivity, jaundice, and facial edema. Biliary obstruction occurs due to accumulation of microliths high in sulfur and lower in sodium and potassium (Aslani et al. 2004; Smith and Henderson 1991).

Diuretic activity of tribulus was observed in rats orally administered 5 g/kg of an aqueous extract of a combination of tribulus fruit and leaf (Al-Ali et al. 2003).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In sheep fed hay containing tribulus herb on days 103–112 of pregnancy, no adverse effects on maternal health or pregnancy outcome were observed. The incidences of fetal breathing movements were lower in the tribulus group as compared to the control group, and the breathing movements did not show the typical day-night variation (Walker et al. 1992).

No information on the safety of tribulus aboveground parts during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

T

Trichosanthes kirilowii Maxim.

Cucurbitaceae

SCN: trichosanthes
PN: *gua lou* (fruit); *gua lou pi* (fruit rind); *gua lou ren* (seed)

OCN: Chinese cucumber; Mongolian snakegourd
Part: fruit, fruit rind, seed

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Occasional cases of mild diarrhea and gastric discomfort have been reported in persons taking tablets of trichosanthes fruit (Chang and But 1986).

Unprocessed trichosanthes seed may cause nausea. The seed is typically processed by dry-frying to reduce the frequency of nausea (Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of trichosanthes in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

Trifolium pratense L.

Fabaceae

SCN: red clover

Part: flower, herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Red clover herb and flower contain approximately 0.17% isoflavones (DerMarderosian and Beutler 2005), with the herb generally containing a higher percent isoflavone content than the flower (Booth et al. 2006). Commercially available red clover products include products with this normal percentage of isoflavones and those modified to contain up to 100% isoflavones. Products with modified concentrations of selected compounds may be expected to have different physiological effects than traditional preparations of the herb. Information on both red clover and red clover derived isoflavones is provided in this entry.

Adverse Events and Side Effects

Adverse events reported in clinical trials of red clover products were minor and similar in the placebo and red clover groups (Coon et al. 2007; Lethaby et al. 2007; Low Dog 2005; Nelson et al. 2006).

Pharmacological Considerations

Red clover is commonly cited as a potential anticoagulant due to the presence of coumarins and confusion between coumarins and the anticoagulant drug coumadin (sometimes referred to as coumarin) (Abebe 2002; Booth et al. 2004; Fugh-Berman and Kronenberg 2001; Heck et al. 2000). However, a screening of red clover for 17 naturally occurring coumarins identified 5 coumarin compounds in red clover, 1 with anticoagulant activity, 1 with procoagulant activity, and 3 with no activity reported (Booth et al. 2004). No changes in bleeding or blood clotting were observed in women after 30 days of red clover supplementation (Booth et al. 2004).

Red clover contains isoflavones, compounds that are structurally similar to the human hormone estradiol and capable of binding to estrogen receptors (Umland et al. 2000). Some studies have indicated that red clover isoflavones have a greater affinity for the estrogen receptor β (found primarily in bone, brain, heart, and vascular system) than estrogen receptor α (found primarily in uterus, breast, ovaries, and adrenal glands) (Beck et al. 2005; Dornstauder et al. 2001).

In human studies, conflicting data on the estrogenic activity of red clover have been reported. Some studies have shown no effect on endometrial thickness or vaginal cytology, indicating a lack of estrogenic activity (Baber et al. 1999; Clifton-Bligh et al. 2001; Powles et al. 2008), whereas others showed a decrease in (Imhof et al. 2006) or no effect on (Hale et al. 2001) endometrial thickness or a significant improvement in vaginal cytology (Hidalgo et al. 2005).

Pregnancy and Lactation

Limited information on the safety of red clover in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a meta-analysis of clinical trials of monopreparations containing red clover isoflavones, the reviewers noted that there was no apparent evidence of adverse events during short-term use of red clover, but long-term studies were lacking. Doses of products in the meta-analysis ranged from 40 to 82 mg daily (Coon et al. 2007).

A second meta-analysis, including six placebo-controlled red clover isoflavone trials, with doses ranging from 40 to 80 mg daily, and study duration from 12 to 16 weeks, concluded that adverse events did not differ between isoflavone and placebo groups, although the events were not well characterized in several trials. Gastrointestinal symptoms were generally the most common adverse events in both isoflavone and placebo groups (Nelson et al. 2006).

A systematic review of phytoestrogens for vasomotor menopausal symptoms, including seven studies on red clover-derived isoflavone extracts, concluded that phytoestrogen products do not appear to have an estrogen agonistic effect on the endometrium when given for up to 1 year. The authors noted that the long-term endometrial safety of high doses of phytoestrogen supplements has not been fully established (Lethaby et al. 2007). Similarly, a review of red clover clinical trials indicated that no adverse effects have been reported, but that the question of safety

in hormone-sensitive tissue is important, especially when considering high doses over long periods of time (Low Dog 2005).

Case Reports of Adverse Events

No case reports of adverse reactions were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No increase in mammographic breast density and no significant effects were observed on estradiol, follicle-stimulating hormone, or luteinizing hormone levels in a trial of women, ages 49 to 65, taking 44 mg red clover-derived isoflavones daily for 1 year (Atkinson et al. 2004).

No significant differences in vaginal cytology, endometrial thickness, serum estradiol, follicle-stimulating hormone, or sex hormone-binding globulin were observed after administration of 40 mg daily of a red clover-based isoflavone extract (Baber et al. 1999). No increase in endometrial thickness was observed after administration of doses up to 85.5 mg daily of a red clover isoflavone preparation for 6 months (Clifton-Bligh et al. 2001). A decrease in endometrial thickness and increase in plasma testosterone levels were observed in postmenopausal women after administration of 80 mg red clover-derived isoflavones daily for 90 days (Imhof et al. 2006). After administration of 50 g daily of a red clover-derived isoflavone extract to perimenopausal women for 3 months, no evidence of an antiproliferative effect in the Ki-67 proliferative marker of endometrial biopsies was found (Hale et al. 2001). In postmenopausal women administered 80 mg daily of a red clover isoflavone supplement for 90 days, significant improvement in all vaginal cytology indices (karyopyknotic index, cornification index, maturation index), as compared to placebo, was observed (Hidalgo et al. 2005).

In women aged 35 to 70 with at least one first-degree relative with breast cancer, administration of 40 mg of red clover isoflavones daily for 3 years did not result in any significant differences in breast density, endometrial thickness, serum cholesterol, follicle-stimulating hormone levels, or bone mineral density, as compared to placebo. In postmenopausal women, some differences in bone marker levels were seen between active and placebo groups at 6 and 12 months (Powles et al. 2008).

In a noncontrolled clinical study of postmenopausal women administered 80 mg daily of red clover-derived isoflavone extract for 6 months, some changes in endometrial activity but no changes in endometrial thickness were observed. Of the 32 study participants, 6 presented with vaginal bleeding and 3 presented with endometrial alteration as compared to the initial exams, 2 developed endometrial cell proliferation, and 1 developed endometrial hyperplasia (Wolff et al. 2006).

A review of studies on red clover and soy-derived isoflavones concluded that 2 mg/kg was a safe daily dose of isoflavones for most populations (Barnes 2003). A second review of studies on red clover and soy-derived isoflavones indicated that 40–50 mg of isoflavones is recommended as the daily dose. This recommendation was based on the daily intake of isoflavones in a traditional Japanese diet (Beck et al. 2005).

No change in prothrombin time or INR time was found after administration of 400 mg daily of red clover extract to postmenopausal women for 30 days (Booth et al. 2004).

Animal Pharmacological Studies

In ovariectomized rats administered 250, 500, or 750 mg daily of a red clover extract (15% isoflavones) for 21 days, a dose-dependent increase in uterine weight and differentiated vaginal cells were observed at the two higher doses, but no stimulation of cell proliferation was observed in the mammary glands. Neither antiestrogenic nor additive estrogenic properties were observed in any of the tissues studied (Burdette et al. 2002).

In ovariectomized rats administered 20 or 40 mg daily of red clover-derived total isoflavones for 14 weeks, treatment with isoflavones significantly increased bone mineral content, mechanical strength of the tibia, femoral weight, and femoral density and prevented the rise of serum alkaline phosphatase levels. In addition, the treatment with isoflavones significantly reduced the number of osteoclasts compared with the ovariectomized control rats (Occhiuto et al. 2007).

In Vitro Pharmacological Studies

In vitro assays of red clover extracts in endometrial cells and MCF-7 (estrogen receptor-positive) breast cancer cells, differential estrogenic activity was observed in the endometrial cells, whereas nondifferential activity was observed in the MCF-7 cells, indicating the significance of the type of bioassay used to determine the estrogenic activity of red clover (Booth et al. 2006).

An extract of a red clover isoflavone preparation increased MCF-7 breast cancer cell proliferation rates (Bodinet and Freudenstein 2004). A standardized red clover isoflavone extract (9% isoflavones by dry weight) showed an affinity for both estrogen receptor (ER) α and β with a significantly stronger affinity for the ERβ receptor in a yeast two-plasmid system (Dornstauder et al. 2001).

A red clover-derived extract of 30% isoflavone aglycones was shown to bind to mu- and delta-opiate receptors in Chinese hamster ovaries (Nissan et al. 2007).

An ethanolic extract of a commercial red clover preparation inhibited the drug-metabolizing isoenzyme CYP3A4 in a fluorometric microtiter plate assay (Budzinski et al. 2000). Genistein and daidzein, metabolites of the predominant red clover isoflavones biochanin A and formononetin, were shown to inhibit the enzyme CYP1B1 (Roberts et al. 2004).

IV. Pregnancy and Lactation

In a study of amniotic fluid samples in women between weeks 15 and 23 of pregnancy, isoflavonoids were detected in 92% of samples. The isoflavonoids daidzein, genistein, formononetin, biochanin A, and coumestrol were detected (Foster et al. 2002).

No information was identified on the safety of red clover use during lactation.

V. Toxicity Studies

Short-Term Toxicity

In ovariectomized sheep, feeding with 3.5 kg daily of red clover silage for 14 days as the sole source of food (81–95 mg/kg daily total phytoestrogens) resulted in increased plasma concentrations of T_3 and T_4 and increased thyroid follicle size as compared to sheep fed hay (Madej et al. 2002).

Trigonella foenum-graecum L. — Fabaceae

SCN: fenugreek
AN: *methi; methika*
PN: *hu lu ba* (seed)
Part: seed

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Friedman et al. 2007; Kassem et al. 2006; Petropoulos 2002; Sethi et al. 1990).

Other Precautions

None known.

Drug and Supplement Interactions

Other drugs should be taken 1 h our prior to consumption of fenugreek or several hours after consumption, as the mucilage present in fenugreek may slow the absorption of orally administered drugs (Leung and Foster 1996; Petropoulos 2002).

Notice

Mucilages (17–22%) (Leung and Foster 1996; Petropoulos 2002); *see* Appendix 3.

Editors' Notes

The classifications and concerns for this herb are based on relatively higher doses used for therapeutic purposes in contrast to lower amounts generally used in cooking, and have not been associated with its use as a spice.

Fenugreek contains steroidal saponins (0.28–2.2%), notably diosgenin and yamogenin (Taylor et al. 2002; Petropoulos 2002).

Adverse Events and Side Effects

Infants administered large quantities of fenugreek, either directly or through maternal ingestion, have been observed to smell of maple syrup, which has led in some cases to false suspicion of maple syrup urine disease, a metabolic disease characterized by maple-scented urine (Bartley et al. 1981; Korman et al. 2001; Sewell et al. 1999). The compound sotolon is responsible for the maple scent (Korman et al. 2001).

Allergic reactions to fenugreek have been reported (Patil et al. 1997).

Pharmacological Considerations

Human studies have demonstrated that fenugreek may modify glucose regulation (Bordia et al. 1997; Gupta et al. 2001; Madar et al. 1988; Ragurham et al. 1994; Sharma and Raghuram 1990; Sharma et al. 1990). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Purported anticoagulant activity of fenugreek has been widely cited due to the presence of coumarins (Abebe 2002; Czigle et al. 2006; Heck et al. 2000; Holbrook et al. 2005; Izzo 2005; Izzo et al. 2005; Juurlink 2007; Myers 2002). This effect has not been observed in human or animal studies at standard therapeutic doses (Bordia et al. 1997; Sharma et al. 1996), although some anticoagulant effects have been observed in rats at doses many times the standard therapeutic dose (Bordia et al. 1997; Hannan et al. 2003; Xue et al. 2007).

Pregnancy and Lactation

Information on the use of fenugreek during pregnancy is conflicting. No adverse effects were observed in rats fed fenugreek as 5 or 20% of the diet (Mital and Gopaldas 1986), while some adverse effects on the fetus were observed in rabbits fed fenugreek as 30% of the diet (Kassem et al. 2006). Some antifertility or abortifacient properties have been attributed to fenugreek in surveys of herbs used in India as antifertility and abortifacient agents (Casey 1960; Nath et al. 1997), although no such activities are recognized in the traditional Chinese medicine literature (Bensky et al. 2004; Chen and Chen 2004). Fenugreek contains steroidal saponins (0.28–2.2%), notably diosgenin and yamogenin (Friedman et al. 2007; Petropoulos 2002).

Fenugreek has traditionally been used in a number of cultures to stimulate milk production in lactating women (Tiran 2003).

Also see Adverse Events and Side Effects for this entry.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of interactions in patients taking fenugreek monopreparations were identified. One case of

increased INR was reported in a patient taking warfarin, boldo (*Peumus boldus*), and fenugreek (Lambert and Cormier 2001). This case report and the coumarin content of fenugreek seed have led to frequent warnings regarding concomitant use of warfarin and fenugreek (Abebe 2002; Czigle et al. 2006; Heck et al. 2000; Holbrook et al. 2005; Izzo 2005; Izzo et al. 2005; Juurlink 2007; Myers 2002).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a systematic review of human studies on the effects of fenugreek seed powder and defatted seed powder in persons with diabetes mellitus, adverse events were listed as "not reported" in three studies, while no side effects were observed in a fourth study (Yeh et al. 2003).

Case Reports of Adverse Events

The scent of maple syrup has been observed from the skin and urine of several infants, in some cases leading to a false suspicion of maple syrup urine disease, a metabolic disease characterized by maple-scented urine. Two infants were administered teas containing fenugreek seed, and the mother of a third infant had ingested a fenugreek seed paste at the onset of labor (Bartley et al. 1981; Korman et al. 2001; Sewell et al. 1999). Persons consuming fenugreek sometimes have the characteristic odor of maple syrup due to the presence of the compound sotolon, an aromatic compound present in fenugreek that is used in the production of artificial maple syrup (Korman et al. 2001).

Two cases of allergic reaction to fenugreek have been reported. In the first case, inhalation of fenugreek seed powder resulted in rhinorrhea, wheezing, and fainting. In the second case, a patient with chronic asthma developed numbness of the head, facial angioedema, and wheezing after application of fenugreek paste to her scalp. Skin scratch tests indicated that both patients had a strong sensitivity to fenugreek and chickpeas (Patil et al. 1997).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Studies on the effects of fenugreek seed and defatted fenugreek seed have shown beneficial effects on blood sugar levels in persons with type 1 or 2 diabetes mellitus. Increases in glucose tolerance test (GTT) scores and serum clearance rates of glucose were observed in persons with type 2 diabetes controlled on glibenclamide and administered 25 g/day of fenugreek seed powder (added to the diet in the form of fiber) for 15 days (Ragurham et al. 1994). Improvements in fasting blood glucose (FBG), GTT, and 24-hour urinary glucose excretion test were observed in type 2 diabetes patients in a study in which 100 g/day of defatted fenugreek seed powder was administered for 10 days (Sharma and Raghuram 1990). In persons with type 2 diabetes, administration of 1 g daily of a hydroalcoholic extract of fenugreek seed or standard dietary discretion for 2 months resulted in a decrease in FBG in both the fenugreek and dietary controlled groups (Gupta et al. 2001). A review of several case series on the efficacy of fenugreek for glucose control in type 2 diabetes patients indicated that fenugreek may improve glucose control in this population (Basch et al. 2003). In healthy patients administered 5 g/day of fenugreek seed for 3 months, no effect on blood sugar was observed. In the same study, patients with mild cases of type 2 diabetes, however, experienced a significant reduction in postprandial glucose (PPG) and FBG, while in patients with severe diabetes only a slight reduction in PPG and FBG was observed (Bordia et al. 1997). A significant reduction in PPG was observed in type 2 diabetes patients administered a single 15 g dose of fenugreek seed soaked in water. A nonsignificant reduction in plasma insulin was also observed (Madar et al. 1988).

In patients with type 1 diabetes, decreases in 24-hour urine glucose levels, GTT scores, and fasting serum glucose were observed after administration of 100 g/day of fenugreek seed powder in meals (Sharma et al. 1990).

No changes in platelet aggregation, fibrinolytic activity, or fibrinogen were observed in patients with coronary artery disease administered 5 g /day of fenugreek for 3 months (Bordia et al. 1997). In type 2 diabetic persons administered diets containing 25 g fenugreek seed daily for 24 weeks, no changes in hematological parameters were observed (Sharma et al. 1996).

Fenugreek is reported as being rich in iron (6.5 mg/100 g) and has been promoted to prevent anemia (Gopaldas 1995), although a study of anemic preschool children correlated the consumption of fenugreek (part and doses unspecified) with an increased risk of anemia. The authors of the study indicated that the mucilage content of fenugreek inhibits iron absorption (Adish et al. 1999).

Animal Pharmacological Studies

Modification of glucose regulation has been observed in a number of studies of fenugreek preparations in rats and mice (Ajabnoor and Tilmisany 1988; Hannan et al. 2003, 2007; Khosla et al. 1995; Mohammad et al. 2006; Mondal et al. 2004; Puri et al. 2002; Raju et al. 2001; Vijayakumar et al. 2005; Xue et al. 2007; Zia et al. 2001).

No significant effect on platelet aggregation was found in type 2 model diabetic rats administered 1 g /kg daily of fenugreek soluble dietary fiber fraction for 28 days, although a tendency to lower aggregation was observed (Hannan et al. 2003). In diabetic rats orally administered fenugreek extract at doses of 0.44, 0.87, or 1.74 g/kg daily for 6 weeks, the plasma viscosity, whole blood viscosity of high and low shear rates, erythrocyte sedimentation rate, whole

blood reduction viscosity, and platelet conglutination were significantly reduced in diabetic rats treated with high and middle doses of fenugreek extract but not in those treated with the low dose of the extract (Xue et al. 2007).

Administration of a dried hydroalcoholic extract of fenugreek seed in male mice and rats at doses of 110 mg/kg for 15 days resulted in decreases in the serum triiodothyronine (T_3) level and T_3:T_4 ratio but caused an increase in serum thyroxine (T_4) level and body weight. The authors indicated that inhibition of T_4 to T_3 conversion was not peroxidation mediated and the inhibition in SOD activity could be the result of a decrease in the protein anabolic hormone, T_3 (Panda et al. 1999).

In Vitro Pharmacological Studies

In vitro studies were identified but omitted due to the availability of similar human and animal studies.

IV. Pregnancy and Lactation

Fenugreek was listed as one of nearly 300 reported antifertility plants identified in a review of the Ayurvedic literature (Casey 1960). Abortifacient activity was attributed to fenugreek, although reviewers of the research have noted that the definition of abortifacient was broad and included emmenagogues, ecbolics (uterine contractors), and "antimetabolites" (Mills and Bone 2005). A survey of plants used to promote abortion in northeastern India indicated that fenugreek seed was one of 14 plants commonly used; no information on efficacy was reported (Nath et al. 1997). Antifertility activity was observed in rats administered a petroleum extract of fenugreek at doses of 0.5 to 1.25 g/kg daily for days 1 to 10 of pregnancy (Adhikary et al. 1990).

In pregnant rats, intake of fenugreek seed as 5 or 20% of the diet produced no adverse effects on fertility or growth and development of the fetus (Mital and Gopaldas 1986). In pregnant rats orally administered 175 mg/kg fenugreek powder on days 1 to 10 of pregnancy, some increase in fetal abnormalities was observed (Sethi et al. 1990). Aqueous and alcoholic extracts of fenugreek produced a stimulating effect on isolated guinea pig uteri (Abdo and al-Kafawi 1969).

In male rabbits fed a diet of 30% fenugreek seed for 3 months, testis weight was reduced, and damage to the seminiferous tubules and interstitial tissues was observed. Plasma concentration of androgen hormones and sperm concentrations were halved in the treated animals. In female rabbits fed the same diet for 3 months prior to conception, a significant reduction in the number of developing fetuses was observed at 20 days of gestation. The circulating plasma progesterone concentrations at 10 and 20 days of gestation were significantly increased, with no significant effect on prebreeding estrogen levels. Histopathological changes were observed in endometrial glands (Kassem et al. 2006).

Fenugreek is considered a galactagogue and has been traditionally used by lactating women in Ayurvedic, traditional Chinese medicine, and Western medicine traditions (Tiran 2003). An increase in prolactin levels was observed in rats administered fenugreek during different phases of reproductive life, including during pregnancy and lactation. No adverse effects were reported in offspring of animals administered fenugreek (Basha et al. 1987).

Also see Case reports of adverse events for this entry.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered ethanol extract of fenugreek in rats is 500 mg/kg (Sharma et al. 1978). The LD_{50} of the compound trigonelline orally administered to rats is 5 g/kg (Mishkinsky et al. 1974).

No signs of toxicity or mortality were observed in mice orally administered acute doses of 2 g/kg debitterized fenugreek powder or rats orally administered 5 g/kg defatted fenugreek powder (Muralidhara et al. 1999).

Short-Term Toxicity

In chicks administered crude seed saponins of fenugreek at doses of 10 mg/kg intramuscularly, 50 mg/kg intraperitoneally, 50 mg/kg subcutaneously, or 500 mg/kg orally in drinking water daily for 21 days, reductions in body weight, pathological changes in the liver and kidneys, and varying degrees of hemorrhage in the thigh and breast were observed (Nakhla et al. 1991).

In rats orally administered fenugreek extract at doses of 1.0, 1.5, or 2.0 g/kg twice a week for 4 weeks, a necrotic effect on the liver and the kidney tissues was observed at all dose levels (Effraim et al. 1999).

Subchronic Toxicity

In rats fed a diet of 0, 1, 5, or 10% debitterized fenugreek powder daily for 90 days, no effects on food intake, growth, vital organ weights, liver biochemistry, or hematological parameters were observed (Muralidhara et al. 1999). Similarly, in rats fed diets of 0, 5, 10, or 20% fenugreek seed for 90 days, no significant differences in body weight, food intake, feed efficiency, hematological parameters, or liver function tests were observed between the fenugreek and control groups (Udayasekhara Rao et al. 1996).

Chronic Toxicity

In type 2 diabetic persons administered diets containing 25 g fenugreek seed daily for 24 weeks, no renal or hepatic toxicity or changes in hematological parameters were observed, although blood urea levels were seen to decrease after week 12 (Sharma et al. 1996).

Genotoxicity

No genotoxic effects of a fenugreek seed extract were observed in standard genotoxicity assays including the reverse mutation assay, mouse lymphoma forward mutation assay, and the mouse micronucleus assay (Flammang et al. 2004).

Trillium erectum L.

Liliaceae

SCN: bethroot
OCN: birth root; purple trillium; red trillium; wakerobin

Part: root

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Cook 1869; Foster and Johnson 2008; Wood and LaWall 1918).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Trillium may cause gastrointestinal irritation (McGuffin et al. 1997).

Pharmacological Considerations

None known.

Pregnancy and Lactation

Bethroot has been used to facilitate childbirth (Cook 1869; Foster and Johnson 2008; Wood and LaWall 1918). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of bethroot during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

Bethroot has been used to facilitate childbirth (Cook 1869; Foster and Johnson 2008; Wood and LaWall 1918).

No information on the safety of bethroot during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Turnera diffusa Willd. ex Schult. var. *diffusa*

Turneraceae

SCN: damiana

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Cyanogenic glycosides (0.26% tetraphyllin B) (Spencer and Seigler 1981) *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

Studies in animals have yielded conflicting results on the effects of damiana on glucose levels in healthy and diabetic animals, with one study indicating a r eduction in blood sugar and another study indicating no effect (Alarcon-Aguilar et al. 2002; Alarcon-Aguilara et al. 1998).

Pregnancy and Lactation

No information on the safety of damiana in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

After consumption of 8 oz of damiana extract, a person with a history of alcohol abuse experienced tetanus-like convulsions and sudden outbursts. Further details on this case are lacking (Kumar et al. 2005).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In healthy rabbits orally administered 4 ml/kg of a decoction of damiana, a reduction in peak blood glucose levels and a mild reduction in the area under the glucose tolerance curve was observed in the glucose tolerance test (Alarcon-Aguilara et al. 1998).

No significant hypoglycemic activity was observed in healthy or diabetic mice orally administered 500 mg/kg of a hydroethanolic extract of damiana (Alarcon-Aguilar et al. 2002).

In Vitro Pharmacological Studies

In a yeast estrogen screen assay, damiana exhibited estrogenic activity. In a tritiated-water release assay, a methanol extract of damiana dose-dependently inhibited aromatase (Zhao et al. 2008).

IV. Pregnancy and Lactation

No information on the safety of damiana during pregnancy or lactation was identified.

V. Toxicity Studies

Genotoxicity

No mutagenic activity of a hydroethanolic extract of damiana was observed in the Ames test for mutagenicity with *Salmonella typhimurium* strain TA98 with or without metabolic activation by S9 (Schimmer et al. 1994).

Tussilago farfara L.

Asteraceae

SCN: coltsfoot
PN: *kuan dong hua* (flower bud)

Part: flower bud

Quick Reference Summary

Safety Class: * 2b, 2c, 2d

Interaction Class: A

* Extracts of coltsfoot that have had the pyrrolizidine alkaloids removed (PA-free coltsfoot) are commercially available. Concerns regarding the internal use of coltsfoot products do not apply to PA-free products.

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Blumenthal et al. 1998; Wichtl 2004).

Not for use in excess of 6 weeks per year (Wichtl 2004).

Other Precautions

Use is cautioned in those with coughing of blood or pus and blood (Bensky et al. 2004).

Drug and Supplement Interactions

None known.

Notice

Pyrrolizidine alkaloids (0.004–0.03%, calculated as senkirkine) (Culvenor et al. 1976; De Smet 1992; Lebada et al. 2000; Wichtl 2004; Williamson 2003; Yu et al. 2005); *see* Appendix 1.

Editors' Notes

The American Herbal Products Association has established a trade requirement (AHPA 2011) that all products with botanical ingredients that contain toxic pyrrolizidine alkaloids, including coltsfoot flower bud, are not offered for sale for internal use and display the following cautionary label: "For external use only. Do not apply to broken or abraded skin. Do not use when nursing."

Coltsfoot flower buds of European origin are reported to contain a smaller amount of pyrrolizidine alkaloids than those of Chinese origin (De Smet 1992).

Tussilagone and isotussilagone are pyrrolizidine alkaloids that have a saturated necine ring and are thus not toxic. Senkirkine and senecionine, however, have shown hepatotoxic and/or carcinogenic effects (Wichtl 2004).

Adverse Events and Side Effects

A Chinese herbal reference text indicates that although no adverse reactions to coltsfoot are reported in the literature, long-term administration of the herb in high doses may present a risk of liver cancer (Bensky et al. 2004), presumably due to the presence of pyrrolizidine alkaloids.

Overdose of coltsfoot flower bud may cause restlessness, excitation, irritability, and increased respiration (Chen and Chen 2004).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of coltsfoot flower bud in pregnancy or lactation was identified (Hirono et al. 1979). Data from animal studies indicate that pyrrolizidine alkaloids can cross the placenta and may be transferred through breast milk to nursing infants (Cheeke 1988; Panter and James 1990; Schoental 1968). Based on this information, use during pregnancy or lactation is not recommended except under the supervision of a qualified healthcare practitioner.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of coltsfoot flower bud may cause restlessness, excitation, irritability, and increased respiration (Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

The compound tussilagone was found to be a potent cardiovascular and respiratory stimulant. In anesthetized dogs, cats, and rats administered the compound intravenously, tussilagone produced an instant and dose-dependent pressor effect similar to that of dopamine; however, no tachyphylaxis was observed (Li and Wang 1987, 1988).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of coltsfoot flower bud in pregnancy or lactation was identified. Data from animal studies indicate that pyrrolizidine alkaloids can cross the placenta and may be transferred through breast milk to nursing infants (Cheeke 1988; Panter and James 1990; Schoental 1968).

V. Toxicity Studies

Acute Toxicity

The LD_{50} values of different preparations of coltsfoot flower bud in mice are 124 g/kg after oral administration of a decoction, 112 g/kg after intraperitoneal administration of an alcohol extract, and 43 g/kg after intraperitoneal administration of an ether extract (Chen and Chen 2004). Overdose of the flower bud led to restlessness, excitation, mania, increased respiration, muscle stiffness, tremor, and muscle spasms (Chen and Chen 2004).

The LD_{50} of intravenously administered tussilagone in mice is 28.9 mg/kg (Li and Wang 1988). The LD_{50} of intraperitoneally administered senkirkine in rats is 220 mg/kg (Hirono et al. 1979).

Chronic Toxicity

In rats administered coltsfoot flower buds as 32% of the diet for 4 days then as 16% of the diet for 380 days, 8 of 12 rats developed hemangioendothelial sarcoma in the liver. Adverse effects were attributed to the compound senkirkine (Hirono et al. 1976).

In rats administered coltsfoot flower buds as 4 or 8% of the diet for 600 days, 1 of 10 rats in the 8% group developed hemangioendothelial sarcoma in the liver, and no tumors were observed in the 4% group (Hirono et al. 1976).

Genotoxicity

No increase in the number of structural chromosomal aberrations was observed in human lymphocytes treated with the compounds senkirkine and tussilagone at concentrations up to 1000 µ*M*. In contrast, heliotrine, a pyrrolizidine alkaloid used for comparison, induced chromosomal aberrations when tested at a concentration of 100 µ*M* (Kraus et al. 1985).

Tussilago farfara L.

Asteraceae

SCN: coltsfoot

Part: leaf

Quick Reference Summary

Safety Class: * 2b, 2c, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy or lactation except under the supervision of a qualified healthcare practitioner (Blumenthal et al. 1998; Wichtl 2004).

Not for use in excess of 6 weeks per year (Wichtl 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 1.5 to 6 g of fresh or dried leaf or its equivalent in finished preparations; daily consumption of unsaturated pyrrolizidine alkaloids must not exceed 10 µg for teas, or 1 µg for extracts or juice pressed from fresh leaves (Blumenthal et al. 1998; Wichtl 2004).

Notice

Pyrrolizidine alkaloids (0–0.007%, primarily senkirkine, with smaller amounts of senecionene and tussilagone and isotussilagone) (Bartkowski et al. 1997; Culvenor et al. 1976; De Smet 1992; Lebada et al. 2000; Miething and Steinbach 1990; Wichtl 2004); *see* Appendix 1.

* Extracts of coltsfoot that have had the pyrrolizidine alkaloids removed (PA-free coltsfoot) are commercially available. Concerns regarding the internal use of coltsfoot products do not apply to PA-free products.

Editors' Notes

The American Herbal Products Association maintains as a trade requirement that all products with botanical ingredients that contain toxic pyrrolizidine alkaloids, including coltsfoot leaf, are not offered for sale for internal use and display the following cautionary label: "For external use only. Do not apply to broken or abraded skin. Do not use when nursing."

Alone among plants containing unsaturated pyrrolizidine alkaloids, coltsfoot leaf is allowed for internal use by the German Commission E, with duration of use limited to 4 to 6 weeks per year (Wichtl 2004).

Tussilagone and isotussilagone are saturated pyrrolizidine alkaloids and are thus not toxic. Senkirkine and senecionine, however, are unsaturated and have shown hepatotoxic and carcinogenic effects (Wichtl 2004).

The leaves of coltsfoot, *Petasites,* and *Adenostyles* are similar in appearance. Cases of poisoning have been reported in persons who accidentally ingested plants of those species instead of coltsfoot (Roulet et al. 1988; Sperl et al. 1995).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of coltsfoot leaf in pregnancy or lactation was identified. Data from animal studies indicate that pyrrolizidine alkaloids can cross the placenta and may be transferred through breast milk to nursing infants (Cheeke 1988; Panter and James 1990; Schoental 1968). Based on this information, use during pregnancy or lactation is not recommended except under the supervision of a qualified healthcare practitioner.

T

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Two cases of adverse effects have been reported from the use of plants mistaken for coltsfoot. In both cases, the plants used (*Petasites hybridus* and *Adenostyles alliariae*) contained pyrrolizidine alkaloids (Roulet et al. 1988; Sperl et al. 1995).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Coltsfoot demonstrated a weak sensitizing capacity in a guinea pig sensitization test (Zeller et al. 1985).

The compound tussilagone was found to be a potent cardiovascular and respiratory stimulant. In anesthetized dogs, cats, and rats administered the compound intravenously, tussilagone produced an instant and dose-dependent pressor effect similar to that of dopamine; however, no tachyphylaxis has been observed (Li and Wang 1987, 1988).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of coltsfoot leaf in pregnancy or lactation was identified. Data from animal studies indicate that pyrrolizidine alkaloids can cross the placenta and may be transferred through breast milk to nursing infants (Cheeke 1988; Panter and James 1990; Schoental 1968).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intravenously administered tussilagone in mice is 28.9 mg/kg (Li and Wang 1988). The LD_{50} of intraperitoneally administered senkirkine in rats is 220 mg/kg.

Genotoxicity

No increase in the number of structural chromosomal aberrations was observed in human lymphocytes treated with the compounds senkirkine and tussilagone at concentrations up to 1000 µ*M*. In contrast, heliotrine, a pyrrolizidine alkaloid used for comparison, induced chromosomal aberrations when tested at a concentration of 100 µ*M* (Kraus et al. 1985).

Ulmus rubra Muhl. — Ulmaceae

SCN: slippery elm
Syn: *Ulmus fulva* Michx.

Part: bark

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Slippery elm should be taken with at least 250 ml (8 oz) of liquid.

Drug and Supplement Interactions

Other drugs should be taken 1 hour prior to or several hours after consumption of slippery elm, as the mucilage may slow the absorption of orally administered drugs (Brinker 1997; Evans 2002).

Notice

Mucilages (Brinker 1997; Evans 2002); *see* Appendix 3.

Adverse Events and Side Effects

Bladder stones have been reported in women after vaginal insertion of slippery elm bark in attempted abortions (Williams 1954). Such events would not occur during normal oral administration of slippery elm.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of slippery elm in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Two cases of bladder calculus have been reported in pregnant women who had vaginally administered pieces of slippery elm bark in an attempt to induce abortion. In both cases, the bark pieces had passed into the bladder and remained to form a stone while the pregnancy continued (Williams 1954). Such events would not occur during normal oral administration of slippery elm.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

See Adverse Events. No other information was identified on the safety of slippery elm in pregnancy or lactation.

V. Toxicity Studies

No information on the toxicity of slippery elm was identified.

Uncaria gambir (Hunter) Roxb. — Rubiaceae

SCN: gambir (dried extract of leaf and twig)
PN: *zong er cha*

OCN: brown cutch; pale catechu; white cutch
Part: leaf, twig

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Tannins (calculated as catechin, 30–35%) (Bradley 1992; Leung and Foster 1996; List and Hörhammer 1973); *see* Appendix 1.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of gambir in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

Intravenous administration of the compound gambirine at doses of 0.2 to 10.0 mg/kg caused a dose-related fall in both systolic and diastolic blood pressures as well as heart rate in rats. At all doses, gambirine showed a prompt onset of action; at doses over 5 mg/kg, marked persistence of hypotension accompanied by severe bradycardia was observed (Merlini et al. 1967; Mok et al. 1992).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the use of gambir during pregnancy or lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Uncaria tomentosa (Willd.) DC. — Rubiaceae

SCN: cat's claw
OCN: *uña de gato*

Part: root bark, stem bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use during pregnancy or in women attempting to become pregnant except under the supervision of a qualified healthcare practitioner (De Feo 1992; Jones 1995; Reinhard 1999; Valerio and Gonzales 2005).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Although some researchers have reported that two chemotypes (chemically distinct types of a plant species) of cat's claw are recognized, one containing pentacyclic oxindole alkaloids (POA) and the other containing tetracyclic oxindole alkaloids (TOA) (Laus et al. 1997), others have indicated that such chemotypes are not typically found and that cat's claw contains both POAs and TOAs (Taylor 2002a, 2002b).

Adverse Events and Side Effects

In a trial of HIV patients taking a cat's claw extract high in POAs, a small number of cases of a mild erythrocytosis, constipation, loose stool, and aggravation of preexisting acne were reported (Immodal Pharmaka 1996).

One case of kidney failure was reported in a woman taking cat's claw (Hilepo et al. 1997).

Pharmacological Considerations

Several references have indicated a theoretical caution against the use of cat's claw in persons with autoimmune diseases (Jones 1995; Immodal Pharmaka 1996; Mills and Bone 2005). Jones lists a wide range of contraindications, e.g., patients undergoing skin grafts and organ transplants; hemophiliacs prescribed fresh blood plasma; simultaneous administration of certain vaccines, hormone therapies, thymus extracts, and insulin; and children under 3 years of age (Jones 1995). Concerns regarding cat's claw use in these conditions are theoretical, and definitive data supporting or refuting these concerns are lacking. One clinical trial of a high-POA content cat's claw extract in persons with rheumatoid arthritis (an inflammatory autoimmune disorder) demonstrated a reduction in joint pain and swelling (Mur et al. 2002).

The anticancer effect of cat's claw can be partly attributed to the pentacyclic oxindole alkaloids that are likely accompanied by tetracyclic oxindole alkaloids, some of which are calcium channel blockers and hence hypotensive (Bacher et al. 2006; Garcia Prado et al. 2007; Laus et al. 1997; Reinhard 1999; Shi et al. 2003).

Pregnancy and Lactation

Traditional usage of cat's claw as a contraceptive suggests that the herb should be avoided in pregnancy and in women attempting to conceive (De Feo 1992; Jones 1995).

No information on the safety of cat's claw during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

In a year-long clinical trial examining the effects of a high-POA content cat's claw extract in patients with active rheumatoid arthritis undergoing sulfasalazine or hydroxychloroquine treatment, a reduction in the number of painful and swollen joints was observed (Mur et al. 2002).

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a trial with HIV patients taking a cat's claw extract high in pentacyclic oxindole alkaloids, a small number of cases of a mild erythrocytosis, constipation, loose stool, and aggravation of preexisting acne were reported. In rare cases, a rise in uric acid values due to increased cellular immune system activity was also reported (Immodal Pharmaka 1996).

Case Reports of Adverse Events

Acute renal failure was reported in a 35-year-old woman with systemic lupus erythematosus taking four capsules daily of a cat's claw product (species unspecified) for an unspecified length of time. The woman was also taking other medications including prednisone, atenolol, metolazone, furosemide, and nifedipine. Biochemical parameters for renal function were reported to return to normal after cessation of the cat's claw product (Hilepo et al. 1997).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

One in vitro study indicated that cat's claw inhibited the drug-metabolizing isoenzyme CYP3A4, although the applicability of this finding to human use is unknown (Budzinski et al. 2000).

IV. Pregnancy and Lactation

In pregnant mice administered 0.125 to 0.5 mg/ml of cat's claw extract in drinking water for 72 hours after copulation, a significant number of abnormal embryos were observed (Iziga et al. 1998).

Oral administration of 6.25 mg/kg of a tannin-free extract of cat's claw to female mice prevented pregnancy (Keplinger 1982).

High doses of cat's claw preparations have traditionally been used as contraceptives in South America (De Feo 1992; Jones 1995).

No information on the safety of cat's claw during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered aqueous cat's claw extract in rats is greater than 8 g/kg. The LD_{50} of a cat's claw powder is over 2 g/kg and that of an aqueous/ethanolic extract (4% alkaloids) is over 5 g/kg (Sheng et al. 1999). The LD_{50} of an orally administered freeze-dried aqueous cat's claw root extract in mice is greater than 16 g/kg (Kynoch and Lloyd 1975). The LD_{50} of an intraperitoneally administered aqueous cat's claw extract in mice is greater than 2 g/kg (Kreutzkamp 1984).

Short-Term Toxicity

In rats orally administered 1000 mg/kg daily of an aqueous cat's claw extract (0.75% oxindole alkaloids) for 28 days, increases in lymphocytes and kidney weight and a decrease in neutrophil granulocytes were observed (Svendsen and Skydsgaard 1986).

In rats orally administered 5 to 80 mg/kg of an aqueous extract of cat's claw for 56 days, an increase in white blood cells was observed at the highest dose, and no significant signs of toxicity were noted (Sheng et al. 2000).

Cytotoxicity

No cytotoxicity of cat's claw extract at doses up to 100 mg/ml was observed in Chinese hamster ovary cells using the tetrazolium assay and a Microtox bacterial test in vitro (Santa Maria et al. 1997).

Genotoxicity

No genotoxicity of an aqueous extract of cat's claw was observed in a somatic mutation and recombination test in *Drosophila melanogaster* (Romero-Jimenez et al. 2005).

Mutagenicity

No mutagenicity of cat's claw was observed in tests on *Salmonella typhimurium* strains with or without metabolic activation at doses up to 100 µg/plate (Rizzi et al. 1993).

Urtica dioica L. ssp. *dioica*

Urticaceae

SCN: stinging nettle
OCN: nettle

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Fresh stinging nettle leaf causes skin irritation and should be used with care. Uncooked fresh nettle should not be consumed.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Kirchhoff 1983; Tahri et al. 2000); *see* Appendix 2.

Adverse Events and Side Effects

The stems and leaves of stinging nettle have tiny tubular hairs (trichomes) that contain biologically active substances including histamine, acetylcholine, serotonin, leukotrienes, oxalic acid, and tartaric acid (Collier and Chesher 1956; Czarnetzki et al. 1990; Emmelin and Feldberg 1947; Fu et al. 2006; Ganora 2009; Oliver et al. 1991). On contact with skin, hollow hairs on live plants will release their contents into skin, causing a range of cutaneous reactions, from mild to severe burning and stinging sensation and irritant and allergic contact dermatitis (Lovell 1993; Oliver et al. 1991). Although properly dried whole or chopped stinging nettle may cause skin irritation due to preservation of some of the contents of the stinging trichomes, no such reaction occurs after contact with or ingestion of powdered, extracted, or cooked stinging nettle leaf.

A review of clinical trials of stinging nettle leaf preparations indicated that no serious adverse events were reported in any of the trials. Mild gastrointestinal discomfort or allergic reaction was reported in 1.2 to 2.7% of the 10,368 participants (ESCOP 2003).

Pharmacological Considerations

Animal studies have demonstrated that stinging nettle leaf may modify glucose regulation (Bnouham et al. 2003; Farzami et al. 2003; Swanston-Flatt et al. 1989). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Several in vitro studies have shown some inhibition of platelet aggregation (El Haouari et al. 2006; Goun et al. 2002; Mekhfi et al. 2004; Sajid et al. 1991), although one study showed enhancement of platelet aggregation by phospholipids isolated from stinging nettle (Antonopoulou et al. 1996). The relevance of these in vitro studies to human use is unknown.

Pregnancy and Lactation

Limited information on the safety of stinging nettle leaf in pregnancy or lactation was identified in the scientific and traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical studies of stinging nettle leaf indicated that no serious adverse events were reported in five clinical studies with a total of 10,368 participants taking 670 mg twice daily of a dried hydroethanolic extract (~9.7 g dried leaf) for 3 to 52 weeks. Minor gastrointestinal upset or allergic reaction occurred in 1.2 to 2.7% of participants (ESCOP 2003). Abdominal gas was reported in 3 of 19 patients administered 50 g daily of a stinging nettle leaf puree for 14 days (Chrubasik et al. 1997).

Case Reports of Adverse Events

Immediate and delayed hypersensitivity to stinging nettle leaf was reported in a boy who fell into a stinging nettle patch. Urticaria was present for 12 hours, and a fine vesicular rash erupted at 48 hours (Edwards 1992). A case of severe tongue edema was reported in a woman who placed a fresh leaf of dwarf stinging nettle (*U. urens*) on her tongue (Caliskaner et al. 2004).

Gynecomastia was reported in a man who had consumed two cups of stinging nettle tea (part unspecified) daily for 1 month prior to the onset of the gynecomastia. Testing ruled out malnutrition, hepatic and renal diseases, gonadal insufficiency, testicular tumors, paraneoplastic syndromes, and hyperthyroidism. No medications were noted, and the gynecomastia had resolved by a follow-up visit, 2 months after cessation of stinging nettle consumption (Sahin et al. 2007).

In a woman with an 18-month history of galactorrhea (inappropriate secretion of breast milk), tests revealed a complicated breast cyst, very high levels of estrogen (543 pg/ml), and low levels of follicle-stimulating hormone (1.2 mIU/ml) and luteinizing hormone (1.7 mIU/ml). The

woman had begun drinking stinging nettle tea (dose and part used unspecified) daily for 1 month prior to seeing the reporting physician (17 months after diagnosis of galactorrhea). After cessation of stinging nettle, estrogen levels decreased (45 pg/ml) and follicle-stimulating hormone (5.9 mIU/ml) and luteinizing hormone (2.9 mIU) levels increased (Sahin et al. 2007).

Atropine poisoning was reported in a woman who had consumed a tea labeled as stinging nettle. On analysis, the tea was shown to be contaminated with belladonna (*Atropa belladonna*), a plant known to contain atropine (Scholz et al. 1980).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

An open study in patients with myocardial or chronic venous insufficiency indicated that administration of 45 ml stinging nettle leaf juice daily caused an increase in the volume of urine of patients. The effect was more pronounced in patients with chronic venous insufficiency, with a 24% increase in urine volume in this group as compared to a 9% increase in the myocardial insufficiency group (Kirchhoff 1983).

Animal Pharmacological Studies

In healthy rats, 250 mg/kg of an aqueous extract of stinging nettle leaf showed a strong glucose-lowering effect when administered 30 minutes before an oral glucose tolerance test. In contrast, no hypoglycemic effects were observed in alloxan-induced diabetic rats (Bnouham et al. 2003). An increase in serum insulin and a decrease in blood sugar levels were reported in rats intraperitoneally administered an extract of stinging nettle leaf. The results showed that the blood sugar-lowering effect of the extract was due to the enhancement of insulin secretion by pancreatic islets (Farzami et al. 2003). No effect on blood sugar in healthy rats was seen after administration of nettle aqueous extract as the sole source of drinking water or nettle leaf as 6.25% of the diet for 28 days. In diabetic rats, ingestion of the same diet was reported to adversely affect glucose homeostasis (Swanston-Flatt et al. 1989).

Hypotensive, diuretic, and natriuretic activity of an aqueous extract of stinging nettle leaf was observed in anesthetized rats intravenously administered a continuous perfusion at a rate of 4 mg/kg per hour or 24 mg/kg per hour for 1.25 h. The decrease in arterial blood pressure was reduced by 15% at the lower dose and 38% at the higher dose (Tahri et al. 2000). A rapid but transient blood pressure decrease of 37% in rats was observed after intravenous administration of an aqueous extract of 25 mg/kg stinging nettle leaf (Lasheras 1986). In cats, administration of 26.6 mg/kg produced a hypotensive effect and bradycardia that was not compensated by administration of adrenaline (Broncano 1983).

A fraction of a water-methanol extract of stinging nettle leaf produced a marked decrease of inotropic activity in spontaneously beating atria of guinea pigs as well as marked but transient hypotensive activity on the blood pressure of anesthetized rats (Testai et al. 2002).

Case reports indicate that horses exposed to stinging nettle leaf sometimes become distressed and develop ataxia and muscle weakness. Such incidents of stinging nettle exposure are often accompanied by the characteristic nettle rash (Bathe 1994; Conwell and Findlay 2008).

In Vitro Pharmacological Studies

Weak inhibition of thrombin- and ADP-induced platelet aggregation was observed, with IC_{50} values of an aqueous extract of the aerial parts of stinging nettle of 15.5 mg/ml for thrombin- and 12.8 mg/ml for ADP-induced aggregation (Mekhfi et al. 2004). Lipophilic extracts of stinging nettle leaf had more potent antithrombotic effects than aqueous extracts (El Haouari et al. 2006), although a methanolic extract had weak antithrombotic activity (Goun et al. 2002). Inhibition of adrenaline-induced platelet aggregation was observed with an IC_{50} of 2.17 mg/ml of a stinging nettle extract (Sajid et al. 1991). Conversely, a phospholipid from stinging nettle produced a dose-dependent induction of platelet aggregation (Antonopoulou et al. 1996).

IV. Pregnancy and Lactation

No adverse effects on implantation were observed in rats orally administered 250 mg/kg of an ethanol extract of stinging nettle leaf (Sharma et al. 1983). No other information on the safety of stinging nettle leaf during pregnancy or lactation was identified, although stinging nettle leaf is traditionally used as a nutritional supplement for pregnant and lactating women (Yarnell 1998).

V. Toxicity Studies

Acute Toxicity

Minimal toxicity of an ethanol extract of stinging nettle was observed in mice and rats orally and intraperitoneally administered doses up to 2 g/kg (dried herb equivalent) (Tita et al. 1993), although other studies have shown LD_{50} values lower than that dose. The LD_{50} of orally administered stinging nettle leaf infusion in rats is reported as 1.31 g/kg (Baraibar et al. 1983). In mice intraperitoneally administered extracts of stinging nettle, the LD_{50} of the leaf infusion is reported as 1.92 g/kg (Baraibar et al. 1983), 3.5 g/kg (Bnouham et al. 2003), and 3.625 g/kg (Lasheras 1986), whereas the decoction has an LD_{50} value of 1.72 g/kg (Baraibar et al. 1983).

Genotoxicity

No mutagenic activity of saline, aqueous, or chloroform extracts of the aerial parts of stinging nettle was observed in *Salmonella typhimurium* strains TA98 or TA100 with or without metabolic activation (Basaran et al. 1996). The same

extracts showed some activity in the comet assay, although the relevance of results of that test to humans is difficult to determine (Basaran et al. 1996). Weak genotoxic activity, similar to that of the flavonoids rutin and quercetin, of a stinging nettle aqueous extract was observed in the *Drosophila* wing somatic mutation and recombination test (Graf et al. 1994).

Urtica dioica L. ssp. *dioica* — Urticaceae

SCN: stinging nettle
OCN: nettle

Part: root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

A review of 15 clinical studies, with a total of over 16,000 participants, indicated that stinging nettle root was generally well tolerated with no serious adverse events reported (ESCOP 2003).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of stinging nettle root in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of 15 clinical studies of stinging nettle root, with a total of over 16,000 participants, indicated that no serious adverse events were reported in any of the studies. Daily doses taken by participants were up to 756 mg of hydroalcoholic dry native extract for up to 6 months, although several studies included doses of 300 mg daily for 24 months. Adverse events reported in the studies were primarily mild gastrointestinal upset, with fewer than 5% of participants experiencing such events (ESCOP 2003). In a study of stinging nettle root extract, adverse events deemed probably or possibly related to treatment occurred in approximately 1% of the 1319 participants (Kaldewey 1995).

Case Reports of Adverse Events

No case reports of adverse events related to stinging nettle root were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of stinging nettle root in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered stinging nettle root extract in rats could not be determined at doses up to 30 g/kg (Chrubasik et al. 2007).

Genotoxicity

No mutagenic activity of a stinging nettle root extract was observed in the Ames mutagenicity test with

Salmonella typhimurium strains TA98 and TA100 at concentrations of extract up to 5000 µg/plate (de Meester and Leonard 1988).

Cytotoxicity

No effects on cell viability were observed in mouse white blood cells (splenocytes and peritoneal macrophages) treated with an aqueous extract of stinging nettle root (Harput et al. 2005).

Literature Cited

Usnea barbata (L.) F.H. Wigg.

Usneaceae

SCN: usnea
OCN: usnea lichen; old man's beard

Part: lichen

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Most safety concerns reported for usnea are based on studies of the compound usnic acid, which is present at a concentration of 1 to 3% (Cansaran et al. 2006, 2008; Cocchietto et al. 2002). Data regarding this isolated compound may not apply directly to products or extracts made from usnea.

Adverse Events and Side Effects

A case of liver failure was reported in a woman who had taken 500 mg of the compound usnic acid daily for 2 weeks (Durazo et al. 2004). Other cases of liver toxicity have been reported in persons taking different multiherbal products containing the compound usnic acid (Durazo et al. 2004; Favreau et al. 2002; Neff et al. 2004; Sanchez et al. 2006). Daily doses of usnic acid in the products used ranged from 300 to 1350 mg (Guo et al. 2008).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of usnea in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Fulminant liver failure requiring a transplant was reported in a 28-year-old woman who had taken 500 mg of the compound usnic acid daily for 2 weeks, followed by a 2-week break, and then again for 4 days. The woman had not taken any other drugs or supplements, aside from two doses of a weight-loss product that contained albumin, oligopeptides, gelatin, cellulose, and magnesium 3 weeks prior to the onset of symptoms (Durazo et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Usnic acid was tested for activity with the drug-metabolizing isoenzymes CYP1A2, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, and CYP3A4/5. Results suggested that the oxidative metabolism of usnic acid was mainly mediated by CYP1A2. Usnic acid was a weak inhibitor of CYP2D6, a potent inhibitor of CYP2C19 and CYP2C9, and a less potent inhibitor of CYP2C8 and CYP2C18 (Foti et al. 2008).

In a study of usnic acid in isolated rat hepatocytes, treatment with 100 or 1000 μM usnic acid for 1 hour induced the release of hepatic transaminases (AST and ALT), decreased the content of reduced glutathione, and caused loss of cell membrane integrity. The hepatotoxin carbon tetrachloride and usnic acid exhibited similar cellular responses, suggesting that the compounds elicited activity via the same mechanisms (Pramyothin et al. 2004).

In mouse primary hepatocytes, treatment with 5 μM usnic acid for 16 hours resulted in 98% cell death that appeared to be associated with cell necrosis rather than apoptosis. Results indicated that usnic acid was associated with inhibition and uncoupling of the electron transport chain in mitochondria. Usnic acid triggered oxidative stress by increasing free radical generation, and the oxidative stress appears to be critical in usnic acid-induced hepatotoxicity (Han et al. 2004).

IV. Pregnancy and Lactation

No information on the safety of usnea in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of a hydroalcoholic extract of usnea in rats is 22.53 g/kg after intraperitoneal administration, 7.43 g/kg after intravenous administration, and could not be determined at doses up to 32 g/kg after oral administration (Dobrescu et al. 1993).

In male rats intraperitoneally administered 50 or 200 mg/kg of the compound usnic acid daily for 5 days, swelling of the liver mitochondria and endoplasmic reticulum were observed by electron microscopy. Serum transaminase activity was unchanged (Pramyothin et al. 2004).

In rats orally administered single doses of 500, 1000, or 2000 mg/kg of the compound usnic acid, no signs of toxicity were observed at doses up to 1000 mg/kg, while unspecified "toxic effects" were observed at the 2000 mg/kg dose (Odabasoglu et al. 2006).

Short-Term Toxicity

In mice and rats orally administered 5, 30, 100, or 200 mg/kg of the compound usnic acid daily for 14 days, liver toxicity was observed at doses of 100 mg/kg or higher (Guo et al. 2008).

In mice intraperitoneally administered 15 mg/kg of usnic acid daily for 15 days, elevated levels of serum transaminase activity and extensive liver necrosis were observed. No signs of toxicity in other organs, such as the kidney or spleen, were detected. A similar pattern of toxicity was revealed in tumor-bearing mice (da Silva Santos et al. 2006; Ribeiro-Costa et al. 2004).

In sheep fed diets containing usnic acid at doses of 323 to 776 mg/kg daily for up to 9 days, lethargy and anorexia, and in some cases death, were observed. The estimated median toxic dose was between 485 and 647 mg/kg. Serum lactate dehydrogenase, aspartate aminotransferase, and creatine kinase were elevated at those doses. Complete postmortem examination revealed that pathological changes in the sheep occurred exclusively in skeletal muscles (Dailey et al. 2008). A review of usnic acid toxicology noted that the skeletal muscle toxicity observed in sheep is in sharp contrast to findings in mice, rats, and humans, in which the liver is considered to be the most vulnerable organ to usnic acid (Guo et al. 2008).

A reduction in weight gain was observed in female guinea pigs with tuberculosis subcutaneously administered 20 mg/animal of usnic acid daily for 6 days. No apparent organ-specific toxicities in the liver, spleen, or lung were observed (Marshak and Kuschner 1950).

Genotoxicity

In the Ames test for mutagenicity with *Salmonella typhimurium* strains TA98 and TA100, no mutagenic activity of the compound usnic acid was observed in either strain without or with activation by S9 (Shibamoto and Wei 1984).

No genotoxic activity of the compounds (+)-usnic acid and (–)-usnic acid was observed in the cytokinesis-blocked micronucleus assay with lymphocytes from two healthy male donors (Koparal et al. 2006).

Vaccinium myrtillus L. — Ericaceae

SCN: bilberry
OCN: European blueberry; huckleberry; whortleberry

Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Bilberry fruit is traditionally consumed as a food (Upton 2001).

Adverse Events and Side Effects

A systematic review of clinical trials of bilberry or anthocyanosides of bilberry indicated that no significant adverse events were reported in any of the trials (Canter and Ernst 2004).

A postmarketing survey of persons taking bilberry fruit extract indicated that respondents reported adverse events involving the gastrointestinal tract, skin, or nervous system, although no causal association between bilberry and the symptoms could be established (Eandi 1987).

Pharmacological Considerations

A study on the use of bilberry fruit extract prior to surgery showed reduced bleeding during surgery (Gentile 1987). One ex vivo human study, one animal study, and two in vitro studies indicated that bilberry fruit may reduce blood coagulation (Gomez-Serranillos et al. 1983; Morazzoni and Magistretti 1990; Pulliero et al. 1989; Zaragoza et al. 1985).

Pregnancy and Lactation

A limited number of human studies of bilberry fruit extract used during pregnancy have not shown any adverse effects on mother or fetus (Eandi 1987; Grismondi 1980; Pourrat et al. 1967; Zaragoza et al. 1985). No information was identified on the safety of bilberry fruit or leaf during lactation, although traditional consumption as a food suggests that no adverse effects are expected from bilberry fruit (Upton 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of placebo-controlled studies on anthocyanosides of bilberry fruit indicated that no adverse effects were reported in any of the clinical trials on bilberry extracts (Canter and Ernst 2004). In a postmarketing survey of persons taking bilberry fruit extract, 94 of the 2295 survey respondents noted side effects, mostly related to the gastrointestinal, skin, or nervous system. Due to the nature of the survey, a causal association between bilberry and the symptoms could not be established (Eandi 1987).

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

After oral administration of bilberry fruit extract (173 mg daily) to healthy volunteers, platelet aggregation was inhibited in blood samples tested ex vivo after 30 days of bilberry administration and was further inhibited after 60 days of consumption (Pulliero et al. 1989). In contrast, preoperative treatment with bilberry fruit standardized extract (160–320 mg daily) in patients undergoing ear, nose, or throat surgery significantly reduced the incidence and severity of intraoperative and postoperative bleeding and hemorrhagic complications (Gentile 1987). One older study reported that bilberry anthocyanins had a tendency to reduce hemorrhagic retinopathy due to anticoagulant therapy (Scharrer and Ober 1981).

Animal Pharmacological Studies

A bilberry fruit extract high in anthocyanosides administered to rats in single oral doses from 2.5 to 400 mg/kg significantly increased bleeding time at doses of 5 mg/kg or more (Morazzoni and Magistretti 1990).

In Vitro Pharmacological Studies

Two in vitro studies of bilberry fruit anthocyanosides indicated that inhibition of platelet aggregation by bilberry was greater than that of aspirin (Gomez-Serranillos et al. 1983; Zaragoza et al. 1985).

IV. Pregnancy and Lactation

No treatment-related adverse events were reported in a study of pregnant women taking a standardized bilberry fruit extract (320 mg anthocyanins daily) for 60 to 90 days, starting in the sixth month of pregnancy (Grismondi 1980), nor in pregnant women taking a standardized bilberry fruit extract (160–320 mg daily) for 90 days (Teglio et al. 1987).

A standardized bilberry fruit extract demonstrated no adverse effects on fertility in rats (Eandi 1987). Administration of anthocyanins or standardized bilberry fruit extracts did not produce any teratogenic activity in a single generation of rats or in three generations of rats and rabbits (Eandi 1987; Pourrat et al. 1967).

No information on the safety of bilberry fruit during lactation was identified. Based on the traditional safe consumption of bilberry fruit as a food, no adverse effects are expected (Upton 2001).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered standardized bilberry fruit extract in rats is 2.4 g/kg, and 0.24 g/kg for intravenously administered extract. No lethal dose could be determined for orally administered standardized extract at doses up to 20 g/kg in rats (Pourrat et al. 1967). In mice, the LD_{50} of intraperitoneally administered standardized bilberry fruit extract is 4.1 g/kg, and 0.84 g/kg for intravenously administered extract. No lethal dose could be determined for an orally administered standardized extract at doses up to 25 g/kg in mice (Pourrat et al. 1967). Other acute toxicity studies indicated that no signs of toxicity were observed for orally administered bilberry fruit extract at doses over 2 g/kg in mice and rats and over 3 g/kg in dogs. A darkening of urine and feces was noted in the animals (Eandi 1987).

Short-Term Toxicity

No toxic effects were observed in guinea pigs administered bilberry fruit extract at doses up to 43 mg/kg daily for 2 weeks, nor in rats fed the same dose for 6 weeks (Pourrat et al. 1967).

Similarly, no toxic effects were observed in rats administered up to 36 mg/kg bilberry fruit extract intravenously every day for 4 weeks or in dogs administered 12 mg/kg bilberry extract intravenously every day for 13 weeks, although dark blue pigmentation of urine, skin, eyes, and sometimes liver, kidneys, and ovaries was observed in the rats and dogs (Eandi 1987).

Chronic Toxicity

No changes in urinary, hematological, gross, or microscopic parameters were observed after oral administration of standardized bilberry fruit extract in rats at doses of 125 to 500 mg/kg daily nor in dogs administered 80 to 320 mg/kg daily for 6 months (Eandi 1987).

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

Blueberry fruit is traditionally consumed as a food (McGee 2004; Rombauer et al. 1997).

Adverse Events

No adverse events were reported in recent clinical trials of blueberry fruit (Hiraishi et al. 1995; Kay and Holub 2002; Pedersen et al. 2000).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information was identified on the safety of blueberry fruit during pregnancy or lactation, although traditional consumption as a food suggests that no adverse effects are expected.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

OCN: small cranberry
Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Note

The relatively small number of adverse events reported to date in comparison to the widespread consumption of cranberry juice as a beverage (USDA 2007) provides an indication of the relative low risk of adverse effects.

Adverse Events and Side Effects

Single cases of high levels of potassium, metabolic acidosis, and kidney stones have been reported in persons consuming cranberry juice (Garcia-Calatayud et al. 2002; Terris et al. 2001; Thomson and Perry 2001). The relationship between cranberry juice and those events has not been determined.

Pharmacological Considerations

Although several case reports have indicated a concern for a potential interaction between cranberry juice and warfarin (CSM 2003; Grant 2004; Rindone and Murphy 2006; Suvarna et al. 2003), human clinical trials have indicated no interaction at amounts up to 480 ml (~2 cups) daily (Ansell et al. 2009; Li et al. 2006; Lilja et al. 2007; Mellen et al. 2010). A review of clinical trials and published and unpublished case reports indicated that there is limited evidence to support an interaction between cranberry juice and warfarin (Zikria et al. 2010). A study with cranberry juice concentrate indicated a possible interaction with warfarin (Abdul et al. 2008).

Human studies have provided conflicting data on the association of cranberry extract consumption with calcium oxalate stone formation (Brinkley et al. 1981; Gettman et al. 2005; Kahn et al. 1967; Leahy et al. 2001; Light et al. 1973; Massey et al. 1993; Terris et al. 2001).

Pregnancy and Lactation

No information was identified on the safety of cranberry during pregnancy or lactation, although traditional consumption as a food and beverage suggests that no adverse effects are expected.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

Two studies in patients stable on warfarin indicated no significant changes in prothrombin time or INR (INR, or international normalized ratio, is a system used to report the results of blood coagulation tests, with elevated INR indicating a long blood clotting time) after administration of 250 or 480 ml of cranberry juice daily for 7 or 14 days (Li et al. 2006; Mellen et al. 2010). In another study of patients stable on warfarin, ingestion of 240 ml cranberry juice daily for 2 weeks resulted in a mild increase in INR in 8 of 30 patients. The mean INR level was increased only on the 12th day of treatment. Cranberry juice had no effect on plasma levels of warfarin (Ansell et al. 2009).

In a study of cranberry juice (200 ml daily) and warfarin in healthy volunteers, no clinically significant effects of cranberry juice on warfarin metabolism were observed after 10 days of treatment (Lilja et al. 2007).

Increased INR was observed in healthy volunteers orally administered 1000 mg cranberry juice concentrate (equivalent to 57 g of cranberries) daily, before or after single doses of 25 mg warfarin. Plasma levels of warfarin were unchanged (Abdul et al. 2008).

A study of cranberry juice (240 ml) and cyclosporine indicated that a single dose of cranberry juice had no effect on cyclosporine metabolism, whereas a single dose of a citrus fruit juice (pomelo) had a significant effect (Grenier et al. 2006).

Consumption of cranberry juice (100–150 ml daily) for 7 weeks was reported to interfere with urinary dipstick tests for glucose and hemoglobin (Kilbourn 1987).

Case Reports of Suspected Drug or Supplement Interactions

Several detailed cases of possible interactions between cranberry juice and warfarin have been reported in the literature. In all cases, the patients had elevated INR levels. In two cases, the patients were in poor health and consumed almost nothing except cranberry juice for approximately 2 weeks (Griffiths et al. 2008; Suvarna et al. 2003). In other cases, the patients were drinking approximately 700 or 2000 ml daily of cranberry juice, and INR levels returned to normal after cessation of cranberry (Grant 2004; Rindone and Murphy 2006). One case of elevated INR was in a patient who had been consuming turkey sandwiches with 113 g of cranberry sauce daily during the week following the Thanksgiving holiday (Mergenhagen and Sherman 2008). Between 1999 and 2003, five cases of increased INR due to possible interactions between cranberry and warfarin, including one reported death, were reported to the British Committee on the Safety of Medicines. Details of the cases were not published (CSM 2003).

In a systematic review of interactions between warfarin and selected foods, the interaction potential for cranberry was ranked as "possible" on a scale that included the rankings of "highly probable, probable, possible, and highly improbable" (Holbrook et al. 2005). A review of case reports and clinical trial data on the potential interaction between cranberry and warfarin concluded that the available information does not support a clinically relevant interaction, but that patients taking warfarin should be cautioned about the potential interaction (Pham and Pham 2007). A third review on cranberry and warfarin suggested that large amounts of cranberry juice may adversely affect patients on warfarin, while small amounts of juice are not expected to cause an interaction (Aston et al. 2006).

Animal Trials of Drug or Supplement Interactions

No relevant animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A review of clinical trials on cranberry juice indicated a high dropout rate for many of the trials, although no significant adverse events were reported in the trials reviewed (Jepson et al. 2007).

Case Reports of Adverse Events

One case of hyperkalemia was reported in a man who consumed 2 liters of cranberry juice daily for several days. The man was on other medications and had a history of traumatic injury and urinary problems (Thomson and Perry 2001).

One case of intoxication was reported in a 4-month-old infant fed 180 ml of cranberry juice. Symptoms of intoxication included diarrhea, hyperglycemia, and metabolic acidosis (Garcia-Calatayud et al. 2002).

One case of kidney stones was reported in a man who had been taking cranberry concentrate tablets for 6 months. The man had passed two kidney stones 6 years prior (Terris et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a clinical trial in healthy volunteers, no effects of cranberry juice (200 ml daily for 10 days or 2 doses of 240 ml) were observed on the drug-metabolizing isoenzymes cytochrome P450 CYP2C9, CYP1A2, or CYP3A4 (Greenblatt et al. 2006; Lilja et al. 2007).

Cranberry concentrate tablets taken for 7 days were shown in one study to significantly increase urinary oxalate levels and urinary calcium, phosphate, and sodium along with magnesium and potassium, both inhibitors of urinary stone formation (Terris et al. 2001). The study has been criticized for methodological flaws such as failing to measure

oxalate content of the studied tablets and not assessing dietary intake of calcium and vitamin C, contributors to urinary oxalates (Leahy et al. 2001).

A single dose of 500 ml cranberry juice had no effect on urinary oxalate secretion but significantly increased mean urinary calcium levels (Brinkley et al. 1981). A significant increase in urinary calcium excretion was observed in a small study after consumption of 2 pints of cranberry juice (Kahn et al. 1967). Consumption of 2 pints daily of cranberry juice for 1 month reduced urinary ionized calcium by 50% (Light et al. 1973). A study on dietary intake and urinary excretion of oxalates indicated that cranberry juice had no effect on oxalate excretion (Massey et al. 1993).

In a study of cranberry juice (1 liter daily for 7 days) on urinary tract stone formation risk in normal subjects and in subjects with a history of calcium oxalate stone formation, significant increases in urinary calcium and oxalate levels and a decrease in urinary pH were observed. These results suggest that cranberry juice may increase the risk of calcium oxalate and uric acid stone formation but reduce the risk of brushite stone formation (Gettman et al. 2005).

In patients with a history of struvite kidney stones, consumption of 2 pints of cranberry juice daily for 9 years resulted in no recurrence in 60% of participants, no increase in stone size in 32%, and new stone formation or an increase in stone size in 6%. The study did not include a control group (Zinsser et al. 1968).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

An in vitro trial of cranberry juice on human liver and rat small intestine microsomes demonstrated that cranberry juice significantly inhibited the activity of human and rat drug-metabolizing cytochrome P450 isoenzyme CYP3A (Uesawa and Mohri 2006).

IV. Pregnancy and Lactation

No information on the safety of cranberry fruit during pregnancy or lactation was identified. Based on the traditional safe consumption of cranberry as a food, no adverse effects are expected (Mills and Bone 2005; Upton 2002).

V. Toxicity Studies

No toxicity studies on cranberry were identified.

Part: rhizome, root

Quick Reference Summary

Safety Class: 1
Interaction Class: B

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

Caution is advised during use of barbiturates, benzodiazepines, and other sedative drugs, as valerian has been speculated to potentiate the effects of some sedatives (Brinker 2001).

Editors' Note

Although reports of toxicity of compounds called valepotriates have been published, such reports are not considered to be clinically relevant, as valepotriates are absorbed poorly and degrade quickly into less toxic metabolites (Bradley 1992; Leung and Foster 1996).

Adverse Events and Side Effects

A systematic review of valerian clinical trials indicated that adverse events in valerian groups were reported as diarrhea in one study and headache and gastrointestinal disturbance in another study. In the remaining studies reviewed, adverse events were either similar to placebo or were not observed (Bent et al. 2006).

Cases of liver-associated adverse effects have been reported for 2 women taking products that apparently contained standardized valerian extracts in the U.S. (Cohen and

del Toro 2008) and Greece (Vassiliadis et al. 2009) and one other in France who used valerian as a tea (Mennecier et al. 1999). The identity of the valerian ingredient was not verified in any of these three reports. Each case resolved after the ingested product was discontinued. The authors of the U.S. event expressed their belief "that this represents a case of valerian-associated hepatotoxicity," while acknowledging that, "there is no specific diagnostic test to confirm that valerian was the cause of the liver abnormalities in this case" (Cohen and del Toro 2008). The report from Greece concludes, "We believe that the present case represents an idiosyncratic reaction to valerian herb manifested as acute hepatitis" (Vassiliadis et al. 2009).

Pharmacological Considerations

Although some sources have indicated caution for the use of valerian while driving or operating heavy machinery (Bradley 1992), clinical trials have shown no impairment of cognitive or psychomotor performance at doses up to 1800 mg (Albrecht et al. 1995; Gutierrez et al. 2004; Hallam et al. 2003; Mills and Bone 2005).

Although valerian is generally recognized to have sedative and anxiolytic effects, clinical herbalists have reported that valerian may have stimulant effects, including agitation and increased heart rate, in a small percentage (~2–3%) of the population (Kuhn and Winston 2007).

Human studies have indicated a lack of effect of valerian on the CYP450 drug-metabolizing isoenzymes (Donovan et al. 2004; Gurley et al. 2005).

Pregnancy and Lactation

Animal studies and human case reports have indicated no adverse effects of relatively high doses (2.8 g/kg) of valerian in pregnancy (Czeizel et al. 1997; Tufik et al. 1994; Yao et al. 2003, 2007).

No information on the safety of valerian during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Coadministration of thiopental and 2 mg/kg of an aqueous alkaline extract of valerian to mice increased thiopental-induced sleeping time by a factor of 1.6. Administration of 200 mg/kg increased the thiopental-induced sleeping time by a factor of 7.6 (Leuschner et al. 1993).

In rats provided with drinking water containing 1% valerian tincture (estimated dose 200–250 mg/kg daily) for 12 weeks with intramuscular injection of haloperidol (equivalent to 1 mg/kg daily), an increase in lipid peroxidation levels and dichlorofluorescein-reactive species production was observed in the hepatic tissue. In the liver and kidneys, δ-aminolevulinate dehydratase activity was inhibited. Serum alanine aminotransferase (ALT) was elevated, as compared to controls, while aspartate aminotransferase (AST) levels were unchanged (Dalla Corte et al. 2008).

In rats administered isoflurane alone (5%), isoflurane plus valerian (30 mg/kg), isoflurane plus midazolam (2 mg/kg), or isoflurane plus valerian (30 mg/kg) and midazolam (2 mg/kg), no significant differences in emergence time from anesthesia were observed in the isoflurane plus valerian group. Delayed emergence was observed in the isoflurane plus midazolam group, with a greater delay observed in the group receiving isoflurane, valerian, and midazolam combination (Chaplin et al. 2007).

II. Adverse Events

Adverse Events Reported in Clinical Trials

In a systematic review of 16 clinical trials of valerian, one study was noted to have a significant increase in diarrhea in the valerian group as compared to the control group; in other studies, adverse events were either similar to placebo or were not observed (Bent et al. 2006). Adverse events reported in one clinical trial of valerian included headache and gastrointestinal disturbance (Seifert 1988).

Case Reports of Adverse Events

A case of hepatotoxicity was reported in a 27-year-old woman who had been taking 300 mg daily of valerian for the prior 3 months. Liver enzyme levels returned to normal within 4 weeks after valerian was discontinued (Cohen and del Toro 2008). Elevated liver enzyme levels were observed in a 50-year-old woman who had been taking 5 ml of valerian extract three times per week for 3 weeks along with 10 tablets (unclear as to whether this was a single or total dose) containing 125 mg valerian extract each. Liver enzyme levels returned to normal within 2 months after discontinuation of valerian use (Vassiliadis et al. 2009). A case of acute hepatitis was reported in a woman who had been drinking valerian tea for several weeks (Mennecier et al. 1999). The authors of the 2008 report express their "belie[f] that this represents a case of valerian-associated hepatotoxicity," while acknowledging that, "there is no specific diagnostic test to confirm

that valerian was the cause of the liver abnormalities in this case" (Cohen and del Toro 2008). The report from 2009 concludes, "We believe that the present case represents an idiosyncratic reaction to valerian herb manifested as acute hepatitis" (Vassiliadis et al. 2009).

In an attempted suicide, a woman took 20 g of valerian powder. Thirty minutes after ingestion, she experienced fatigue, abdominal pain, chest tightness, tremors, and lightheadedness. Her blood pressure was low, and her liver enzymes were normal. The woman was treated with activated charcoal, and all symptoms resolved within 24 hours (Willey et al. 1995). One case of chest and abdominal pain was reported in a woman who had intravenously administered herself a homemade aqueous extract of valerian (Wells 1995).

A case of heart failure with delirium was reported in a man with a significant history of cardiovascular disease who had taken valerian (500–2000 mg daily) for 5 years and was also taking numerous other medications and supplements (isosorbide dinitrate, digoxin, furosemide, benazepril, aspirin, lovastatin, ibuprofen, potassium, zinc, and vitamins). The reporting physicians stated that valerian is considered to exert a benzodiazepine-like action through the enhancement of γ-aminobutyric acid neurotransmission; they suggested that symptoms reported in this case were similar to benzodiazepine withdrawal symptoms and hypothesized that the cardiac failure was due to valerian withdrawal (Garges et al. 1998).

Delirium was reported in a woman who had taken valerian regularly for 6 months, along with St. John's wort and loperamide (Khawaja et al. 1999).

A syncopal episode and paranoia were reported in a woman who had been taking valerian for 2 years and prior to the episode consumed 3.5 liters of wine, over 1.25 liters of vodka, and an unspecified amount of ginkgo (Chen et al. 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In healthy volunteers orally administered 375 mg of valerian daily for 28 days, no significant changes in activity of the drug-metabolizing isoenzymes CYP1A2, CYP2D6, CYP2E1, or CYP3A4/5 were observed. Probe drugs used in the study were midazolam (CYP3A4/5), caffeine (CYP1A2), chlorzoxazone (CYP2E1), and debrisoquin (CYP2D6) (Gurley et al. 2005).

In healthy volunteers orally administered 1000 mg valerian nightly for 14 nights, mild, clinically insignificant inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed, with no changes in CYP2D6 activity (Donovan et al. 2004).

In studies of valerian (500–1800 mg) on cognitive and psychomotor performance, no significant effects were observed on any of the parameters measured, including reaction time and concentration (Albrecht et al. 1995; Gutierrez et al. 2004; Hallam et al. 2003).

Animal Pharmacological Studies

In rats and mice orally administered alcohol extracts of valerian at doses up to 1000 mg/kg, anxiolytic and antidepressant effects were observed without sedative or muscle relaxant activity (Hattesohl et al. 2008).

In Vitro Pharmacological Studies

In cultured human hepatocytes, an extract of valerian was found to weakly induce the drug-metabolizing isoenzyme CYP2C19, inhibit CYP3A4 and CYP2D6, and had no effect on CYP2E1 (Hellum et al. 2007, 2009).

In tests of hepatotoxicity, human hepatoma cells incubated in vitro with 2.0 and 20 mg/ml valerian (no further description provided) showed some cell death only at the higher concentration (Vo et al. 2003).

IV. Pregnancy and Lactation

In pregnant rats orally administered 2790 mg/kg (~65 times the human dose) of an ethanolic valerian extract on gestational days 1 to 8 or 8 to 15, no adverse effects on fetal development and no signs of maternal toxicity were observed (Yao et al. 2007).

Observations of pregnant rats fed varying concentrations of valerian on days 1 through 8 of pregnancy indicated that the highest nontoxic dose of valerian was 2.8 g/kg. Doses above 2.8 g/kg resulted in reduced placental weight but not reduced birth weight as compared to control (Yao et al. 2003).

In female rats fed a mixture of valepotriates, 6 to 24 mg/kg daily, for 30 days before pregnancy or on days 1 through 19 of pregnancy, no effects on fertility or signs of fetotoxicity were observed. An increased number of fetuses with slowed bone formation were observed with the higher doses (12 and 24 mg/kg) of valerian (Tufik et al. 1994).

No adverse effects of valerian were noted in three cases termed by the report authors as "intentional valerian overdose" (2 to 5 g) during weeks 3 to 10 of pregnancy (Czeizel et al. 1997). Authoritative sources list the standard dose of valerian as 1-5 g daily (ESCOP 2003; Wichtl 2004).

No information on the safety of valerian during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered valerian extract (9.5:1 ethanol extract) in mice is 3.3 g/kg (Rosecrans et al. 1961). The LD_{50} of orally administered valerian essential oil in rats is 15 g/kg (Skramlik 1959). The LD_{50} of orally administered Mexican valerian extract is 3.8 g/kg (Deciga-Campos et al. 2007).

Short-Term Toxicity

No remarkable adverse effects were observed in rats fed 600 mg/kg valerian extract daily for 30 days (Fehri et al. 1991).

Subchronic Toxicity

In rats intraperitoneally administered 400 to 600 mg/kg of valerian daily for 45 days, no significant changes in weight, blood, or urine were observed as compared to controls (Rosecrans et al. 1961).

In rats fed valerian at daily doses of 3.1 g/kg for 28 days or a single oral dose of 18.6 g/kg, no changes in bile flow, liver enzyme activity, or liver histology were observed (Vo et al. 2003).

Genotoxicity

In the Ames test for mutagenicity, a tincture of Mexican valerian did not show signs of mutagenicity, although a methanol-dichloromethane extract induced mutations in *S. typhimurium* TA100, in the presence of human liver S9 fractions, at the highest concentration tested (Deciga-Campos et al. 2007).

In a test for genotoxicity, valerian showed no mutagenic activity in fruit flies (*Drosophila melanogaster*) exposed to concentrations of valerian aqueous extract up to 55.2 mg/ml (Romero-Jimenez et al. 2005).

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of vanilla during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} of the compound vanillin is 3 g/kg in rabbits, 1.58 to 2.8 g/kg in rats, and 1.4 g/kg in guinea pigs

(Deichmann and Kitzmiller 1940; Hake and Rowe 1963; Hodge and Downs 1961; Jenner et al. 1964; Taylor et al. 1964).

The intravenous LD_{50} of the compound vanillin in dogs is 1.32 g/kg (Caujolle and Meynier 1954).

The intraperitoneal LD_{50} of the compound vanillin is 0.47 to 0.78 g/kg in mice, 1.19 g/kg in guinea pigs, and 1.16 g/kg in rats (Caujolle and Meynier 1954; Caujolle et al. 1956; NIOSH 1975).

No deaths and no macroscopic changes in livers were observed in rats orally administered 530 mg/kg of vanillin daily for 4 days (Taylor et al. 1964).

Subchronic Toxicity

No adverse effects were observed in rats orally administered 300 mg/kg of the compound vanillin twice weekly for 14 weeks (Deichmann and Kitzmiller 1940).

Rats fed diets containing doses of 20 mg/kg of vanillin for 18 weeks had no adverse effects, while doses of 64 mg/kg daily for 10 weeks resulted in growth depression and damage to the myocardium, liver, kidney, lung, spleen, and stomach (Deichmann and Kitzmiller 1940).

In rats fed diets containing vanillin for 13 weeks, growth depression and enlargement of the liver, kidney, and spleen were observed at the 5% dietary level (2500 mg/kg daily), while mild changes were observed at the 1% level (500 mg/kg daily), and no changes were observed at the 0.3% level (150 mg/kg daily) (Deichmann and Kitzmiller 1940).

In rats fed diets containing 3000, 10,000, or 50,000 ppm of the compound vanillin (dose equivalent of 150, 500, or 2500 mg/kg daily), no adverse effects were observed at the 3000 ppm level, while mild adverse effects were observed at 10,000 ppm and growth depression and enlargement of the liver, kidneys, and spleen were observed at 50,000 ppm (Hake and Rowe 1963).

Chronic Toxicity

No adverse effects on growth or hematology or macroscopic or microscopic changes in tissues were observed in rats fed diets containing the compound vanillin at 10,000 ppm (500 mg/kg daily) for 16 weeks, 1000 ppm (50 mg/kg daily) for 27 weeks, 20,000 or 50,000 ppm (1000 or 2500 mg/kg daily) for 1 year, or 5000, 10,000, or 20,000 ppm (250, 500, or 1000 mg/kg daily) for 2 years (Hagan et al. 1967).

Veratrum viride Aiton — Liliaceae

SCN: American hellebore
OCN: American white hellebore; false hellebore; Indian poke

Part: root

V

Quick Reference Summary

Safety Class: 3
Interaction Class: A

Contraindications

Not for use except under the supervision of an expert qualified in the appropriate use of this substance (Felter and Lloyd 1898; Freis et al. 1949; Prince and Stork 2000; Remington and Wood 1918).

Other Precautions

See Adverse Events and Side Effects below.

Drug and Supplement Interactions

Caution is required for use with blood pressure or cardiac medications (Coe et al. 1950; Elek et al. 1953; Freis et al. 1949).

Adverse Events and Side Effects

Side effects are common with the therapeutic use of American hellebore and include nausea, vomiting, flushing of the face, sweating, and burning of the mouth and throat (Alban et al. 1952; Assali 1950; Assali et al. 1950). Larger doses may produce a slowed heart rate (Crummett et al. 1985; Freis et al. 1949; Jaffe et al. 1990; Prince and Stork 2000).

Symptoms of American hellebore poisoning include vomiting accompanied by nausea, a slowed heart rate (bradycardia), muscular weakness, reduced body temperature, cold sweat, dizziness, faintness, failure of sight, dilation of the pupils, slow and shallow breathing, syncope, and atrioventricular block (interruption of the electrical signal in the heart) (Crummett et al. 1985; Felter and Lloyd 1898; Freis et al. 1949; Jaffe et al. 1990; Prince and Stork 2000; Remington and Wood 1918; Zumoff 1954).

Pharmacological Considerations

Human studies and clinical use have indicated that American hellebore can rapidly reduce blood pressure (Coe et al. 1950; Elek et al. 1953; Freis et al. 1949). American hellebore was used in the 1930s through the 1960s in the treatment of hypertension. Effects were observed after both oral and intravenous administration. Use was discontinued due to the relatively severe side effects (*see* Adverse Events and Side Effects above).

Pregnancy and Lactation

American hellebore was formerly used to treat preeclampsia and eclampsia (pregnancy-induced high blood pressure). Due in part to side effects noted above, use was discontinued in the 1960s (Alban et al. 1952; Assali 1950; Assali et al. 1950, 1954; Bryant and Fleming 1962; Remington and Wood 1918).

Animal studies have reported teratogenic effects of some compounds isolated from American hellebore (Omnell et al. 1990; Young et al. 1976).

No information on the safety of American hellebore during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established, and this substance is not recommended for use except under the supervision of an expert qualified in its appropriate use.

II. Adverse Events

Case Reports of Adverse Events

Medical texts from the late 1800s and early 1900s indicate that American hellebore poisoning includes vomiting accompanied by severe nausea and much retching, a slowed pulse, muscular weakness, reduced body temperature, cold sweat, dizziness, faintness, failure of sight, dilation of the pupils, slow and shallow breathing, sleepiness, coma, and unconsciousness, sometimes with stertorous breathing. The rapid onset of emesis from American hellebore reportedly prevents lethal effects (Felter and Lloyd 1898; Remington and Wood 1918).

Several cases of American hellebore poisoning have been reported in persons who mistook the plant for ramps (*Allium tricoccum*), a type of wild edible leek. Cases typically involved vomiting, slowed heart rate, and reduced blood pressure. Some cases include first- and second-degree atrioventricular block (Crummett et al. 1985; Jaffe et al. 1990; Prince and Stork 2000).

A number of cases of poisoning were reported in persons accidentally poisoned by sneezing powders that contained alkaloids from American hellebore (Carlier et al. 1983; Charles et al. 1984). Of nine cases reported together, all in boys aged 7 to 18, one ingested the sneezing powder, five both ingested and inhaled the powder, and three only inhaled the powder. Aside from sneezing, vomiting was reported in all nine patients, epigastric pain was reported in two patients, syncope in three patients, a slowed heart rate in seven patients, and decreased blood pressure in five patients (Carlier et al. 1983).

Applied to the skin, American hellebore is rubefacient, and applied to the nose, causes sneezing (Felter and Lloyd 1898).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

In the early 1900s through the 1960s, alkaloids isolated from American hellebore were used in the treatment of pre-eclampsia and eclampsia (pregnancy-induced high blood pressure). Preparations were originally used orally, but later use, as preparations and technologies were developed, was intravenous. Side effects of treatment were common and included nausea, vomiting, flushing of the face, sweating, and burning of the mouth and throat (Alban et al. 1952; Assali 1950; Assali et al. 1950, 1954; Bryant and Fleming 1962; Jaffe et al. 1990; Remington and Wood 1918).

In mice orally administered a single dose of 70, 150, or 300 mg/kg of the compound jervine on day 8, 9, or 10 of pregnancy, teratogenic effects were observed in some strains of mice (C57BL/6J and A/J) but not in others (Swiss N:GP[S] and Swiss Webster). Teratogenic effects included cleft lip, cleft palate, isolated cleft palate, and mandibular and limb malformations. Fetal teratogenicity and maternal and fetal toxicity were highly correlated (Omnell et al. 1990).

Teratogenic effects were observed in hamsters orally administered steroidal alkaloids (cyclopamine and jervine) from American hellebore. The doses used were not reported in the published abstract (Young et al. 1976).

No information on the safety of American hellebore during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of American hellebore orally administered to rabbits is 300 mg/kg. In rats, the LD_{50} of American hellebore is 118 mg/kg after intraperitoneal administration but could not be determined at doses up to 8 g/kg after oral administration (Perdue et al. 1950).

Subchronic Toxicity

In rats fed diets containing 0.66, 1.8, 2.0, 2.9, or 3.7% American hellebore for 60 days, severe toxicity was observed at the 2.9% level and above. Toxic effects reported were attributed to lack of nutrition (presumably due to vomiting), and no significant adverse effects on organ weights or blood chemistry were observed (Perdue et al. 1950).

Chronic Toxicity

Weight loss and emesis were reported in adult dogs fed diets containing a purified extract of American hellebore. The daily dose was dependent on each dog's recent history of emesis and diet refusal. The mean daily intake of the American hellebore preparation was 0.19 mg/kg, a limit determined by emesis and failure to eat. No organ-specific toxicities were observed after 6 or 13 months of dosing (Gourzis and Bauer 1951).

Growth retardation was observed in rats fed diets containing 7.3, 11, or 19% of a purified extract of American hellebore daily for 12 months. No pathological changes in organs were observed (Gourzis and Bauer 1951).

Verbascum spp.

Scrophulariaceae

Verbascum densiflorum Bertol.
SCN: mullein

Verbascum phlomoides L.
SCN: mullein
OCN: orange mullein

Verbascum thapsus L.
SCN: mullein
OCN: Aaron's rod
Part: flower, leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Editors' Note
Small hairs on mullein leaf may cause mechanical irritation in the mouth and throat if not filtered out of extracts prior to consumption.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of mullein in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of mullein in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered ethanol extract of mullein in mice is 1 g/kg (Bhakuni et al. 1969).

In the brine shrimp bioassay, extracts of mullein are toxic at concentrations around 1 g/l, with decoctions showing a greater toxicity than infusions (Turker and Camper 2002).

Verbena spp. Verbenaceae

Verbena hastata L.
SCN: blue vervain
OCN: American blue vervain; wild hyssop

Verbena officinalis L. ssp. ***officinalis***
SCN: European vervain
PN: *ma bian cao*
Part: herb

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Allergic contact dermatitis from European vervain has been reported (Del Pozo et al. 1994).

Pharmacological Considerations

Coadministration of European vervain tea and iron-fortified bread reduced absorption of the iron (Hurrell et al. 1999).

Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that European vervain should be used with caution during pregnancy (Bensky et al. 2004; Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of European vervain during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic contact dermatitis from European vervain has been reported (Del Pozo et al. 1994).

Overdose of European vervain (standard dose listed as 4.5–30 g as an infusion) may cause abdominal pain, diarrhea, nausea, vomiting, vertigo, and headache. Symptoms reportedly disappear after cessation of the herb (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Coadministration of iron-fortified bread and European vervain tea reduced absorption of the iron by 59%, an effect that was less pronounced than that of black tea, cocoa, or teas made with peppermint or European pennyroyal, but greater than the inhibitory effects of linden flower tea or chamomile tea (Hurrell et al. 1999).

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In an in vitro model of digestion and dialysis used to determine the effects of an infusion of European vervain on iron absorption by infants, two gastric pHs were used: pH 4, as in the first week of life, and pH 2.5, as in older infants. At pH 4 and at pH 2.5, iron availability was decreased by vervain alone and increased by ascorbic acid alone. Iron absorption was increased by the administration of European vervain and ascorbic acid together, but the combined activity was not as high as ascorbic acid alone (Zaida et al. 2006).

In a competitive binding assay in human breast cancer cells with estrogen and progesterone receptors, European vervain bound to both receptor types and was one of the six highest binding herbs of 150 species of herbs tested (Zava et al. 1998).

IV. Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that European vervain should be used with caution during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

Texts from India from the 1950s indicate that European vervain has been listed as an abortifacient. Details on use, such as part and doses used, and whether the plant was used singly or as part of a formula, are lacking (Casey 1960).

No information on the safety of European vervain during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Veronicastrum virginicum (L.) Farw.

Scrophulariaceae

SCN: Culver's root
Syn: *Leptandra virginica* (L.) Nutt.

OCN: blackroot
Part: dried root

Quick Reference Summary

Safety Class: 1
Interaction Class: A

V

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Fresh Culver's root is strongly cathartic and has produced violent emesis and bloody purging, accompanied by vertigo. The dried root, which is the subject of this entry, acts as a mild laxative (Felter and Lloyd 1898; Remington and Wood 1918).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of Culver's root in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Vinca minor L. — Apocynaceae

SCN: lesser periwinkle

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Lesser periwinkle contains small amounts (0.02–0.13%) of the compound vincamine (Karabaev et al. 1972; Proksa and Grossmann 1991; Vachnadze et al. 2001). Vincamine and the closely related compound vinpocetine have been widely studied, and vinpocetine is sold as a dietary supplement (EMEA 1999; NCI 2003; Szatmari and Whitehouse 2003).

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of lesser periwinkle in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of lesser periwinkle during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The oral LD_{50} for the compound vincamine is reported as 810 or 1200 mg/kg in rats and 460, 825, or 1000 mg/kg in mice (EMEA 1999; NCI 2003).

In animal studies, administration of lesser periwinkle has been reported to cause leukocytopenia, lymphocytopenia, and reductions in α-, α_2-, and γ-globulin levels. Information on doses used, duration of study, and the type of animal subject were not reported in available English language translations (Blumenthal et al. 1998).

Ventricular extrasystole was observed in rabbits after oral administration of 20 mg/kg vincamine (EMEA 1999).

Short-Term Toxicity

No signs of toxicity were observed in rats orally administered 30 or 100 mg/kg of vincamine daily for 6 weeks (EMEA 1999).

In rats orally administered 120 mg/kg of vincamine daily for 6 days, no changes in liver enzyme levels were observed (Porquet et al. 1992).

Subchronic Toxicity

No signs of toxicity were observed in rats orally administered 6.6, 20, or 62 mg/kg of vincamine or in guinea pigs given 2.5 mg/kg daily for 3 months (EMEA 1999).

In dogs orally administered 1, 7, or 20 mg/kg of vincamine daily for 3 months, behavioral changes were observed at the 20 mg/kg dose, with no effects reported at lower doses (EMEA 1999).

Viola odorata L. — Violaceae

SCN: sweet violet
OCN: English violet; garden violet; sweet blueviolet

Part: leaf

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
An animal study indicated that sweet violet exhibited diuretic activity (Rebuelta et al. 1983).

Pregnancy and Lactation
No information on the safety of sweet violet in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events
No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
Diuretic activity of violet leaf extracts was observed after oral administration in rats of 77.4 mg/animal of an aqueous infusion or dried methanolic extract of violet leaf or 34.3 mg/animal of violet leaf ash (animal weight not specified in available English language translation). The diuretic effects were reportedly greater than those observed for 5 mg/kg of theophylline. Minor natriuretic and kaliuretic activity was also observed (Rebuelta et al. 1983).

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of sweet violet during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity
Hexane, chloroform, and aqueous extracts of sweet violet are well tolerated in rabbits after oral administration of doses of 1.2 g/kg (Khattak et al. 1985).

Cytotoxicity
Cyclotide compounds from sweet violet have demonstrated cytotoxic activity in human tumor lines in vitro (Lindholm et al. 2002). Cycloviolacin O2, isolated from sweet violet, exhibited significant cytotoxicity in human tumor cell lines, with an IC_{50} of 0.1 to 0.3 µ*M* (Lindholm et al. 2002).

Viola tricolor L. — Violaceae

SCN: heartsease
OCN: European wild pansy; Johnny-jump-up; wild violet

Part: herb

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Editors' Notes

Use of this species as a food additive in the U.S. is limited to its function as a flavoring substance in alcoholic beverages (CFR 2011). Dietary ingredients for use in dietary supplements, however, are specifically excluded from the federal food additive definition (U.S.C. 2010).

Adverse Events and Side Effects

An infant with glucose-6-phosphate dehydrogenase (G6PD) deficiency (a hereditary disease also known as favism) developed moderate hemolysis after ingesting water extract of heartsease (Behmanesh and Abdollahi 2002).

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of heartsease in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

A 9-month-old infant with a history of G6PD deficiency (a hereditary disease also known as favism) developed moderate hemolysis after ingesting half a c up of boiled heartsease (Behmanesh and Abdollahi 2002).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of heartsease during pregnancy or lactation was identified.

V. Toxicity Studies

Cytotoxicity

Cyclotide compounds, such as those from heartsease, have demonstrated cytotoxic activity in human tumor lines in vitro (Goransson et al. 2003; Lindholm et al. 2002). In human cancer cell lines, the most active cyclotides isolated from heartsease had IC_{50} values of 0.6 to 6 µ*M* (Svangård et al. 2004).

Viscum album L. — Viscaceae

SCN: European mistletoe

Part: herb

Quick Reference Summary

Safety Class: 2b, 2d
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Büssing 1996).

Do not exceed recommended dose (McGuffin et al. 1997).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Standard Dose

The standard dose is 2.5 g infused in cold water for 10 to 12 hours, up to two times daily (Wichtl 2004).

Adverse Events and Side Effects

Systematic reviews of several dozen clinical trials (all subcutaneous injections of 1 to 200 mg) indicated that European mistletoe is generally very well tolerated, with no serious adverse events reported. Minor localized reactions at the injection site are sometimes associated with injections of European mistletoe, but such effects are not expected after oral use (Horneber et al. 2009; Kienle et al. 2009; Stein and Berg 2000).

Allergic reactions, including anaphylactic reactions, to European mistletoe have been reported (Bauer et al. 2005; Horneber et al. 2009; Hutt et al. 2001; Kienle et al. 2009).

Pharmacological Considerations

Animal studies have demonstrated that European mistletoe may modify glucose regulation (Eno et al. 2008; Nwaegerue et al. 2007; Ohiri et al. 2003). People with diabetes are advised to monitor their blood sugar closely and discuss the use of this herb with a qualified healthcare practitioner prior to use.

Some authorities suggest that blood pressure should be checked regularly in persons consuming European mistletoe tea (Wichtl 2004).

Pregnancy and Lactation

No information on the safety of European mistletoe during pregnancy or lactation was identified in the scientific or traditional literature. Due to the relative toxicity of some compounds in European mistletoe, use during pregnancy is not recommended unless under the care of a qualified healthcare practitioner (Büssing 1996).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

Systematic reviews of clinical trials indicate that European mistletoe is generally well tolerated, with very few adverse events reported. The reviews examined 46 clinical trials that met inclusion criteria, with a total of 9949 patients subcutaneously administered standardized extracts of European mistletoe at doses ranging from 1 to 200 mg daily for a time span of several weeks to over a year (treatment longer than several months usually consisted of cycles of treatment and breaks) (Horneber et al. 2009; Kienle et al. 2009). Localized reactions at the injection site, including redness, swelling, itching, prurigo, and induration (a hardening at the site), occurred in approximately one-third of patients. Reactions were reported to be dose-dependent and may intensify during concomitant chemotherapy (Horneber et al. 2009; Kienle et al. 2009; Stein and Berg 2000). Flulike symptoms and eosinophilia have also been reported after injection of European mistletoe (Horneber et al. 2009; Kienle et al. 2009; Stein and Berg 2000). These reactions are generally attributed to the route of administration and are not expected after oral use.

An increase in eosinophil (a type of white blood cell) counts has been reported after administration of lectin-rich European mistletoe preparations (Huber et al. 2005; Stein and Berg 2000).

Case Reports of Adverse Events

Allergic reactions, including anaphylactic reactions, to European mistletoe have been reported (Bauer et al. 2005; Horneber et al. 2009; Hutt et al. 2001; Kienle et al. 2009).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In a study of mistletoe on T lymphocytes in patients with prostate, breast, or colorectal cancer, a decrease in T lymphocyte function was observed in colorectal and prostate cancer patients on the "swift" dose escalation scheme. Patients on a "slow" dose escalation scheme had less of a decline in T lymphocytes. An escalation of dose over the course of treatment is a standard practice for European mistletoe. In this study, the subcutaneous doses began at 0.01 mg and went to 20 mg (Bussing et al. 2007).

Animal Pharmacological Studies

In diabetic and healthy rats intravenously administered 100 mg/kg of European mistletoe, a reduction in blood glucose levels was observed in diabetic animals but not in healthy animals. An increase in insulin secretion was observed in both healthy and diabetic animals (Eno et al. 2008).

In diabetic mice and rabbits intraperitoneally administered 200 or 400 mg/kg of an aqueous extract of European mistletoe, a reduction in blood glucose levels was observed (Ohiri et al. 2003).

In diabetic and healthy rats administered 250, 500, 750, or 1000 mg/kg of a hydroethanolic extract of European mistletoe, a dose-dependent reduction in glucose levels was observed (Nwaegerue et al. 2007).

In Vitro Pharmacological Studies

Some inhibition of the drug-metabolizing isoenzyme CYP3A4 was observed after treatment with European mistletoe, although the authors indicated that clinically relevant systemic or intestinal interactions with CYP3A4 were considered unlikely (Engdal and Nilsen 2009).

An aqueous extract of European mistletoe was found to stimulate insulin secretion from clonal pancreatic B cells (Gray and Flatt 1999).

IV. Pregnancy and Lactation

No information on the safety of European mistletoe during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of an intraperitoneally administered aqueous extract of European mistletoe in mice is 4.18 g/kg (Ohiri et al. 2003).

The LD_{50} of intraperitoneally administered standardized extracts of European mistletoe is 700 mg/kg in mice and 378 mg/kg in rats (Stein 2000). The LD_{50} after intravenous administration to mice is 500 mg/kg and after subcutaneous administration to mice is 1200 mg/kg (Luther et al. 1986).

The LD_{50} of viscotoxins is 0.5 mg/kg after intraperitoneal administration to mice and 0.1 mg/kg after intravenous administration to cats. Sublethal doses were reported to cause hypotension, bradycardia, and negative inotropic effects (Samuelsson 1974).

Short-Term Toxicity

In rats intravenously administered up to 5 mg/kg of a standardized extract of European mistletoe daily for 28 days, no relevant organ toxicity was observed, and no changes in clinical signs, organ weights, hematology, histology, or other parameters were seen (Mengs 1998).

Genotoxicity

No genotoxic activity of European mistletoe was observed in a variety of assays, including a bacterial mutation assay, mammalian cell gene mutation assay, in vitro cytogenetic assay, cell transformation assay, and the Ames test (Mengs 1998; Mengs et al. 1997).

Vitex agnus-castus L.

Verbenaceae

V

SCN: chastetree
AN: *renuka*

OCN: agnus-castus; chasteberry; monk's pepper
Part: fruit (berry)

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

Chaste tree is not recommended for use with hormonal contraceptives (Hobbs 1990; Krochmal et al. 2004; Mills and Bone 2000; Stargrove et al. 2008).

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

Reviews of clinical trials and case reports of chaste tree products have concluded that chaste tree is generally well tolerated and that any adverse events reported were mild and transient (Daniele et al. 2005).

Pharmacological Considerations

Human studies have indicated that chaste tree may inhibit prolactin secretion (Upton 2001).

Pregnancy and Lactation

Herbal practitioners have traditionally used chaste tree to prevent miscarriages in women with a history of prior miscarriages. In studies where pregnancy has been achieved while taking chaste tree, no follow-up studies have been completed on pregnancy outcomes or newborn health (Romm 2010).

Chaste tree has traditionally been used as a galactagogue (a substance that promotes lactation) (Brown 1994; Upton 2001). No recent human or animal studies on the safety of chaste tree during lactation were identified, although a review of human studies indicated that chaste tree may decrease prolactin secretion (Upton 2001).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of adverse events reported in clinical trials, case reports, pharmacovigilance data, and postmarketing surveillance studies concluded that although further studies are needed to assess the safety of chaste tree, the available data indicate that chaste tree is not associated with serious risk to health and that the vast majority of adverse events reported in association with chaste tree use have been mild and transient (Daniele et al. 2005). A review of human studies on chaste tree products indicated that adverse events were generally similar in the chaste tree and placebo groups and that adverse events reported were often the same as the symptoms being treated. The most common adverse events were listed as gastrointestinal disturbance (notably nausea) and skin conditions, with side effects occasionally reported including headache, fatigue, and hormone-related symptoms (Upton 2001).

Case Reports of Adverse Events

Occasional minor skin irritations have been reported in persons taking chaste tree preparations (Leung and Foster 1996).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No effects on blood pressure, heart rate, testosterone, follicle-stimulating hormone, or luteinizing hormone were observed in healthy men administered 120 to 480 mg chaste tree extract daily for 14 days (Loew et al. 1996; Merz et al. 1996).

Compounds in chaste tree are reported to bind to the estrogen receptor β (ERβ) in the heart, vasculature, bone, and bladder (Wuttke et al. 2003).

Animal Pharmacological Studies

A reduction in prolactin secretion in rats administered chaste tree extract was reported (Winterhoff et al. 1991).

In Vitro Pharmacological Studies

Chaste tree has been shown to bind to estrogen receptor β (ERβ) but not ERα in one in vitro study (Jarry et al. 2003), whereas a second study showed that a methanol extract of chaste tree was found to competitively bind to ERα and ERβ (Liu et al. 2001). Chaste tree has also been shown to bind to the μ-opiate receptor in Chinese hamster ovaries (Webster et al. 2006).

In high concentrations, chaste tree has agonistic effects on the pituitary dopamine (D2) receptors (Jarry et al. 1994; Wuttke 1996).

In cultured rat pituitary cells, a chaste tree extract was observed to inhibit basal as well as thyrotropin-releasing hormone-stimulated prolactin secretion (Sliutz et al. 1993).

IV. Pregnancy and Lactation

Herbal practitioners have traditionally used chaste tree to prevent miscarriages in women with a history of prior miscarriages. Increased progesterone levels as a result of improved luteal function associated with use of chaste tree have been hypothesized as a mechanism of action for miscarriage prevention. In studies where pregnancy has been achieved while taking chaste tree, no follow-up studies

have been completed on pregnancy outcomes or newborn health (Romm 2010).

No reduction in number of fetuses was observed in pregnant rats orally administered chaste tree fruit at doses of 1 to 2 g/kg daily for days 1 through 10 of pregnancy (Lal et al. 1985).

Chaste tree has been traditionally used as a galactagogue (Brown 1994; Upton 2001). Although older human studies have indicated that chaste tree helps to increase milk production (Mohr 1954; Noack 1943), a review of nine human studies (including placebo-controlled and open studies) on the effects of chaste tree on prolactin secretion indicated that four studies showed a significant decrease in prolactin, one showed a significant increase, one showed a nonsignificant increase, and three showed no effect (Upton 2001).

A review of the safety of chaste tree during lactation concluded that "the low toxicity profile and tolerability of chaste tree makes it unlikely to be toxic for the newborn, especially after filtration and dilution through the mother" (Dugoua et al. 2008).

V. Toxicity Studies

Acute Toxicity

In acute toxicity tests, no deaths were observed in rats and mice orally administered up to 2 g/kg of a standardized chaste tree extract (Bionorica 2001).

Short-Term Toxicity

In rats and mice orally administered a standardized chaste tree extract for 28 days, the no-observed-adverse-effect level (NOAEL) was 50 mg/kg. At higher doses, a slight increase in hemopoietic activity in the spleen and an increase in liver weight were observed. These changes were noted as being transient and interpreted as adaptive rather than toxic (Bionorica 2001).

Subchronic Toxicity

In a chronic oral toxicity study of a standardized chaste tree extract orally administered to mice and rats, the NOAEL was 40 mg/kg after 26 weeks of administration (Bionorica 2001).

Genotoxicity

No genotoxic effects of a standardized chaste tree extract were observed in a mammalian cell line assay, a DNA-breakage assay, or a chromosomal breakage assay (Bionorica 2001).

Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chadha 1988; Upton 2000).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

"Large" but undefined doses of ashwagandha have been reported to cause irritation of mucous and serous membranes, resulting in gastrointestinal upset, diarrhea, and vomiting (Chadha 1976).

Pharmacological Considerations

Human and animal studies have indicated that ashwagandha may modify glucose levels, suggesting that diabetic persons taking ashwagandha should continue to monitor blood glucose levels (Andallu and Radhika 2000).

Several older studies suggest that ashwagandha may potentiate the effects of barbiturates (Malhotra et al. 1960; Rao and Karanth 1990; Singh et al. 1979), although one study showed that ashwagandha reduced the effects of barbiturates (Singh et al. 1978).

In vitro, falsely elevated digoxin levels were observed in some types of digoxin assays when ashwagandha was added to tested serum (Dasgupta and Reyes 2005; Dasgupta et al. 2008).

Pregnancy and Lactation

In the ethnobotanical literature, there are references of ashwagandha use as both an "abortifacient" (Badhwar and Chopra 1946; Casey 1960; Chadha 1976) and as a "pregnancy tonic" (Kapoor 1990; Tirtha 1998; Upton 2000). The strength or accuracy of this information is difficult to assess given the lack of detail regarding dose, duration, and plant part used. In a review of the scientific literature, an animal study failed to detect any decreased number of pregnancies, change in litter size, or fetal loss in rats when administered 100 mg/kg/day of an aqueous root extract for 8 months (Sharma et al. 1986). Based upon this data, it may be that low doses of ashwagandha pose little danger; however, clinicians should discuss the strengths and limitations of the evidence when counseling about its use in pregnancy.

In Ayurvedic medicine, ashwagandha is traditionally used to promote lactation (Kapoor 1990).

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

Ashwagandha was reported to potentiate the activity of pentobarbital sodium in mice after intraperitoneal administration of doses of 700 mg/kg or more (Malhotra et al. 1960). Studies of administration of 300 mg/kg ashwagandha report a barbiturate potentiation (Rao and Karanth 1990) or a reduction in barbiturate-induced sleeping time (Singh et al. 1978). A fourth study indicated that a dose of 1 g/kg of ashwagandha produced a potentiation of barbiturates (Singh et al. 1979).

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

In contrast to animal studies that reported a decrease in libido and sexual performance, an increase in sexual performance was reported in healthy men (age 50 to 59) administered 3 g daily of ashwagandha for one year (Kuppurajan et al. 1980).

In patients with mild non-insulin-dependent diabetes, administration of 3 g powdered ashwagandha root daily for 30 days resulted in a decrease in blood glucose that was comparable to that of an oral hypoglycemic drug (Andallu and Radhika 2000).

Animal Pharmacological Studies

In rats with non-insulin-dependent diabetes, oral administration of 200 or 400 mg/kg ashwagandha daily for 5 weeks reduced elevated levels of blood glucose, HbA(1)c, and insulin. Improved glucose tolerance was observed in an oral glucose tolerance test, and treatment significantly improved the insulin sensitivity index (Anwer et al. 2008; Jain et al. 2006).

A decrease in fasting blood glucose levels was observed in diabetic rats intraperitoneally administered 20 mg/kg of an alcohol extract of ashwagandha (Jain et al. 2006).

An increase in serum T_3 and T_4 levels was observed in mice intragastrically administered 1.4 g/kg of ashwagandha root daily for 20 days (Panda and Kar 1998).

Ashwagandha has been shown to bind to the GABA receptor in mice, with studies showing a reduction in effective dose of diazepam (Kulkarni et al. 1998) and an increased seizure threshold for pentylenetetrazol-induced seizures (Kulkarni et al. 2008; Kulkarni and Dhir 2008).

In male rats administered 470 mg/kg of a lyophilized aqueous extract of ashwagandha, an increase in testicular weight was observed, and histological examination revealed an apparent increase in the diameter of seminiferous tubules and the number of seminiferous tubular cell layers in the testes of treated rats, as compared with control animals. A decrease in serum testosterone and FSH levels, and an increase in LH levels was also observed (Abdel-Magied et al. 2001).

In male rats orally administered 3 g/kg of a methanol extract of ashwagandha daily for 7 days, impairment in libido, sexual performance, and sexual vigor was observed, along with penile erectile dysfunction. The effects were partly reversible on cessation of treatment, and were not due to changes in testosterone levels or toxicity, but instead were attributed to hyperprolactinemic, GABAergic, serotonergic or sedative activities of the extract (Ilayperuma et al. 2002).

A decrease in litter size and some infertility were observed in male and female mice orally administered 25 mg/kg daily of ashwagandha for 10 days (Garg and Parasar 1965).

In Vitro Pharmacological Studies

Falsely elevated levels were observed in the Digoxin III digoxin assay in serum treated with 25 or 50 µl/ml of an aqueous/ethanolic extract of ashwagandha, but not after treatment with 10 µl/ml. In the Tina-quant and FPIA digoxin assays, falsely elevated digoxin levels were observed in serum treated with 50 µl/ml but not in serum treated with 10 or 25 µl/ml (Dasgupta and Reyes 2005; Dasgupta et al. 2008).

The compound withaferin A has been shown to induce apoptosis in leukemia cells (Malik et al. 2007; Mandal et al. 2008; Oh et al. 2008; Senthil et al. 2007).

IV. Pregnancy and Lactation

Offspring from pregnant mice administered 100 mg/kg ashwagandha decoction daily for 8 months had a higher birthweight than offspring from control animals (Sharma et al. 1986).

Information on the history of ashwagandha use in pregnancy is conflicting. While some literature indicates that ashwagandha has been used for abortion (Casey 1960; Chadha 1976; Svoboda 1992), other studies indicate that ashwagandha is used to prevent miscarriage and stabilize the fetus (Kapoor 1990; Tirtha 1998). The strength or accuracy of this information is difficult to assess given the lack of detail regarding plant part used, dose, and duration. One of the articles citing abortifacient activity uses a broad definition of abortifacients, including botanicals used for amenorrhea, those that have ecbolic (stimulating uterine contractions) activity, anti-metabolites, and "others."

In Ayurvedic medicine, ashwagandha is traditionally used to promote lactation (Kapoor 1990).

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered ashwagandha in mice was approximately 7.7 g/kg (Singh et al. 1982). In mice intraperitoneally administered single doses of 1.1, 1.2, 1.3, 1.4, or 1.5 g/kg of an ethanol extract of ashwagandha, the 1.1 g/kg dose did not kill any animals, while the 1.5 g/kg dose was lethal to all animals. Based on these results, the LD_{50} of the extract was estimated to be 1.26 g/kg (Sharada et al. 1993). No toxic effects were observed in mice intraperitoneally administered 1 g/kg of an ethanol extract of ashwagandha (Sharada et al. 1993).

The LD_{50} of intraperitoneally administered sitoindosides VII, VIII, IX, and X in mice were 1076, 1564, 518, and 808 mg/kg, respectively (Bhattacharya et al. 1987; Ghosal et al. 1989). No deaths were reported in mice orally administered up to 1 g/kg of sitoindosides IX and X (Ghosal et al. 1989).

The LD_{50} of intraperitoneally administered alcohol extract of ashwagandha in mice was 1.26 g/kg (Sharada et al. 1993).

Short-Term Toxicity

In rats administered ashwagandha as 25% of the diet (approximate dose of 5 g per mouse daily) for 10 to 14 days, no macroscopic abnormalities were observed, but microscopic examination revealed centrilobular hydropic degeneration in the liver, peribronchial and perivenous edema in the lungs, intertubular vascular congestion, tubular casts, and tubular degeneration in the kidneys (Arseculeratne et al. 1985).

In mice intraperitoneally administered 100 mg/kg of an ethanol extract of ashwagandha daily for 30 days, a significant reduction in the weights of spleen, thymus, and adrenal glands was observed in male rats, and a significant increase in blood acid phosphatase activity was observed in animals of both sexes (Sharada et al. 1993).

Other Toxicity

Treatment of neonatal and adult rat cardiomyocytes with 100 µl of a 10% extract of ashwagandha resulted in cessation of beating in neonatal cardiomyocytes due to calcium overload, while sequential dilutions revealed that treatment with a low dose (0.01% v/v, 0.1 µl/ml of the medium) resulted in constant, regular beats (transients), and a slight elevation of diastolic calcium without overload. Addition of ashwagandha to sparking, calcium-tolerant adult cardiomyocytes resulted in initiation of calcium transients, and adult cells were able to tolerate exposure to high concentrations of extract (Poindexter et al. 2006).

Wolfiporia cocos (F.A. Wolf) Ryvarden & Gilb. — Polyporaceae

SCN: poria
Syn: *Poria cocos* F.A. Wolf
PN: *fu ling* (sclerotium)
OCN: hoelen; Indian bread (sclerotium); polyporus
Part: sclerotium

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Adverse Events and Side Effects
None known.

Pharmacological Considerations
None known.

Pregnancy and Lactation
No information on the safety of poria in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to poria have been reported. In sensitive individuals, contact with powdered poria may elicit allergic asthma, allergic rhinitis, rapid breathing, and cold sweats (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

In a human hepatocellular liver cancer cell line, an extract of poria was found to induce expression of gene transcription of the drug metabolizing isoenzyme CYP3A4 through activation of the pregnane X receptor (Dong et al. 2008a).

In rat liver microsomes, no effect of poria was observed on the drug metabolizing isoenzymes CYP3A, CYP3A1, or CYP3A2 (Dong et al. 2008b).

In a screening on the effects of poria on chemotherapy drug uptake in human cervical carcinoma cells, an aqueous extract of poria enhanced the target cell sensitivity to the p-glycoprotein (P-gp) substrate paclitaxel, with no changes in sensitivity to 5-fluorouracil, which is not a substrate for P-gp. Poria increased cellular uptake of rhodamine 123 (Takara et al. 2005).

In a monocyte culture medium containing 10% poria extract, significant inhibition of secretion of TNF-alpha, IL-beta, IL-6, and GM-CSF from the monocytes was observed (Tseng and Chang 1992).

No significant anti-cholinesterase activity of a methanol extract of poria was observed in a screening of plants for anti-cholinesterase activity (Oh et al. 2004).

IV. Pregnancy and Lactation

No information on the safety of poria during pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of aqueous extracts of poria in mice could not be determined at doses up to 10 g/kg after oral administration and 2 g/kg after intraperitoneal administration (Zhu 1998).

OCN: amole
Part: root

Quick Reference Summary

Safety Class: 2d
Interaction Class: A

Contraindications
Do not exceed the recommended dose.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Standard Dose
The standard dose is 2 to 4 g of the herb daily (Moore 2003).

Adverse Events and Side Effects
Allergic reactions to yucca have been reported and confirmed by skin prick testing (Kanerva et al. 2001).

Pharmacological Considerations
None known.

Pregnancy and Lactation
In pigs, a reduction in stillbirths and improvement in piglet health were observed after feeding of Mojave yucca powder to pregnant sows for 3 weeks prior to giving birth (Herpin et al. 2004).

No information on the safety of any of the listed *Yucca* species during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials
No significant adverse effects were observed in a clinical trial of yucca saponins in approximately 700 patients with arthritis (Bingham et al. 1975).

Case Reports of Adverse Events
Occupational contact dermatitis was reported in an atopic worker routinely exposed to yucca (*Yucca aloifolia*) leaves, weeping fig (*Ficus benjamina*), and spathe flower (*Spathiphyllum wallisii*). Skin prick tests were positive to all three plants, and IgE antibodies were found to weeping fig and spathe flower (Kanerva et al. 2001).

Positive reactions to skin prick testing with yucca (*Yucca aloifolia*) were observed in 5.8% of approximately 600 individuals (Kanerva et al. 2001).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound sarsasapogenin has been shown to have hemolytic activity in human blood samples (Zhang et al. 1999). Saponin compounds such as sarsasapogenin are recognized to have hemolytic activity in vitro, although the activity is reduced when given intravenously or orally. Saponins are thought to be poorly absorbed in the gastrointestinal tract and are typically regarded as a safe food additive (Bingham et al. 1975; Oakenfull 1981).

In pig blood platelets, application of phenolic compounds, including *trans*-3,3′,5,5′-tetrahydroxy-4′-methoxystilbene and yuccaols A and C, as a pretreatment slightly reduced platelet aggregation stimulated by ADP. With thrombin-induced platelet aggregation, the selected compounds exhibited significant inhibition of aggregation (Olas et al. 2002).

Phenolic compounds isolated from Mojave yucca, including resveratrol, yuccaol C, and other compounds, have been shown to inhibit NF-κB (Cheeke et al. 2006).

IV. Pregnancy and Lactation

In pregnant pigs fed 120 mg/kg Mojave yucca powder daily from day 107 of pregnancy to day 21 of lactation, a reduction in the number of stillbirths was observed. Piglets from sows fed Mojave yucca powder exhibited improved thermoregulatory abilities after birth and tended to have a lower incidence of stillbirth and preweaning mortality (Herpin et al. 2004).

No information on the safety of any of the listed *Yucca* species during lactation was identified.

V. Toxicity Studies

Short-Term Toxicity

In cats orally administered 150 mg/kg Mojave yucca extract daily for 40 days, no adverse effects or changes in hematological parameters, including red and white blood cell count, hematocrit, hemoglobin, or blood urea nitrogen, were observed (Lowe and Kershaw 1997).

No adverse effects were observed in cows (average animal weight 730 kg) orally administered 60 g of Mojave yucca extract (10% saponins) daily for 28 days (Benchaar et al. 2008).

In lambs intraruminally administered 55 mg/kg Mojave yucca saponins for 11 days, no signs of toxicity were observed (Flaoyen et al. 2002).

In a toxicity study, three groups of lambs were administered varying amounts of Mojave yucca extract or Mojave yucca juice daily for 21 days. In group 1, animals were administered 1.5 g/kg Mojave yucca extract (63 mg sapogenin); in group 2, animals were administered 1.5 g/kg Mojave yucca juice. In group 3, the lambs were dosed as follows: 1.5 g/kg juice on days 1 and 2, 3.0 g/kg on days 3 and 4, 4.5 g/kg on day 5, 3.0 g/kg on days 6 and 7, 1.5 g/kg days 8, 9 and 10, 3.0 g/kg on days 11 to 21. During the first 11 days of the experiment, six lambs from group 2 and six lambs from group 3 were found dead or had to be euthanized for ethical reasons. In these animals, diarrhea and dehydration were the main signs, and these signs were typically accompanied by elevated levels of creatinine and urea, acute tubular necrosis in the kidneys, and watery content in the gastrointestinal tract. Saponins were found in the liver and kidney samples from all lambs that were dosed with the juice of Mojave yucca (Wisloff et al. 2008).

Genotoxicity

No mutagenic activity of compounds isolated from Mojave yucca, including yuccaols A, B, and C, *trans*-resveratrol, and *trans*-3,3′,5,5′-tetrahydroxy-4′-methoxystilbene, was observed in the Ames test for mutagenicity in *Salmonella typhimurium* strains TA97, TA98, TA100, or TA102 with or without metabolic activation by S9 (Czeczot et al. 2003).

Zanthoxylum spp. Rutaceae

Zanthoxylum americanum Mill.
SCN: prickly ash
OCN: northern prickly ash; toothache tree

Zanthoxylum clava-herculis L.
SCN: southern prickly ash
OCN: Hercules' club
Part: bark

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bradley 1992).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Emmenagogue (Felter and Lloyd 1898); *see* Appendix 2.

Adverse Events and Side Effects

Prickly ash and southern prickly ash are toxic to cattle and fish (Bowen et al. 1996; Yin et al. 2007). No cases of toxicity associated with human use were identified.

Pharmacological Considerations

None known.

Pregnancy and Lactation

A British reference text contraindicates the use of prickly ash and southern prickly ash during pregnancy (Bradley 1992).

No information on the safety of prickly ash during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

Prickly ash and southern prickly ash have caused toxic and sometimes fatal reactions in cattle that grazed on the bark (Bowen et al. 1996). The bark is also toxic to fish (Yin et al. 2007). Testing in nerves isolated from rats indicated that southern prickly ash extract appeared to exert action on neuromuscular transmission, probably through blockade of postjunctional, end-plate receptors or enhanced release of neurotransmitters (Bowen et al. 1996).

IV. Pregnancy and Lactation

A British reference text contraindicates the use of prickly ash and southern prickly ash during pregnancy (Bradley 1992).

No information on the safety of prickly ash during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Bensky et al. 2004; Chen and Chen 2004).

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that Sichuan pepper should be used with caution during pregnancy (Bensky et al. 2004; Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of Sichuan pepper during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Overdose of Sichuan pepper (standard dose is an aqueous extract of 3–6 g) may cause nausea, vomiting, dry mouth, and vertigo. Severe cases of overdose have been associated with delirium, spasms, difficulty breathing, loss of consciousness, and respiratory failure (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies

The compound chelerythrine chloride inhibited platelet aggregation induced by ADP, arachidonic acid, PAF, collagen, ionophore A23187, and thrombin in washed rabbit platelets. Less inhibition was observed in platelet-rich plasma. Treatment of washed platelets with chelerythrine chloride decreased thromboxane B_2 formation induced by arachidonic acid, collagen, ionophore A23187, and thrombin (Ko et al. 1990).

IV. Pregnancy and Lactation

Texts on traditional Chinese medicine indicate that Sichuan pepper should be used with caution during pregnancy (Bensky et al. 2004; Chen and Chen 2004).

No information on the safety of Sichuan pepper during lactation was identified.

V. Toxicity Studies

No toxicity studies were identified.

Zea mays L. Poaceae

SCN: corn
PN: *yu mi xu* (stigma)

OCN: maize
Part: stigma

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications

None known.

Other Precautions

None known.

Drug and Supplement Interactions

None known.

Notice

Diuretic (Chen and Chen 2004; Felter and Lloyd 1898; Remington and Wood 1918; Velazquez et al. 2005; Wichtl 2004); *see* Appendix 2.

Adverse Events and Side Effects

None known.

Pharmacological Considerations

None known.

Pregnancy and Lactation

No information on the safety of corn stigma during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

No case reports of adverse events were identified.

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In water-loaded rats orally administered single doses of 25, 50, 200, 350, and 500 mg/kg corn stigma extract, an increase in potassium excretion was observed at doses of 350 and 500 mg/kg. At the 500 mg/kg dose, diuretic activity was observed. In rats administered a single dose of 500 mg/kg of the same extract, glomerular filtration and filtered load decreased without affecting proximal tubular function, sodium, or uric acid excretion (Velazquez et al. 2005).

In Vitro Pharmacological Studies

No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation

No information on the safety of corn stigma in pregnancy or lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intravenously administered corn stigma in rabbits is 250 mg/kg (Chen and Chen 2004). The LD_{50} of an intraperitoneally administered corn stigma aqueous extract in rats is 14.5 g/kg (Al-Ali et al. 2003).

Short-Term Toxicity

In rats orally administered 50, 100, or 150 mg/kg of an aqueous extract of corn stigma daily for 21 days, no significant toxicity was observed at the 50 and 100 mg/kg doses. Reductions in levels of hemoglobin, red blood corpuscles, clotting time, mean corpuscular volume, hematocrit, blood urea nitrogen, aspartate transaminase, alanine transaminase, calcium, total protein, total albumin, and total acid phosphatase were reported. Increases were reported in white blood corpuscles, mean corpuscular hemoglobin, alkaline phosphatase, and creatinine (Garg and Goyal 1992).

Subchronic Toxicity

In rats administered corn silk as 0.5%, 2.0% and 8.0% (w/w) of the diet for 90 days, no adverse changes in body weight, food consumption, hematology, blood chemistry, organ weights, or gross and microscopic appearance of tissues were observed. The authors of this study indicated that the no-observed-adverse-effect level (NOAEL) of corn silk is at least 8.0%, which corresponds to a mean daily corn silk intake of approximately 9.354 g/kg for males and 10.308 g/kg for females (Wang et al 2011).

Part: rhizome

Quick Reference Summary

Safety Class: 1

Interaction Class: B

Contraindications

None known.

Other Precautions

In persons with active gallstone disease, use of ginger should be under the supervision of a qualified healthcare practitioner (Mills and Bone 2005; Srinivasan and Sambaiah 1991; Yamahara et al. 1985).

Drug and Supplement Interactions

A human trial indicated that nifedipine with ginger had a greater antiplatelet action than nifedipine alone (Young et al. 2006).

Adverse Events and Side Effects

Gastrointestinal symptoms, such as heartburn, are occasionally associated with ginger use, especially with large doses of ginger (Chittumma et al. 2007; Sripramote and Lekhyananda 2003; Vutyavanich et al. 2001; Wigler et al. 2003; Willetts et al. 2003). Allergic reactions to ginger have been reported, primarily in spice factory workers (Futrell and Rietschel 1993; Kanerva et al. 1996; Stager et al. 1991; Zuskin et al. 1988).

Excessive doses of preparations made from fresh ginger have been reported to cause dry mouth, sore throat, nosebleeds, and kidney inflammation (Bensky et al. 2004).

Pharmacological Considerations

Although ginger has been reported to have antiplatelet activity (Srivastava 1984), thus slowing blood clotting, human studies have not demonstrated any antiplatelet activity (Bordia et al. 1997; Janssen et al. 1996; Lumb 1994; Srivastava 1989). Bile-stimulating effects have been reported in animal studies (Srinivasan and Sambaiah 1991; Yamahara et al. 1985).

No effects on coagulation were observed in a human study of ginger and warfarin (Jiang et al. 2005, 2006).

Pregnancy and Lactation

Although the use of dried ginger in pregnancy is cautioned in texts on traditional Chinese medicine (Bensky et al. 2004; Chen and Chen 2004), data from several clinical trials, including over 900 pregnant women, have not reported any adverse effects of 1 to 2 g ginger daily on pregnancy outcomes (Chittumma et al. 2007; Fischer-Rasmussen et al. 1991; Keating and Chez 2002; Smith et al. 2004; Sripramote and Lekhyananda 2003; Vutyavanich et al. 2001; Willetts et al. 2003).

No information on the safety of ginger during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No effect on warfarin (25 mg) was observed after administration of ginger (3.6 g daily) for 7 days (Jiang et al. 2005, 2006).

Administration of 1 g ginger daily for 7 days along with 10 mg of nifedipine daily exhibited a more significant inhibition of platelet aggregation than ginger or nifedipine separately, suggesting a synergistic effect of the two agents. The effect was more pronounced in subjects with normal blood pressure than in those with hypertension. While nifedipine is a calcium channel blocker typically used to treat high blood pressure, this drug has also been shown to decrease platelet aggregation (Young et al. 2006).

Case Reports of Suspected Drug or Supplement Interactions

Two case reports of suspected drug interactions with phenprocoumon and celecoxib were identified, but the reports did not identify the doses or type of products used (Handler 2003; Kruth et al. 2004).

Animal Trials of Drug or Supplement Interactions

No relevant animal trials of drug or supplement interactions were identified.

II. Adverse Events

Adverse Events Reported in Clinical Trials

A systematic review of randomized controlled studies on the use of ginger during pregnancy, including a total of 675 participants, indicated a lack of significant side effects or adverse effects on pregnancy outcomes. The review concluded that, "observational studies, with a larger sample size, are needed to confirm the encouraging preliminary data on ginger safety" (Borrelli et al. 2005). Heartburn has been reported as an adverse effect of ginger in several clinical trials (Chittumma et al. 2007; Sripramote and Lekhyananda 2003; Vutyavanich et al. 2001; Wigler et al. 2003; Willetts et al. 2003).

Case Reports of Adverse Events

Cases of allergic reactions to ginger have been reported; these cases have primarily been observed in allergic patch testing of spice factory or food service workers (Futrell and Rietschel 1993; Kanerva et al. 1996; Stager et al. 1991; Zuskin et al. 1988). A correlation has been suggested between ginger allergy and birch-mugwort-celery allergy syndrome, although the correlation has been challenged (Moneret-Vautrin et al. 2002; Stager et al. 1991).

Gastrointestinal symptoms, such as heartburn, are occasionally associated with ginger use, especially with large doses of ginger (De Smet 1997; Desai et al. 1990).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

Although ginger has been reported to have antiplatelet activity (Srivastava 1984), data from human studies has not substantiated such concerns. No effects on platelet aggregation or fibrinolytic activity were observed in volunteers with coronary artery disease or non-insulin-dependent diabetes mellitus who had taken 4 g of powdered ginger daily for 3 months (Bordia et al. 1997), although a significant reduction in platelet aggregation was observed in men after a single dose of 10 g of powdered ginger (Bordia et al. 1997). No effects were observed after a single dose of 2 g of powdered ginger (Lumb 1994). Likewise, no significant change in thromboxane B_2 formation was observed in healthy women after consumption of 5 g raw ginger daily for 7 days (Srivastava 1989). No ex vivo effects on thromboxane production were observed in blood from healthy volunteers who had taken 15 g of raw ginger or 40 g of cooked ginger daily for 2 weeks (Janssen et al. 1996).

Animal Pharmacological Studies

An acetone extract of ginger administered intraduodenally resulted in an increase in bile secretion of rats. In the same study, an aqueous ginger extract had no effects on bile secretion (Yamahara et al. 1985). In rats, ginger has been shown to stimulate hepatic cholesterol 7α-hydroxylase, an enzyme responsible for the conversion of cholesterol to bile acids (Srinivasan and Sambaiah 1991).

Other animal pharmacological studies were identified but omitted due to the availability of human data.

In Vitro Pharmacological Studies

Ginger was shown to lower blood pressure in several in vitro models (Ghayur and Gilani 2005). Estrogenic effects of ginger extracts were observed at high concentrations in one in vitro yeast assay study (Kang et al. 2006).

IV. Pregnancy and Lactation

A number of clinical trials and epidemiological studies evaluating the use of ginger in morning sickness have been completed. A systematic review of randomized controlled studies on the use of ginger during pregnancy, including a total of 675 participants, indicated that no adverse events were reported during the studies. The review concluded that, "observational studies, with a larger sample size, are needed to confirm the encouraging preliminary data on ginger safety" (Borrelli et al. 2005).

Clinical trials of ginger in pregnancy have generally been limited to 4 days of treatment, although some studies lasted 2 or 3 weeks (Keating and Chez 2002; Smith et al. 2004). Doses in the studies ranged from 1 to 2 g daily, with 1 g daily divided into three doses being the most common regimen. Most products studied were capsules of dried ginger, although one study used a ginger syrup. No significant adverse effects were observed on mothers, on pregnancy, or on fetuses (Chittumma et al. 2007; Fischer-Rasmussen et al. 1991; Keating and Chez 2002; Smith et al. 2004; Sripramote and Lekhyananda 2003; Vutyavanich et al. 2001; Willetts et al. 2003). In one study with women taking 1.95 g daily of ginger, heartburn was reported in 12% of the participants (Chittumma et al. 2007). In a prospective study, no significant differences were found between pregnant women self-administering ginger-containing products and a control group of pregnant women (Portnoi et al. 2003).

Surveys of pregnant women in Australia and Canada indicated a relatively high incidence of ginger use, with approximately 12 to 30% of women responding to the survey having used ginger for relief of nausea during pregnancy (Forster et al. 2006; Hollyer et al. 2002; Maats and Crowther 2002).

In rats administered tea of fresh ginger on days 6 to 15 of gestation, a higher embryonic loss was observed in the treatment group as compared to the untreated control group, although fetuses that survived were heavier and had more advanced skeletal development as compared to controls. No fetal malformations or signs of maternal toxicity were observed (Wilkinson 2000).

No information on the safety of ginger during lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of orally administered ginger in rats is over 250 g/kg (Wu et al. 1990).

Ziziphus jujuba Mill. — Rhamnaceae

SCN: jujube
Syn: *Ziziphus vulgaris* Lam.

AN: *badara*
PN: *da zao* (fruit)

OCN: Chinese date; Chinese jujube; jujube date

Part: fruit

Quick Reference Summary

Safety Class: 1
Interaction Class: A

Contraindications
None known.

Other Precautions
None known.

Drug and Supplement Interactions
None known.

Editors' Note
Jujube fruit, often referred to as jujube date, is a sweet dried fruit commonly used in Asian cooking (Chen and Chen 2004).

Adverse Events and Side Effects
None known.

Pharmacological Considerations
Allergic reactions to jujube fruit have been reported (Bensky et al. 2004).

Pregnancy and Lactation
No information on the safety of jujube fruit in pregnancy or lactation was identified in the scientific or traditional literature. Although this review did not identify any concerns for use while pregnant or nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions
Clinical Trials of Drug or Supplement Interactions
No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions
No case reports of suspected drug or supplement interactions were identified.

Animal Trials of Drug or Supplement Interactions
No animal trials of drug or supplement interactions were identified.

II. Adverse Events
Case Reports of Adverse Events
Allergic reactions to jujube fruit have been reported (Bensky et al. 2004).

III. Pharmacology and Pharmacokinetics
Human Pharmacological Studies
No relevant human pharmacological studies were identified.

Animal Pharmacological Studies
No relevant animal pharmacological studies were identified.

In Vitro Pharmacological Studies
No relevant in vitro pharmacological studies were identified.

IV. Pregnancy and Lactation
No information on the safety of jujube fruit during pregnancy or lactation was identified.

V. Toxicity Studies
No toxicity studies were identified.

Ziziphus jujuba Mill. var. *spinosa* (Bunge) Hu ex H.F. Chow — Rhamnaceae

SCN: ziziphus
Syn: *Ziziphus spinosa* (Bunge) Hu ex Chen
PN: *suan zao ren* (seed)
OCN: sour date; sour jujube

Part: seed

Quick Reference Summary

Safety Class: 2b
Interaction Class: A

Contraindications

Not for use in pregnancy except under the supervision of a qualified healthcare practitioner (Chen and Chen 2004).

Other Precautions

Use with caution in persons with diarrhea (Bensky et al. 2004; Chen and Chen 2004).

Drug and Supplement Interactions

None known.

Notice

Uterine stimulant (Chen and Chen 2004); *see* Appendix 2.

Adverse Events and Side Effects

An acute serotonin reaction was reported in a woman taking ziziphus who subsequently began to take venlafaxine (Stewart 2004).

Allergic reactions to ziziphus seed have been reported (Bensky et al. 2004).

Pharmacological Considerations

Ziziphus seed may cause drowsiness and sedation (Chen and Chen 2004; Jiang et al. 2007; Ma et al. 2008; Peng et al. 2000).

An in vitro study indicated that ziziphus seed had an antagonistic effect on serotonin receptors and dopamine receptors (Koetter et al. 2009).

Pregnancy and Lactation

A text on traditional Chinese medicine indicates that ziziphus seed should be used with caution during pregnancy due to uterine-stimulating activity (Chen and Chen 2004). Based on this information, use during pregnancy is not recommended except under the supervision of a qualified healthcare practitioner.

No information on the safety of zizyphus seed during lactation was identified. While this review did not identify any concerns for use while nursing, safety has not been conclusively established.

Review Details

I. Drug and Supplement Interactions

Clinical Trials of Drug or Supplement Interactions

No clinical trials of drug or supplement interactions were identified.

Case Reports of Suspected Drug or Supplement Interactions

A severe acute serotonin reaction with some anaphylactic features was reported in a 40-year-old woman. The woman had been taking 0.5 g of ziziphus seed daily for several weeks and was subsequently prescribed 37.5 mg daily of venlafaxine. Approximately 1 hour after ingesting the first dose of venlafaxine and ziziphus at bedtime, the patient became agitated, restless, nauseated, dizzy, and ataxic, and subsequently collapsed. On examination, she was pale, drooling, unable to sit, profusely diaphoretic, tachypneic, trembling, and shivering. The patient was instructed to stop taking ziziphus and instead take 150 mg venlafaxine daily, which she did for 1 month without adverse effects (Stewart 2004).

Animal Trials of Drug or Supplement Interactions

No animal trials of drug or supplement interactions were identified.

II. Adverse Events

Case Reports of Adverse Events

Allergic reactions to ziziphus seed have been reported. Symptoms included pruritus, urticaria, numbness of the mouth and lips, shortness of breath, dizziness, nausea, vomiting, facial pallor, and cold sweat (Bensky et al. 2004).

While one text on traditional Chinese medicine indicates that overdose (standard dose listed as an extract of 9–15 g) of ziziphus seed should be avoided (Bensky et al. 2004), another text indicates that up to 30 g may be used and that 70 g has been used under professional supervision without toxic reactions (Chen and Chen 2004).

III. Pharmacology and Pharmacokinetics

Human Pharmacological Studies

No relevant human pharmacological studies were identified.

Animal Pharmacological Studies

In mice orally administered 1 g/kg of an ethanol extract of ziziphus seed, a prolongation of hexobarbital-induced sleeping time was observed (Peng et al. 2000). A cyclopeptide alkaloid fraction of ziziphus seed shortened sleeping onset and prolonged sleeping time induced by hypnotic doses of pentobarbital (42 mg/kg) and increased the falling asleep rate and duration of sleeping time at a subhypnotic dosage of pentobarbital (28 mg/kg) (Ma et al. 2008). Saponin compounds from ziziphus seed were also found to prolong

pentobarbital-induced sleeping time in mice (Jiang et al. 2007).

In Vitro Pharmacological Studies

A hydroethanolic extract of ziziphus seed had an antagonistic effect with the serotonin 5-HT_{1B} receptor, with 23% inhibition of control (10 µ*M* imipramine) binding at 100 µg/ml. Antagonism of the dopamine D1 receptor, with inhibition of control (10 µ*M* dopamine) binding at 100 µg/ml was reported (Koetter et al. 2009).

IV. Pregnancy and Lactation

A text on traditional Chinese medicine indicates that ziziphus seed should be used with caution during pregnancy, due to uterine-stimulating activity (Chen and Chen 2004).

No information on the safety of zizyphus seed during lactation was identified.

V. Toxicity Studies

Acute Toxicity

The LD_{50} of intraperitoneally administered ziziphus seed in mice is 14.3 g/kg (Chen and Chen 2004). Intraperitoneal administration of 10 to 15 g/kg of an aqueous extract of ziziphus seed was lethal to guinea pigs (Zhu 1998).

Short-Term Toxicity

No signs of toxicity were observed in rats orally administered 20 g/kg of an aqueous extract of ziziphus seed daily for 30 days (Zhu 1998).

APPENDIX I: HERBAL CONSTITUENT PROFILES

Alkenylbenzenes

Written by Soaring Bear, Ph.D.

Alkenylbenzenes, also known as allylbenzenes or allylphenols, contribute to the flavor of some plants. Alkenylbenzenes found in medicinal plants include, among others, asarone, estragole, safrole, and methyleugenol. β-asarone is found in species of *Acorus* and *Asarum*. Traces of estragole can be found in herbs such as tarragon (*Artemisia dracunculus*), basil (*Ocimum basilicum*), and fennel (*Foeniculum vulgare*) (EMEA 2005). Safrole is a minor component of aromatic oils of nutmeg (*Myristica fragrans*), cinnamon leaf (*Cinnamomum verum*), and camphor (*Cinnamomum camphora*), and a major constituent of sassafras (*Sassafras albidum*) essential oil (Keeler and Tu 1983). Safrole is also found in black pepper (*Piper nigrum*) and in trace amounts in basil (*Ocimum basilicum*) (Farag and Abo-Zeid 1997; Leung and Foster 1996).

Adverse Effects

There is some controversy regarding the safety of the use of plants containing alkenylbenzenes, with some of them limited in usage by regulatory authorities. Extract of sassafras was used for many years as a flavoring agent in the soft-drink industry, providing one of the familiar natural root beer flavors. In 1960, however, researchers began to question the safety of safrole (Barceloux 2008). Animal studies showed an increase in liver tumors in animals fed the purified compound safrole in relatively high amounts (0.01 to 0.1 % of the diet) for extended periods of time (2 years, equivalent to approximately 68 years of human exposure) (Abbott et al. 1961; Hagan et al. 1967; Hagan et al. 1965; Long et al. 1963).

A 1961 report, "Toxic and possible carcinogenic effects of 4-allyl-1,2-methylenedioxybenzene (safrole) in rats," led to further in vitro studies that culminated in a ban by the FDA (CFR 2011; Homburger et al. 1961). Safrole's potential damage of DNA has not been confirmed in humans, yet it is of such substantial consequence that public health agencies are inclined to err on the side of safety. Safrole is also used as a precursor in the synthesis of the insecticide synergist piperonyl butoxide and for the clandestine manufacture of MDMA (ecstasy) (Barceloux 2008), which raises suspicions about politicization of the regulation.

Animal studies with isolated estragole raised similar concerns with regulatory agencies regarding the association between estragole and liver cancer, although estragole has been regarded as a "weak inducer" in regards to liver cancer. Metabolic studies indicate that in high doses (150–600 mg/kåg), the production of 1′-hydroxyestragole, expressed as percentage of the dose, is about 5–10 times higher than that at lower doses (0.05–50 mg/kg). European authorities have recommended on precautionary grounds that the content of estragole and methyleugenol in foods be reduced as far as possible (BGVV 2002). The Committee on Herbal Medicinal Products of the EMEA issued a public statement on the use of herbal medicinal products containing estragole and concluded that, "The present exposure to estragole resulting from consumption of herbal medicinal products (short time use in adults at recommended posology) does not pose a significant cancer risk" (EMEA 2005).

Generally in toxicology, there is some threshold dose below which toxicity is inconsequential and above which our normal detoxification systems are overwhelmed. There is evidence that small quantities of alkenylbenzenes are quickly broken down by the cytosolic and microsomal epoxide hydrolases of the liver and that the potential hazard to humans of low doses of allylbenzenes (e.g., β-asarone, estragole, and safrole) is minimal. The question of exactly how much is too much has not yet been answered.

Mechanism of Action

Alkenylbenzenes are not directly hepatotoxic or hepatocarcinogenic. Cytochrome P450 enzymes in the liver oxidize the double bond of alkenylbenzenes to an epoxide, which is mostly conjugated by glutathione for excretion, but at levels exceeding the detoxification capacity, the overflow can be reactive electrophilic and mutagenic sulfuric acid esters that give rise to DNA adducts. The propenyl analogues isosafrole, anethole, and methylisoeugenol, which cannot undergo 1-hydroxylation, are not genotoxic (Hasheminejad and Caldwell 1994).

Relative to other carcinogens, the hazard of alkenylbenzenes is small yet present. One study compared the number of liver tumors (hepatomas) induced in mice by a set of compounds with well known carcinogenic effects. Diethylnitrosamine and aflatoxin B1 respectively induced 1100 and 350 hepatomas per micromole per gram of body weight, whereas the estragole and safrole hydroxyl-metabolites respectively induced 32 and 20 hepatomas per micromole per gram of body weight (Wiseman et al. 1987).

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain alkenylbenzenes:

- *Acorus calamus* rhizome of the asarone-containing triploid or tetraploid varieties
- *Acorus gramineus* rhizome
- *Artemisia dracunculus* herb
- *Cinnamomum camphora* wood distillate
- *Foeniculum vulgare* fruit
- *Pimpinella anisum* fruit
- *Piper nigrum* fruit
- *Ocimum basilicum* leaf
- *Ocimum gratissimum* aboveground parts
- *Ocimum tenuiflorum* leaf
- *Sassafras albidum* root

Berberine

Written by Lisa Ganora

Berberine is a bitter, yellow compound belonging to the subclass of the isoquinoline alkaloids known as the protoberberines. Berberine has a positively-charged quaternary amine group and thus is quite soluble in water. Berberine is found in a number of medicinal plants including goldthread (*Coptis* spp.), goldenseal (*Hydrastis canadensis*), barberry (*Berberis* spp.), Oregon grape (*Mahonia* spp.), phellodendron (*Phellodendron* spp.), California poppy (*Eschscholzia californica*), celandine (*Chelidonium majus*), and bloodroot (*Sanguinaria canadensis*). Traditionally, berberine-rich herbs have been used as bitter choleretic and cholagogue, astringent, anti-inflammatory, antimicrobial, anticarcinogenic, and antidiabetic agents. Berberine-rich herbs have been used for conditions involving the mucous membranes in the digestive, reproductive, ocular, and respiratory systems. Berberine also has activity on the cardiovascular system, with antihypertensive, anti-atherosclerotic, antiarrhythmic, and anti-aggregatory effects.

Adverse Effects

Berberine is not usually considered to be harmful at clinical doses (Imanshahidi and Hosseinzadeh 2008). However, some authors suggest that berberine-rich herbs should be contraindicated during pregnancy and lactation, based on the fact that higher doses of berberine can strongly displace bilirubin both from human serum albumin *in vitro* and at a dosage over 2 mg/kg intraperitoneally administered to rats (Chan 1993). High concentrations of unconjugated bilirubin can accumulate in and cause damage to human brain tissue. If an excessive dose of berberine were to be ingested during pregnancy, this could be of concern especially for neonates with pre-existing jaundice or hereditary diseases (such as Gilbert's syndrome and Crigler–Najjar syndrome) which also involve hyperbilirubinemia.

There is some controversy regarding the clinical significance of berberine's bilirubin-displacing effect. Chinese literature from the 1970s and 1980s reported an association between the maternal and neonatal use of formulas containing *Coptis chinensis* (approx. 7–9% berberine content) and an increased incidence of kernicterus in infants with neonatal jaundice (Chan 1993; Upton 2001). There is also a widespread belief in China that formulas containing *Coptis* can be hazardous to infants born with an erythrocyte glucose-6-phosphate dehydrogenase (G6PD) deficiency, in whom such formulas could cause hemolytic anemia. However, it is unclear if *Coptis* or some other substance in the formulas commonly given to neonates could be responsible for such an effect (Yeung et al. 1990). A review of traditional Chinese medicine use in cases of neonatal jaundice identified one case that associated exposure to coptis with fatal hemolysis and kernicterus in a baby (Fok 2001). There are no reports in the contemporary literature of these conditions being associated with berberine-containing Western herbs such as goldenseal, barberry, and Oregon grape. Mills and Bone, however, recommend that berberine-containing herbs not be used during pregnancy except with professional supervision (Mills and Bone 2005).

Another rationale for contraindicating berberine during pregnancy is based on a few older reports claiming that it could induce uterine contractions in mice (Furuya 1957; Imaseki et al. 1961). A recent literature search found no contemporary reports of such activity ascribed to the use of berberine-containing herbs. Some studies (using several types of isolated tissue) have found berberine to have a contractile effect on smooth muscle, while others have found it to be antispasmodic and relaxant (Tice 1997). Hydrastine, a related alkaloid found along with berberine in goldenseal, was historically employed as a uterine astringent and hemostatic by the Eclectic physicians (Felter and Lloyd 1898). At least one historical source notes that goldenseal was not observed to cause or enhance contractions when used for this purpose (Shoemaker 1906).

In high doses, isolated berberine salts are moderately toxic; the LD_{50} for intraperitoneally administered berberine chloride dihydrate (BCD) was reported to be 30 mg/kg in the mouse and 205 mg/kg in the rat (Jahnke et al. 2006). The LD_{50} of orally administered berberine sulfate was reported to be greater than 1000 mg/kg in the rat (Kowalewski et al. 1975). These dosages are far beyond what one would obtain from the clinical use of berberine-containing herbs, which typically contain concentrations ranging from 0.5 to 6% in goldenseal root and 4 to 7% in coptis (Chang and But 1986; Upton 2001).

In an evaluation of reproductive toxicity, isolated berberine salts were given by oral gavage to pregnant mice over the course of eleven days. The maternal lowest-observed-adverse-effect-level (LOAEL) was determined to be 841 mg/kg daily of BCD (equivalent to approximately 698 mg of pure berberine). No signs of developmental toxicity were observed until the dosage reached approximately 938 mg BCD/kg/day, and these were limited to a 5 to 6% decrease in average fetal body weight; there was no evidence of teratogenicity (Price and George 2003). Another evaluation found no adverse effects at dosages up to 1000 mg/kg/day of BCD in rats. The authors noted that the no-observed-adverse-effect-level (NOAEL) for both rats and mice was approximately 500 times greater than the amount of berberine that one would obtain from herbs used as dietary supplements (Jahnke et al. 2006).

A 2005 reproductive screening in rats, which found no adverse effects from a hydroethanolic extract of goldenseal at a dosage of 1.86 g/kg daily (reported as 65 times the recommended human dose), concluded that toxic levels of berberine were unlikely to be reached in the plasma due to poor intestinal absorption (Yao et al. 2005). In humans, symptoms of berberine overdose are reported to include hypotension, bradycardia, dyspnea, and gastrointestinal disturbances (Lau et al. 2001).

Mechanism of Action

Berberine has demonstrated a number of anti-inflammatory and anti-cancer properties in numerous different cell lines and tissue types. A recent investigation identified NF-κβ modulation as a major mechanism underlying these effects. Berberine was found to suppress NF-κβ activation when induced by several different pro-inflammatory and carcinogenic agents. This activity led to the down-regulation of gene products responsible for blocking apoptosis in cancer cells, for promoting inflammation via COX-2 induction, and for enabling tumor metastasis (Pandey et al. 2008).

In a mechanism distinct from that of the statin drugs, berberine can significantly reduce plasma levels of LDL cholesterol. The mechanism involves upregulation of the low-density lipoprotein receptors (LDLR) in the liver. The LDL receptor system coordinates cholesterol metabolism, allowing excessive LDL cholesterol to be cleared from the bloodstream (Goldstein and Brown 2009). Berberine was found to extend the half-life of LDLR mRNA (without having an effect on gene transcription), resulting in a strong increase in LDLR protein expression (Abidi et al. 2006). A clinical study of hypercholesterolemic patients in China found that an oral dose of one gram of berberine/day for three months lowered total cholesterol by 29%, LDL by 25%, and triglycerides by 35% (Kong et al. 2004).

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain berberine:

- *Berberis vulgaris* root, root bark
- *Chelidonium majus* herb
- *Coptis chinensis* rhizome
- *Coptis groenlandica* rhizome
- *Corydalis yanhusuo* tuber
- *Hydrastis canadensis* rhizome, root
- *Mahonia aquifolium* root
- *Mahonia nervosa* root
- *Mahonia repens* root
- *Phellodendron amurense* bark
- *Phellodendron chinense* bark
- *Sanguinaria canadensis* rhizome, root

Caffeine

Written by Zoë Gardner, Ph.D.(c)

Caffeine is an alkaloid classified as a methylxanthine, a group of closely related compounds including caffeine, theophylline, and theobromine, that have similar physiological effects. Caffeine is the most widely consumed and researched psychoactive substance in the world. The worldwide average daily intake of caffeine is 159 mg per person, with Americans consuming approximately 168 mg daily, while the Dutch are the heaviest consumers at an average of 414 mg per day (Fredholm et al. 1999).

Adverse Effects

Ingestion of caffeine results in a number of physiological effects including central nervous system stimulation, acute elevation of blood pressure, increased metabolic rate, increased gastric and colonic activity, and diuretic activity (Higdon and Frei 2006; James 2000). Long-term use of caffeine usually results in tolerance to some of the physiological and behavioral effects (Griffiths and Mumford 1996). *See* Appendix 2 for more information on the diuretic activity of caffeine.

Overdose of caffeine may result in caffeine intoxication with symptoms including nervousness, anxiety, restlessness, insomnia, gastrointestinal upset, tremors, and a rapid heart rate (APA 1994). Symptoms of caffeine intoxication may be similar to those of anxiety or other mood disorders (Greden 1974). In rare cases, caffeine overdose can be fatal, although such cases are generally from intentional self-poisoning with caffeine pills or tablets rather than from drinking caffeine-containing beverages (Holmgren et al. 2004; Mrvos et al. 1989).

Regular use of caffeine produces physical dependence on caffeine, and withdrawal symptoms are common with reduction or cessation of caffeine (Hughes et al. 1998; Strain et al. 1994). Withdrawal symptoms begin to occur 12 to 24 hours after abstaining from caffeine consumption. The most common symptom of withdrawal is headache, with fatigue, decreased energy, decreased alertness, a depressed mood, irritability, and other related symptoms also being commonly reported (Juliano and Griffiths 2004).

Studies on the effects of caffeine on blood pressure indicate that caffeine causes an acute rise in blood pressure, usually occurring 30 minutes to 4 hours after ingestion (Nurminen et al. 1999). The blood-pressure raising effects may be more pronounced in persons with high blood pressure (Nurminen et al. 1999). With routine consumption of caffeine, most individuals develop tolerance to the blood-pressure raising effects, while some do not (James 1994; Lovallo et al. 2004). Studies on the effects of caffeine or coffee on blood pressure have mixed results. Some studies show a mild elevation of blood pressure after caffeine consumption (James 2004), while others show no effect or a habituation to the effect. In addition, the effects of coffee on blood pressure may be different than those of caffeine, since coffee contains other compounds, such as polyphenols, soluble fiber, and potassium, which typically have a beneficial effect on the cardiovascular system (Geleijnse 2008).

The effects of caffeine on human reproduction and pregnancy have been widely studied. While current reviews suggest a lack of adverse effects of caffeine on fetal development and pregnancy outcomes (Christian and Brent 2001; Peck et al. 2010), women are generally advised to limit caffeine intake to approximately 300 mg daily during pregnancy and 200 to 300 mg daily while nursing (AAP 2001; ADA 2008; PDR 2006).

The American Herbal Products Association has established a trade requirement (AHPA 2011) that dietary supplement products that contain caffeine,* whether as a direct ingredient or as a constituent of herbal ingredients, conform to all of the following:

1. The label of caffeine-containing dietary supplements discloses the presence of caffeine in the product.
2. The label or labeling of caffeine containing dietary supplements, except for such supplements as are described in paragraph 3 below, discloses the quantity of caffeine per recommended serving of the dietary supplement, stated in both milligrams per serving and in equivalent approximate cups of coffee, where 100 mg of caffeine represents one cup of coffee.
3. The label of caffeine-containing dietary supplements discloses the presence of caffeine, but not necessarily the quantity of caffeine per recommended serving, if at least one of the following conditions is met:
   The caffeine-containing dietary ingredient is an herb or herbal source ingredient that is less concentrated than a 1:1 weight/weight or weight/volume concentration ratio of raw herb to dietary ingredient; or

* Consisting of caffeine and all so-called caffeine analogues that include, but are not limited to, the following terms: caffeine, guaranine, mateina, mateine, methyltheobromine, thein, theine, 1,3,7-trimethylxanthine, 1,3,7-trimethyl-2,6-dioxopurine, and 7-methyltheophylline.

The amount of caffeine per recommended serving of the caffeine-containing dietary supplement is less than 25 mg.

4. Caffeine-containing dietary supplements are formulated and labeled in a manner to recommend a maximum of 200 mg of caffeine per serving, not more often than every 3 to 4 hours.
5. The following or similar statement is included on the label of any dietary supplement that contains caffeine in sufficient quantity to warrant such labeling:

   Too much caffeine may cause nervousness, irritability, sleeplessness, and, occasionally, rapid heartbeat. Not recommended for use by children under 18 years of age.

Drug Interactions

Caffeine is metabolized by the isoenzyme CYP1A2. Drugs that inhibit this isoenzyme (including fluvoxamine, ciprofloxacin, cimetidine, amiodarone, fluoroquinolones, furafylline, interferon, methoxsalen, and mibefradil) may slow the metabolism of caffeine. In persons drinking multiple cups of coffee daily, high levels of caffeine could accumulate (Carrillo and Benitez 2000).

Mechanism of Action

Methylxanthines, including caffeine, stimulate the central nervous system and the heart, elicit a diuretic effect in the kidneys, and relax smooth muscles.

Caffeine works in part by competing with adenosine, a neurotransmitter that accumulates in the brain during periods of wakefulness and helps to induce sleep. Caffeine binds to the adenosine receptors, effectively blocking the adenosine, thus promoting alertness and reducing the ability to fall asleep. Changes in motor activity are due to the effect of caffeine on neurotransmitters in the basal ganglia, an area of the brain responsible for motor control and other activities (Fisone et al. 2004).

Average amount of caffeine per 8 oz. cup

Green tea	25–40 mg
Black tea	25–55 mg
Espresso (single shot)	60–75 mg
Brewed coffee	70–125 mg
Cola beverage	23–31 mg

(China et al. 2008; McCusker et al. 2003)

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain caffeine:

- *Camellia sinensis* leaf, stem
- *Coffea arabica* seed kernel
- *Cola acuminata* seed
- *Cola nitida* seed
- *Ilex paraguariensis* leaf
- *Paullinia cupana* seed

Cyanogenic Glycosides

Written by Michael McGuffin; revised by Zoë Gardner, Ph.D.(c)

Cyanogenic glycosides are sugar-containing compounds with a nitrile group (hydrogen triple-bonded to nitrogen). After being metabolized, these compounds can release cyanide (in the form of hydrocyanic acid), a substance that can, in significant amounts, be toxic to humans and other animals. The best-known cyanogenic glycoside, amygdalin, is found in the seeds of many common fruits of the Rosaceae family, such as cherries, apples, peaches, apricots, almonds and pears (Vetter 2000).

Several common food plants, including bamboo shoots, cassava, and lima beans, contain cyanogenic glycosides (FSANZ 2004; Ologhobo et al. 1984). Medicinally, a number of plants containing cyanogenic glycosides, including black cherry bark (*Prunus serotina*) and loquat leaf (*Eriobotrya japonica*), have traditionally been used as cough remedies (Mills and Bone 2000). Foods and botanicals containing low levels of cyanogenic glycosides are generally not dangerous to consume.

Adverse Effects

Cyanide is released during the metabolism of cyanogenic glycosides. The best established and probably most important toxic action of cyanide is incapacitation of the cell's mechanism for using oxygen, resulting in chemical asphyxiation (oxygen deprivation) (Nelson 2006).

Of the plants included in this text that contain this class of glycosides, the seeds of several species of *Prunus* present the most, and possibly the only, concern. Peach kernels contain 2 to 6% amygdalin, while apricot kernels contain up to 8% amygdalin (Encarna et al. 1998; Femenia et al. 1995; Gunders et al. 1969; Holzbecher et al. 1984; Machel and Dorsett 1970). The toxic dose for apricot seeds has been reported as 10 to 20 seeds in children and 40 to 60 seeds in adults, though removal of the seed skin and heating of the seeds reduce the amygdalin content (Bensky et al. 2004; Chen and Chen 2004). Levels of cyanogenic glycosides in other species listed below are generally not of toxicological concern.

The LD_{50} of hydrocyanic acid is 3.7 mg/kg in mice and 4 mg/kg in dogs, while the LD_{50} of amygdalin, the compound found in apricot seeds, is 522 mg/kg in rats (Milne 1995; Newton et al. 1981). Based on the concentration of amygdalin in apricot seeds, a toxic dose would be equivalent to 34–39 g of amygdalin in an adult of normal weight. An adult would need to consume 425–480 grams of apricot seeds, for example, in order to reach this toxic intake level.

The symptoms of cyanide poisoning are well known from industrial exposure or exposure to cyanide in smoke from residential or industrial fires. Early signs and symptoms of acute cyanide poisoning include attempts of the

respiratory, neurologic, and cardiovascular systems to overcome tissue hypoxia (whole body oxygen deprivation). These include transient increases in blood pressure and heart rate, hyperventilation, shortness of breath, heart palpitations, and headache. Late symptoms or symptoms of severe poisoning include neurologic, respiratory, and cardiovascular depression, as tissues fail to compensate for their inability to use oxygen (Borron 2006; Nelson 2006). A number of sources review the available treatment protocols for cyanide poisoning (Cummings 2004; Goldfrank and Flomenbaum 2006; Hall et al. 2009).

Mechanism of Action

Plants containing cyanogenic glycosides do not contain detectable free hydrocyanic acid. Instead, the glycosides and enzymes that break down the glycosides are stored separately until the plant tissue is crushed, chewed, wilted, or otherwise disturbed, at which time the glycosides and enzymes come together, and cyanide (in the form of hydrocyanic acid) is released (Ganora 2009; Thayer and Conn 1981).

Cyanide is a normal waste product of protein degradation, and humans are able to detoxify about 1 mg/kg of cyanide per hour (Aminlari et al. 2007; Nelson 2006). Additionally, the acidic environment of the human stomach is not optimal for β-glucosidase, the main enzyme that liberates hydrocyanic acid from cyanogenic glycosides. Ruminant animals, such as cows, are more susceptible to poisoning from plants containing cyanogenic glycosides due to the relatively neutral pH of the ruminant digestive tract (Ganora 2009; Majak 1992).

Different methods of processing have been developed for reducing the cyanide content in food products. Cassava, a root crop widely used as a staple food in tropical countries, contains two cyanogenic glycosides and must be processed prior to consumption. Processing is done through a combination of several steps that may include crushing, soaking, drying, fermenting, or roasting (Cardoso et al. 2005; Lancaster et al. 1982).

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain cyanogenic glycosides:

- *Eriobotrya japonica* leaf (0.06% amygdalin)
- *Hydrangea arborescens* root (1–3% hydrangin)
- *Linum usitatissimum* seeds (0.1 to 1.5% linustatin and neolinustatin)
- *Prunus armeniaca* seed (up to 8% amygdalin)
- *Prunus persica* seed (2–6% amygdalin; leaf, 0.5 to 1.5% amygdalin)
- *Prunus serotina* dried bark (prunasin yielding up to 0.15% hydrocyanic acid)
- *Prunus spinosa* seeds and fresh flowers (minor amounts)
- *Sambucus canadensis* leaves, bark, seeds, and raw unripe fruits (minor amounts)
- *Sambucus nigra* leaves, bark, seeds, and raw unripe fruits (minor amounts)
- *Turnera diffusa* leaf (0.26% tetraphyllin B)

Pyrrolizidine Alkaloids

Written by Michael McGuffin; revised by Zoë Gardner, Ph.D.(c)

Pyrrolizidine alkaloids (PAs) are compounds found in a number of plant species that have been associated with liver toxicity. Based on their chemistry, different PAs may be saturated or unsaturated (the difference between the two is determined by whether a chemical bond between two particular carbons in the central ring structure is double or single). Saturated PAs, such as those found in *Euphrasia* spp. and *Echinacea* spp., are nontoxic. Unsaturated PAs, such as those in *Senecio* species, are recognized as causing liver toxicity when ingested in sufficient amounts. Certain unsaturated PAs are more toxic than others.

Adverse Effects

Initial concern regarding PAs was probably based on cases of livestock poisoning due to consumption of *Senecio* and *Amsinckia* (Cheeke 1988; Johnson et al. 1985). Supplies of grain have been contaminated by PA-containing weeds in grain fields, leading to outbreaks of PA toxicity, causing acute cases of liver damage in persons eating the contaminated grain (Prakash et al. 1999). Serious liver damage has also occurred after chronic consumption of PA-containing medicinal plants that have traditionally been used for therapeutic purposes.

The herbs most widely used in the United States that contain PAs are comfrey root and leaf (*Symphytum* spp.), coltsfoot leaf and flower (*Tussilago farfara*), and borage leaf (*Borago officinale*). The amounts and relative safety of PAs in these plants and in the various plant parts vary widely. For example, in comfrey, the concentration of alkaloids is measured at about 10 times higher in the root than in the leaf (Tyler 1994). Moreover, echimidine, the most toxic of the alkaloids found in comfrey, is present in *Symphytum asperum* and *S.* x *uplandicum* but is absent in most samples of *S. officinale* (Awang et al. 1993; Huizing et al. 1982; Jaarsma et al. 1989). Although a number of species of *Eutrochium* (recently reclassified from *Eupatorium*) are known to contain PAs (Zhang et al. 2008), the PA content of several species used in the U.S. (*E. fistulosum, E. purpureum*, and *E. maculatum*) has not been adequately investigated. For other plants, such as borage, the amounts of PAs are generally cited to be "low," although reliable information on the concentration of PAs in these plants is lacking.

While some of these alkaloids have shown carcinogenic and mutagenic properties, and kidney toxicity has been reported (Fu et al. 2004), the primary concern for use of these herbs is the potential for serious liver damage, specifically hepatic veno-occlusive disease (a condition in which veins in the liver become blocked). This potentially fatal condition manifests symptoms such as abdominal pain, swelling of the liver and spleen, accumulation of fluid in the abdominal cavity, elevated levels of bilirubin, jaundice, cirrhosis of the liver, and liver failure (Chen and Huo 2010; McDermott and Ridker 1990).

Cautious restrictions on the use of all of the herbs containing unsaturated (toxic) PAs have been recommended by the American Herbal Products Association, with suggestions to limit use to external application on unbroken skin only, and to refrain from use while nursing (AHPA 2011). All use is contraindicated in pregnancy and in persons with a history of liver disease.

Mechanism of Action

PAs are metabolized in the liver by the drug metabolizing isoenzyme CYP3A4 to form N-oxides and conjugated dienic pyrroles (alkylating compounds that are highly reactive with proteins and nucleic acids). The complex of

pyrroles with proteins and nucleic acids may remain in tissues and cause chronic injury, while the N-oxides may be transformed into epoxides and toxic necines. Substances that induce CYP3A4 may enhance the toxicity of PAs, while inhibitors of this isoenzyme may reduce the toxicity. The development of veno-occlusive disease remains poorly understood, although studies suggest that endothelial cell injury, cytokines, and hemostatic derangement are all involved. A strict dose-dependent association between PA consumption and veno-occlusive disease development may not be present, and not all persons taking PAs develop the disease (Chen and Huo 2010).

An animal study demonstrated that the systemic bioavailability of PAs after external use is about 20 to 50 times lower than that after oral ingestion, although absorption may be increased after application to inflamed, cut, or abraded skin (Brauchli et al. 1982).

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain unsaturated pyrrolizidine alkaloids*:

- *Alkanna tinctoria* root
- *Borago officinalis*† herb
- *Eutrochium fistulosum* herb, root, and rhizome
- *Eutrochium maculatum* herb, root, and rhizome
- *Eutrochium purpureum*‡ herb, root, and rhizome
- *Symphytum asperum*§ leaf, root
- *Symphytum officinale*§ leaf, root
- *Symphytum* x *uplandicum*§ leaf, root
- *Tussilago farfara*§ flower, leaf.

* Note that although medicinal species of *Petasites*, including purple butterbur (*Petasites hybridus*) and Arctic butterbur (*Petasites frigidus*), are not listed in this text, these species also contain pyrrolizidine alkaloids. PA-free extracts of *Petasites* species are available, and PA-free products are considered appropriate for internal use.

† Processing of borage seed oil eliminates PAs.

‡ Presence and type of PAs has not been confirmed.

§ PA-free extracts of *Symphytum* spp., *Tussilago farfara*, and other botanicals are available commercially.

Salicylates

Written by Michael McGuffin; revised by Zoë Gardner, Ph.D.(c)

Salicylates are phenolic acids derived from salicylic acid, and include salicin (in *Salix* species), populin (in *Populus* species), methyl salicylate (in *Gaultheria* and *Betula* species), and acetylsalicylic acid (aspirin). Salicylic acid was first synthesized in 1860, and the salicylate-containing plants were soon supplanted by the synthetic analog, acetylsalicylic acid (Weissmann 1991). Salicylates are commonly

consumed for pain relief, especially for low intensity pain, with an estimated 40,000 metric tons of aspirin being consumed worldwide every year (Warner and Mitchell 2002).

Adverse Effects

Concern regarding the consumption of the salicin-containing plants is addressed here primarily to assure that the known adverse effects of aspirin have been examined in relationship to these naturally occurring related compounds. While persons with known sensitivity to aspirin and other salicylates should exercise caution with these plants, there is no evidence that the types of reactions known to be associated with the pharmaceutical salicylates is observed with *Salix* or any other salicin-rich plant. A study using serum from human volunteers taking willow bark extract (providing 240 mg of salicin daily for 28 days) did note a modest effect on platelet aggregation, but it was less than the effect seen with 100 mg per day aspirin (acetylsalicylic acid) (Krivoy, et al. 2001). At this dose, there is reassurance that salicin will not adversely affect bleeding, though there have not been studies conducted in patients with disorders of thrombotic function. It also suggests that salicin should not be used as a substitute for aspirin in the prevention of heart attacks and strokes.

The concentration of salicylates in most botanicals listed here is quite low, and salicylate overdose is unlikely except in the case of wintergreen essential oil (which contains 98% methyl salicylate), for which multiple cases of overdose have been reported after oral and topical use (Chan 1996; Chyka et al. 2007; Stevenson 1937). Symptoms of mild salicylate poisoning (serum concentrations of 30–50 mg/dl) include deep breathing (hyperpnea), nausea, vomiting, tinnitus, and dizziness. Moderate poisoning (serum concentrations of 50–70 mg/dl) can produce symptoms of rapid breathing (tachypnea), fever, sweating, dehydration, incoordination, and listlessness. With severe intoxication (> 75mg/dl), symptoms may include coma, seizures, hallucinations, stupor, cerebral edema, dysrhythmias, heart failure, low blood pressure, decreased urine production (oliguria), or kidney failure (Pearlman and Gambhir 2009).

Mechanism of Action

Most research has focused on the ability of salicylates to suppress the synthesis of prostaglandins, hormones thought to play an integral role in pain, inflammation, and fever. Two specific enzymes, cyclooxygenase 1 and 2 (COX1 and COX2), are considered to be predominant in this process. COX1 occurs in platelets, blood vessels, and other organs; COX2 acts primarily in inflamed tissue.

Aspirin is the most commonly used salicylate. It blocks the synthesis of prostaglandins through the acetylation of cyclooxygenase, especially COX1, by an irreversible transfer of the acetyl group into the enzyme (Hardman and Limbird 1996). Salicylic acid and salicylates (such as salicin) that lack an acetyl group are not as effective as aspirin in inhibiting platelet aggregation. Therefore, there is little concern for salicin-containing plants causing hematological disturbances. Conversely, these plants are not appropriate as a preventative treatment against stroke, a benefit associated with aspirin consumption.

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain salicylates:

- *Betula lenta* leaf and bark
- *Filipendula ulmaria* herb
- *Gaultheria procumbens* leaf
- *Populus balsamifera* ssp. *balsamifera* leaf buds
- *Salix alba* bark
- *Salix daphnoides* bark
- *Salix fragilis* bark
- *Salix pentandra* bark
- *Salix purpurea* bark

Tannins

Written by Michael McGuffin

Tannins are a broad class of complex phenolic compounds that are comprised of two chemical groups: the hydrolyzable tannins (gallotannins) and the condensed tannins (proanthocyanidins). Tannins bind to and precipitate proteins, producing the astringent activity of tannin-containing herbs. Tannins are natural components of many herbs and common foods, and some tannins are used in the processing of foods, alcoholic beverages, and medicines. Condensed tannins are found in grapes (*Vitis vinifera*), green tea (*Camellia sinensis*), hawthorn (*Crataegus* spp.), and many other plants, while hydrolyzable tannins are found in pomegranate (*Punica granatum*), green and black tea (*Camellia sinensis*), white oak (*Quercus alba*), witch hazel (*Hamamelis virginiana*), and cranesbill (*Geranium maculatum*). Both types of tannins have astringent properties, providing the basis for many of the historical medicinal uses of the plants containing them.

Adverse Effects

Tannins are broadly distributed throughout the plant kingdom, occurring in the barks, roots, leaves, fruits, seeds, and other parts of many different species. Only those plants which are reported to contain at least 10% tannins have been identified as relevant to this discussion of the potential adverse effects of tannin consumption.

Tannins have been shown to reduce the availability of certain nutrients. In the digestive tract, tannins form complexes with proteins, starch, and digestive enzymes, thereby reducing the nutritional values of ingested foods. Condensed tannins, in particular, inhibit digestive enzymes, although the major effects of condensed tannins within the digestive tract are thought to be due to the formation of less digestible complexes with dietary proteins, rather than by inhibition of digestive enzymes (Chung et al. 1998a). Tannins are also known to reduce the absorption of certain vitamins and minerals, notably iron (Chung et al. 1998a; Disler et al. 1975; Salunkhe et al. 1990). To optimize nutrient absorption, supplements or beverages that contain tannins should be taken separately from meals.

Most of the known adverse effects related to tannins are specifically recorded for consumption of tannic acid, an ethereal or hydroalcoholic extract of nutgalls (from *Quercus* spp.), and include gastrointestinal disturbances and kidney damage, as well as severe necrotic conditions in the liver (Gilman et al. 1985; Osol and Farrar 1955). While these concerns may be theoretically relevant to the use of high tannin content herbs, only the digestive irritating properties of tannins are traditionally associated with the consumption of these other plants.

Both carcinogenic and anti-cancer properties of tannins have been reported in experimental settings that measured the effect of tannins on laboratory animals (Chung et al. 1998a; Chung et al. 1998b). Condensed tannins, also called proanthocyanidins, are recognized to have significant anti-oxidant activity and potential anti-cancer activity (Nandakumar et al. 2008).

Mechanism of Action

The therapeutic activities of tannins are associated with their ability to bind with and precipitate proteins and to force dehydration of mucosal tissues. In external use, these actions allow the formation of a protective layer of harder, constricted cells; internally, both normal and pathologic secretions of all types are reduced. During internal use, tannins alter the fluidity of the bowel contents, hence their use as anti-diarrheal remedies.

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain over 10% tannins:

- *Agrimonia eupatoria* herb
- *Alchemilla xanthochlora* herb
- *Arctostaphylos uva-ursi* leaf
- *Camellia sinensis* leaf and stem
- *Castanea dentata* leaf
- *Corylus avellana* leaf and bark
- *Corylus cornuta* leaf and bark

- *Epilobium parviflorum* herb
- *Eucalyptus globulus* leaf
- *Euphrasia rostkoviana* herb
- *Euphrasia stricta* herb
- *Filipendula ulmaria* herb
- *Geranium maculatum* root
- *Hamamelis virginiana* bark and leaf
- *Heuchera micrantha* root
- *Ilex paraguariensis* leaf
- *Juglans nigra* leaf
- *Krameria argentea* root
- *Krameria lappacea* root
- *Paullinia cupana* seed
- *Polygonum bistorta* root
- *Potentilla erecta* rhizome
- *Punica granatum* fruit husk
- *Quercus alba* bark
- *Quercus petraea* bark
- *Quercus robur* bark
- *Rheum officinale* rhizome and root
- *Rheum palmatum* rhizome and root
- *Rheum tanguticum* rhizome and root
- *Rubus fruticosus* leaf
- *Rumex acetosa* leaf
- *Rumex acetosella* leaf
- *Rumex crispus* root
- *Rumex hymenosepalus* root
- *Rumex obtusifolius* root
- *Salix alba* bark
- *Salix daphnoides* bark
- *Salix fragilis* bark
- *Salix pentandra* bark
- *Salix purpurea* bark
- *Schinus molle* bark
- *Schinus terebinthifolius* bark
- *Terminalia arjuna* bark
- *Terminalia bellerica* fruit
- *Terminalia chebula* fruit
- *Uncaria gambir* leaf and twig

Thujone

Written by Lisa Ganora

Thujone (which occurs as both α-thujone and its isomer, β-thujone) is a bicyclic monoterpene ketone found as a constituent of certain volatile oils. α-Thujone is a modulator of $GABA_A$ and $5\text{-}HT_3$ receptors; high doses are neurotoxic and cause epileptiform convulsions in mammals (Dettling et al. 2004). β-Thujone is less active in this respect. Because of toxicological concerns, isolated thujone is banned in many countries as a food additive. Contemporary EU regulations limit its content in sage-containing foods to 25 mg/kg, while bitters may contain 35 mg/L of thujone (ECSCF 2003). In a draft document issued in January 2011, the European Medicines Agency recommended that thujone intake from herbal medicines be limited to 6 mg per day, and indicated that higher amounts may be acceptable if deemed appropriate on a case by case basis (EMA 2011).

One analysis found that the total thujone content in essential oil of common garden sage (*Salvia officinalis*) ranged from 9 to 44% (Perry et al. 1999), while wormwood (*Artemisia absinthium*) essential oil has been reported to contain anywhere from 0 to 90% total thujone (Lachenmeier et al. 2006). Thuja (*Thuja occidentalis*) oil may have up to 73% total thujone (Naser et al. 2005), tansy oil (*Tanacetum vulgare*) up to 81% (Rohloff et al. 2004), and yarrow (*Achillea millefolium*) oil from 0 to 27% α-thujone and 0 to 11% β-thujone (Orav et al. 2006). Depending on any given plant's developmental stage, chemotype, and geographical origin, there can be wide variations in total thujone content as well as in the proportion of α-thujone to β-thujone.

It was formerly assumed that thujone (from *A. absinthium*) was responsible for the alleged psychotropic activity and toxicity of absinthe; this notion has recently been

refuted by multiple analyses demonstrating that insignificant concentrations of the compound are present in both historical and contemporary examples of the beverage. It is now generally believed that absinthe's high ethanol content, and perhaps the presence of chemical adulterants (e.g., copper salts added as green dyes to inferior grades of absinthe) or other potential toxins, were responsible for any actual neurological effects (Lachenmeier et al. 2008).

Adverse Effects

Thujone has very low solubility in water; therefore little can be found in aqueous preparations (e.g., teas); however, it can be present in hydroethanolic extracts having a high percentage of ethanol, and especially in distilled products (Tegtmeier and Harnischfeger 1994).

In a toxicological assessment of thujone in mice, no adverse effects were found at concentrations below 5 mg/kg body weight, given orally for fourteen weeks (Council of Europe 1999). The LD_{50} for orally administered thujone in the rat has been reported as 192 to 500 mg/kg (ECSCF 2003).

Numerous investigations have established that essential oil of wormwood can cause convulsions in animals (Padosch et al. 2006). A case report relates that the ingestion of approximately 10 ml of the oil produced seizures, mental confusion, and agitation in a 31-year-old man; this was followed by apparent rhabdomyolysis and subsequent acute renal failure which resolved after treatment (Weisbord et al. 1997). In another case, a 2-year-old ingested up to 15 ml of dilute *Thuja* oil; the resulting seizures responded to treatment with lorazepam and phenytoin, and she was released after fifteen hours in the hospital with no apparent adverse sequelae (Friesen and Phillips 2006).

In a recent investigation, an ethanol drink high in thujone (100 mg/l) was demonstrated to have a negative effect on attention performance in human volunteers and to counteract the anxiolytic effects of ethanol alone; a low-thujone (10 mg/l) preparation did not have these properties (Dettling et al. 2004).

Mechanism of Action

α-Thujone, which binds at a non-competitive blocker site, has been established as a reversible modulator of $GABA_A$ receptors. This monoterpene has an analeptic effect similar to picrotoxinin and the pesticide dieldrin, both $GABA_A$ receptor antagonists. In the case of all three compounds, binding and toxicity is blocked by diazepam, phenobarbital, and ethanol. β-Thujone was found to have a 2.3-fold lower binding affinity and has demonstrated lesser toxicity in mice (Hold et al. 2000). It seems likely that thujone's activity on $GABA_A$ receptors is largely responsible for its seizure-promoting effects.

One study has reported that α-thujone reduced the activity of cloned human $5\text{-}HT_3$ receptors, resulting in an inhibition of serotonergic responses. It is not yet known if this mechanism contributes to the observed neurological effects of the compound (Deiml et al. 2004).

It was formerly suggested that thujone might interact with cannabinoid receptors in the CNS to bring about a psychotropic effect. Despite internet marketing claims, this idea has been discredited by a study which found that thujone has low affinity for cannabinoid receptors and does not demonstrate cannabimimetic properties (Meschler and Howlett 1999).

In chick embryo liver cells, thujone has demonstrated porphyrogenic activity; on this basis, it has been suggested that it could be hazardous to patients with acquired or genetic defects of heme synthesis in the liver (Bonkovsky et al. 1992).

In human cells, the thujone isomers are metabolized by several cytochrome P450 enzymes, including CYP2D6 and CYP3A4. 7-Hydroxy-α-thujone and 7-hydroxy-β-thujone are the major metabolites, followed by their 4-hydroxylated congeners (Jiang et al. 2006). These metabolites have significantly reduced $GABA_A$ binding affinity compared to their parent compounds and are therefore considered to be less toxic (Hold et al. 2000). Little is known about the pharmacokinetics of thujone in humans.

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* that contain thujone:

- *Achillea millefolium* herb
- *Artemisia absinthium* herb
- *Artemisia capillaris* herb
- *Artemisia douglasiana* herb
- *Artemisia lactiflora* herb
- *Artemisia scoparia* herb
- *Artemisia vulgaris* herb
- *Evernia furfuracea* thallus*
- *Evernia prunastri* thallus*
- *Hyssopus officinalis* herb
- *Platycladus orientalis* cacumen
- *Salvia officinalis* leaf

* May contain thujone.

- *Tanacetum vulgare* herb*
- *Thuja occidentalis* leaves

* Some chemotypes contain thujone.

APPENDIX 2. HERBAL ACTION PROFILES

Abortifacients

Written by Michael McGuffin, revised by Aviva Romm, M.D. and Tieraona Low Dog, M.D.

Abortifacients are agents that are used to induce abortion and terminate pregnancy. Herbal abortion is not a recommended method of intentional pregnancy termination.

Adverse Effects

There is a long history of use of select botanicals as abortifacients. Research on the use of botanicals to induce abortion is extremely limited, and most information on the topic comes from historical or empirical reports. Little reliable data exists on the effectiveness, toxic levels, or possible effects of these plants on the developing fetus.

Terminating a fetus in a healthy human being is a difficult and potentially dangerous process. When using botanicals for this purpose, the dose of the herb required to produce an abortion is generally extremely high and may pose toxicity risks to the mother or may have negative effects on the developing fetus should the attempt fail. Because of this, a follow-up medical abortion should be considered if an attempt to abort with an herbal agent is not effective. To date, no reports of failed abortions resulting in fetal damage have been found, although cases of maternal toxicity have been reported. Such cases include a single fatal event of a mother recorded in 1978 following consumption of an extremely high dose (one ounce) of pennyroyal essential oil (identified as *Mentha pulegium* or *Hedeoma pulegioides*) in an attempted abortion. The victim suffered two heart attacks, liver and kidney failure, and disseminated vascular coagulation before her death (Sullivan et al. 1979). Additionally, a case of nicotinic poisoning was reported after an abortion attempt using blue cohosh (*Caulophyllum thalictroides*) in excessive doses (Rao and Hoffman 2002; Rao et al. 1998).

Abortifacient or potential harmful effects to a fetus typically require very high amounts of a botanical or botanical formula over a continuous period of time. Thus, ingesting small amounts of the herbs listed below during pregnancy, except in rare cases, is not a cause for alarm. In addition, some of the herbs listed below as abortifacients, such as saffron (*Crocus sativus*), safflower (*Carthamus tinctorius*), and Roman chamomile (*Chamaemelum nobile*), may be safely used during pregnancy in amounts typically consumed in foods or beverages.

Mechanism of Action

Abortifacients have many different mechanisms of action. Some abortifacients act indirectly, meaning that they induce abortion through peripheral systems such as the endocrine, cardiovascular, gastrointestinal, or nervous systems. Others are direct-acting abortifacients that target the uterus, endometrium, and/or fetus, causing abortion to commence. It is not possible to generalize the action, efficacy, or safety of plants listed in this text as abortifacients, since the mechanisms of action of these plants have not been well studied (Bingel and Farnsworth 1980).

Certain abortifacients have drastic purgative effects or are gastrointestinal irritants that can produce reflex uterine contraction. Many volatile oils, such as oil of tansy (*Tanacetum vulgare*), and saponin glycosides, such as those found in bethroot (*Trillium erectum*), act in this manner.

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* with potential abortifacient action:

- *Andrographis paniculata* herb
- *Carthamus tinctorius* flower
- *Catharanthus roseus* herb
- *Caulophyllum thalictroides* root
- *Chamaemelum nobile* flower
- *Chrysopogon zizanoides* root

- *Crocus sativus* stigma
- *Cytisus scoparius* flowering tops
- *Gossypium herbaceum* root bark
- *Gossypium hirsutum* root bark
- *Juniperus virginiana* leaf, berry
- *Mentha pulegium* leaf, essential oil
- *Podophyllum peltatum* root
- *Podophyllum hexandrum* root
- *Ruta graveolens* herb
- *Tanacetum vulgare* herb
- *Thuja occidentalis* leaves

Bulk-forming Laxatives

Written by Michael McGuffin; revised by Eric Yarnell, N.D.

Bulk-forming laxatives are substances that promote bowel evacuation by increasing the bulk volume and water content of the stool. These are generally considered to be the safest laxative agents.

Adverse Effects

Bulk-forming laxatives are contraindicated in bowel obstruction and must be taken with adequate liquid to avoid paradoxical constipation and esophageal or bowel obstruction (Frohna 1992; Herrle et al. 2004; Noble and Grannis 1984; Schapira et al. 1995). Cases of esophageal or bowel obstruction typically occur in persons with abnormal esophageal or intestinal narrowing or in persons who took the laxative product with insufficient liquid (Angueira and Kadakia 1993; Frohna 1992; Herrle et al. 2004).

The U.S. Food and Drug Administration (FDA) requires specific labeling of products classified as over-the-counter drug products that contain certain of the herbs listed here, including agar (*Gelidiella acerosa* and *Gelidium* spp.), guar gum (*Cyamopsis tetragonolobus*), and psyllium (*Plantago* spp.) if these are marketed in a "dry or incompletely hydrated form," such as capsules and powders. The designated labeling is as follows:

> **Choking** [highlighted in bold type]: Taking this product without adequate fluid may cause it to swell and block your throat or esophagus and may cause choking. Do not take this product if you have difficulty in swallowing. If you experience chest pain, vomiting, or difficulty in swallowing or breathing after taking this product, seek immediate medical attention (CFR 2011).

Additional language is required under the directions for use, as follows:

> **Directions** [highlighted in bold type]: (Select one of the following, as appropriate: "Take" or "Mix") this product (child or adult dose) with at least 8 ounces (a full glass) of water or other fluid. Taking this product without enough liquid may cause choking. See choking warning.

Although the above labeling is not specifically required by FDA for dietary supplements, it is suggested that the above or significantly similar language be included on the label of dietary supplements that contain bulk-forming laxative ingredients and posted at the point of sale in any retail setting where any of these are sold in bulk.

Bulk-forming laxatives may inhibit the absorption of other drugs. The drugs usually associated with this consideration are aspirin, digitalis and other cardiac glycosides, antibiotics, thyroid hormones, and anticoagulants. To ensure complete absorption of drugs, bulk-forming laxatives and other drugs should be taken several hours apart

(Brunton et al. 2006). The absorption of dietary nutrients, including calcium, iron, zinc, sodium, and potassium, can also be inhibited (ESCOP 2003). Appropriate supplementation must therefore be considered when using bulk-forming laxatives for extended periods. For individuals accustomed to a low-fiber diet, gradual use of less refined fiber in the diet is recommended before using bulk fiber agents.

Mechanism of Action

Bulk-forming laxative herbs include gel-forming fibers such as psyllium husk (*Plantago* spp.) and flax seed (*Linum usitatissimum*). Gel-forming fibers contain a form of starch called mucilage, composed of mucopolysaccharides, and roughage or indigestible plant fiber called cellulose. These plant starches are hydrophilic, absorbing water or other liquid to form a mucilaginous or gel-like substance. Because these herbs also expand on contact with liquid, they add moisture and bulk to stools in the colon (Brunton et al. 2006; Williams et al. 2006).

Bulk-forming laxatives that contain mucilage have additional minor benefits complementing their primary effect of relieving constipation. Mucilaginous herbs are demulcent, meaning that they are soothing to inflamed mucosal surfaces (Brunton et al. 2006). Demulcents form a temporary gelatinous barrier which protects the intestinal wall from irritation caused by caustic material in the intestines, thus allowing repair of the adjoining tissues.

Besides providing the demulcent properties associated with these plants' mucilage content, the indigestible cellulose fiber of bulk-forming laxatives plays additional roles related to diet and digestion. Fiber absorbs dietary fats, decreasing the absorption of cholesterol into the bloodstream. In addition, since dietary fiber from bulk laxatives cannot be digested, these herbs add a feeling of fullness without calories. Fiber also slows the release of dietary sugar from the digestive tract into the blood stream, assisting in the stabilization of blood sugar (Brennan 2005; Singh 2007; Sirtori et al. 2009).

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* as bulk forming laxatives:

- *Gelidiella acerosa* (thallus)
- *Gelidium amansii* (thallus)
- *Gelidium cartilagineum* (thallus)
- *Gelidium crinale* (thallus)
- *Gelidium divaricatum* (thallus)
- *Gelidium pacificum* (thallus)
- *Gelidium vagum* (thallus)
- *Linum usitatissimum* (seed)
- *Plantago arenaria* (seed, seed husk)
- *Plantago asiatica* (seed, seed husk)
- *Plantago ovata* (seed, seed husk)

Diuretics

Written by Zoë Gardner, Ph.D.(c), reviewed by Roy Upton, RH (AHG), DAyu and Lana Dvorkin-Camiel, Pharm.D., R.Ph.

A diuretic is a substance that increases the volume and/or rate of urinary output.

Botanicals with diuretic activity can be divided into two general categories: those that induce urinary output and thus fluid loss through excretion of sodium ions (natriuretics), and those that induce urinary output without impacting electrolyte balance (aquaretics).

In conventional medicine, diuretics are employed to assist the kidneys in eliminating excess fluid from the body, fluid that accumulates in conditions such as congestive heart failure, pulmonary edema, and liver failure (Brunton et al. 2006). To be clinically useful for such indications, a diuretic must also cause excretion of sodium or sodium chloride ions in order to cause substantial fluid output (Wright 2007). Diuretics may also be employed for relief of conditions such as mild primary hypertension or to increase the flow of urine in cases of urinary tract infections and other conditions of the urinary tract (Brunton et al. 2006; Yarnell 2001).

The listing of herbs as diuretics in this text is generally based on traditional use and clinical observation. While there are a number of botanicals for which diuretic activity has been confirmed, formal research is lacking on the specific activity (i.e., natriuretic or aquaretic) and degree of effect of most of these (Wright et al. 2007). This makes it difficult to provide clear guidance on which species and what dosage may cause the level of diuresis that invokes the concerns typically ascribed to diuretics. At the same time, there is evidence to suggest that select botanical diuretics (e.g., dandelion leaf; *Taraxacum officinale*) do not result in the potassium loss common to many conventional diuretics (Racz-Kotilla et al. 1974). The magnitude of diuretic activity of the species listed here is considered by many to be generally more mild than those of pharmaceutical diuretics (Racz-Kotilla et al. 1974; Wright et al. 2007). Therefore, formal investigation would be helpful in determining the clinical efficacy, potential adverse effects profile, and potential advantage of using botanical as compared to conventional diuretics.

Adverse Effects

The potential adverse effects associated with diuretics are generally related to shifts in electrolyte balances. Although botanical diuretics are generally not as strong as pharmaceutical diuretics, and have not been associated with many of the adverse effects (i.e., hypotension, dehydration, and significant electrolyte loss) of pharmaceutical diuretics, botanical diuretics may theoretically cause electrolyte imbalances (Brunton et al. 2006; Wright et al. 2007). Therefore, individuals with conditions that may cause electrolyte imbalances (i.e., congestive heart failure, liver failure, kidney failure, etc.) should be cautious when taking diuretic herbs or do so under medical supervision, as shifts in electrolyte balance may exacerbate the disease state.

Use of diuretics is generally cautioned in persons taking drugs with narrow therapeutic ranges (small differences between the effective and toxic doses), such as warfarin, steroids (i.e., prednisone), digoxin, tacrolimus, cyclosporine, valproic acid, phenytoin, and carbemazepine, as shifts in serum levels of sodium and potassium may affect serum levels of these drugs. Serum electrolyte shifts, notably sodium, can also cause an increase in serum lithium levels, and may result in lithium toxicity (Finley et al. 1995). Use of lithium with diuretics is not recommended, but if taken concomitantly, serum drug and electrolyte levels need to be monitored closely. Corticosteroids or licorice may amplify the potassium-depleting effects of diuretics (Brunton et al. 2006; Isbrucker and Burdock 2006).

Concomitant use of diuretic herbs with prescription loop diuretics, thiazide diuretics, osmotic diuretics, and potassium-sparing diuretics may cause excessive fluid loss. Reductions in potassium levels caused by diuretics may increase the toxicity of cardiac glycosides, such as digoxin, and their combination should be avoided (Anon 2010).

Diuretics may irritate or exacerbate symptoms of kidney stones, and professional guidance is recommended when employing these therapies for this condition (Chitme et al. 2010). Some naturopathic treatment protocols suggest that kidney stones smaller than 5 mm in size may be passed with the assistance of herbal diuretics, but such protocols should only be followed under the supervision of a qualified health professional (Yarnell 2001).

Mechanism of Action

Due to lack of research, it is not yet known whether botanical diuretics have the same or different mechanisms of action as non-botanical diuretic drugs.

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* as diuretics:

- *Agathosma betulina* leaf
- *Agathosma crenulata* leaf
- *Agathosma serratifolia* leaf
- *Alisma plantago-aquatica* rhizome
- *Anethum graveolens* herb and fruit
- *Apocynum androsaemifolium* root
- *Apocynum cannabinum* root
- *Asparagus officinalis* rhizome
- *Asparagus racemosus* rhizome
- *Betula pendula* leaf
- *Betula pubescens* leaf
- *Boerhavia diffusa* root
- *Camellia sinensis* leaf and stem
- *Chamaesyce hirta* herb
- *Coffea arabica* seed kernel
- *Cola acuminata* seed
- *Cola nitida* seed
- *Daucus carota* fruit
- *Equisetum arvense* herb
- *Equisetum hyemale* herb
- *Equisetum telmateia* herb
- *Gossypium herbaceum* root bark
- *Gossypium hirsutum* root bark
- *Ilex paraguariensis* leaf
- *Juniperus communis* fruit
- *Juniperus monosperma* fruit
- *Juniperus osteosperma* fruit
- *Juniperus oxycedrus* fruit
- *Nardostachys jatamansi* rhizome and root
- *Parietaria judaica* herb
- *Parietaria officinalis* herb
- *Paullinia cupana* seed
- *Petroselinum crispum* root
- *Phyllanthus amarus* whole plant
- *Phyllanthus fraternus* whole plant
- *Phyllanthus niruri* whole plant
- *Polygala senega* root
- *Polygala sibirica* root
- *Polygala tenuifolia* root
- *Portulaca oleracea* herb
- *Prunus spinosa* seeds and fresh flowers
- *Ribes nigrum* leaf
- *Satureja hortensis* leaf
- *Satureja montana* leaf
- *Selenicereus grandiflorus* flowers and stem
- *Solidago canadensis* var. *lepida* herb
- *Solidago gigantea* herb
- *Solidago virgaurea* herb
- *Stephania tetrandra* root
- *Tanacetum vulgare* herb
- *Taraxacum officinale* leaf, root
- *Tinospora cordifolia* root, stem, and leaf
- *Tribulus terrestris* fruit
- *Urtica dioica* leaf
- *Zea mays* stigma

Emetics

Written by Michael McGuffin; revised by Zoë Gardner, Ph.D.(c)

An emetic is a substance that induces vomiting in a sufficient dose. Emetics have two primary functions. The first is to empty the stomach, especially in cases of ingestion of non-caustic poisons; the second is as an expectorant for respiratory diseases, primarily to expel mucus and phlegm from the bronchioles. Historically, use in respiratory conditions was mainly in children with conditions such as asthma, bronchitis, and diphtheria before they were able to expectorate effectively. Doses for this latter use are significantly smaller than doses used to empty the stomach.

Adverse Effects

The concerns related to herbs with emetic potential are of importance only when they are consumed in dosage levels sufficient to produce vomiting. Such use is typically limited in duration to one or several doses, and use of emetics for more than three to four days can produce dehydration and severe electrolyte imbalances. Continual retching action from chronic vomiting will strain the abdominal and stomach muscles and the diaphragm, causing severe cramping and potential development of hernias (Rakel 1996; Hardman & Limbird 1996; Katcher et al. 1983). Chronic use by persons with eating disorders may lead to generalized muscle weakness, diarrhea, mild tremors, fluid retention, dehydration, and metabolic disturbances (hypokalemia, hypochloremic acidosis, elevation of creatinine phosphokinase) (Manno and Manno 1977; Quang and Woolf 2000).

Emetics are contraindicated in those with aneurysms, hernia, arteriosclerosis, or in cases of hemorrhage. The use of emetics is often associated with depression of central motor functions, and so is best used under appropriate medical supervision.

The following guidelines have been developed for the use of ipecac (*Cephaelis ipecacuanha*), one of the most common botanical emetics used, but are applicable to any botanical being used for emetic purposes in the case of poisonings. Ipecac (and other emetics) should not be used unless directed by a qualified healthcare professional (physician, poison control center, or other professional), and should not be used if:

- A patient is comatose or has altered mental status and the risk of breathing in the stomach contents is high.
- The patient is having convulsions.
- The substance ingested is capable of causing altered mental status or convulsions.
- The substance ingested is a caustic or corrosive agent.
- The substance ingested is a low viscosity petroleum distillate with the potential for pulmonary aspiration.
- The patient has a medical condition that may be exacerbated by vomiting (e.g., severe high blood pressure, slow heart rate, or tendency for bleeding) (Manoguerra and Cobaugh 2005).

Other guidelines list additional "relative contraindications" beyond the "absolute contraindications" listed above. These guidelines indicate that ipecac should not be used if:

- The patient is already vomiting.
- More than one hour has passed since ingestion of the product of concern.
- The patient is susceptible to bleeding or hemorrhaging (bleeding diathesis).
- An oral antidote to the consumed poison is available.
- The patient is less than 6 months of age.
- The patient is elderly or has a history of heart disease.
- The patient ingested cardiotoxic drugs (i.e., calcium channel blockers, beta blockers) (Quang and Woolf 2000).

While emetics such as ipecac were, in the past, remedies of choice for emptying the stomach in the case of poisonings, more recent recommendations indicate that emetics should not be used in certain circumstances, and that other treatment methods may be preferable (Manoguerra and Cobaugh 2005; Quang and Woolf 2000). Activated charcoal and emetics should not be administered together since the charcoal can absorb the emetic substance and reduce the emetic effect and because the charcoal will be expelled through vomiting (Hardman and Limbird 1996).

Ipecac contains the compound emetine, which may adversely affect the heart. In the event that vomiting does not occur after administration of ipecac, gastric lavage (stomach pumping) should be performed to avoid a toxic reaction to emetine (Manno and Manno 1977).

Mechanism of Action

There are two primary classes of emetics: those that work on the vomiting centers in the medulla (central emetics), and those that act directly on the stomach itself (gastric emetics). There are botanical emetics that fall into each class, although the mechanism of action of most botanical emetics is not fully understood. Central emetics act by affecting a section of the brain stem known as the chemoreceptor trigger zone. This zone is affected by certain chemical abnormalities in the body and sends a signal to the vomiting centers, which stimulate and coordinate the process of vomiting. Gastric emetics, such as ipecac, act as irritants in the gastrointestinal tract and signal the vomiting center via the vagus nerve (Hardman and Limbird 1996).

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* as emetics:

Apocynum androsaemifolium root
Apocynum cannabinum root
Asclepias tuberosa root
Cephaelis ipecacuanha rhizome
Genista tinctoria herb and flower
Ipomoea purga root
Iris versicolor rhizome and root
Iris virginica rhizome and root
Lobelia inflata herb
Lobelia siphilitica herb
Melia azedarach fruit, root bark
Podophyllum peltatum root
Podophyllum hexandrum root
Sanguinaria canadensis root

Emmenagogues and Uterine Stimulants

Written by Tieraona Low Dog, M.D.

Emmenagogues are agents used to promote menstrual flow. Uterine stimulants are used to cause a woman's uterus to contract, or to increase the frequency and intensity of the contractions.

As a category, emmenagogues are not well defined, and their mechanisms of action have not been well studied or understood. Emmenagogues are principally used for amenorrhea, a condition that can be due to a wide variety of causes. Logically thinking through the etiology of amenorrhea, the category could include herbs with inherent nutritive value, herbs that have a calming effect on the nervous system, herbs that enhance or promote circulation, agents that induce or increase uterine contractions (uterine stimulants), and herbs that interact with the hypothalamic-adrenal-gonadal axis (part of the neuroendocrine system). Examples might include the following:

Amenorrhea secondary to anemia or malnourishment might be treated with nutritive herbs (i.e., nettles, red clover, dong quai).

Amenorrhea secondary to trauma or great emotional stress might be treated with nervines (i.e., chamomile, motherwort, bupleurum).

Amenorrhea due to pregnancy might be addressed using herbs with abortifacient or uterine stimulant activity (e.g., pennyroyal, artemisia, cotton root bark). Abortifacient activity may involve reduction in maternal progestogen and testosterone levels, as well as an increase in immunoreactive cells (Al-Dissi et al. 2001; Boareto et al. 2008; Mukherjee et al. 1996; Talwar et al. 1997).

In traditional Chinese medicine, blood-moving herbs, or "herbs which invigorate the blood," are thought to increase menstrual blood flow by regulating the blood vessels in the uterus or stimulating the general blood circulation (e.g., safflower (*Carthamus tinctorius*) flower and myrhh (*Commiphora wightii*) gum resin (Bensky et al. 2004; Chen and Chen 2004).

The broad variation in herbs used to "bring about menstruation" makes it impossible to generalize mechanistic activity.

Adverse Effects

Depending upon the plant and the intended use, one could predict to some degree the adverse effects that might occur. Herbs that are widely known to be used as abortifacients and/or uterine stimulants should be avoided during pregnancy and in women with menorrhagia (heavy menstrual bleeding) (Chalker and Downer 1992).

Uterine stimulants for labor induction should always be used under the direct supervision of a qualified and experienced individual. If used improperly, these herbs could potentially lead to such complications as uterine hypercontractility, uterine rupture, and maternal hypotension (Kelsey and Prevost 1994).

Adverse effects in pregnancy from emmenagogues that do not have abortifacient activity, such as chamomile or catmint, are unlikely when they are used at normal and customary doses. The same is true for the culinary herbs, such as thyme, parsley, and rosemary, when they are used to flavor food.

The editors of this text acknowledge that there is a lack of consensus regarding which herbs should be listed as emmenagogues, and that safety is a grey area when it comes to their use in pregnancy. The editors actively discourage the use of any emmenagogue as an abortifacient due to the potential for serious and significant risk to both mother and fetus; they encourage the herbal, medical and research communities to explore the category more fully and conduct studies that would help to clarify mechanisms of action and safety.

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* as emmenagogues or uterine stimulants:

- Emmenagogues
  - *Angelica archangelica* root and fruit
  - *Angelica atropurpurea* root and fruit
  - *Anthriscus cerefolium* herb
  - *Artemisia abrotanum* herb
  - *Artemisia douglasiana* herb
  - *Artemisia lactiflora* herb
  - *Artemisia vulgaris* herb
  - *Caulophyllum thalictroides* root
  - *Chamaemelum nobile* flower
  - *Ferula assa-foetida* oleo-gum-resin
  - *Ferula foetida* oleo-gum-resin
  - *Forsythia suspensa* fruit
  - *Gentiana lutea* root
  - *Hyssopus officinalis* herb
  - *Inula helenium* root
  - *Leonurus cardiaca* herb
  - *Leonurus heterophyllus* herb
  - *Leonurus sibiricus* herb
  - *Marrubium vulgare* herb
  - *Mentha pulegium* leaf and essential oil
  - *Monarda clinopodia* herb
  - *Monarda didyma* herb
  - *Monarda fistulosa* herb
  - *Monarda pectinata* herb
  - *Monarda punctata* herb
  - *Nardostachys jatamansi* rhizome, root
  - *Nepeta cataria* herb
  - *Petroselinum crispum* leaf
  - *Polygala senega* root
  - *Rosmarinus officinalis* leaf
  - *Ruta graveolens* herb
  - *Satureja hortensis* leaf
  - *Satureja montana* leaf
  - *Tanacetum vulgare* herb
  - *Taxus brevifolia* needles
  - *Thymus vulgaris* herb
  - *Zanthoxylum americanum* bark
  - *Zanthoxylum clava-herculis* bark
- Uterine stimulants
  - *Achyranthes bidentata* root
  - *Capsella bursa-pastoris* herb
  - *Carthamus tinctorius* flower
  - *Commiphora mukul* gum resin
  - *Commiphora wightii* gum resin
  - *Corydalis yanhusuo* tuber
  - *Cytisus scoparius* flowering tops
  - *Gossypium herbaceum* root bark
  - *Gossypium hirsutum* root bark
  - *Leonurus heterophyllus* herb
  - *Leonurus sibiricus* herb
  - *Ziziphus jujuba* var. *spinosa* seed

Photosensitizing Agents

Written by Zoë Gardner, Ph.D.(c)

Photosensitizing substances cause the development of abnormally heightened reactivity of the skin or eyes to sunlight. Exposure to either the substance or light alone is not sufficient to induce the reaction, which may include rashes, blistering, skin irritation, swelling, or hyperpigmentation. Such reactions may occur after topical application or ingestion of the photosensitizing substance (Moore 2002).

A number of plants that may cause reactions after topical exposure do not pose any risk after internal use. For example, furanocoumarin compounds, such as those present in fragrant angelica (*Angelica dahurica*), have photosensitizing effects after contact with skin, although no cases of photosensitivity after ingestion of fragrant angelica are known (Bensky et al. 2004). While certain plants elicit photosensitivity in most people, the majority of photosensitizing plants listed in this text affect sensitive or otherwise predisposed people (i.e., those who are fair skinned) or those undergoing phototherapy (laser or UV treatment).

Adverse Effects

There are two distinct types of photosensitizing reactions associated with the use of photosensitizing agents: phototoxic reactions and photoallergic reactions. Phototoxic reactions are dose dependent and may occur several minutes or hours after exposure to sunlight. These reactions are limited to sun-exposed skin and generally resemble severe sunburns, sometimes accompanied by erythema (reddening of the skin), edema (swelling and fluid retention), and blistering. Skin pigmentation may also occur (Stein and Scheinfeld 2007). Phototoxic reactions are generally associated with products containing psoralens (linear furocoumarins), although other compounds, such as hypericin in St. John's wort (*Hypericum perforatum*), may contribute to photosensitivity (Brockmöller et al. 1997; Stein and Scheinfeld 2007). Psoralens are found in more than two dozen plant sources, including species of the Rutaceae (i.e., *Ruta graveolens*, *Citrus aurantifolia,* and *C. bergamia*), Apiaceae (i.e., *Ammi majus* and *Apium graveolens*), Fabaceae (*Psoralea* spp.), and Moraceae (*Ficus carica*) families (Bollero et al. 2001; Egan and Sterling 1993; Eickhorst et al. 2007; Maso et al. 1991; Thomson et al. 2007; Wagner et al. 2002; Wang et al. 2002).

Photoallergic reactions occur after light causes a substance to change from one that is non-allergenic to one that is allergenic. These reactions are less common than phototoxic reactions and are not dependent on the dose (which may be very small) of the substance taken or the amount of light exposure, but do require prior sensitization. Photoallergic reactions typically occur 24 hours or more after initial exposure and present as an eczema-like rash that may spread beyond the sun-exposed skin (Nigel et al. 2003; Stein and Scheinfeld 2007). Photoallergic reactions are exhibited as skin conditions characteristic of allergic contact dermatitis, with the reaction limited to sun-exposed areas of the body. However, when the reactions are severe or prolonged, they may extend into covered areas of skin (Stein and Scheinfeld 2007).

Photosensitivity associated with the use of common herbs such as St. John's wort generally occurs at doses many times higher than standard recommended dosages, though there are exceptions. While photosensitivity reactions may

occur after oral use of some botanicals, reactions are more common after topical use or accidental topical exposure. Fair-skinned individuals are more susceptible to developing photosensitivity than others. Severe reactions may occur during exposure to high levels of ultraviolet (UV) light, and especially during therapeutic UV treatment (Beattie et al. 2005).

Mechanism of Action

Phototoxic reactions occur by light activation of plant compounds such as psoralens. The psoralen or other compound in the skin absorbs energy which increases the energy state of the compound's electrons, creating an excited state. As the electrons return to ground state, energy is released that incites an inflammatory response and damages cellular molecules and organelles. Damage may occur from formation of radicals or by production of singlet oxygen, which then oxidizes cell structures (Stein and Scheinfeld 2007).

Photoallergic reactions occur after light causes a conversion from a non-allergenic substance to an allergenic substance (Nigel et al. 2003; Stein and Scheinfeld 2007). Radiant energy converts a compound (from a botanical or drug) in the skin into a photoactive compound, initiating an immunologic, cell-mediated hypersensitivity reaction. This can occur through the production of stable photodrugs, one of which acts as a hapten that conjugates with a carrier molecule to form an antigen (a substance that elicits production of antibodies). Alternatively, the compound may be converted by radiant energy to a higher energy state and, upon return to resting state, the released energy promotes conjugation of a compound to a carrier protein, forming a completely new antigen (Stein and Scheinfeld 2007).

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* with potential photosensitizing action:

- *Angelica pubescens* root
- *Apium graveolens* fruit
- *Citrus* × *aurantifolia* peel
- *Citrus bergamia* peel
- *Cullen corylifolia* seed
- *Hypericum perforatum* herb
- *Ruta graveolens* herb

Stimulant Laxatives

Written by Michael McGuffin, updated by Eric Yarnell, N.D.

Stimulant laxatives are agents used to relieve constipation by local stimulation and contraction of the smooth muscle of the lower bowel. This results in increased peristalsis that empties stools more quickly.

Adverse Effects

Short-term side effects of stimulant laxative consumption may include intestinal cramps, uterine contractions, and watery diarrhea. Continuous use for more than 10 days can cause dependency, resulting in colonic atonicity requiring the aid of stimulant laxatives to have bowel movements. When used in excess or for long periods, the resultant loss of fluids and electrolytes, especially potassium, can cause pathological alterations to the colon, kidney malfunction, or heart palpitations. Patients taking cardiac glycosides are particularly susceptible to cardiotoxicity (De Smet 1993).

The American Herbal Products Association (AHPA) recommends the following labeling for products that contain *Aloe* spp. latex, *Frangula alnus* bark, *Frangula purshiana* bark, *Rhamnus catahrtica* fruit, *Rheum* spp. root/rhizome, and *Senna* spp. fruit (pod) and leaf:

> NOTICE: Do not use this product if you have abdominal pain or diarrhea. Consult a health care provider prior to use if you are pregnant or nursing a baby. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use.

The State of California has established labeling requirements that supersede the AHPA recommendation for products sold in California. All dietary supplements that contain any of the above listed ingredients are required to bear the following label (California 2010):

> NOTICE: This product contains [name of substance(s) and common name(s) if different]. Read and follow directions carefully. Do not use if you have or develop diarrhea, loose stools, or abdominal pain because [insert common name] may worsen these conditions and be harmful to your health. Consult your physician if you have frequent diarrhea or if you are pregnant, nursing, taking medication, or have a medical condition.

Beyond these regulations, stimulant laxatives must not be given to patients with eating disorders, and every attempt should be made to determine if such patients are abusing them. Chronic abuse by such patients has resulted in severe muscle damage, kidney failure, and death. Urine tests exist to detect the presence of anthraquinones in such patients (Roerig et al. 2010).

Cathartic laxatives can turn the urine and/or stool a red or dark color (Roerig et al. 2010). While this does not represent any health problem, people taking laxatives should be warned of this, so they do not mistake the color for blood and seek unnecessary health care.

The majority of evidence supports that, although anthraquinone-containing glycosides cause dark patches in the colon that can last for months (known as pseudomelanosis coli), this is not a precursor to nor does it increase the risk of colorectal cancer (Sonnenberg and Müller 1993).

While most stimulant laxatives have traditionally been contraindicated in pregnancy due to concerns regarding stimulation of the uterus, senna (*Senna alexandrina*) and sickle-pod senna (*Senna obtusifolia, S. tora*) have shown a lack of adverse effects on pregnancy or the fetus when used according to the recommended dosage schedule (Ács et al. 2010; ESCOP 2003). Thus, senna laxatives are now considered appropriate for use during the second and third trimesters of pregnancy (ESCOP 2003; Prather 2004). Due to the potential genotoxicity of certain anthraquinones, however, it is recommended that use of senna be avoided in the first trimester of pregnancy or used under professional supervision (ESCOP 2003).

Mechanism of Action

The action of stimulant laxative herbs is, in most cases, due primarily to their content of anthraquinones. The one exception among the herbs listed in this category is castor oil (from *Ricinus communis*), the action of which is due to ricinoleic acid (Brunton et al. 2006).

Stimulant laxatives increase the motility of the colon, induce changes in the surface cells of the colon, and cause the loss of water and electrolytes. Although intensive research has been performed, the exact mechanism of action is still unclear. However, herbs that contain anthraquinones do affect the colonic mucosa and produce a laxative effect. Anthraquinones disturb the equilibrium between the absorption of water from the intestinal lumen (via an active sodium transport) and the secretion of water

into the lumen by the hydrostatic blood pressure or a prostaglandin-dependent chloride secretion. Anthraquinone glycosides utilize the intestinal flora to produce a laxative effect and are stronger in action than anthraquinone aglycones, which are absorbed in the stomach and duodenum (De Smet 1993). Both aglycones and glycosides occur in *Aloe*, *Rhamnus*, and *Rheum*.

Listed Herbs

Herbs listed in the *Botanical Safety Handbook* as stimulant laxatives:

- *Aloe ferox* latex
- *Aloe perryi* latex
- *Aloe vera* latex
- *Frangula alnus* bark
- *Frangula purshiana* bark
- *Ipomoea purga* root
- *Iris versicolor* rhizome, root
- *Iris virginica* rhizome, root
- *Podophyllum peltatum* root
- *Podophyllum hexandrum* root
- *Reynoutria multiflora* unprocessed root tuber
- *Rhamnus cathartica* fruit
- *Rheum officinale* rhizome, root
- *Rheum palmatum* rhizome, root
- *Rheum tanguticum* rhizome, root
- *Ricinus communis* seed oil
- *Senna alexandrina* fruit (pod), leaf
- *Senna obtusifolia* fruit (pod), leaf
- *Senna tora* fruit (pod), leaf

APPENDIX 3. HERBAL INTERACTION PROFILES

Pharmacokinetic Drug Interactions: CYP450 and P-Glycoprotein

Written by Bill Gurley, Ph.D. and Zoë Gardner, Ph.D.(c)

Drug interactions are generally split into two classes. The first is pharmacodynamic interactions, which are interactions that happen due to additive or opposing effects of two different substances. Pharmacodynamic interactions can be predicted based on the biological activities of the different drugs or herbs (i.e., stimulants and sedatives have opposing effects). The second type of interactions, pharmacokinetic interactions, are unrelated to the therapeutic activity of the herbs and drugs being taken. Pharmacokinetic interactions involve enzymes or transporter proteins that metabolize drugs or compounds from herbs and foods or transport these substances into and out of cells. Several herbs and foods, and a number of drugs, can change the activity of these enzymes and proteins, which can be inhibited or induced, in turn influencing the blood levels of specific drugs or other compounds. While some changes in activity may be minor, with little change in the efficacy of herbs or drugs involved, other changes may produce clinically relevant interactions. In pharmacokinetic interactions, the severity of an interaction is based on the potential toxicity of the drug being used (in the case of increased blood levels of a drug) or the consequences of the therapeutic dose not being achieved (in the case of decreased blood levels of a drug). Until identified through testing or well-documented case reports, these interactions generally cannot be predicted. Once identified, however, these interactions can be easily avoided.

Once understood, herb-drug interactions may also be used therapeutically. Inhibition of drug metabolizing enzymes or transporter proteins, for example, can help increase or maintain levels of certain drugs in the blood or in cells, allowing for a reduced dose (and sometimes reduced side effects) of drugs or increased therapeutic activity (Dresser et al. 2000; Padowski and Pollack 2010). Therapeutic interactions are an emerging area of research, although few human studies have been completed (Bano et al. 1987; Kasibhatta and Naidu 2007).

While some foods and herbs, such as grapefruit (*Citrus* × *paradisi*), St. John's wort (*Hypericum perforatum*), and schisandra (*Schisandra sphenanthera*), have been shown to affect CYP450 enzymes or P-glycoprotein in a clinically significant manner, some other botanicals, such as black cohosh and milk thistle, have shown a lack of metabolic interactions in human studies (Fuhr et al. 2007; Gurley et al. 2006a; Gurley et al. 2006b; Gurley et al. 2008; Rajnarayana et al. 2004; Rao et al. 2007).

Cytochrome P450

The cytochrome P450 enzymes are known as a "superfamily" of enzymes found in nearly all living organisms. These enzymes are important in metabolizing a variety of compounds from foods, medicines, environmental contaminants, and compounds produced in the body. In humans, cytochrome P450 enzymes are primarily responsible for the initial metabolism (phase I) of many drugs to prepare them for conjugation (phase II) and then elimination. These enzymes are important for understanding potential drug interactions and an individual's response to certain drugs (Danielson 2002).

CYP-Based Drug Interactions

Certain CYP enzymes may be induced or inhibited by conventional drugs or by compounds in plants, leading to an increase or decrease in the activity of the enzyme. If a CYP enzyme is induced, plasma levels of drugs metabolized by that enzyme may be decreased, which, in turn, may result in plasma levels too low to be effective. For example, the compound hyperforin in St. John's wort induces CYP3A4 and reduces plasma levels of cyclosporine, a drug used for immune system suppression in patients who have had organ transplants (Mai et al. 2004). This interaction has resulted in sub-therapeutic levels of cyclosporine, causing organ rejection in transplant patients (Barone et al. 2000; Breidenbach et al. 2000). Conversely, if a CYP enzyme is inhibited, metabolism of a drug metabolized by that enzyme will be slowed and plasma levels will increase, leading to potential overexposure and drug toxicity. Grapefruit juice

is a well-known inhibitor of CYP3A4 (David et al. 1998) and thus should not be consumed by patients taking drugs metabolized by CYP3A4.

Induction or inhibition of CYP enzymes occurs at different levels, with some inhibitors or inducers producing weak effects and others producing strong effects. For drugs with narrow therapeutic indices (a small difference between the effective dose and the toxic dose), a potentially "weak" induction or inhibition could result in significant adverse side effects (Huang et al. 2007). By understanding the effects of herbal products and drugs on different CYP enzymes and cross-referencing with known substrates, inducers, and inhibitors, potentially dangerous interactions can be avoided.

Effects on CYP enzymes have been shown to last several days, with patients drinking a single glass of grapefruit juice showing normal enzyme activity after three days, while those taking St. John's wort for two weeks had normal enzyme activity one week after stopping St. John's wort (Greenblatt et al. 2003; Imai et al. 2008). Such a multiday time to return to normal enzyme activity suggests that simply separating ingestion of a CYP-metabolized drug and a CYP inducer or inhibitor by several hours is not sufficient to prevent interactions, and that products affecting CYP enzymes should not be used during treatment with CYP-metabolized drugs.

While most concern has been placed on herbs that can modify the effects of drugs, drugs may also modify the activity of herbs or herbal compounds. For example, drugs that inhibit CYP1A2 may slow the metabolism of caffeine (Carrillo and Benitez 2000; Christensen et al. 2002). While this is not likely to pose any risk with average caffeine consumption, persons taking a drug that inhibits CYP1A2 and drinking large amounts of coffee (10 cups or more daily) may experience prolonged or more pronounced effects of caffeine.

P-Glycoprotein

P-glycoprotein (P-gp), also known as ABCB1, or multi-drug resistance protein 1 (MDR1), is a multi-drug efflux pump (a protein that removes drugs and related compounds from cells) that can move a wide variety of compounds across cellular membranes. P-gp is concentrated in the excretory tissues (liver and kidney) and in barrier tissues (intestines, blood-brain barrier, placental barrier, blood-testes barrier, and blood-ovary barrier), helping to detoxify or protect certain organs and the fetus (Cordon-Cardo et al. 1989; Fojo et al. 1987; Thiebaut et al. 1987).

P-gp is also concentrated in tumor cells and is primarily responsible for multi-drug resistance found in some patients undergoing chemotherapy (Bellamy 1996).

P-Glycoprotein-Based Drug Interactions

Like CYP450 enzymes, P-gp can be both inhibited and induced. Induction of P-gp can lead to low plasma levels of P-gp-transported drugs, potentially reducing the efficacy of the drug. For example, St. John's wort has been shown to induce P-gp, leading to reduced plasma levels of digoxin, a drug transported by P-gp and used to treat heart failure and abnormal heart rhythms (Durr et al. 2000; Johne et al. 1999). Inhibition of P-gp can lead to higher intracellular (inside the cell) levels of drugs transported by P-gp, resulting in potential drug toxicity.

Differences in Human, Animal, and In Vitro Study Findings

To determine potential CYP450 interactions, in vitro, animal, and human studies are used, each with varying levels of accuracy for predicting clinically relevant interactions. While most research to date has been in vitro, the results of *in vitro* studies are often quite different from animal and human studies. Such differences may be caused by chemicals added to in vitro studies to promote uptake of some compounds that can exaggerate experimental findings by changing solubility that would otherwise limit uptake. *In vitro* studies sometimes use phytochemical concentrations that exceed those achieved in humans or other animals, or focus on isolated compounds that do not reflect the phytochemical complexity typical of extracts that may contribute to the bioactivity. Many compounds and extracts also undergo extensive metabolism in the intestines or liver, which may also change the bioactivity (Brinker 2009; Hines 1999; Markowitz et al. 2008; Venkataramanan et al. 2006). While animal studies may be more accurate in predicting clinically relevant drug interactions, these studies cannot be taken as conclusive, since large, non-physiological doses are often administered and, due to species variation in metabolism and transport, results are rarely generalizable to humans (Brinker 2009; Venkataramanan et al. 2006). In considering interaction ratings for herbs in this text, the types of evidence (human, animal, or in vitro) available were important for determining the level of concern for a potential interaction.

Mucilages

Written by Zoë Gardner, Ph.D.(c)

Definition

Mucilages are polysaccharides that form gels or viscous solutions when mixed with water. These compounds are highly branched and form large hydrophilic (water-loving) cage-like structures that are capable of trapping water (Williams et al. 2006). After being mixed with water, mucilaginous herbs swell to many times their original size as the water is absorbed (Mills and Bone 2000).

Mucilage-Based Drug Interactions

Mucilages are a source of dietary fiber, and, like certain other sources of soluble fiber, are capable of inhibiting the absorption of some drugs (Brunton et al. 2006). To ensure complete absorption of drugs, mucilaginous plants should be taken at least one hour after other drugs or supplements (Wichtl 2004).

Mucilages may also inhibit the absorption of certain nutrients, so diabetics taking mucilaginous herbs should continue to monitor blood sugar levels (Ziai et al. 2005).

Drinking a glass of water with mucilaginous plants (especially when taken in powdered or granular form) is important to prevent the plant material from swelling in clumps and causing an obstruction in the esophagus or intestines (Angueira and Kadakia 1993; Frohna 1992; Herrle et al. 2004). Many mucilaginous herbs are also used as bulk-forming laxatives. See Appendix 2 for further information.

Herbs listed in the *Botanical Safety Handbook* containing mucilages:*

- *Alcea rosea* root
- *Aloe ferox* leaf gel
- *Aloe perryi* leaf gel
- *Aloe vera* leaf gel
- *Althaea officinalis* root, leaf, and flower
- *Laminaria digitata* thallus
- *Laminaria hyperborea* thallus
- *Laminaria japonica* thallus
- *Laminaria setchellii* thallus
- *Laminaria sinclairii* thallus
- *Linum usitatissimum* seed
- *Malva sylvestris* leaf and flower
- *Nereocystis luetkeana* thallus
- *Plantago arenaria* seed, seed husk
- *Plantago asiatica* seed, seed husk
- *Plantago ovata* seed, seed husk
- *Trigonella foenum-graecum* seed
- *Ulmus rubra* bark

* Many other herbs, such as mullein (*Verbascum thapsus*) and cinnamon (*Cinnamomum verum*), contain small amounts of mucilages that are unlikely to interfere with drug or nutrient absorption.

Piperine

Written by Zoë Gardner, Ph.D.(c)

Piperine is an alkaloid found in black pepper (*Piper nigrum*), long pepper (*Piper longum*), cubeb (*Piper cubeba*) and grains-of-paradise (*Aframomum melegueta*), and is responsible in part for the pungent taste of these spices. In addition to being found naturally in these botanicals, isolated piperine is sometimes added to other herbal products to help increase absorption and bioavailability.

Piperine-Based Drug Interactions

The compound piperine has been shown to increase the bioavailability of a number of drugs and other substances. Human studies have indicated that piperine generally increases the absorption and plasma concentrations and reduces the elimination rate of drugs including phenytoin (Bano et al. 1987; Pattanaik et al. 2006; Velpandian et al. 2001), carbamazepine (Pattanaik et al. 2009), propranolol (Bano et al. 1991), theophylline (Bano et al. 1991), rifampicin (Zutshi et al. 1985), nevirapine (Kasibhatta and Naidu 2007), and the supplements coenzyme Q_{10} (Badmaev et al. 2000) and curcumin (Shoba et al. 1998). Increases in the plasma levels of these substances have ranged from 30 to 120%. The standard dose of piperine used in human studies is 20 mg daily, though one study measured a delay in elimination of phenytoin in human subjects fed soup with black pepper (Velpandian et al. 2001). In many cases, increases in bioavailability can result in enhanced therapeutic effects, while in the case of drugs with a narrow therapeutic window (a small difference between the effective dose and the toxic dose), piperine and piperine-containing herbs may need to be used with caution.

Animal studies have shown that piperine can increase the bioavailability of the drug fexofenadine (Jin and Han 2010), the compounds curcumin, from turmeric (Shoba et al. 1998), and EGCG, from green tea (Lambert et al. 2004).

Mechanism of Action

Piperine's mechanism of enhancing bioavailability is not yet fully understood, although it is generally attributed to increased absorption, which may be due to alteration in membrane lipid dynamics and changes in the conformation of enzymes in the intestine (Khajuria et al. 2002).

An animal study demonstrated that piperine slowed the gastric emptying time and gastrointestinal transit time of solid foods (Bajad et al. 2001). An in vitro study suggested that piperine inhibited both the drug metabolizing isoenzyme CYP3A4 and the drug transporter protein P-gp (Bhardwaj et al. 2002; Han et al. 2008). Several studies have suggested that piperine acts as an MAO inhibitor (Rahman and Rahmatullah 2010).

Herbs listed in the *Botanical Safety Handbook* that contain piperine:

- *Aframomum melegueta* fruit, seed
- *Piper cubeba* unripe fruit
- *Piper longum* fruit
- *Piper nigrum* fruit

APPENDIX 4. SAFETY OF BOTANICALS IN PREGNANCY AND LACTATION

Written by Aviva Romm

Introduction

Herbs have been used by women during pregnancy, to help prepare for birth, and to promote lactation since time immemorial, with texts and treatises dating at least back to ancient Egypt (O'Dowd 2001). Herbal medicines are still commonly used by childbearing women for a variety of reasons, for example, ginger to treat "morning sickness," raspberry leaf (*Rubus* spp.) as a uterine tonic, or echinacea (*Echinacea* spp.) for colds (Ernst 2002; Gibson et al. 2001; Hepner et al. 2002; Pinn and Pallett 2002). Studies suggest the safety of these commonly used herbs during pregnancy. Two human clinical trials evaluated raspberry leaf for its effects on labor outcome and did not demonstrate any adverse effects (Parsons et al. 1999; Simpson et al. 2001). An observational study showed no harmful effects of echinacea when used during various stages of pregnancy (Gallo et al. 2000), and numerous studies have evaluated ginger root (*Zingiber officinale*) for the reduction of nausea and vomiting of pregnancy, finding it both safe and effective at the doses used (dried rhizome 1000–1500 mg per day) (Bryer 2005). There is considerable evidence that modern obstetric professionals such as midwives and obstetricians are recommending herbs during pregnancy, particularly for labor stimulation and for other concerns as well (Allaire et al. 2000; Chez and Jonas 1999; Hardy 2000; Hepner et al. 2002; Low Dog 2009; Pinn and Pallett 2002; Romm 2009b). Because pregnancy is the most sensitive time in human development, and many substances cross the placenta, questions have been raised about the safety of herbal medicines taken during pregnancy.

Similar safety concerns are raised about the safety of herbal remedies used by breastfeeding mothers. About one percent of any substance a lactating mother ingests will be passed to her baby through the breast milk; thus, while many herbs would likely be safe, we must also be mindful about the maternal ingestion of some herbal products during lactation. Consideration should also be given to the age of the infant, as there are considerable differences between the liver and kidney function of a 4-week-old and a 12-month-old infant (Humphrey and McKenna 1997).

Most herbs have not been evaluated for safety in the childbearing cycle; thus, there is little scientific evidence to support or refute their safety during this time. Ethical considerations surrounding experimentation on pregnant women and the need for large sample sizes severely limit human clinical investigation during pregnancy (Hepner et al. 2002; Low Dog 2009; Romm 2009b). This chapter elucidates some of the key issues surrounding the use of herbs during pregnancy and lactation, and explains the careful process involved in creating the pregnancy and lactation safety ratings found in this book.

Contraindicated Herb Lists and Botanical Safety Classifications

The herbal literature is rife with lists of herbs contraindicated in pregnancy and lactation. There are limitations inherent in most lists, particularly in their lack of specifics as to how, when, and why each herb is contraindicated. Herbs may sometimes be broadly contraindicated in pregnancy yet in actuality be only contextually contraindicated. For example, some herbs are absolutely contraindicated during the first and second trimesters but may be reasonably used during labor, or they may be safe in small doses for a very limited duration. Culinary herbs, appearing on many contraindicated lists, represent no harm to the fetus or mother when ingested in the small amounts typically used as food seasonings. Herbs such as goldenseal root (*Hydrastis canadensis*) may be used topically with no risk but should be avoided for internal use, yet are contraindicated on such lists with no differentiation, leading

to confusion about safety. Certain contraindications have become pervasive myths; for example, the frequent contraindication of chamomile (*Matricaria recutita*) in pregnancy due to its alleged action as an abortifacient (McKenna et al. 2002). In fact, chamomile provides an excellent example of how misapplication of a scientific finding can lead to unjustified contraindication of a safe herb. A study conducted in 1979 found that a concentrated extract of the compound a-bisabolol caused birth defects at high doses. No birth defects were seen at lower doses, and the dose of a-bisabolol required to cause defects is far greater than would be possible to ingest by someone drinking the tea. However, based on this single study, chamomile continues to be improperly contraindicated for consumption during pregnancy (Low Dog 2004).

Finally, herbs may be contraindicated based on limited or conflicting information. For example, information on traditional use indicates that ashwagandha (*Withania somnifera*) is used as both an "abortifacient" (Badhwar and Chopra 1946; Casey 1960; Chadha 1976) and as a "pregnancy tonic" (Kapoor 1990; Tirtha 1998; Upton 2000). However, no details are available regarding plant part, doses used, and duration of use. A more recent study in animals indicated a lack of adverse effects of ashwagandha in pregnancy (Sharma et al. 1986). To complicate matters, certain herbs that are contraindicated by western herbalists for use during pregnancy may be routinely used in traditional medicines of non-western cultures. For example, dong quai is prescribed in blood tonic formulas for pregnant women in China, and listed in official Chinese and Japanese texts for the prevention of miscarriage, yet is considered contraindicated for use in pregnancy by some western herbalists (Brinker 2001; Mills and Bone 2005).

Safety of Herbs in Pregnancy and Lactation

There is a lack of human clinical trials on the safety or efficacy for many botanical therapies during pregnancy. Risks associated with the use of herbs during pregnancy include:

- Toxicity to the mother which might indirectly affect the embryo/fetus
- Direct teratogenicity, mutagenicity, or fetal toxicity
- Abortifacient activity
- Poor neonatal outcomes
- Delayed administration of necessary medical therapy in favor of herbs, regardless of their safety (Mills and Bone 2005; Romm 2009b)

In general, most herbs on the market in the U.S. have a relatively high track record of safety, with few case reports of adverse effects (Hansten 2000). Negative outcomes have been reported for only a very limited number of herbal products used by women in or about to be in labor (Beal 1998; Ernst 2002; Mabina et al. 1997; Romm 2009a). When apparent adverse events have occurred, cause and effect have been difficult to establish due to a wide range of confounding factors (Ernst and Schmidt 2002). Adverse events have typically involved the consumption of known toxic herbs, contaminated or adulterated herbal products, or inappropriate use or dosage of specific botanical therapies. However, lack of proof of harm is not synonymous with proof of safety. Some of the harmful effects of herbs may not be readily apparent until after they have been discontinued, or may only occur with cumulative use. Some researchers therefore believe that, in the absence of scientific proof of safety, herbs that are used for therapeutic reasons should be avoided during pregnancy (Ernst 2002). However, many practitioners, including herbalists, naturopaths, and midwives, continue to use herbs based on historical data and observational evidence, tempered by the knowledge that many pharmaceutical preparations recommended during pregnancy also carry unknown risks (Low Dog 2004; Romm 2009b).

After much careful consideration, the editors of this text deemed that the most reasonable standard on which to base pregnancy safety ratings is a combination of the best available evidence including:

- Clinical evidence in the medical/scientific literature
- Animal and in vitro studies
- Case reports
- Known and suspected mechanisms of action of the herb
- Safety and bioavailability of the herb in the form most likely to be used (i.e., powder, tea, tincture, concentrated extract, etc.)
- Dose of the herb typically ingested and typical duration of use
- Clinical (empiric, observational) consensus of safety/risk
- Chemical constituent profile
  - teratogenicity
  - mutagenicity
  - toxicity
  - extractability
  - bioavailability
- Historical information and traditional use as derived from a circumscribed set of approved texts and sources

There are virtually no formal studies that can definitively make a determination that a particular herb, or drug for that matter, is absolutely safe during pregnancy. There are also a number of botanicals for which there are little data or clinical experience regarding their use in pregnancy and lactation. It is the opinion of the editors that the absence of formal data and clinical experience regarding the use of a botanical in pregnancy or lactation, in and of itself, is not justification to contraindicate the botanical in pregnancy and lactation. In cases where there is neither substantial historical nor scientific data, the editors have used their best judgment in looking at the totality of the data available to make the most appropriate determination. However, consumers and health professionals should be cautioned about taking any botanical in pregnancy and lactation regardless of its classification. This is especially true for those botanicals for which there is insufficient traditional or scientific evidence of safety. For such botanicals, the following Editors' Note was included to highlight the relative lack of data specifically regarding use in pregnancy and lactation, but also a lack of data to suggest that any safety concern exists:

> No information on the use of wild lettuce during pregnancy or lactation was identified in the scientific or traditional literature. While this review did not identify any concerns for pregnant or lactating women, safety has not been conclusively established.

Herbal medicines may be used during lactation for a variety of concerns, ranging from increasing the quantity of breast milk (lactagogues) to the treatment of any number of postpartum or common general conditions. The risks of using herbs during lactation appear to be less significant than in pregnancy, as only very small quantities of plant constituents ingested by the mother actually pass into the breast milk, and risks of birth defects and abortifacient activity are no longer present (Humphrey 2009). However, quantification of chemical constituents from herbal medicines appearing in breast milk has not been conducted for most herbs, so some element of caution is still required. As with pregnancy, it is prudent to avoid known toxic herbs or those with possible effects on still developing biological systems, such as the nervous and endocrine systems. The editors of this text have taken these points into consideration when assigning safety classifications to herbs in pregnancy and lactation.

Emmenagogues, Uterine Stimulants, Abortifacients, and Partus Preparator

Much of the literature on these categories comes from late 19th century references, such as Felter & Lloyd's *King's American Dispensatory* (Felter and Lloyd 1898), as well as the experience of contemporary practicing herbalists.

Historically, as in modern times, the term emmenagogue has referred to a plant or substance that was used with the intention of bringing about menstruation (Santow 2001). For this reason, many of these herbs have been contraindicated during pregnancy. While some of these herbs were undoubtedly used as abortifacients, it is also quite plausible that a number were used to nourish and strengthen a woman who might have lost her menstrual cyclicity due to anemia, malnourishment, or severe stress. This has led to considerable disagreement about what should and shouldn't be called an emmenagogue. Those that are considered to be unsafe during pregnancy include rue (*Ruta graveolens*), Scotch broom (*Cytisus scoparius*), tansy (*Tanacetum vulgare*), thuja (*Thuja occidentalis*), wormwood (*Artemisia absinthium*), and pennyroyal (*Mentha pulegium*).

Uterine tonics have been used historically with the belief that they improve the strength and tone of the uterine muscle, while uterine stimulants were thought to bring on menses or induce labor. Although both of these are important categories in modern herbal therapeutics, there is little understanding or research regarding their mechanism of action, effective doses, or safety. Some herbs, such as dong quai (*Angelica sinensis*), are considered by some sources to be emmenagogues but are also believed to have both uterine relaxant and uterine stimulatory activity, and are used in Chinese and Japanese herbal formulas for the prevention of miscarriage (Chen and Chen 2004; Liang 2004; Upton 2003; Zhu 1998). Clearly, this is an area where more research is needed. Herbs that are intentionally being used to induce labor should be administered under the direct supervision of a qualified and experienced individual, usually a midwife, knowledgeable in such therapies.

Abortifacients are herbs used to facilitate a miscarriage or induce abortion. How effective these herbs are for inducing abortion is unknown; however, the amount required to terminate pregnancy is likely enough to pose significant risk to the mother's health, including kidney and liver damage, and may not result in a successful abortion attempt. However, because the risks of these herbs to the fetus are unknown, women who have attempted to abort unsuccessfully may be well advised to obtain a clinical abortion. Abortifacients should be entirely avoided during pregnancy, and herbal abortion is not a recommended method of intentional pregnancy termination (also see Abortifacients in Appendix 2).

Partus preparators are herbs generally taken during the last few weeks of pregnancy and were historically used to facilitate a timely delivery. Blue cohosh (*Caulophyllum thalictroides*) is the herb most commonly used for this purpose. Case reports of adverse events, along with the activity of different compounds present in blue cohosh (see entry for *Caulophyllum thalictroides*) suggest that it should be avoided as a partus preparator, with use limited to short-term application to induce or augment labor, and then only with the proper guidance and monitoring of an expert qualified in the appropriate use of the selected herb or formula (Jones and Lawson 1998; Wright 1999).

Teratogens and Mutagens

Teratogens are substances that cause structural abnormalities and other birth defects in the fetus. There is extremely limited knowledge about which herbs may act as teratogens. Most of what is known is derived primarily from animal studies, observation of teratogenesis in grazing animals, and from human ingestion of suspected harmful herbal products. The primary means for identifying the propensity for this type of reaction is through toxicological screenings or through pharmacovigilance programs (monitoring of drugs and supplements for adverse effects).

Mutagens are substances that cause genetic mutations in cells. The potential for mutagenicity is typically discerned through in vitro assays followed by animal studies. In both types of tests, isolated compounds rather than whole herbs are most often investigated. While in vitro tests can be useful, they are generally quite limited for extrapolation to human use. The presence of a mutagen in an herb does not automatically contraindicate its use in pregnancy. There are many commonly consumed plants such as basil (*Ocimum basilicum*), black pepper (*Piper nigrum*), coffee (*Coffea arabica*), tomatoes (*Solanum lycopersicum*), and potatoes (*Solanum tuberosum*) that contain compounds with mutagenic potential (ACHS 1996). However, consumption of these in pregnancy is not contraindicated when consumed as a normal part of the diet, and the presence of such compounds in a food or herb does not mean that this substance crosses the placenta or reaches the fetus in appreciable or clinically significant quantities.

Phytoestrogens

Phytoestrogens are weak forms of plant estrogens found in numerous plants, including common foods such as beans and other legumes (most notably soy foods) and dark leafy greens (Franke et al. 1994; Kuiper et al. 1998). Some traditional Asian diets, which include large amounts of tofu and other soy products, are particularly high in phytoestrogens, but abnormal levels of fetal and neonatal problems have not been observed when compared to other populations. Nonetheless, there is concern that consumption of concentrated doses of phytoestrogens (i.e., isolated soy isoflavones) during pregnancy may exert abnormal hormonal effects on the developing embryo or fetus, particularly in female embryogenesis, as occurred with the drug diethylstilbestrol (DES), a synthetic nonsteroidal estrogen. Although the amounts found in plant sources are incomparably minute compared to DES (Kuiper et al. 1998), it is generally recommended that women not supplement with concentrated phytoestrogen products such as soy isoflavone concentrates during pregnancy. Additionally, herbs with known or suspected estrogenic activity or activity on the endocrine system, including hops, alfalfa, or red clover, are best avoided for long-term use or in large doses during pregnancy.

Nervous System Stimulants or Depressants

Herbs which strongly affect the nervous system, including stimulants such as ephedra (*Ephedra sinica*), guarana (*Paullinia cupana*), coffee (*Coffea arabica*), or green and black teas (*Camellia sinensis*), may have adverse effects on pregnancy and the developing fetal nervous system. Caffeine should be avoided or limited to no more than 300 mg (approx. 3 cups coffee) per day during pregnancy (ADA 2008). Kava (*Piper methysticum*), a strong anxiolytic and sedative herb, has been implicated in a number of cases of liver toxicity (Teschke et al. 2008). While causality is uncertain, kava should be avoided during pregnancy and lactation until the relationship between kava and liver toxicity is fully understood.

Summary

Women may turn to herbs for the relief of common complaints and concerns that arise during pregnancy, childbirth, and breastfeeding. The power of herbs should be respected and, therefore, used with caution during the childbearing cycle. However, a number of herbs have been contraindicated in modern herbal literature on the basis of very limited findings and erroneous or incomplete reports. Consumers, manufacturers, and practitioners need to be educated when it comes to the safe use of herbal medicine during pregnancy and lactation. Further research needs to be conducted not only into the safety and efficacy of herbs for both the mother and her baby, but also a comparative safety analysis should be done on herbs and pharmaceuticals commonly used during pregnancy. The editors of this text have done their best to shine light on a complicated subject by providing a safety ranking to help healthcare professionals, manufacturers, and consumers differentiate those herbs which are generally considered safe from those which should be avoided during pregnancy and lactation.

APPENDIX 5. HERB LISTINGS BY CLASSIFICATION

Lists are provided below of all of the plants classified in the main section of the text in either Safety Class 2a, 2b, 2c, or 3, or in Interaction Class B or C. Note that the restrictions described for plants in each of these Safety Classes (as well as in Class 2d, not listed here) apply unless otherwise directed by an expert qualified in the use of the described substance.

The lists presented here are provided as a compilation of the classifications found at individual entries in the text. Additional information, including in some cases exceptions to one of these classifications, may be found at specific entries.

Safety Class 2a: For External Use Only

- *Alkanna tinctoria* root
- *Borago officinalis* herb
- *Eutrochium fistulosum* herb, rhizome, root
- *Eutrochium maculatum* herb, rhizome, root
- *Eutrochium purpureum* herb, rhizome, root
- *Lawsonia inermis* leaf
- *Mentha pulegium* herb essential oil
- *Symphytum asperum* leaf, root
- *Symphytum officinale* leaf, root
- *Symphytum* × *uplandicum* leaf, root

Safety Class 2b: Not To Be Used during Pregnancy

- *Achyranthes bidentata* root
- *Actaea racemosa* rhizome
- *Adiantum capillus-veneris* herb
- *Adiantum pedatum* herb
- *Agathosma betulina* leaf
- *Agathosma crenulata* leaf
- *Agathosma serratifolia* leaf
- *Albizia julibrissin* bark
- *Alkanna tinctoria* root
- *Aloe ferox* latex
- *Aloe perryi* latex
- *Aloe vera* latex
- *Andrographis paniculata* herb
- *Angelica archangelica* fruit, root
- *Angelica atropurpurea* fruit, root
- *Anthriscus cerefolium* herb
- *Apium graveolens* fruit
- *Aralia racemosa* rhizome
- *Artemisia abrotanum* herb
- *Artemisia absinthium* herb
- *Artemisia annua* aboveground parts
- *Artemisia douglasiana* herb
- *Artemisia lactiflora* herb
- *Artemisia vulgaris* herb
- *Asclepias asperula* root
- *Asclepias tuberosa* root
- *Baptisia tinctoria* root
- *Berberis vulgaris* root, root bark
- *Boswellia sacra* gum resin
- *Boswellia serrata* gum resin
- *Capsella bursa-pastoris* herb
- *Carica papaya* leaf
- *Carthamus tinctorius* flower
- *Catharanthus roseus* herb
- *Caulophyllum thalictroides* root
- *Chamaemelum nobile* flower
- *Changium smyrnioides* root
- *Chelidonium majus* herb
- *Chrysopogon zizanioides* root
- *Cinchona calisaya* bark
- *Cinchona officinalis* bark
- *Cinchona pubescens* bark
- *Cinnamomum aromaticum* bark
- *Cinnamomum camphora* distillate of the wood
- *Cinnamomum verum* bark
- *Coix lacryma-jobi* seed
- *Commiphora madagascariensis* gum resin
- *Commiphora molmol* gum resin
- *Commiphora myrrha* gum resin
- *Commiphora wightii* gum resin
- *Coptis chinensis* rhizome
- *Coptis trifolia* rhizome
- *Corydalis yanhusuo* tuber
- *Crocus sativus* stigma
- *Cullen corylifolium* seed
- *Curculigo orchioides* rhizome
- *Curcuma zedoaria* rhizome
- *Cyathula officinalis* root
- *Daemonorops draco* resin
- *Daucus carota* ssp. *carota* seed
- *Equisetum hyemale* aboveground parts
- *Eschscholzia californica* whole plant in flower

- *Eucalyptus globulus* essential oil
- *Euonymus atropurpureus* root bark
- *Eutrochium fistulosum* herb, rhizome, root
- *Eutrochium maculatum* herb, rhizome, root
- *Eutrochium purpureum* herb, rhizome, root
- *Ferula assa-foetida* oleo gum resin
- *Ferula foetida* oleo gum resin
- *Fouquieria splendens* stem
- *Frangula alnus* bark
- *Frangula purshiana* bark
- *Fraxinus americana* bark
- *Genista tinctoria* flower, herb
- *Glycyrrhiza echinata* rhizome, root
- *Glycyrrhiza glabra* rhizome, root
- *Glycyrrhiza uralensis* rhizome, root
- *Gossypium herbaceum* root bark
- *Gossypium hirsutum* root bark
- *Hedeoma pulegioides* herb
- *Hepatica nobilis* var. *obtusa* herb
- *Hydrastis canadensis* rhizome, root
- *Hyssopus officinalis* herb
- *Iris versicolor* rhizome, root
- *Iris virginica* rhizome, root
- *Juniperus communis* fruit
- *Juniperus monosperma* fruit
- *Juniperus osteosperma* fruit
- *Juniperus oxycedrus* fruit
- *Juniperus virginiana* berry, leaf
- *Larrea tridentata* leaf
- *Leonurus cardiaca* herb
- *Leonurus japonicus* aboveground parts, herb
- *Leonurus sibiricus* aboveground parts, herb
- *Ligusticum porteri* rhizome
- *Ligusticum sinense* 'Chuanxiong' rhizome
- *Ligusticum wallichii* rhizome
- *Lobelia inflata* herb
- *Lobelia siphilitica* herb
- *Lomatium dissectum* root
- *Lycopus americanus* herb
- *Lycopus europaeus* herb
- *Lycopus virginicus* herb
- *Magnolia biondii* flower bud
- *Magnolia denudata* flower bud
- *Magnolia officinalis* bark, root bark
- *Magnolia sprengeri* flower bud
- *Magnolia virginiana* bark
- *Marrubium vulgare* herb
- *Mentha* × *piperita* essential oil
- *Mentha pulegium* essential oil
- *Mentha pulegium* herb
- *Monarda clinopodia* herb
- *Monarda didyma* herb
- *Monarda fistulosa* herb
- *Monarda pectinata* herb
- *Monarda punctata* herb
- *Morinda citrifolia* fruit
- *Mucuna pruriens* root, seed
- *Myristica fragrans* aril, seed
- *Nardostachys jatamansi* rhizome, root
- *Ocimum basilicum* leaf
- *Ocimum gratissimum* aboveground parts
- *Paeonia suffruticosa* root bark
- *Pausinystalia johimbe* bark
- *Phyllanthus amarus* aboveground parts, whole plant
- *Phyllanthus fraternus* aboveground parts, whole plant
- *Phyllanthus niruri* aboveground parts, whole plant
- *Picrasma excelsa* bark, root, wood
- *Piper longum* fruit
- *Piper methysticum* rhizome, root
- *Polygala senega* root
- *Polygala sibirica* root
- *Polygala tenuifolia* root
- *Portulaca oleracea* aboveground parts
- *Punica granatum* fruit husk
- *Quassia amara* bark, root, wood
- *Rhamnus cathartica* fruit
- *Rheum officinale* rhizome, root
- *Rheum palmatum* rhizome, root
- *Rheum palmatum* var. *tanguticum* rhizome, root
- *Ricinus communis* seed oil
- *Ruta graveolens* herb
- *Salvia miltiorrhiza* root
- *Salvia officinalis* leaf
- *Sanguinaria canadensis* rhizome, root
- *Sassafras albidum* root
- *Spigelia marilandica* root
- *Symphytum asperum* leaf, root
- *Symphytum officinale* leaf, root
- *Symphytum* × *uplandicum* leaf, root
- *Tanacetum parthenium* herb
- *Tanacetum vulgare* herb
- *Taxus brevifolia* needles
- *Terminalia arjuna* bark
- *Thuja occidentalis* leaf
- *Thymus vulgaris* herb
- *Tribulus terrestris* aboveground parts
- *Tribulus terrestris* fruit
- *Trigonella foenum-graecum* seed
- *Trillium erectum* root
- *Tussilago farfara* flower bud
- *Tussilago farfara* leaf
- *Uncaria tomentosa* root bark, stem bark
- *Verbena hastata* herb
- *Verbena officinalis* ssp. *officinalis* herb
- *Viscum album* herb
- *Withania somnifera* root

- *Zanthoxylum americanum* bark
- *Zanthoxylum bungeanum* fruit pericarp
- *Zanthoxylum clava-herculis* bark
- *Zanthoxylum schinifolium* fruit pericarp
- *Zanthoxylum simulans* fruit pericarp
- *Ziziphus jujuba* var. *spinosa* seed

Safety Class 2c: Not To Be Used while Nursing

- *Alkanna tinctoria* root
- *Aloe ferox* latex
- *Aloe perryi* latex
- *Aloe vera* latex
- *Artemisia absinthium* herb
- *Chelidonium majus* herb
- *Euonymus atropurpureus* root bark
- *Eutrochium fistulosum* herb, rhizome, root
- *Eutrochium maculatum* herb, rhizome, root
- *Eutrochium purpureum* herb, rhizome, root
- *Frangula alnus* bark
- *Frangula purshiana* bark
- *Hedeoma pulegioides* herb
- *Lycopus americanus* herb
- *Lycopus europaeus* herb
- *Lycopus virginicus* herb
- *Mentha pulegium* essential oil
- *Mentha pulegium* herb
- *Pausinystalia johimbe* bark
- *Piper methysticum* rhizome, root
- *Rhamnus cathartica* fruit
- *Rheum officinale* rhizome, root
- *Rheum palmatum* rhizome, root
- *Rheum palmatum* var. *tanguticum* rhizome, root
- *Symphytum asperum* leaf, root
- *Symphytum officinale* leaf, root
- *Symphytum* × *uplandicum* leaf, root
- *Tanacetum vulgare* herb
- *Thuja occidentalis* leaf
- *Tussilago farfara* flower bud
- *Tussilago farfara* leaf

Safety Class 3: For Use Only under the Supervision of Qualified Expert

- *Aconitum carmichaelii* prepared root
- *Acorus calamus* rhizome
- *Acorus gramineus* rhizome
- *Apocynum androsaemifolium* root
- *Apocynum cannabinum* root
- *Arisaema amurense* prepared rhizome
- *Arisaema erubescens* prepared rhizome
- *Arisaema heterophyllum* prepared rhizome
- *Arnica latifolia* root, rhizome, whole plant
- *Arnica montana* root, rhizome, whole plant
- *Atropa belladonna* leaf
- *Buxus sempervirens* leaf
- *Cephaelis ipecacuanha* rhizome
- *Convallaria majalis* entire plant
- *Cytisus scoparius* flowering top
- *Digitalis purpurea* leaf
- *Digitalis lanata* leaf
- *Dryopteris filix-mas* rhizome
- *Ipomoea purga* root
- *Melia azedarach* bark, fruit, root bark
- *Phoradendron leucarpum* herb
- *Phytolacca americana* root
- *Pilocarpus jaborandi* leaf
- *Pilocarpus microphyllus* leaf
- *Pilocarpus pennatifolius* leaf
- *Pinellia ternata* prepared rhizome
- *Podophyllum hexandrum* rhizome, root
- *Podophyllum peltatum* root
- *Prunus armeniaca* seed
- *Prunus persica* leaf, seed, twig
- *Reynoutria multiflora* unprocessed root tuber
- *Stillingia sylvatica* root
- *Veratrum viride* root

Interaction Class B: Herbs for Which Clinically Relevant Interactions Are Biologically Plausible

- *Apocynum androsaemifolium* root
- *Apocynum cannabinum* root
- *Astragalus mongholicus* root
- *Carthamus tinctorius* flower
- *Commiphora wightii* gum resin
- *Convallaria majalis* entire plant
- *Cytisus scoparius* flowering top
- *Ginkgo biloba* leaf
- *Glycyrrhiza echinata* rhizome, root
- *Glycyrrhiza glabra* rhizome, root
- *Glycyrrhiza uralensis* rhizome, root
- *Lycopus americanus* herb
- *Lycopus europaeus* herb
- *Lycopus virginicus* herb
- *Panax quinquefolius* root
- *Pausinystalia johimbe* bark

- *Pilocarpus jaborandi* leaf
- *Pilocarpus microphyllus* leaf
- *Pilocarpus pennatifolius* leaf
- *Piper longum* fruit
- *Piper methysticum* rhizome, root
- *Piper nigrum* fruit
- *Scutellaria baicalensis* root
- *Selenicereus grandiflorus* flower, stem
- *Tetradium ruticarpum* unripe fruit
- *Valeriana edulis* ssp. *procera* rhizome, root
- *Valeriana jatamansi* rhizome, root
- *Valeriana officinalis* rhizome, root
- *Valeriana sitchensis* rhizome, root
- *Zingiber officinale* rhizome

Interaction Class C: Herbs for Which Clinically Relevant Interactions Are Known to Occur

- *Angelica sinensis* root
- *Atropa belladonna* leaf
- *Camellia sinensis* leaf, stem
- *Citrus* × *aurantium* fruit
- *Coffea arabica* roasted seed kernel
- *Cola acuminata* seed
- *Cola nitida* seed
- *Digitalis purpurea* leaf
- *Digitalis lanata* leaf
- *Hypericum perforatum* flowering top, herb
- *Ilex paraguariensis* leaf
- *Paullinia cupana* seed
- *Salvia miltiorrhiza* root
- *Schisandra chinensis* fruit
- *Schisandra sphenanthera* fruit

INDEX

A

Aaron's rod, 918
Abata cola, 251
Abdominal distention, *Nelumbo nucifera* cautions, 594
Abdominal ecchymoses, with *Matricaria chamomilla*, 550
Abdominal pain
  Polygonum bistorta and, 695
  Punica granatum cautions, 716
  Rehmannia glutinosa and, 727
  Rhamnus cathartica cautions, 734
  Senna spp. cautions, 804
  Tricosanthes kirilowii and, 876
  Valeriana spp. and, 912
  Verbena spp., 919
***Abies balsamea*,** 1
Abortifacient activity
  Agathosma spp., 30
  Andrographis paniculata, 56
  Artemesia absinthium, 93
  Artemisia spp., 98
  Asclepias asperula, 100, 101
  Boerhavia diffusa, 139, 140
  Capsella bursa-pastoris, 162, 163
  Carica papaya, 170
  Carthamus tinctorius, 171
  Catharanthus roseus, 177, 178
  Caulophyllum thalictroides, 181
  Chamaemelum nobile, 194
  Chrysopogon zizanioides, 205
  Clematis chinensis, 239
  Coffea arabica, 247
  Crocus sativus, 281
  Cuminum cyminum, 286
  Curculigo orchioides, 288
  Curcuma longa, 292
  Cymbopogon citratus, 298, 299
  Cytisus scoparius, 304
  Ferula spp., 366
  Fraxinus americana, 379
  Gossypium spp., 422, 423
  Hyssopus officinalis, 466, 467
  Ilex paraguariensis, 471
  Juniperus spp., 487
  Juniperus virginiana, 489, 490
  Laminaria spp., 495
  Ligusticum porteri, 517
  Marrubium vulgare, 548
  Mentha pulegium, 564, 567
  Morinda citrifolia, 575, 577
  Myristica fragrans, 588
  Ocimum gratissimum, 601
  Paeonia officinalis, 615
  Petroselinum crispum, 638, 639
  Phoradendron leucarpum, 646
  Phytolacca americana, 651
  Pimpinella anisum, 658
  Pinellia ternata, 660
  Podophyllum hexandrum, 682, 683
  Podophyllum peltatum, 685
  Rosmarinus officinalis, 748, 750
  Ruta graveolens, 761, 762
  Tanacetum vulgare, 852, 853
  Thuja occidentalis, 865, 866
  Thymus vulgaris, 867, 868
  Trigonella foenum-graecum, 880, 882
  Verbena spp., 920
  Withania somnifera, 935, 936
Abortifacients, 971
  adverse effects, 971
  herbs acting as, 971–972
  mechanism of action, 971–972
  in pregnancy and lactation, 991–992
Absinthism, 92
Abyssinian myrrh, 255
Açaí, 358
Acanthaceae, *Andrographis paniculata*, 55
Acanthopanax senticosus, 329
ACE inhibition, by *Rosmarinus officinalis*, 749
ACE inhibitor-induced cough, by capsaicin, 165
Acetaminophen
  Allium sativum and, 41
  Hibiscus sabdariffa and, 441, 442
  Rorippa nasturtium-aquaticum interactions, 745, 746
  Tetradium ruticarpum interactions, 863
Acetylcholinesterase inhibition
  by *Nardostachys jatamansi*, 593
  by *Ptychopetalum* spp., 711
Acetyleugenol, 843
Achillea millefolioum, 2–3
Achiote, 136
Achyranthes, 4
Achyranthes bidentata, 4–5
Acid reflux, *Allium sativum* and, 40
Aconitine, 5, 6
Aconitum carmichaelii, 5–8
Acoraceae, *Acorus calamus*, 8–11, 11–13
Acorus, 11
Acorus calamus, 8–11, 11–13
Acorus gramineus, 13–14
Acorus tatarinowii, 13
Actaea cimicifuga, 15
Actaea racemosa, 16–22
Actaea spp., 15–16
Acute hepatitis
  Actaea racemosa, 17
  Aloe spp. and, 46
  Chelidonium majus and, 199
  cholestatic, *Cullen corylifoium* and, 283
  Hoodia gordonii and, 444
  Reynoutria multiflora and, 730
  Valeriana spp. and, 911
Acute liver failure, *Actaea racemosa*, 18
Acute renal failure
  Artemesia absinthium, 92
  Rheum spp. and, 737
Acute serotonin reactions, with *Ziziphus jujuba*, 953
Acute toxic psychosis, *Mucuna pruriens* and, 584
Acute tubular necrosis
  Paullinia cupana and, 632
  Yucca spp. and, 942
Acyclovir, potentiation by *Astragalus mongholicus*, 108
Additives, exclusion from studies, xxvi
Adenocarcinoma, *Capsicum* spp. and, 167

Adenomas, *Hydrastis canadensis* and, 454
Adenophora spp., 23
Adenophora stricta, 23
Adenophora triphylla, 23
Adiantum capillus-veneris, 24
Adiantum pedatum, 24
Adiantum spp., 24
Adrenal gland
  changes with *Sassafras albidum*, 787
  increased weight with *Azadirachta indica*, 116–117
Adrenaline, elevation with *Citrus aurantium*, 232
Adrenergic drugs
  Coffea arabica and, 244
  interaction with *Camellia sinensis*, 155
  Pausinystalia johimbe and, 634
Adriamycin, *Schisandra* spp. protective effects, 796
Adulteration
  Eleutherococcus senticosus, 329
  Equisetum spp., 339
  Fritillaria spp., 381
  Hoodia gordonii, 444
  Illicium verum, 473
  Juniperus spp., 487
  Plantago spp., 674
  Platycladus orientalis, 680
  of *Scutellaria lateriflora*, 801
  Spigelia marilandica, 823
  Symphytum officinale, 835
  Urtica dioica spp. *dioica* with belladonna, 897
Adverse effects
  abortifacients, 971
  alkenylbenzenes, 955
  berberine, 957
  bulk-forming laxatives, 972
  caffeine, 959–960
  cyanogenic glycosides, 961–962
  diuretics, 974
  emetics, 976
  emmenagogues, 978
  photosensitizing herbs, 979
  pyrrolizidine alkaloids, 963
  salicylates, 965
  stimulant laxatives, 981
  tannins, 966
  thujone, 968
  uterine stimulants, 978
Aesculus hippocastanum, 25–27
Aframommum melegueta, 28–29
African basil, 600
African psyllium, 675
Agar, 398
Agastache rugosa, 29
Agathosma betulina, 30
Agathosma crenulata, 30
Agathosma serratifolia, 30
Agathosma spp., 30–31
Agavaceae, *Yucca* spp., 941
Aggression, reduction with *Morus alba*, 580
Agitation, with *Valeriana* spp., 911
Agnus-castus, 930
Agrimonia eupatoria, 31–32
Agrimony, 31
Agropyron repens, 332
Alanine aminotransferase (ALT), *Valeriana* spp. and, 911
Alantolactone, 475
Albizia julibrissin, 32–33, 33–34
Albumin levels
  Myristica fragrans and, 589
  reductions with *Zea mays*, 948
Alcea rosea, 34–35
Alchemilla vulgaris, 35
Alchemilla xanthochlora, 35–36
Alcohol, *Piper methysticum* and, 666
Alder buckthorn, 375
Aldosterone, *Glycyrrhiza* spp. and, 418
Alertness, reduction with *Melissa officinalis*, 558
Aletris, 36
Aletris farinosa, 36–37
Alexanders, 69
Alexandrian senna, 804
Alfalfa, 552
Algodao, 422
Alisma, 37
Alisma orientale, 37
Alisma plantago-aquatica, 37–38
Alismataceae
  Alisma plantago-aquatica, 37–38
  Echinodorus macrophyllus, 325
Alkaloids, in
  Aconitum carmichaelii, 5, 6
  Berberis vulgaris, 130
  Caulophyllum thalictroides, 179
  Chelidonium majus, 200
  Cinchona spp., 208
  Citrus aurantium, 228, 231
  Coptis chinensis, 262
  Equisetum spp., 339
  Erythrina variegata, 345
  Ginkgo biloba, 411
  Hydrastis canadensis, 451
  Lobelia siphilitica, 532
  Lycium spp., 534
  Magnolia officinalis, 539
  Selenicereus grandiflorus, 803
  Stephania tetrandra, 828
Alkanet, 39
Alkanna tinctoria, 39–40
Alkenylbenzenes
  adverse effects, 955
  herbal constituent profile, 955
  herbs containing, 956
  mechanism of action, 955–956
Allergic contact dermatitis
  Alpinia galanga and, 51
  Anethum graveolens and, 61
  Arnica spp. and, 88
  Avena spp. and, 115
  Boswellia spp. and, 144
  Centella asiatica, 185, 186
  Cinnamomum verum, 216
  Citrus bergamia, 235
  Citrus limon, 236
  Commiphora spp. and, 256
  Commiphora wightii and, 257
  Curcuma longa and, 291
  Cymbopogon citratus, 298
  Eupatorium perfoliatum, 355
  Hamamelis virginiana, 431
  Hydrangea arborescens, 450
  Inula helenium and, 475
  Inula spp., 476
  Laurus nobilis and, 502
  Lavandula spp. and, 503, 504
  Lawsonia inermis and, 505
  Mentha spicata, 569
  Myroxylon spp. and, 591
  Pimenta dioica, 656
  Pterocarpus santalinus, 710

herbal constituent profile, 956
herbs containing, 958
mechanism of action, 957–958
uterine stimulation by, 264, 266
Berberis aquifolium, 543
Berberis vulgaris, 130–133, 645
Bergamot orange, 234
Bergamottin, 220
Bergapten, 234, 235
Beta-adrenergic blockers, *Hypericum perforatum* and, 456, 458–459
Beta-carboline alkaloids, in *Tribulus terrestris*, 872
Beta-lactam antibiotics, 81
Bethroot, 884
Betonica officinalis, 825
Betula alba, 134
Betula lenta, 133–134
Betula pendula, 134
Betula pubescens, 134
Betula spp., 134–135
Betula verrucosa, 134
Betulaceae
Betula lenta, 133
Betula spp., 134
Corylus spp., 276
Bezoars, from *Helianthus annuus*, 436, 437
Bhringaraja, 326
Bhumyamalaki, 648
Bhutrina, 297
Bi ba, 663
Bi ma you, 741
Bibitaki, 859
Bigarade, 220, 223, 228, 230
Bignoniaceae, *Tabebuia impetiginosa*, 847
Bilberry, 903
Bile acids, reductions with *Stevia rebaudiana*, 831
Bile duct hyperplasia, and Camellia sinesis, 158
Bile duct obstructions, *Peumus boldus* and, 641
Bile-stimulating effects, *Zingiber officinale*, 949
Biliary obstruction, *Chelidonium majus* and, 198
Bilirubin, 769
Berberis vulgaris and, 131
decrease with *Coptis trifolia*, 266
displacement by berberine, 266, 452, 544
elevated levels with *Camellia sinensis*, 156
elevated levels with *Morinda citrifolia*, 576
increased with *Lawsonia inermis*, 507
Ocimum gratissimum and, 601
Binding affinities, 101
Bioavailability, xx
Biological Abstracts searches, xxiii
Biota orientalis, 678, 680
Birch, 134
Birch-celery syndrome, 72
Birch-mugwort-celery allergy syndrome, 949
Birth root, 884
Birth weight, increased with *Withania somnifera*, 936
Biscuit root, 533
Bissy nut, 251
Bistort, 695
Bitter dock, 758
Bitter fennel, 368
Bitter orange, 220, 223, 228, 230
Bitterwood, 653
Bixa orellana, 136–139
Bixaceae, *Bixa orellana*, 136
Black birch, 133
Black bugbane, 16
Black cherry, 707
Black cohosh, 16
Black currant, 740
Black elder, 776, 777
Black-end swallowwort, 300
Black hair dye, 506
Black hairy tongue, *Helianthus annuus* and, 436, 437
Black haw, 922
Black henna, 505, 506
Black horehound, 124
Black maca, 515
Black mustard, 145
Black psyllium, 675
Black snakeroot, 16
Black walnut, 485
Blackberry, 754
Blackthorn, 708
Bladder calculi, *Ulmus rubra* and, 891
Bladder cancer
Ilex paraguariensis and, 469, 470
smoking and, 470
Bladderwrack, 382, 383
Blazing star, 36, 193
Bleeding
abnormal, with *Ginkgo biloba*, 407, 409
with *Allium sativum*, 40
with *Crocus sativus*, 281
reduced postsurgical with *Vaccinium myrtillus*, 903, 904
risk with *Salvia miltiorrhiza*, 768
Salvia miltiorrhiza and, 767
Senna spp. and, 806
spontaneous, 409
Bleeding diarrhea, *Aloe* spp. and, 46
Bleeding disorders, 171
Bleeding time
Ginkgo biloba and, 408
increased with *Vaccinium myrtillus*, 904
prolongation with *Allium sativum*, 42
Blessed thistle, 240
Blindness, *Dryopteris filix-mas* and, 319, 320
Blood coagulation
with *Berberis vulgaris*, 131
Carthamus tinctorius effects on, 173
increased speed with *Ceanothus americanus*, 182, 183
Morinda citrifolia and, 575
Panax ginseng and, 619
promotion by *Hydrastis canadensis*, 452
reduction with *Vaccinium myrtillus*, 903
slowing with *Lycium* spp., 534
slowing with *Matricaria chamomilla*, 550
Blood glucose levels
Alpinia galanga, 51
Althaea officinalis, 54
Andrographis paniculata, 56, 57
Anemarrhena asphodeloides, 59
Anethum graveolens, 61
Artemisia dracunculus, 96, 97
Artemisia spp. effects, 98
Azadirachta indica, 119
Ballota nigra, 125
Bauhinia forficate, 127
Bixa orellana and, 136
Boerhavia diffusa and, 139, 140
Brassica spp. and, 146
Carum carvi, 174
Catharanthus roseus, 177, 178

Cichorium intybus, 206, 207
Cinnamomum aromaticum, 210, 211, 212
Cinnamomum verum, 216, 217
Coix lacryma-jobi, 250
Cordyceps sinensis, 268
Coriandrum sativum, 271
Cornus officialis, 274
Curculigo orchioides, 287, 288
Cymbopogon citratus, 298
Cyperus rotundus, 303
Dioscorea oppositifolia, 315
Eclipta prostrata, 327
Eleutherococcus senticosus, 330
Equisetum spp., 340
Eriobotrya japonica, 341, 342
Euphrasia spp., 356
Ganoderma lucidum, 387, 389
Gardenia jasminoides, 394
Grifola frondosa and, 425
Gymnema sylvestre and, 428, 429
Hibiscus sabdariffa, 442
Hordeum vulgare, 445
Juniperus spp., 487, 488
Larrea tridentata, 498–499
Lepidium meyenii and, 515–516
Ligustrum lucidum, 521
Lintinula edodes, 510
Lycium spp., 536
Marrubium vulgare, 548
Morus alba, 580, 582
Mucuna pruriens, 584
Myrcia multiflora, 586
Ocimum basilicum, 599
Ocimum gratissimum, 601
Ocimum tenuiflorum, 602, 603
Nelumbo nucifera, 595
Ophiopogon japonicus and, 607, 608
Oplopanax horridus, equivocal results with, 608, 609
Paeonia lactiflora, 613, 614
Paeonia suffruticosa, 616, 617
Panax ginseng, 619
Panax quinquefolius, 625
Petroselinum crispum, 638
Phyllanthus spp., 648
Platycodon grandiflorum, 681
Polygala senega, 688, 689
Polygonatum odoratum, 692, 693
Polygonatum sibiricum, 694
Portulaca oleracea, 697
Prunella vulgaris, 701
Pterocarpus santalinus, 710
Pueraria montana, 713
Punica granatum, 716
Rehmannia glutinosa, 727, 729
Rosmarinus officinalis, 748
Rubia cordifolia, 752
Rubus spp., 754, 755
Salvia officinalis, 772
Sesamum indicum, 813
Silybum marianum, 816
silymarin and, 817
Sinapis spp., 146
Stephania tetrandra, 828
Syzygium cumini, 845–846
Terminalia arjuna, 858
Terminalia chebula, 860
Tinospora cordifolia, 870, 871
Trigonella foenum-graecum effects, 881
Turnera diffusa and, 885, 886
Urtica dioica, 896, 897
Viscum album, 928, 929
Withania somnifera, 935, 936
Blood pressure
Brassica spp. and, 146
Buxus sempervirens and, 149
Citrus aurantium and, 224, 225, 231, 232
Coffea arabica and, 245, 246
Corydalis yanhusuo and, 275
decrease with *Berberis vulgaris*, 131
decrease with *Hydrastis canadensis*, 452
Glycyrrhiza spp. and, 419
increase with *Pausinystalia johimbe*, 634
increased in hypotension with *Schisandra* spp., 796
Lobelia inflata effects, 529
Lycopus spp. effects, 538
mixed results with *Panax ginseng*, 619
Oenothera biennis and, 605
Panax ginseng, and, 621
reduction with *Azadirachta indica*, 119
reduction with *Ceanothus americanus*, 183
reduction with *Sida cordifolia*, 815
reduction with *Uncaria gambir*, 892
reduction with *Veratrum viride*, 916
reduction with *Zingiber officinale*, 950
Veratrum viride Aiton cautions, 916
Viscum album and, 928
Blood urea, elevation with *Myristica fragrans*, 589
Blood urea nitrogen, increases with *Calendula officinalis*, 152
Blood viscosity
reduction with *Pueraria montana*, 713
Salvia miltiorrhiza and, 769
Trigonella foenum-graecum and, 881–882
Bloodroot, 779
Blue cohosh, 179
Blue flag, 480
Blue gum, 348, 349
Blue skullcap, 801
Blue verbain, 919
Blue violet, 926
Blueberry, 905, 906
Blunimba, 55
Blurred vision, *Citrus bergamia* and, 234
Body weight reduction, with *Santalum album*, 781
Boerhavia, 139
Boerhavia diffusa, 139–140
Bog bean, 570
Bola, 255
Boldine, 642
Boldo, 641
Bombilla, 470
Bone calcium, decrease with *Coffea arabica*, 247
Bone changes, with *Gaultheria procumbens*, 397
Bone loss
inhibition by *Humulus lupulus*, 448
prevention with *Lepidium meyenii*, 515
reduction with *Cuminum cyminum*, 286
reduction with *Curculigo orchioides*, 288
reduction with *Epimedium* spp., 336, 337
Bone marrow depression, *Catharanthus roseus*, 177, 178
Bone mineral density, *Trifolium pratense* and, 878
Boneset, 355
Borage, 141, 142
Boraginaceae
Borago officinalis, 141, 142
Cordia ecalyculata, 267
Pulmonaria officinalis, 714
Symphytum officinale, 834
Symphytum spp., 838
Borago officinalis, 141–142, 142–143
Boswellia carterii, 143
Boswellia serrata, 143
Boswellia spp., 143–145
Botanical classifications, xxiii–xxvi
Bourbon vanilla, 914
Bowel inflammation, *Linum usitatissimum* and, 524
Bowel obstruction

Linum usitatissimum cautions, 523
Plantago spp. contraindications, 675
Box holly, 759
Boxwood, 149
Bradyarrhythmia
Artemesia absinthium, 92
Convallaria majalis, 260
Veratrum viride and, 916
Bradycardia, 189
Clematis chinensis, 230
Digitalis spp. and, 312
with *Uncaria gambir*, 892
Urtica dioica and, 897
Brahmi, 123, 185
Brain damage
neonatal protection by *Punica granatum*, 718–719
protective effects of *Punica granatum*, 717
Brain enlargement, *Ocimum gratissimum* and, 602
Brain stem effects, 95
Brassica alba, 145
Brassica juncea, 145
Brassica nigra, 145
Brassica spp., 145–147
Brassicaceae
Armoracia rusticana, 86
Brassica spp., 145
Capsella bursa-pastoris, 162
Isatis spp., 481
Lepidium meyenii, 514
Rorippa nasturtium-aquaticum, 745
Sinapis spp., 145
Brazilian krameria, 492
Brazilian peppertree, 791, 792
Brazilian rhatany, 492
Breast cancer
Actaea racemosa and, 19
Allium sativum and docetaxel in, 41
cell proliferation and *Carthamus tinctorius*, 172
Epimedium spp. and, 337
estrogenic effects of *Panax quinquefolius*, 626
Ganoderma lucidum in, 389
gestational *Linum usitatissimum* exposure and, 526
Grifola frondosa and, 425
inhibition by *Tabebuia impetiginosa*, 848
Lavandula spp. effects, 504
Linum usitatissimum effects, 524, 525, 526
Medicago sativa in, 553
Petroselinum crispum and, 639
protective effects of *Linum usitatissimum*, 524
Pueraria montana and, 713
Sesamum indicum and tamoxifen in, 813
Trifolium pratense and, 878
Verbena spp. and receptor binding, 920
Viburnum opulus receptor binding, 922
Viscum album effects, 929
Breast density, *Trifolium pratense* and, 878
Breast-feeding mothers
Aloe spp. and, 45, 46
Anethum graveolens, 61
Angelica sinensis and, 67
Breast milk
Berberis vulgaris in, 132
GLA in, 142, 143
glucosinolates in, 162, 163
Brihadela, 28
Brindall berry, 391
British elecampane, 476
Brittle willow, 765
Broad-leaf dock, 758
Broad-leaf plantain, 674
Bronchitis, *Angelica pubescens* in, 65
Bronchodilators
Coffea arabica and, 244
Hypericum perforatum and, 459, 460
interaction with *Camellia sinensis*, 155
Bronchopneumonia, *Humulus lupulus* and, 448
Broom, 303
Broomrape, 219
Brown cutch, 892
Brown mustard, 145
Brown rhatany, 492
Brown sarsaparilla, 819
Brown's lily, 522
Bu gu zhi, 283
Buchu, 30
Buck bean, 570
Buckthorn, 375, 734
Budd-Chiari syndrome, 835
Buffalo bean, 584
Bugleweed, 537
Bulimia, *Cephaelis ipecacuanha* and, 189
Bulk-forming laxatives, 676, 972
adverse effects, 972
mechanism of action, 973
Bull kelp, 494
Bupleurum, 147
Bupleurum chinense DC, 147
Bupleurum spp., 147–149
Burdock, 78
Burning mouth/throat
Lobelia inflata, 529
Veratrum viride and, 916
Burseraceae
Boswellia spp., 143
Canarium album, 161
Commiphora spp., 255
Commiphora wightii, 257
Butcher's broom, 759
Butterfly weed, 101
Butternut, 484
Button eryngo, 344
Buxaceae, *Buxus sempervirens*, 149
Buxus sempervirens, 149–150

C

Cabbage palm, 358
Cabbage rose, 747
Cactaceae, *Selenicereus grandiflorus*, 803
Cactus grandiflorus, 803
Cade juniper, 487
Cadmium exposure, *Linum usitatissimum* and, 525
Caffeine, 244
adverse effects, 959–960
combining *Citrus aurantium* with, 230, 231
drug interactions, 960
herbal constituent profile, 959
herbs containing, 960
interaction with *Citrus aurantium*, 223
mechanism of action, 960
with other CNS stimulants, 469
in pregnancy and lactation, 154
reduction in plasma levels with *Echinacea* spp., 322
Calamus, 8, 11
Calcium channel blockers
Hypericum perforatum and, 456, 457
Pueraria montana, 713
Salvia miltiorrhiza, 769
in *Uncaria tormentosa*, 893
Calcium channel inhibition, by *Crocus sativus*, 281
Calcium oxylate crystals, 85
in *Symplocarpus foetidus*, 841
Vaccinium spp. and, 908
Calcium oxylate stones, conflicting *Vaccinium* spp. role, 907
Calendula, 151
Calendula officinalis, 151–153
California chia, 775
California pepper tree, 791, 792

California poppy, 347
California sage, 775
California spikenard, 75
Calisaya, 208
Calming the fetus
with *Atractylodes macrocephala*, 111
Cuscuta spp., 295
Dipsacus spp., 317, 318
Calmness, elevation with *Melissa officinalis*, 558
Camellia sinensis, 153–155, 155–160
Campanulaceae
Adenophora spp., 23
Codonopsis spp., 242
Lobelia inflata, 528
Lobelia siphilitica, 532
Platycodon grandiflorum, 681
Camphor, 213, 214
Camphora camphora, 213
Camphora officinalis, 213
Canada fleabane, 261
Canada hemp, 74
Canadian goldenrod, 820
Canadian horseweed, 261
Canaigre, 756
Cananga odorata, 160–161
Canarium album, 161–162
Cancer
antiestrogenic effects with *Prunella vulgaris*, 702
antiproliferative effects of *Pueraria montana*, 713
Coffea arabica and, 245
Ganoderma lucidum in, 388
Ilex paraguariensis and, 469, 470
inhibition by *Epimedium* spp., 337
inhibition by *Paeonia suffruticosa*, 617
Morinda citrifolia toleration in, 576
Phytolacca americana in, 651
Prunus armeniaca and, 702
Santalum album and, 780
Sassafras albidum and, 786
Cancer inhibition
Alisma plantago-aquatica, 38
Hydrastis canadensis and, 451
Candle berry, 574
Cang zhu, 110
Canker root, 265
Cannabinaceae, *Humulus lupulus*, 447
Cao guo, 54
Cape aloe, 44
Cape jasmine, 393
Capillaris, 99
Capillary artemisia, 99
Caprifoliaceae
Sambucus spp., 776, 777
Viburnum opulus, 921
Viburnum prunifolium, 922
Capsella bursa-pastoris, 162–164
Capsicum annuum, 164
Capsicum frutescens, 164
Capsicum spp., 164–169
Caraway, 173
Carcinogenic activity
Capsicum spp., 167
Hydrastis canadensis and, 454
hydroquinone, 82
Juglans nigra, 486
Tussilago farfara, 887, 889
Cardamom, 327
Cardiac activity
Selenicereus grandiflorus, 803
Taxus brevifolia, 856
Cardiac arrest, wtih *Azadirachta indica*, 117, 118
Cardiac drugs
Crataegus spp. and, 279
reduction with *Crataegus* spp., 277, 278
Selenicereus grandiflorus cautions, 803
Veratrum viride cautions, 916
Cardiac glycosides, 45
in *Apocynum* spp., 74
Frangula purshiana and, 378
Glycyrrhiza spp. and, 417
interactions with *Salvia miltiorrhiza*, 767
Iris spp. cautions, 480
Rhamnus cathartica interactions, 734–735
Rheum spp. cautions, 737
Ricinus communis interactions, 741
Senna spp. cautions, 805
Cardiac ischemia, *Lawsonia inermis* and, 506
Cardioactive glycosides, adulteration of *Eleutherococcus senticosus*, 329
Cardiotoxicity, *Schisandra* spp. protective effects, 796
Cardiovascular stimulants, *Tussilago farfara*, 887
Cardiovascular symptoms
with *Digitalis* spp., 312
Eucalyptus globulus, 350
Lobelia inflata, 530
Passiflora incarnata, 629
Paullinia cupana, 632

Catuaba, 346
Caulophyllum thalictroides, 179–182
Caulophyllumine, 181
Caulosaponin, 179
Cayenne, 164
gastric ulcers and, 166
Ce bai ye, 678
Ceanothus americanus, 182–183
Celandine, 198
Celastraceae, *Euonymus atropurpureus*, 354
Celery, 71
Celery-carrot-mugwort-spice syndrome, 473
Celiac disease, 115
Centaurea benedicta, 240
Centaurea cyanus, 183–184
Centaurium erythraea, 184–185
Centaury, 184
Centella asiatica, 185–187
Central nervous system disturbances
Ginkgo biloba and, 414, 415

Vaccinium myrtillus and, 903
Cephaelis ipecacuanha, 187–190
Ceratonia siliqua, 190–191
Cerebral hemorrhage, 189
with *Ginkgo biloba*, 409
Cerebrovascular risk factors, *Allium sativum* with, 41
Cereus grandiflorus, 803
Cervical carcinoma, *Cnidium monnieri* activity against, 242
Cervical dilation, with *Laminaria* spp., 495
Cesarian sections, reduced need with *Ricinus communis*, 742
Cetraria islandica, 191–192
Ceylon cinnamon, 215
Chá-de-bugre, 267
Chaenomeles legemaria, 192
Chaenomeles speciosa, 192–193
Chagas disease, 358, 359
Chai hu, 147
Chamaelirium luteum, 193–194
Chamaemelum nobile, 194–196
Chamaenerion angustifolium, 334
Chamaesyce hirta, 196–197
Chamerion angustifolium, 334
Chamomile, 549
Chamomilla recutita, 549
Chamomilla suaveolens, 551
Chanda, 69
Chandana, 783
Changium, 197
Changium smyrnioides, 197–198
Chaparral, 498
Chapéau de couro, 32
Chastetree, 930
Che qian zi, 675
Chebulic myrobalan, 850
Checkerberry, 396
Cheilitis, *Rosmarinus officinalis* and, 749
Chelidonine, 200
Chelidonium majus, 198–201
Chemopreventive activity, *Lawsonia inermis*, 507
Chemotherapy agents
Catharanthus roseus, 177
Stephania tetrandra synergistic effects, 828
Wolfporia cocos effects on, 939
Chen pi, 237
Cherry birch, 133
Chervil, 70
Chest circumference, *Cola* spp. and, 253
Chest oppression, *Hydrangea arborescens* and, 450
Chestnut
American, 175
Spanish, 176
Chi shao, 613
Chia, 775
Chickweed, 826
Chicory, 206
Childbirth
Asclepias asperula effects, 100, 101
facilitation with *Trillium erectum*, 884, 885
Children
avoiding *Cinnamomum camphora* in, 213
caution with *Equisetum* spp., 339
eucalyptus poisoning in, 350
Frangula alnus in, 375
Rhamnus cathartica contraindications, 734
Rheum spp. contraindications, 736
Schinus spp. and gastrointestinal irritation in, 793
Thuja occidentalis in, 865
Chili pepper, 164

SAFETY AND INTERACTION CLASSIFICATIONS

Each of the herbs included in *AHPA's Botanical Safety Handbook*, 2nd edition is classified into one or more Safety Class, and also into an Interaction Class. These classes are defined as described below. See pages xxiii–xxxvi for more information on these classifications, including lists of the criteria and considerations for inclusion in each particular class.

SAFETY CLASSES

Class 1. Herbs that can be safely consumed when used appropriately.

Class 2. Herbs for which the following use restrictions apply, unless otherwise directed by an expert qualified in the use of the described substance:

- **2a:** For external use only;
- **2b:** Not to be used during pregnancy;
- **2c:** Not to be used while nursing;
- **2d:** Other specific use restrictions as noted.

Class 3. Herbs to be used only under the supervision of a qualified expert. Specific labeling is recommended for Class 3 herbs (see page xxii).

INTERACTION CLASSES

Class A. Herbs for which no clinically relevant interactions are expected.

Class B. Herbs for which clinically relevant interactions are biologically plausible.

Class C. Herbs for which clinically relevant interactions are known to occur.
